Notice Concerning Liability: Publication of this handbook is for the purpose of circulating information and opinion among those concerned for fire and life safety and related subjects. While every effort has been made to achieve a work of high quality, neither the NFPA nor the authors and contributors to this work guarantee the accuracy or completeness of or assume any liability in connection with the information and opinions contained in this handbook. The NFPA and the authors and contributors shall in no event be liable for any personal injury, property, or other damages of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of or reliance upon this work.

This handbook is published with the understanding that the NFPA and the authors and contributors to this handbook are supplying information and opinion but are not attempting to render engineering or other professional services. If such services are required, the assistance of an appropriate professional should be sought.

Notice Concerning Code Interpretations: This ninth edition of the *Life Safety Code® Handbook* is based on the 2003 edition of NFPA 101,® *Life Safety Code*.® All NFPA codes, standards, recommended practices, and guides are developed in accordance with the published procedures of the NFPA by technical committees comprised of volunteers drawn from a broad array of relevant interests. The handbook contains the complete text of NFPA 101®, and any applicable Formal Interpretations and Tentative Interim Amendments issued by the Association. These documents are accompanied by explanatory commentary and other supplementary materials.

The commentary and supplementary materials in this handbook are not a part of the *Code* and do not constitute Formal Interpretations of the NFPA (which can be obtained only through requests processed by the responsible technical committees in accordance with the published procedures of the NFPA). The commentary and supplementary materials, therefore, solely reflect the personal opinions of the editors or other contributors and do not necessarily represent the official position of the NFPA or its technical committees.

PART TWO
Supplements 981

1 Case Histories: Fires Influencing the *Life Safety Code* 983

Preface

For 80 years, the National Fire Protection Association has been the developer and publisher of the *Life Safety Code*. Formerly known as the *Building Exits Code*, the *Code* is prepared by the NFPA Committees on Safety to Life — 14 of the more than 200 technical committees operating within the framework of NFPA's consensus standards-development system. The members of the Committees on Safety to Life are highly qualified individuals who have demonstrated knowledge and competence in the design and construction of buildings and structures, in the manufacture and testing of building components and accessories, and in the enforcement of regulations pertaining to life safety from fire and other related hazards encountered in buildings and structures. Most of these committee members also participate in the development of *NFPA 5000™*, *Building Construction and Safety Code™*. There are many similarities between the two codes, especially within the occupancy chapters.

The *Life Safety Code* is a unique document; its contents address specific requirements that have a direct influence on safety to life in both new construction and existing buildings — not new construction alone. Moreover, although the *Code's* paramount concern is life safety and not protection of property per se, there are also — by observance of the *Code's* requirements — ancillary benefits to property protection.

The impact that application of the *Code* can have on saving lives is difficult to measure; however, it is reasonable to assume that its influence is extremely significant. For example, of the many fatal public building fires investigated by NFPA, invariably one or more of the building features contributing to loss of life from fire were in violation of the requirements of the *Code*.

NFPA recognizes that a code suitable for enforcement must — by the nature of its purpose — be concise and without explanatory text. In addition, a code cannot be written to cover every situation that will be encountered; thus, it must be applied with judgment and used with good sense and with an awareness of the rationale for the requirements to be enforced. A little help and counsel along the way can make the job a lot easier; hence, NFPA has also developed this *Life Safety Code Handbook*.

This handbook gives users of the *Life Safety Code* background information on the reasons for certain *Code* provisions. It also provides some suggestions, through its text and illustrations, on how some *Code* requirements can be implemented effectively. This kind of information is intended to provide users of the *Code* with a better understanding of, and appreciation for, the requirements contained in the *Code*. The net result should be buildings and structures that are increasingly more fire safe. The reader is cautioned, however, to look upon the commentary that appears in the handbook as the views of the editors and — where commentary reads relatively the same as in earlier editions — the contributors to earlier editions of the handbook. The commentary does not necessarily reflect the official position of NFPA.

This edition of the handbook reflects the reformatting of the *Code* as required by the *NFPA Manual of Style*. Exceptions have been reworded into self-contained, independently numbered or lettered paragraphs, and SI (metric) units appear first with the inch-pound units shown in parentheses. For this edition, Gregory Harrington revised the commentary for Chapters 8, 9, 11, 24, 26, 28 through 33, and 36 through 39; Ron Coté revised the commentary for Chapters 1 through 7, 10, 12 through 23, 40, and 42.

Where a pair of occupancy chapters address a given occupancy (for example, Chapter 12 for new assembly occupancies and Chapter 13 for existing assembly occupancies), the *Code* text for both chapters is presented in side-by-side columns to permit easy comparison. Further, the accompanying commentary points out differences between the provisions applicable to new construction and to existing buildings.

Gregory E. Harrington, P.E.
Senior Fire Protection Engineer
NFPA

.....

PART ONE

Life Safety Code and Commentary

Part One of this handbook includes the complete text of the 2003 *Life Safety Code*, which is made up of mandatory chapters (1 through 42) and nonmandatory annex material. The mandatory *Code* provisions found in Chapters 1 through 42 were prepared by the 14 Committees on Safety to Life within the framework of NFPA's consensus standards-development system. Because these provisions are designed to be suitable for adoption into law, or for reference by other codes and standards, the text is concise, without extended explanation.

The material found in Annex A of the *Code* was also developed by the Committees on Safety to Life within NFPA's standards system. The annex material is designed to assist users in interpreting the mandatory *Code* provisions. It is not considered to be part of the requirements of the *Code*; it is advisory or informational. An asterisk (*) following a *Code* paragraph number indicates that nonmandatory material pertaining to that paragraph appears in Annex A. For readers' convenience, in this handbook, Annex A material has been interspersed to appear immediately following its base paragraph in the body of the mandatory *Code* text.

The explanatory commentary accompanying the *Code* was prepared by the handbook editors—Ron Coté, P.E., and Gregory Harrington, P.E. The commentary follows the *Code* text it discusses and is easily identified by green shading. Designed to help users understand and apply *Code* provisions, the commentary gives detailed explanations of the reasoning behind *Code* requirements, examples of calculations, applications of requirements, and tables of useful information. More than 400 drawings and photographs show practical applications of specific *Code* provisions. Used together with the *Code*, the commentary provides a rich resource for assessing the level of life safety from fires in buildings.

.....

CHAPTER 1

Administration

The basic philosophy and core requirements of the *Life Safety Code* are presented in the first 11 chapters of the *Code*. The scope, purpose, and application of the *Code* are positioned in Chapter 1 to allow the building blocks or fundamentals of the *Code* to be described, understood, and correctly applied.

While any part of this handbook might be relevant and directly applicable to a specific type of structure or occupancy, the user is encouraged to develop a sound understanding of the rudimentary concepts of occupant life safety. Such understanding includes recognizing where the *Code* applies and the extent to which the designer, authority having jurisdiction, or both, should apply the *Code* requirements for new versus existing buildings. See, for example, Section 1.3, Application, and its associated annex material.

The long-standing recognition of “equivalency” (see Section 1.4) is also an important concept not only in NFPA 101 but also in the NFPA codes and standards used in combination with the *Life Safety Code*. The equivalency concept allows for innovative approaches to life safety and fire safety. While the *Code* is a comprehensive document, it is conceivable that a situation that the *Code* does not contemplate might arise. Equivalency considerations allow for such a situation to be evaluated and for a mutually agreeable solution to be developed that would provide the same or better level of life safety than what would have resulted from strict compliance with the prescriptive requirements.

- (1) Determine the occupancy classification by referring to the occupancy definitions in Chapter 6 and the occupancy Chapter 12 through Chapter 42 (*see 6.1.14 for buildings with more than one use*).
- (2) Determine if the building or structure is new or existing (*see the definitions in Chapter 3*).
- (3) Determine the occupant load (*see 7.3.1*).
- (4) Determine the hazard of contents (*see Section 6.2*).
- (5) Refer to the applicable occupancy chapter of the *Code* (Chapter 12 through Chapter 42) [*see Chapter 1 through Chapter 4 and Chapter 6 through Chapter 11, as needed, for general information (such as definitions) or as directed by the occupancy chapter*].
- (6) Determine the occupancy subclassification or special use condition, if any, by referring to Chapter 18 and Chapter 19, health care occupancies; Chapter 22 and Chapter 23, detention and correctional occupancies; Chapter 28 and Chapter 29, hotels and dormitories; Chapter 32 and Chapter 33, residential board and care occupancies; and Chapter 36 and Chapter 37, mercantile occupancies, which contain subclassifications or special use definitions.
- (7) Proceed through the applicable occupancy chapter to verify compliance with each referenced section, subsection, paragraph, subparagraph, and referenced codes, standards, and other documents.
- (8) Where two or more requirements apply, the occupancy chapter generally takes precedence over the base Chapter 1 through Chapter 4 and Chapter 6 through Chapter 11.
- (9) Where two or more occupancy chapters apply, such as in a mixed occupancy (*see 6.1.14*), the most restrictive requirements apply.

Section 1.1* Scope

A.1.1 The following is a suggested procedure for determining the *Code* requirements for a building or structure:

The steps outlined in A.1.1 were developed to help the user determine which *Code* requirements might

apply to a given building if the more prevalent, prescriptive, specification-based life safety systems option is used. If the new performance-based option is used, see 4.4.3.

Because specific occupancy requirements are detailed in separate chapters, the *Code* user should first identify the proper occupancy classification for a building. The *Code* user will then be able to determine the appropriate chapter(s) for that occupancy.

For example, a jewelry retail sales operation (that is, a jewelry store) occupying all of the twelfth floor of a multi-tenant building uses 465 m² (5000 ft²), or 95 percent, of the floor area for sales purposes. Using the occupancy classification criteria and definitions found in Chapter 6, the jewelry store should be classified as a mercantile occupancy (see 6.1.10.1). In determining that the floor is a mercantile occupancy, the *Code* user narrows the range of choice of applicable occupancy chapters from Chapters 12 through 42 to the two that specifically address mercantile occupancies—Chapter 36 and Chapter 37.

Using the definition of *existing building* found in 3.3.27.5, the user can determine whether the building is subject to the requirements for new construction or for existing buildings. If the jewelry store used in the example was occupied subsequent to the adoption of the *Code* currently being enforced, the user determines that the life safety features required are those that apply to new construction. Thus, the user could narrow the applicable occupancy requirements to those for new mercantile occupancies as detailed in Chapter 36.

The *Code* user next identifies the subclassification of the mercantile occupancy as Class A, Class B, or Class C on the basis of the 465-m² (5000-ft²) floor area used for sales purposes. Because the jewelry store occupies more than 280 m² (3000 ft²) but less than 2800 m² (30,000 ft²), it is classified as a Class B mercantile occupancy. The user then locates the requirements of Chapter 36 that specifically apply to Class B mercantile occupancies. The user notes that Chapter 36 does not repeat the requirements found in Chapters 1 through 4 and Chapters 6 through 10 because the *Code* mandatorily references the use of those chapters. Because the jewelry store is located in the high-rise portion of the building, 36.4.2 requires compliance with a portion of the high-rise building requirements of Chapter 11—specifically, the automatic sprinkler system provisions of 11.8.2.1.

In this example, the *Code* user recognizes that the requirements of Chapters 1 through 4, Chapters 6 through 10, a portion of Chapter 11, and Chapter

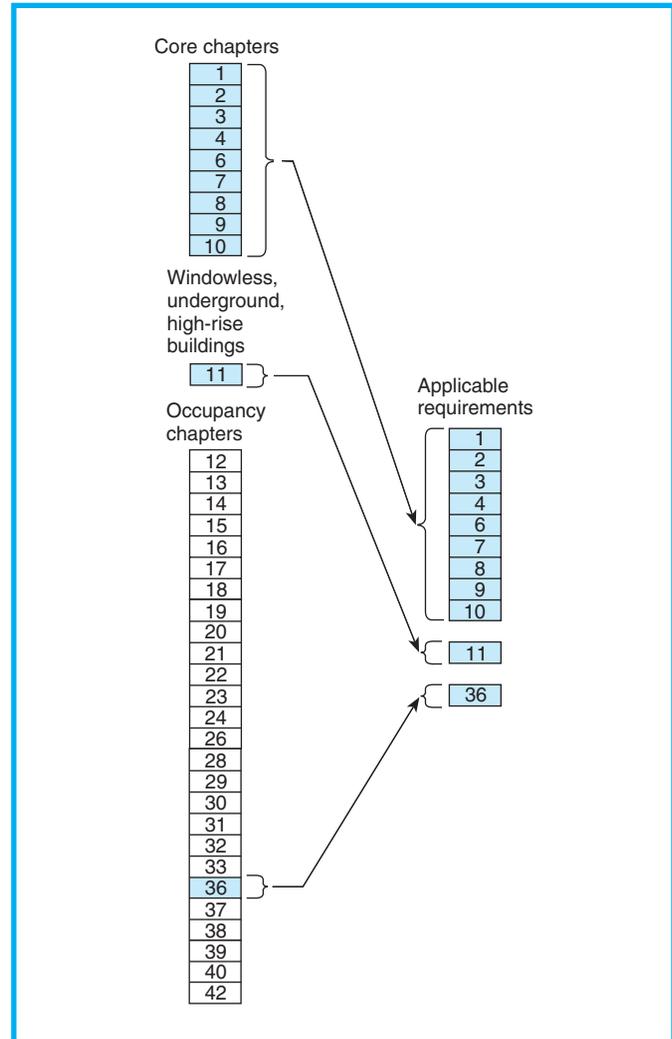

Exhibit 1.1 Selecting specification-based Code requirements that apply to a given occupancy; in this case, a new mercantile occupancy on the 12th floor of a multi-tenant building.

36 apply and are required to be met. This selection process is outlined in Exhibit 1.1.

1.1.1 Title.

NFPA 101®, *Life Safety Code*® shall be known as the *Life Safety Code*®, is cited as such, and shall be referred to herein as “this Code” or “the Code.”

The title of the *Code* was changed from *Building Exits Code* to *Code for Safety to Life from Fire in Buildings and Structures* in 1966. The change in title expanded the

scope of the *Code* from a specification-based code for stairs, doors, and fire escapes to a performance- and specification-based code that addresses the myriad factors that affect life safety in the event of fire.

From 1966 through 2002, the *Code* was referred to by its shortened name, the *Life Safety Code*®. For this 2003 edition, the *Code* has been officially renamed the *Life Safety Code*.

The change in title reflects the *Code's* ever-changing content. In some case, the *Code* addresses non-fire, day-to-day, building occupant use issues. For example, in 12.2.5.4.3 and 13.2.5.4.3, which apply to assembly occupancies, access and egress routes are required to be maintained so that crowd management, security, and emergency medical personnel are able to reach any individual at any time without undue hindrance.

1.1.2* Danger to Life from Fire.

The *Code* addresses those construction, protection, and occupancy features necessary to minimize danger to life from fire, including smoke, fumes, or panic.

A.1.1.2 The *Code* recognizes that panic in a burning building might be uncontrollable but deals with the potential panic hazard through measures designed to prevent the development of panic. Experience indicates that panic seldom develops, even in the presence of potential danger, as long as occupants of buildings are moving toward exits that they can see within a reasonable distance without obstructions or undue congestion in the path of travel. However, any uncertainty as to the location or adequacy of means of egress, the presence of smoke, or the stoppage of egress travel, such as might occur when one person stumbles and falls on the stairs, is potentially conducive to panic. The danger of panic is greatest when there are large numbers of people in a confined area.

Panic is *not* a typical reaction of occupants in a burning building. Studies of building fires indicate that occupants typically exhibit altruistic behavior toward others. Human response to a threatening situation might follow one of a variety of behaviors. Individuals might choose to investigate, sound an alarm, assist with rescue, seek help, or flee. Such actions constitute normal behavior, even when taken collectively. Most people avoid direct contact with a fire while undertaking another action.

Crowd behavior in large assembly occupancy venues is more difficult to predict and manage. The

life safety evaluation, required of large assembly occupancies by the provisions of Chapters 12 and 13, deals not only with fire but also with storm, collapse, crowd behavior, and other related factors, a list of which is provided in A.12.4.1.3 and A.13.4.1.3.

1.1.3 Egress Facilities.

The *Code* establishes minimum criteria for the design of egress facilities so as to allow prompt escape of occupants from buildings or, where desirable, into safe areas within buildings.

Relocating building occupants to safe areas within a building might include moving them to one of the following locations:

- (1) Into an area of refuge
- (2) Through doors in a horizontal exit into another fire compartment
- (3) Through doors in a smoke barrier into another smoke compartment

In some cases, an egress system that relies on total evacuation to the exterior is not practical. For example, in a health care occupancy, building evacuation might expose patients to conditions more dangerous than those encountered in relocating the patients from a fire compartment to a safe smoke compartment on the same floor. For most occupancies, the *Code* provisions permit the designer to choose whether the egress system relies on full evacuation. For occupancies such as health care, a protect-in-place strategy is used that requires the subdivision of floors into two or more smoke compartments, regardless of the presence of fire exit stairs.

1.1.4 Other Fire-Related Considerations.

The *Code* addresses other considerations that are essential to life safety in recognition of the fact that life safety is more than a matter of egress. The *Code* also addresses protective features and systems, building services, operating features, maintenance activities, and other provisions in recognition of the fact that achieving an acceptable degree of life safety depends on additional safeguards to provide adequate egress time or protection for people exposed to fire.

1.1.5* Considerations Not Related to Fire.

The *Code* also addresses other considerations that, while important in fire conditions, provide an ongoing benefit in other conditions of use, including non-fire emergencies.

A.1.1.5 Life safety in buildings includes more than safety from fire. Although fire safety has been the long-standing focus of NFPA 101, its widely known title, *Life Safety Code*, and its technical requirements respond to a wider range of concerns, including, for example, crowd safety.

Numerous elements affect the overall level of life safety. The *Code* addresses many of these factors, including combustibility of interior finishes and the evacuation preparedness of occupants. However, other areas are not addressed, such as the influence of public education on fire safety. See 1.1.6 and related commentary for more information on what the *Code* does not cover.

1.1.6 Areas Not Addressed.

The *Code* does not address the following:

- (1)* General fire prevention or building construction features that are normally a function of fire prevention codes and building codes

A.1.1.6(1) This *Code* is intended to be adopted and used as part of a comprehensive program of building regulations that include building, mechanical, plumbing, electrical, fuel gas, fire prevention, and land use regulations.

- (2) Prevention of injury incurred by an individual due to that individual's failure to use reasonable care
- (3) Preservation of property from loss by fire

The *Code* is not intended to be either a building code or a fire prevention code. However, in the interest of public safety, the *Code* does contain provisions typically associated with a building code or fire prevention code. For example, although construction requirements are typically considered the domain of a building code, Chapters 18 and 19 provide minimum, fire-rated construction requirements for buildings housing health care occupancies. The construction requirements are provided to ensure the structural integrity of the building for the period of time required for staff to evacuate those occupants incapable of self-preservation.

Similarly, the provisions of Chapters 12 and 13—for assembly occupancies—require fire-rated building construction, depending on the number of occupants and the levels of the building occupied as assembly occupancies. The requirement recognizes the lengthy time periods necessary to evacuate large numbers of persons, especially from floors above the level of exit discharge. Thus, fire-rated building con-

struction is intended to ensure the structural integrity of the building for the period of time required for occupants to evacuate.

Although preventative measures are typically associated with a fire prevention code, the operating features sections located at the end of most of the occupancy chapters contain requirements that do the following:

- (1) Limit the flammability of contents introduced into certain occupancies
- (2) Regulate smoking
- (3) Require the training of facility employees

These operational requirements, when combined with egress and other specific occupancy chapter requirements, provide an appropriate life safety package.

The *Code* intentionally excludes traditional building code topics such as wind loads, seismic considerations, and exterior exposure protection.

Although the *Code* requirements were developed to provide life safety from fire, adherence to its requirements might assist in property conservation and prevention of personal injuries. For example, the automatic sprinkler systems required for life safety purposes provide substantial property protection benefits as well.

Section 1.2* Purpose

The purpose of this *Code* is to provide minimum requirements, with due regard to function, for the design, operation, and maintenance of buildings and structures for safety to life from fire. Its provisions will also aid life safety in similar emergencies.

This *Code* specifies the **minimum** requirements that collectively help to ensure safety to occupants from fires and similar emergencies to the degree specified by the objectives stated in Section 4.2. However, it is not the *Code's* intent to prevent the user from exceeding the specified minimum requirements. See also 4.6.9.

A.1.2 The *Code* endeavors to avoid requirements that might involve unreasonable hardships or unnecessary inconvenience or interference with the normal use and occupancy of a building but provides for fire safety consistent with the public interest.

Protection of occupants is achieved by the combination of prevention, protection, egress, and other features with

due regard to the capabilities and reliability of the features involved. The level of life safety from fire is defined through requirements directed at the following:

- (1) Prevention of ignition
- (2) Detection of fire
- (3) Control of fire development
- (4) Confinement of the effects of fire
- (5) Extinguishment of fire
- (6) Provision of refuge and/or evacuation facilities
- (7) Staff reaction
- (8) Provision of fire safety information to occupants

Buildings are normally designed to accommodate a specific functional need. The *Code* considers the normal occupancy of a building and attempts not to interfere with its regular use or to set requirements that cause unreasonable hardship or unnecessary inconvenience to its normal functioning. For example, although self-closing devices on doors help to ensure continuous fire- and smoke-compartmentation, the health care occupancy provisions of this *Code* do not require self-closing devices on patient room doors because of the day-to-day functional need for staff to monitor conditions while doors remain open. The health care occupancy chapters achieve the intended minimum level of life safety, without unduly interfering with normal operation of the facility, by combining other features and protection schemes. For example, 18.7.2 and 19.7.2, which apply to new and existing health care occupancies, respectively, require that staff establish procedures to be followed in case of fire, including closing doors to isolate the fire area and confine the effects of the fire.

In addressing life safety from fire and similar emergencies, the *Code* focuses on the movement of people in an emergency. However, many of the building features that assist with the safe movement of people in an emergency also provide increased safety during normal building use. For example, new stairs are not permitted to have a riser height that exceeds 17.8 cm (7 in.) or to provide a tread depth less than 27.9 cm (11 in.), to reduce the potential to trip under emergency egress use. This safe stair geometry also reduces the potential of tripping whenever the stair is used.

The occupancy chapters make varying use of any or all of the protection features in A.1.2(1) through A.1.2(8). A business occupancy located in a single-story building uses fewer of the protection features to accomplish the intended minimum level of life safety than does a health care occupancy. A health care occupancy accomplishes its minimum level of

life safety by extensively applying the features of A.1.2(1) through A.1.2(7) using a defend-in-place strategy. This strategy recognizes that some occupants of a health care occupancy are both incapable of self-preservation and difficult to move, particularly to other floors or to the exterior of the building.

Section 1.3* Application

A.1.3 It is the intent of Section 1.3 that a building, addition, or alteration designed to meet the requirements of a prior edition of the *Code* be required to meet those requirements for the life of the building. It is intended that the initial assessment of the building, when new, should be based on new occupancy requirements for the edition of the *Code* in effect on the date of plan approval. Subsequent assessments of the building should be based on new occupancy requirements of that same edition of the *Code* for the life of the building. Requirements for existing buildings in this edition of the *Code* apply if those requirements are more restrictive.

In some cases, the requirements for new construction are less restrictive, and it might be justified to permit an existing building to use the less restrictive requirements. However, extreme care needs to be exercised when granting such permission, because the less restrictive provision might be the result of a new requirement elsewhere in the *Code*. For example, in editions of the *Code* prior to 1991, corridors in new health care occupancies were required to have a 1-hour fire resistance rating. Since 1991, these corridors have been required only to resist the passage of smoke. However, this provision is based on the new requirement that all new health care facilities be protected throughout by automatic sprinklers.

1.3.1* New and Existing Buildings and Structures.

The *Code* shall apply to both new construction and existing buildings and existing structures.

A.1.3.1 Various chapters contain specific provisions for existing buildings and structures that might differ from those for new construction.

In order to provide a minimum level of life safety to all occupancies in all structures, the *Code* applies to both new construction and existing buildings. Provisions exist throughout the *Code* that apply specifically to existing buildings. Also, the *Code* contains requirements for new construction that have been modified to apply to existing buildings. The modifications were made to limit the resulting disruption and financial impact on existing buildings while providing the

minimum level of life safety. The requirements applicable to new construction are often more stringent than those for existing buildings, because providing appropriate life safety requirements is considered less disruptive and more cost-effective during construction. If no modification for existing buildings appears within a *Code* requirement, the same provision applies for new construction and existing buildings.

See also 4.6.4, 4.6.5, 4.6.8, and 4.6.10 and the definitions of *existing* and *existing building* in 3.3.60 and 3.3.27.5, respectively.

1.3.2 Vehicles and Vessels.

The *Code* shall apply to vehicles, vessels, or other similar conveyances, as specified in Section 11.6, in which case such vehicles and vessels shall be treated as buildings.

Section 1.4* Equivalency

Nothing in this *Code* is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this *Code*.

A.1.4 Before a particular mathematical fire model or evaluation system is used, its purpose and limitations need to be known. The technical documentation should clearly identify any assumptions included in the evaluation. Also, it is the intent of the Committee on Safety to Life to recognize that future editions of this *Code* are a further refinement of this edition and earlier editions. The changes in future editions will reflect the continuing input of the fire protection/life safety community in its attempt to meet the purpose stated in this *Code*.

Section 1.4, Equivalency, presents a powerful design alternative that permits individual and multiple specification-based requirements to be satisfied by components and systems that the authority having jurisdiction is convinced meet the goals, objectives, and intended level of life safety of the *Code*. Where all life safety systems, rather than individual and multiple specification-based systems, are engineered to meet the goals and objectives of the *Code*, true performance-based design is permitted in accordance with Chapter 5. In other words, equivalency deals with discrete, manageable pieces of the overall life safety system; performance-based design treats the system as a whole. See Section 4.4.

With each new edition, the *Code* continues its

evolution from a specification-based code to a performance-oriented code. Section 4.4 permits a complete performance-based design approach in accordance with Chapter 5. However, the traditional, widely accepted, specification-based approach is maintained as an option.

Section 1.4 recognizes that, although the majority of the *Code* uses specification language as the basis for enforcement, it should not inhibit the use of alternate or equivalent systems or design approaches to comply with *Code*-specified performance criteria. It is stipulated, however, that equivalency must be demonstrated by appropriate technical documentation. The evaluation and approval of such systems and approaches is the responsibility of the authority having jurisdiction.

The *Code* contemplates several forms of equivalency.

(a) *Code-Specified Alternative*. In some instances, the *Code* presents a written requirement and then provides an alternate method of obtaining the desired level of protection, usually via an exemption. For example, for new educational occupancies, 14.3.6 requires that interior corridors be constructed of 1-hour fire resistance-rated assemblies. However, 14.3.6(2) allows the 1-hour rating requirement to be reduced to that of a nonrated smoke partition if the building is protected throughout by an approved, supervised automatic sprinkler system. Thus, the *Code* specifies that the combination of smoke partitions and sprinkler protection is the equivalent of 1-hour fire resistance-rated corridor walls for new educational occupancies.

(b) *NFPA 101A Equivalency Methodologies*. NFPA 101A, *Guide on Alternative Approaches to Life Safety*¹, provides a set of equivalency methodologies that can be used to assess equivalency for health care occupancies, detention and correctional occupancies, board and care occupancies, and business occupancies. Each system awards positive point values for providing a building with strong life safety and fire protection features and assesses negative point values for unsafe conditions. Factors are weighted with respect to their impact on life safety principles. Positive point values are permitted to offset negative point values. The completed evaluations are presented to the authority having jurisdiction for review and approval.

In addition to the fire safety evaluation systems, NFPA 101A contains a procedure for determining the evacuation capability for residents of board and care occupancies. Use of this method is also subject to the review and approval of the authority having jurisdiction. The requirements of Chapter 33, applicable to

existing residential board and care occupancies, vary depending on the evacuation capability of the residents and staff working together as a group.

(c) *More Recent Edition of the Code.* As explained in A.1.4, future editions of the *Code* are considered refinements of earlier editions because they clarify intent with respect to the revised topics. Use of a newer edition in its entirety should be considered as equivalent to use of an earlier edition.

Caution must be exercised when applying this concept. It is important to recognize that specific provisions are part of a carefully crafted set of requirements that result in a desired level of life safety. A revision to one portion of the *Code* might be a part of, or the result of, changes to other parts of the *Code*. Therefore, it would be inappropriate to refer only to a specific section of a more recent edition of the *Code* that reflects a less stringent requirement than previous editions, without taking into account any associated provisions that may have become more stringent to compensate for the more relaxed subject provision.

It is not the intent of the *Code* to limit the user to the three specified methods of judging equivalency. It is the intent to allow emerging technology to be used to satisfy the prescribed performance requirements. Fire modeling (see 3.3.77) has developed to the stage that authorities having jurisdiction are routinely approving equivalency on the basis of such results. Additionally, results of fire tests and other documented forms of engineering analysis have prompted the approval of authorities having jurisdiction.

1.4.1 Technical Documentation.

Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.4.2 Approval.

The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

1.4.3* Equivalent Compliance.

Alternative systems, methods, or devices approved as equivalent by the authority having jurisdiction shall be recognized as being in compliance with this *Code*.

A.1.4.3 An equivalent method of protection provides an equal or greater level of safety. It is not a waiver or deletion of a *Code* requirement.

The prescriptive provisions of this *Code* provide specific requirements for broad classifications of buildings and structures. These requirements are stated in terms of fixed values, such as maximum travel distance, minimum fire resistance

ratings, and minimum features of required systems, such as detection, alarm, suppression, and ventilation, and not in terms of overall building or system performance.

However, the equivalency clause in 1.4.3 permits the use of alternative systems, methods, or devices to meet the intent of the prescribed code provisions where approved as being equivalent. Equivalency provides an opportunity for a performance-based design approach. Through the rigor of a performance-based design, it can be demonstrated whether or not a building design is satisfactory and complies with the implicit or explicit intent of the applicable code requirement.

When employing the equivalency clause, it is important to clearly identify the prescriptive-based code provision being addressed (scope), to provide an interpretation of the intent of the provision (goals and objectives), to provide an alternative approach (proposed design), and to provide appropriate support for the suggested alternative (evaluation of proposed designs).

Performance resulting from proposed designs can be compared to the performance of the design features required by this *Code*. Using prescribed features as a baseline for comparison, it can then be demonstrated in the evaluation whether a proposed design offers the intended level of performance. A comparison of safety provided can be used as the basis for establishing equivalency.

Subsection 1.4.3 emphasizes that there is more than one way to achieve *Code* compliance. A building either follows the specification criteria, achieves equivalency, or meets the requirements that apply to a full performance-based design. Where the equivalency option is used and the authority having jurisdiction has judged the alternative approach to life safety as providing equivalency to the *Code* requirements, a building is considered to be *Code*-compliant. Compliance through equivalency does not differ from compliance through strict adherence to the specification-based requirements; however, compliance through equivalency does differ from a waiver that permits continued use of a noncomplying building.

Section 1.5 Units and Formulas

1.5.1 SI Units.

Metric units of measurement in this *Code* are in accordance with the modernized metric system known as the International System of Units (SI).

1.5.2 Primary Values.

The SI value for a measurement, and the inch-pound value given in parentheses, shall each be acceptable for use as primary units for satisfying the requirements of this *Code*.

As required by the NFPA *Manual of Style*², metric (SI) units appear first and the inch-pound value is given within parentheses. As permitted by 1.5.2, the SI value and the inch-pound value are each acceptable for use as primary values for satisfying requirements of this *Code*.

In earlier editions of the *Code*, inch-pound units were primary and metric (SI) units were approximations developed using conversion factors. The metric (SI) values that now appear first are not intended to be any more precise than the old metric values. The metric values were calculated by taking the inch-pound values, applying conversion factors, and rounding to a specified number of significant digits.

Section 1.6 Enforcement

This *Code* shall be administered and enforced by the authority having jurisdiction designated by the governing authority.

CHAPTER 2

Referenced Publications

This chapter lists the mandatory referenced publications. Annex B lists nonmandatory referenced publications. In editions of the *Code* prior to 2000, the chapter that listed the mandatory referenced publications was located after the occupancy chapters but before the appendices (now called *annexes*). Current NFPA style and format policies dictate that the list of mandatory referenced publications appear in Chapter 2. By positioning the information immediately after Chapter 1, Administration, the *Code* user is presented with the complete list of publications needed for effective use of the *Code* before reading the “meat” of the requirements. The provisions of the publications that are mandated by the *Code* are also requirements, in the same way, for example, that the provisions of Chapter 7, Means of Egress, are mandated. Regardless of whether an actual requirement resides within the *Code* or is mandatorily referenced and appears only in the referenced publication, it is a requirement that must be met to achieve compliance with the *Code*.

The *Life Safety Code* achieves its intended level of occupant safety by mandating the installation of various building features and systems. Where specific equipment and systems are required, their proper installation and maintenance is important. Rather than develop its own installation criteria, the *Code* mandates the use of expert documents. The referenced document becomes a legally enforceable part of NFPA 101.

The level of reference to a particular document varies. For example, although NFPA 72®, *National Fire Alarm Code*®, allows numerous occupant-notification measures, NFPA 101 might limit the options that can be used for an occupancy. Paragraphs 14.3.4.3.1.2 and 15.3.4.3.1.2 permit positive alarm sequence notification for new and existing educational occupancies;

however, rather than specifying the role of positive alarm sequence, those paragraphs refer to 9.6.3.4. Paragraph 9.6.3.4 points the user to NFPA 72 for the detailed criteria applicable to positive alarm sequence, provided that the occupancy chapter has given permission for its use.

Another occupant notification method, the presignal system as described in NFPA 72, is addressed by the *Code*. Once again, though, an occupancy chapter must permit the presignal system. A presignal system is not permitted for use in educational occupancies. Therefore, even though it is recognized in NFPA 72, this occupant notification method is not permitted for schools. Thus, not all of the options offered by a referenced document can be used. The user of the *Code* must be aware of the reference and of any limitations or caveats on use of the referenced documents.

NFPA 101, like other NFPA codes and standards, can mandate the use of a referenced document only if that document is an ANSI consensus code or standard, provided that such an ANSI-accredited document exists. NFPA policy does not permit mandating the use of a referenced document that has not been developed under consensus procedures, nor does it permit reference to those documents developed by committees whose membership is not balanced with respect to user interests. A code or standard written by a committee dominated by an interest group has too great a potential for bias.

The documents listed in Chapter 2 are mandatory only to the extent called for in the *Code*. For example, the inclusion of NFPA 13, *Standard for the Installation of Sprinkler Systems*², here does not mean that all buildings must be sprinklered. Rather, where the *Code* requires buildings to be sprinklered, NFPA 13 is to be used for sprinkler installation. See 9.7.1.1(1)

as an example of *Code* language that mandatorily references the use of other NFPA documents.

The *Code* recognizes that existing installations need not be continuously upgraded as new editions of the referenced standards are adopted. This is specified in 4.6.6.

Section 2.1 General

The documents or portions thereof listed in this chapter are referenced within this *Code* and shall be considered part of the requirements of this document.

This chapter contains mandatory references to other documents. As noted in the commentary that followed the chapter title, the extent to which these documents are mandatory is specified within the *Code*.

The reasons for locating all mandatory references in a single chapter are, first, to simplify use of the

Code and, second, to make it easier for adopting jurisdictions to update the references in only one location rather than throughout the *Code*. The editions of the referenced publications listed in Chapter 2 are legally referenced editions unless the jurisdiction, when adopting the *Code*, has updated the list of codes and standards.

CHAPTER 3

Definitions

Anyone who has ever participated in a code-development process—whether it be NFPA’s or that of another organization—knows of the many hours spent deliberating whether the language is clear and easily understood and whether it expresses the committee’s intent. Establishing the requirements for a code is not an easy task. During committee meetings, the question is usually asked whether everyone will understand the limits or application of a particular rule. Invariably, the same questions are asked about select words or terms.

When words or terms used in the *Code* fall outside of generally accepted meanings or dictionary definitions—or otherwise require a clarification—they are defined in Chapter 3. When a word is not defined, the *Code* intends for the user to employ the dictionary definition—in this case, that found in *Webster’s Third New International Dictionary of the English Language, Unabridged*¹. See Section 3.1.

As an example, the word *exit* has numerous meanings in the dictionary. Included is the definition “goes off the stage,” used as a stage direction for a specified actor to leave the stage. Another definition includes the following three versions: (1) “the act of going out or going away,” (2) “death,” and (3) “a passage” or “a way out.” To the layperson, “passage” or “a way out” is probably what is understood when one hears the term *exit* used or sees an exit sign. The NFPA 101 definition, however, is somewhat more detailed and is used to fix the limits on what actually constitutes an exit. The NFPA 101 definition, in 3.3.62 reads:

Exit. That portion of a means of egress that is separated from all other spaces of a building or structure by construction or equipment as required to provide a protected way of travel to the exit discharge.

This is but one of many terms defined in Chapter 3 of the *Code*. The definitions of the occupancy classifications (for example, assembly occupancy, mercantile occupancy, industrial occupancy) appear in Chapter 3 and are repeated in their entirety in Chapter 6 to assist the user of the *Code* in properly classifying an occupancy.

The final point about defined terms in NFPA documents is that the definitions should not contain any requirements. To the extent possible, defined terms merely provide the meaning of a term within the context of the *Code*.

Section 3.1 General

The definitions contained in this chapter shall apply to the terms used in this code. Where terms are not included, common usage of the terms shall apply. The following terms, for the purposes of this *Code*, shall have the meanings given in this chapter, if not otherwise modified by another chapter. Words used in the present tense shall include the future; words used in the masculine gender shall include the feminine and neuter; the singular number shall include the plural, and the plural number shall include the singular. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Webster’s Third New International Dictionary of the English Language, Unabridged*, shall be a source for ordinarily accepted meaning.

Section 3.2 NFPA Official Definitions

3.2.1* Approved. Acceptable to the authority having jurisdiction.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

3.2.2* Authority Having Jurisdiction (AHJ). The organization, office, or individual responsible for approving equipment, materials, an installation, or a procedure.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase “authority having jurisdiction,” or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

3.2.3* Code. A standard that is an extensive compilation of provisions covering broad subject matter or that is suitable for adoption into law independently of other codes and standards.

A.3.2.3 Code. The decision to designate a standard as a “code” is based on such factors as the size and scope of the document, its intended use and form of adoption, and whether it contains substantial enforcement and administrative provisions.

3.2.4 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.5* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

A.3.2.5 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

3.2.6 Shall. Indicates a mandatory requirement.

3.2.7 Should. Indicates a recommendation or that which is advised but not required.

Section 3.3 General Definitions

3.3.1 Accessible Area of Refuge. See 3.3.17.1.

3.3.2 Accessible Means of Egress. See 3.3.136.1.

3.3.3 Addition. An increase in the building area, aggregate floor area, height or number of stories of a structure. [ASCE 7:9.2.1]

3.3.4 Air-Inflated Structure. See 3.3.217.1.

3.3.5 Airport Loading Walkway. An aboveground device through which passengers move between a point in an airport terminal building and an aircraft. Included in this category are walkways that are essentially fixed and permanently placed, or walkways that are essentially mobile in nature and that fold, telescope, or pivot from a fixed point at the airport terminal building. [415:1.4]

3.3.6 Airport Terminal Building. See 3.3.27.1.

3.3.7* Air-Supported Structure. See 3.3.217.2.

A.3.3.7 Air-Supported Structure. A cable-restrained air-supported structure is one in which the uplift is resisted by cables or webbing that is anchored by various methods to the membrane or that might be an integral part of the membrane. It is not a tensioned-membrane structure.

3.3.8* Aisle Accessway. The initial portion of an exit access that leads to an aisle.

A.3.3.8 Aisle Accessway. *Aisle accessway* is the term used for the previously unnamed means of egress component

leading to an aisle or other means of egress. For example, circulation space between parallel rows of seats having a width of 305 mm to 610 mm (12 in. to 24 in.) and a length not exceeding 30 m (100 ft) is an aisle accessway. Some of the circulation space between tables or seats in restaurants might be considered aisle accessway.

Depending on the width of aisle accessway, which is influenced by its length and expected utilization, the movement of a person through the aisle accessway might require others to change their individual speed of movement, alter their postures, move their chairs out of the way, or proceed ahead of the person.

3.3.9 Alarm.

3.3.9.1 Single Station Alarm. A detector comprising an assembly that incorporates a sensor, control components, and an alarm notification appliance in one unit operated from a power source either located in the unit or obtained at the point of installation. [72:1.4]

3.3.9.2 Smoke Alarm. A single- or multiple-station alarm responsive to smoke. [72:1.4]

3.3.10 Alternative Calculation Procedure. A calculation procedure that differs from the procedure originally employed by the design team but that provides predictions for the same variables of interest.

3.3.11 Ambulatory Health Care Occupancy. See 3.3.152.1.

3.3.12 Analysis.

3.3.12.1 Sensitivity Analysis. An analysis performed to determine the degree to which a predicted output will vary given a specified change in an input parameter, usually in relation to models.

3.3.12.2 Uncertainty Analysis. An analysis performed to determine the degree to which a predicted value will vary.

3.3.13 Anchor Building. See 3.3.27.2.

3.3.14 Apartment Building. See 3.3.27.3.

3.3.15 Approved Existing. See 3.3.60.1.

3.3.16 Area.

3.3.16.1 Detention and Correctional Residential Housing Area. Sleeping areas and any contiguous day room, group activity space, or other common space for customary access of residents.

3.3.16.2 Floor Area.

3.3.16.2.1* Gross Floor Area. The floor area within the inside perimeter of the outside walls of the building under consideration with no deduction for hallways, stairs, closets, thickness of interior walls, columns, or other features.

A.3.3.16.2.1 Gross Floor Area. Where the term *floor area* is used, it should be understood to be gross floor area unless otherwise specified.

3.3.16.2.2 Net Floor Area. The floor area within the inside perimeter of the outside walls, or the outside walls and fire walls of the building under consideration with deductions for hallways, stairs, closets, thickness of interior walls, columns, or other features.

3.3.16.3 Gross Leasable Area. The total floor area designed for tenant occupancy and exclusive use. The area of tenant occupancy is measured from the centerlines of joint partitions to the outside of the tenant walls.

3.3.16.4* Hazardous Area. An area of a structure or building that poses a degree of hazard greater than that normal to the general occupancy of the building or structure.

A.3.3.16.4 Hazardous Area. Hazardous areas include those areas used for the storage or use of combustibles or flammables; toxic, noxious, or corrosive materials; or heat-producing appliances.

3.3.16.5 Living Area. Any normally occupiable space in a residential occupancy, other than sleeping rooms or rooms that are intended for combination sleeping/living, bathrooms, toilet compartments, kitchens, closets, halls, storage or utility spaces, and similar areas.

3.3.17* Area of Refuge. An area that is either (1) a story in a building where the building is protected throughout by an approved, supervised automatic sprinkler system and has not less than two accessible rooms or spaces separated from each other by smoke-resisting partitions; or (2) a space located in a path of travel leading to a public way that is protected from the effects of fire, either by means of separation from other spaces in the same building or by virtue of location, thereby permitting a delay in egress travel from any level.

A.3.3.17 Area of Refuge. An area of refuge has a temporary use during egress. It generally serves as a staging area that provides relative safety to its occupants while potential emergencies are assessed, decisions are made, and mitigating activities are begun. Taking refuge within such an area is, thus, a stage of the total egress process; a stage between egress from the immediately threatened area and egress to a public way.

An area of refuge might be another building connected by a bridge or balcony, a compartment of a subdivided story, an elevator lobby, or an enlarged story-level exit stair landing. An area of refuge is accessible by means of horizontal travel or, as a minimum, via an accessible route meeting the requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

This *Code* recognizes any floor in a building protected throughout by an approved, supervised automatic sprinkler system as an area of refuge. This recognition acknowledges the ability of a properly designed and functioning automatic sprinkler system to control a fire at its point of origin and to limit the production of toxic products to a level that is not life threatening.

The requirement for separated rooms or spaces can be met on an otherwise undivided floor by enclosing the elevator lobby with ordinary glass or other simple enclosing partitions that are smoke resisting.

For some occupancies, one accessible room or space is permitted.

3.3.17.1 Accessible Area of Refuge. An area of refuge that complies with the accessible route requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

3.3.18 Assembly.

3.3.18.1 Fire Door Assembly. Any combination of a fire door, a frame, hardware, and other accessories that together provide a specific degree of fire protection to the opening. [80:1.4]

3.3.18.1.1 Floor Fire Door Assembly. A combination of a fire door, a frame, hardware, and other accessories installed in a horizontal plane, which together provide a specific degree of fire protection to a through-opening in a fire-rated floor.

3.3.18.2 Fire Window Assembly. A window or glass block assembly having a fire protection rating. [80:1.4]

3.3.19 Assembly Occupancy. See 3.3.152.2.

3.3.20 Atmosphere.

3.3.20.1 Common Atmosphere. The atmosphere that exists between rooms, spaces, or areas within a building that are not separated by an approved smoke barrier.

3.3.20.2 Separate Atmosphere. The atmosphere that exists between rooms, spaces, or areas that are separated by an approved smoke barrier.

3.3.21* Atrium. A large-volume space created by a floor opening or series of floor openings connecting two or more stories that is covered at the top of the series of openings and is used for purposes other than an enclosed stairway; an elevator hoistway; an escalator opening; or as a utility shaft used for plumbing, electrical, air-conditioning, or communications facilities.

A.3.3.21 Atrium. As defined in NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*, a large-volume space is an unpartitioned space, generally two or more stories in height, within which smoke from a fire either in the space or in a communicating space

can move and accumulate without restriction. Atria and covered malls are examples of large-volume spaces.

3.3.22 Automatic. That which provides a function without the necessity of human intervention.

3.3.23 Barrier.

3.3.23.1* Fire Barrier. A continuous membrane or a membrane with discontinuities created by protected openings with a specified fire protection rating, where such membrane is designed and constructed with a specified fire resistance rating to limit the spread of fire, that also restricts the movement of smoke.

A.3.3.23.1 Fire Barrier. A fire barrier might be vertically or horizontally aligned, such as a wall or floor assembly.

3.3.23.2* Smoke Barrier. A continuous membrane, or a membrane with discontinuities created by protected openings, where such membrane is designed and constructed to restrict the movement of smoke.

A.3.3.23.2 Smoke Barrier. A smoke barrier might be vertically or horizontally aligned, such as a wall, floor, or ceiling assembly. A smoke barrier might or might not have a fire resistance rating. Application of smoke barrier criteria where required elsewhere in the *Code* should be in accordance with Section 8.3.

3.3.23.3* Thermal Barrier. A material that limits the average temperature rise of an unexposed surface to not more than 139°C (250°F) for a specified fire exposure complying with the standard time-temperature curve of NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*.

A.3.3.23.3 Thermal Barrier. Finish ratings, as published in the *UL Fire Resistance Directory*, are one way of determining thermal barrier.

3.3.24* Birth Center. A facility in which low-risk births are expected following normal, uncomplicated pregnancies, and in which professional midwifery care is provided to women during pregnancy, birth, and postpartum.

A.3.3.24 Birth Center. A birth center is a low-volume service for healthy, childbearing women, and their families, who are capable of ambulation in the event of fire or fire-threatening events. Birth center mothers and babies have minimal analgesia, receive no general or regional anesthesia, and are capable of ambulation, even in second-stage labor.

3.3.25 Bleachers. A grandstand in which the seats are not provided with backrests.

3.3.26 Board and Care. See 3.3.152.13.

3.3.27* Building. Any structure used or intended for supporting or sheltering any use or occupancy.

A.3.3.27 Building. The term *building* is to be understood as if followed by the words *or portions thereof*. (See also *Structure*, A.3.3.217.)

3.3.27.1 Airport Terminal Building. A structure used primarily for air passenger enplaning or deplaning, including ticket sales, flight information, baggage handling, and other necessary functions in connection with air transport operation. This term includes any extensions and satellite buildings used for passenger handling or aircraft service functions. Aircraft loading walkways and “mobile lounges” are excluded. [415:1.4]

3.3.27.2 Anchor Building. An exterior perimeter building of low or ordinary combustible contents having direct access to a mall building, but having all required means of egress independent of the mall.

3.3.27.3* Apartment Building. A building or portion thereof containing three or more dwelling units with independent cooking and bathroom facilities.

A.3.3.27.3 Apartment Building. The *Code* specifies that, wherever there are three or more living units in a building, the building is considered an apartment building and is required to comply with either Chapter 30 or Chapter 31, as appropriate. Townhouse units are considered to be apartment buildings if there are three or more units in the building. The type of wall required between units in order to consider them to be separate buildings is normally established by the authority having jurisdiction. If the units are separated by a wall of sufficient fire resistance and structural integrity to be considered as separate buildings, then the provisions of Chapter 24 apply to each townhouse. Condominium status is a form of ownership, not occupancy; for example, there are condominium warehouses, condominium apartments, and condominium offices.

3.3.27.4 Bulk Merchandising Retail Building. A building in which the sales area includes the storage of combustible materials on pallets, in solid piles, or in racks in excess of 3660 mm (144 in.) in storage height.

3.3.27.5* Existing Building. A building erected or officially authorized prior to the effective date of the adoption of this edition of the *Code* by the agency or jurisdiction.

A.3.3.27.5 Existing Building. With respect to judging whether a building should be considered existing, the deciding factor is not when the building was designed or when construction started but, rather, the date plans were approved for construction by the appropriate authority having jurisdiction.

3.3.27.6* Flexible Plan and Open Plan Educational or Day-Care Building. A building or portion of a building designed for multiple teaching stations.

A.3.3.27.6 Flexible Plan and Open Plan Educational or Day-Care Building. Flexible plan buildings have movable corridor walls and movable partitions of full-height construction with doors leading from rooms to corridors. Open plan buildings have rooms and corridors delineated by tables, chairs, desks, bookcases, counters, low-height partitions, or similar furnishings. It is the intent that low-height partitions not exceed 1525 mm (60 in.).

3.3.27.7* High-Rise Building. A building greater than 23 m (75 ft) in height where the building height is measured from the lowest level of fire department vehicle access to the floor of the highest occupiable story.

A.3.3.27.7 High-Rise Building. It is the intent of this definition that, in determining the level from which the highest occupiable floor is to be measured, the enforcing agency should exercise reasonable judgment, including consideration of overall accessibility to the building by fire department personnel and vehicular equipment. Where a building is situated on a sloping terrain and there is building access on more than one level, the enforcing agency might select the level that provides the most logical and adequate fire department access.

3.3.27.8* Historic Building. A building or facility deemed to have historical, architectural, or cultural significance by a local, regional, or national jurisdiction.

A.3.3.27.8 Historic Building. Designation for a historic building might be in an official national, regional, or local historic register, listing, or inventory.

3.3.27.9* Mall Building. A building, including the mall, enclosing a number of tenants and occupancies wherein two or more tenants have a main entrance into the mall.

A.3.3.27.9 Mall Building. A mall building may enclose one or more uses, such as retail stores, drinking establishments, entertainment and amusement facilities, offices, and other similar uses.

3.3.27.10* Special Amusement Building. A building that is temporary, permanent, or mobile that contains a device or system that conveys passengers or provides a walkway along, around, or over a course in any direction as a form of amusement arranged so that the egress path is not readily apparent due to visual or audio distractions or an intentionally confounded egress path; or is not readily available due to the mode of conveyance through the building or structure.

A.3.3.27.10 Special Amusement Building. Such structures include amusements such as a haunted house, a roller coaster-type ride within a building, a multilevel play structure within a building, a submarine ride, and similar amusements where the occupants are not in the open air.

3.3.28 Bulk Merchandising Retail Building. See 3.3.27.4.

3.3.29 Business Occupancy. See 3.3.152.3.

3.3.30* Cellular or Foamed Plastic. A heterogeneous system comprised of not less than two phases, one of which is a continuous polymeric organic material, and the second of which is deliberately introduced for the purpose of distributing gas in voids throughout the material.

A.3.3.30 Cellular or Foamed Plastic. Cellular or foamed plastic might contain foamed and unfoamed polymeric or monomeric precursors (prepolymer, if used), plasticizers, fillers, extenders, catalysts, blowing agents, colorants, stabilizers, lubricants, surfactants, pigments, reaction control agents, processing aids, and flame retardants.

3.3.31 Combustible (Material). See 3.3.135.1.

3.3.32 Combustion. A chemical process that involves oxidation sufficient to produce light or heat.

3.3.33 Common Atmosphere. See 3.3.20.1.

3.3.34* Common Path of Travel. The portion of exit access that must be traversed before two separate and distinct paths of travel to two exits are available.

A.3.3.34 Common Path of Travel. Common path of travel is measured in the same manner as travel distance but terminates at that point where two separate and distinct routes become available. Paths that merge are common paths of travel.

3.3.35 Compartment.

3.3.35.1* Fire Compartment. A space within a building that is enclosed by fire barriers on all sides, including the top and bottom.

A.3.3.35.1 Fire Compartment. Additional fire compartment information is contained in 8.2.2.

In the provisions for fire compartments utilizing the outside walls of a building, it is not intended that the outside wall be specifically fire resistance-rated unless required by other standards. Likewise, it is not intended that outside windows or doors be protected, unless specifically required for exposure protection by another section of this *Code* or by other standards.

3.3.35.2* Smoke Compartment. A space within a building enclosed by smoke barriers on all sides, including the top and bottom.

A.3.3.35.2 Smoke Compartment. In the provision of smoke compartments using the outside walls or the roof of a building, it is not intended that outside walls or roofs or any openings therein be capable of resisting the passage of smoke. Application of smoke compartment

criteria where required elsewhere in the *Code* should be in accordance with Section 8.5.

3.3.36 Contents and Furnishings. Objects, goods, or products placed inside a structure for functional, operational, or decorative reasons, excluding parts of the building structure, building service equipment, and items meeting the definition of interior finish.

3.3.37 Court. An open, uncovered, unoccupied space, unobstructed to the sky, bounded on three or more sides by exterior building walls.

3.3.37.1 Enclosed Court. A court bounded on all sides by the exterior walls of a building or by the exterior walls and lot lines on which walls are permitted.

3.3.37.2 Food Court. A public seating area located in a mall that serves adjacent food preparation tenant spaces.

3.3.38* Critical Radiant Flux. The level of incident radiant heat energy on a floor-covering system at the most distant flameout point.

A.3.3.38 Critical Radiant Flux. Critical radiant flux is the property determined by the test procedure of NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*. The unit of measurement of critical radiant flux is watts per square centimeter (W/cm²).

3.3.39 Data Conversion. The process of developing the input data set for the assessment method of choice.

3.3.40 Day-Care Home. See 3.3.110.1.

3.3.41 Day-Care Occupancy. See 3.3.152.4.

3.3.42 Design Fire Scenario. See 3.3.80.1.

3.3.43 Design Specification. See 3.3.208.1.

3.3.44 Design Team. A group of stakeholders including, but not limited to, representatives of the architect, client, and any pertinent engineers and other designers.

3.3.45 Detention and Correctional Occupancy. See 3.3.152.5.

3.3.46 Detention and Correctional Residential Housing Area. See 3.3.16.1.

3.3.47 Door.

3.3.47.1 Elevator Lobby Door. A door between an elevator lobby and another building space other than the elevator shaft.

3.3.47.2 Fire Door. The door component of a fire door assembly. [80:1.4]

3.3.48* Dormitory. A building or a space in a building in which group sleeping accommodations are provided for more than 16 persons who are not members of the same family in one room, or a series of closely associated rooms, under joint occupancy and single management, with or without meals, but without individual cooking facilities.

A.3.3.48 Dormitory. Rooms within dormitories intended for the use of individuals for combined living and sleeping purposes are guest rooms or guest suites. Examples of dormitories are college dormitories, fraternity and sorority houses, and military barracks.

3.3.49 Draft Stop. A continuous membrane used to subdivide a concealed space to resist the passage of smoke and heat.

3.3.50 Dwelling Unit. One or more rooms arranged for the use of one or more individuals living together, providing complete, independent living facilities, including permanent provisions for living, sleeping, eating, cooking, and sanitation.

3.3.50.1 One- and Two-Family Dwelling Unit. A building that contains not more than two dwelling units with independent cooking and bathroom facilities.

3.3.50.2 One-Family Dwelling Unit. A building that consists solely of one dwelling unit with independent cooking and bathroom facilities.

3.3.50.3 Two-Family Dwelling Unit. A building that consists solely of two dwelling units with independent cooking and bathroom facilities.

3.3.51 Educational Occupancy. See 3.3.152.6.

3.3.52* Electroluminescent. Refers to a light-emitting capacitor in which alternating current excites phosphor atoms placed between electrically conductive surfaces and produces light.

A.3.3.52 Electroluminescent. This light source is typically contained inside the device.

3.3.53 Elevator Evacuation System. See 3.3.218.1.

3.3.54 Elevator Lobby. A space from which people directly enter an elevator car(s) and into which people directly enter upon leaving an elevator car(s).

3.3.55 Elevator Lobby Door. See 3.3.47.1.

3.3.56 Enclosed Court. See 3.3.37.1.

3.3.57* Evacuation Capability. The ability of occupants, residents, and staff as a group either to evacuate a building or to relocate from the point of occupancy to a point of safety.

A.3.3.57 Evacuation Capability. The evacuation capability of the residents and staff is a function of both the ability of the residents to evacuate and the assistance provided by the staff. It is intended that the evacuation capability be determined by the procedure acceptable to the authority having jurisdiction. It is also intended that the timing of drills, the rating of residents, and similar actions related to determining the evacuation capability be performed by persons approved by or acceptable to the authority having jurisdiction. The evacuation capability can be determined by the use of the definitions in 3.3.57, the application of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, Chapter 5, or a program of drills (timed).

Where drills are used in determining evacuation capability, it is suggested that the facility conduct and record fire drills six times per year on a bimonthly basis, with a minimum of two drills conducted during the night when residents are sleeping, and that the facility conduct the drills in consultation with the authority having jurisdiction. Records should indicate the time taken to reach a point of safety, date and time of day, location of simulated fire origin, escape paths used, and comments relating to residents who resisted or failed to participate in the drills.

Translation of drill times to evacuation capability is determined as follows:

- (1) 3 minutes or less—prompt
- (2) Over 3 minutes, but not in excess of 13 minutes—slow
- (3) More than 13 minutes—impractical

Evacuation capability, in all cases, is based on the time of day or night when evacuation of the facility would be most difficult, such as when residents are sleeping or fewer staff are present.

Evacuation capability determination is considered slow if the following conditions are met:

- (1) All residents are able to travel to centralized dining facilities without continuous staff assistance.
- (2) There is continuous staffing whenever there are residents in the facility.

3.3.57.1 Impractical Evacuation Capability. The inability of a group to reliably move to a point of safety in a timely manner.

3.3.57.2 Prompt Evacuation Capability. The ability of a group to move reliably to a point of safety in a timely manner that is equivalent to the capacity of a household in the general population.

3.3.57.3 Slow Evacuation Capability. The ability of a group to move reliably to a point of safety in a timely manner, but not as rapidly as members of a household in the general population.

3.3.58 Exhibit. A space or portable structure used for the display of products or services.

3.3.59 Exhibitor. An individual or entity engaged in the display of the products or services offered.

3.3.60* Existing. That which is already in existence on the date this edition of the *Code* goes into effect.

A.3.3.60 Existing. See *Existing Building*, A.3.3.27.5.

3.3.60.1 Approved Existing. That which is already in existence on the date this edition of the *Code* goes into effect and is acceptable to the authority having jurisdiction.

3.3.61 Existing Building. See 3.3.27.5.

3.3.62* Exit. That portion of a means of egress that is separated from all other spaces of a building or structure by construction or equipment as required to provide a protected way of travel to the exit discharge.

A.3.3.62 Exit. Exits include exterior exit doors, exit passageways, horizontal exits, exit stairs, and exit ramps. In the case of a stairway, the exit includes the stair enclosure, the door to the stair enclosure, stairs and landings inside the enclosure, the door from the stair enclosure to the outside or to the level of exit discharge, and any exit passageway and its associated doors if such are provided so as to discharge the stair directly to the outside. In the case of a door leading directly from the street floor to the street or open air, the exit comprises only the door.

Doors of small individual rooms, as in hotels, while constituting exit access from the room, are not referred to as exits except where they lead directly to the outside of the building from the street floor.

3.3.62.1* Horizontal Exit. A way of passage from one building to an area of refuge in another building on approximately the same level, or a way of passage through or around a fire barrier to an area of refuge on approximately the same level in the same building that affords safety from fire and smoke originating from the area of incidence and areas communicating therewith.

A.3.3.62.1 Horizontal Exit. Horizontal exits should not be confused with egress through doors in smoke barriers. Doors in smoke barriers are designed only for temporary protection against smoke, whereas horizontal exits provide protection against serious fire for a relatively long period of time in addition to providing immediate protection from smoke. (See 7.2.4.)

3.3.63 Exit Access. That portion of a means of egress that leads to an exit.

3.3.64 Exit Discharge. That portion of a means of egress between the termination of an exit and a public way.

3.3.64.1 Level of Exit Discharge. (1) The lowest story from which not less than 50 percent of the required

number of exits and not less than 50 percent of the required egress capacity from such a story discharge directly outside at grade; (2) the story with the smallest elevation change needed to reach grade where no story has 50 percent or more of the required number of exits and 50 percent or more of the required egress capacity from such a story discharge directly outside at grade.

3.3.65 Exposition. An event in which the display of products or services is organized to bring together the provider and user of the products or services.

3.3.66 Exposition Facility. See 3.3.69.1.

3.3.67* Exposure Fire. A fire that starts at a location that is remote from the area being protected and grows to expose that which is being protected.

A.3.3.67 Exposure Fire. An exposure fire usually refers to a fire that starts outside a building, such as a wildlands fire or vehicle fire, and that consequently exposes the building to a fire.

3.3.68 Externally Illuminated. See 3.3.114.1.

3.3.69 Facility.

3.3.69.1 Exposition Facility. A convention center, hotel, or other building at which exposition events are held.

3.3.69.2* Limited Care Facility. A building or portion of a building used on a 24-hour basis for the housing of four or more persons who are incapable of self-preservation because of age; physical limitations due to accident or illness; or limitations such as mental retardation/developmental disability, mental illness, or chemical dependency.

A.3.3.69.2 Limited Care Facility. Limited care facilities and residential board and care occupancies both provide care to people with physical and mental limitations. However, the goals and programs of the two types of occupancies differ greatly. The requirements in this *Code* for limited care facilities are based on the assumption that these are medical facilities, that they provide medical care and treatment, and that the patients are not trained to respond to the fire alarm; that is, the patients do not participate in fire drills but, rather, await rescue. (See Section 18.7.)

The requirements for residential board and care occupancies are based on the assumption that the residents are provided with personal care and activities that foster continued independence, that the residents are encouraged and taught to overcome their limitations, and that most residents, including all residents in prompt and slow homes, are trained to respond to fire drills, to the extent they are able. Residents are required to participate in fire drills. (See Section 32.7.)

3.3.70 Festival Seating. See 3.3.188.1.

3.3.71 Fire Barrier. See 3.3.23.1.

3.3.72 Fire Barrier Wall. See 3.3.229.1.

3.3.73 Fire Compartment. See 3.3.35.1.

3.3.74 Fire Door. See 3.3.47.2.

3.3.75 Fire Door Assembly. See 3.3.18.1.

3.3.76 Fire Exit Hardware. See 3.3.103.1.

3.3.77* Fire Model. A structured approach to predicting one or more effects of a fire.

A.3.3.77 Fire Model. Due to the complex nature of the principles involved, models are often packaged as computer software. Any relevant input data, assumptions, and limitations needed to properly implement the model will be attached to the fire models.

3.3.78 Fire Protection Rating. See 3.3.177.1.

3.3.79 Fire Resistance Rating. See 3.3.177.2.

3.3.80* Fire Scenario. A set of conditions that defines the development of fire, the spread of combustion products throughout a building or portion of a building, the reactions of people to fire, and the effects of combustion products.

A.3.3.80 Fire Scenario. A fire scenario defines the conditions under which a proposed design is expected to meet the fire safety goals. Factors typically include fuel characteristics, ignition sources, ventilation, building characteristics, and occupant locations and characteristics. The term *fire scenario* includes more than the characteristics of the fire itself but excludes design specifications and excludes any characteristics that do not vary from one fire to another; the latter are called assumptions. The term *fire scenario* is used here to mean only those specifications required to calculate the fire's development and effects but, in other contexts, the term might be used to mean both the initial specifications and the subsequent development and effects (that is, a complete description of fire from conditions prior to ignition to conditions following extinguishment).

3.3.80.1 Design Fire Scenario. A fire scenario used for evaluation of a proposed design.

3.3.81* Fire Watch. A person or persons assigned to an area for the purpose of protecting the occupants from fire or similar emergencies.

A.3.3.81 Fire Watch. Duties of the fire watch might include notifying the fire department and building occupants of an emergency, preventing a fire from occurring, or extinguishing small fires.

3.3.82 Fire Window Assembly. See 3.3.18.2.

3.3.83 Fixed Seating. See 3.3.188.2.

3.3.84* Flame Spread. The propagation of flame over a surface.

A.3.3.84 Flame Spread. See Section 10.2.

3.3.85* Flashover. A stage in the development of a contained fire in which all exposed surfaces reach ignition temperatures more or less simultaneously and fire spreads rapidly throughout the space.

A.3.3.85 Flashover. Flashover occurs when the surface temperatures of combustible contents rise, producing pyrolysis gases, and the room heat flux becomes sufficient to heat all such gases to their ignition temperatures.

3.3.86 Flexible Plan and Open Plan Educational or Day-Care Building. See 3.3.27.6.

3.3.87 Floor Fire Door Assembly. See 3.3.18.1.1.

3.3.88 Flow Time. A component of total evacuation time that is the time during which there is crowd flow past a point in the means of egress system.

3.3.89 Fly Gallery. A raised floor area above a stage from which the movement of scenery and operation of other stage effects are controlled.

3.3.90 Folding and Telescopic Seating. See 3.3.188.3.

3.3.91 Food Court. See 3.3.37.2.

3.3.92 Fuel Load. See 3.3.131.1.

3.3.93 General Industrial Occupancy. See 3.3.152.8.1.

3.3.94 Goal. A nonspecific overall outcome to be achieved that is measured on a qualitative basis.

3.3.95* Grandstand. A structure that provides tiered or stepped seating.

A.3.3.95 Grandstand. Where the term *grandstand* is preceded by an adjective denoting a material, it means a grandstand the essential members of which, exclusive of seating, are of the material designated.

3.3.96 Gridiron. The structural framing over a stage supporting equipment for hanging or flying scenery and other stage effects.

3.3.97 Gross Floor Area. See 3.3.16.2.1.

3.3.98 Gross Leasable Area. See 3.3.16.3.

3.3.99 Guard. A vertical protective barrier erected along exposed edges of stairways, balconies, and similar areas.

3.3.100 Guest Room. An accommodation combining living, sleeping, sanitary, and storage facilities within a compartment.

3.3.101 Guest Suite. An accommodation with two or more contiguous rooms comprising a compartment, with or without doors between such rooms, that provides living, sleeping, sanitary, and storage facilities.

3.3.102 Handrail. A bar, pipe, or similar member designed to furnish persons with a handhold.

3.3.103 Hardware.

3.3.103.1 Fire Exit Hardware. A door-latching assembly incorporating a device that releases the latch upon the application of a force in the direction of egress travel and provides fire protection where used as part of a fire door assembly.

3.3.103.2 Panic Hardware. A door-latching assembly incorporating a device that releases the latch upon the application of a force in the direction of egress travel.

3.3.104 Hazardous Area. See 3.3.16.4.

3.3.105 Health Care Occupancy. See 3.3.152.7.

3.3.106* Heat Release Rate (HRR). The rate at which heat energy is generated by burning.

A.3.3.106 Heat Release Rate (HRR). The heat release rate of a fuel is related to its chemistry, physical form, and availability of oxidant and is ordinarily expressed as British thermal units per second (Btu/s) or kilowatts (kW).

Chapter 40 and Chapter 42 include detailed provisions on high hazard industrial and storage occupancies.

3.3.107 High Hazard Industrial Occupancy. See 3.3.152.8.2.

3.3.108 High-Rise Building. See 3.3.27.7.

3.3.109 Historic Building. See 3.3.27.8.

3.3.110 Home.

3.3.110.1* Day-Care Home. A building or portion of a building in which more than 3 but not more than 12 clients receive care, maintenance, and supervision, by other than their relative(s) or legal guardians(s), for less than 24 hours per day.

A.3.3.110.1 Day-Care Home. A day-care home is generally located within a dwelling unit.

3.3.110.2 Nursing Home. A building or portion of a building used on a 24-hour basis for the housing and nursing care of four or more persons who, because of mental or physical incapacity, might be unable to provide for their own needs and safety without the assistance of another person.

3.3.111 Horizontal Exit. See 3.3.62.1.

3.3.112 Hospital. A building or portion thereof used on a 24-hour basis for the medical, psychiatric, obstetrical, or surgical care of four or more inpatients.

3.3.113* Hotel. A building or groups of buildings under the same management in which there are sleeping accommodations for more than 16 persons and primarily used by transients for lodging with or without meals.

A.3.3.113 Hotel. So-called apartment hotels should be classified as hotels because they are potentially subject to the same transient occupancy as hotels. Transients are those who occupy accommodations for less than 30 days.

3.3.114 Illuminated.

3.3.114.1* Externally Illuminated. Refers to an illumination source that is contained outside of the device or sign legend area that is to be illuminated.

A.3.3.114.1 Externally Illuminated. The light source is typically a dedicated incandescent or fluorescent source.

3.3.114.2* Internally Illuminated. Refers to an illumination source that is contained inside the device or legend that is illuminated.

A.3.3.114.2 Internally Illuminated. The light source is typically incandescent, fluorescent, electroluminescent, photoluminescent, light-emitting diodes, or self-luminous.

3.3.115 Impractical Evacuation Capability. See 3.3.57.1.

3.3.116 Incapacitation. A condition under which humans do not function adequately and become unable to escape untenable conditions.

3.3.117 Industrial Occupancy. See 3.3.152.8.

3.3.118 Input Data Specification. See 3.3.208.2.

3.3.119 Interior Ceiling Finish. See 3.3.120.1.

3.3.120* Interior Finish. The exposed surfaces of walls, ceilings, and floors within buildings.

A.3.3.120 Interior Finish. Interior finish is not intended to apply to surfaces within spaces such as those that are concealed or inaccessible. Furnishings that, in some cases, might be secured in place for functional reasons should not be considered as interior finish.

3.3.120.1 Interior Ceiling Finish. The interior finish of ceilings.

3.3.120.2* Interior Floor Finish. The interior finish of floors, ramps, stair treads and risers, and other walking surfaces.

A.3.3.120.2 Interior Floor Finish. Interior floor finish includes coverings applied over a normal finished floor or stair treads and risers.

3.3.120.3 Interior Wall Finish. The interior finish of columns, fixed or movable walls, and fixed or movable partitions.

3.3.121 Interior Floor Finish. See 3.3.120.2.

3.3.122 Interior Wall Finish. See 3.3.120.3.

3.3.123 Internally Illuminated. See 3.3.114.2.

3.3.124 Legitimate Stage. See 3.3.210.1.

3.3.125 Level of Exit Discharge. See 3.3.64.1.

3.3.126 Life Safety Evaluation. A written review dealing with the adequacy of life safety features relative to fire, storm, collapse, crowd behavior, and other related safety considerations.

3.3.127 Limited Access Structure. See 3.3.217.3.

3.3.128 Limited Care Facility. See 3.3.69.2.

3.3.129 Limited-Combustible (Material). See 3.3.135.2.

3.3.130 Living Area. See 3.3.16.5.

3.3.131 Load.

3.3.131.1* Fuel Load. The total quantity of combustible contents of a building, space, or fire area.

A.3.3.131.1 Fuel Load. Fuel load includes interior finish and trim.

3.3.131.2 Occupant Load. The total number of persons that might occupy a building or portion thereof at any one time.

3.3.132 Lodging or Rooming House. A building or portion thereof that does not qualify as a one- or two-family dwelling, that provides sleeping accommodations for a total of 16 or fewer people on a transient or permanent basis, without personal care services, with or without meals, but without separate cooking facilities for individual occupants.

3.3.133 Mall. A roofed or covered common pedestrian area within a mall building that serves as access for two or more tenants and does not exceed three levels that are open to each other.

3.3.134 Mall Building. See 3.3.27.9.

3.3.135 Material.

3.3.135.1 Combustible (Material). A material that, in the form in which it is used and under the conditions anticipated, will ignite and burn; a material that does not meet the definition of noncombustible or limited-combustible.

3.3.135.2* Limited-Combustible (Material). Refers to a building construction material not complying with the definition of *noncombustible* (see 3.3.135.3) that, in the form in which it is used, has a potential heat value not exceeding 8140 kJ/kg (3500 Btu/lb), where tested in accordance with NFPA 259, *Standard Test Method for Potential Heat of Building Materials*, and includes (1) materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 3.2 mm (in.) that has a flame spread index not greater than 50; and (2) materials, in the form and thickness used, other than as described in (1), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. [220:2.1]

A.3.3.135.2 Limited-Combustible (Material). Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition are considered combustible. See NFPA 259, *Standard Test Method for Potential Heat of Building Materials* and NFPA 220, *Standard on Types of Building Construction*.

3.3.135.3 Noncombustible (Material). Refers to a material that, in the form in which it is used and under the conditions anticipated, does not ignite, burn, support combustion, or release flammable vapors, when subjected to fire or heat. Materials that are reported as passing ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750 Degrees C*, are considered noncombustible materials.

3.3.135.4 Weathered-Membrane Material. Membrane material that has been subjected to not less than 3000 hours in a weatherometer in accordance with ASTM G 155, *Standard Practice for Operating Xenon Arc Light Apparatus for Exposure of Non-Metallic Materials*, or approved equivalent.

3.3.136* Means of Egress. A continuous and unobstructed way of travel from any point in a building or structure to a public way consisting of three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge.

A.3.3.136 Means of Egress. A means of egress comprises the vertical and horizontal travel and includes intervening room spaces, doorways, hallways, corridors, passageways, balconies, ramps, stairs, elevators, enclosures, lobbies, escalators, horizontal exits, courts, and yards.

3.3.136.1 Accessible Means of Egress. A means of egress that provides an accessible route to an area of refuge, a horizontal exit, or a public way.

3.3.137 Means of Escape. A way out of a building or structure that does not conform to the strict definition of *means of egress* but does provide an alternate way out.

3.3.138 Membrane. For the purposes of membrane structures, thin, flexible, water-impervious material capable of being supported by an air pressure of 38 mm (1½ in.) water column.

3.3.139 Membrane Structure. See 3.3.217.4.

3.3.140 Mercantile Occupancy. See 3.3.152.9.

3.3.141 Mezzanine. An intermediate level between the floor and the ceiling of any room or space.

3.3.142 Mixed Occupancy. See 3.3.152.10.

3.3.143* Modification. The reconfiguration of any space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.

A.3.3.143 Modification. Modification does not include repair or replacement of interior finishes.

3.3.144 Multilevel Play Structure. See 3.3.217.5.

3.3.145 Multiple Occupancy. See 3.3.152.11.

3.3.146 Multiple Station Alarm Device. Two or more single-station alarm devices that can be interconnected so that actuation of one causes all integral audible alarms to operate; or one single-station alarm device having connections to other detectors or to a manual fire alarm box. [72:1.4]

3.3.147 Multipurpose Assembly Occupancy. See 3.3.152.2.1.

3.3.148 Net Floor Area. See 3.3.16.2.2.

3.3.149 Noncombustible (Material). See 3.3.135.3.

3.3.150 Nursing Home. See 3.3.110.2.

3.3.151* Objective. A requirement that needs to be met to achieve a goal.

A.3.3.151 Objective. Objectives define a series of actions necessary to make the achievement of a goal more likely. Objectives are stated in more specific terms than goals and are measured on a more quantitative, rather than qualitative, basis.

3.3.152 Occupancy. The purpose for which a building or portion thereof is used or intended to be used.

3.3.152.1* Ambulatory Health Care Occupancy. A building or portion thereof used to provide services or treatment simultaneously to four or more patients that

provides, on an outpatient basis, one or more of the following: (1) Treatment for patients that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others; (2) Anesthesia that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others; (3) Emergency or urgent care for patients who, due to the nature of their injury or illness, are incapable of taking action for self-preservation under emergency conditions without the assistance of others.

A.3.3.152.1 Ambulatory Health Care Occupancy. It is not the intent that occupants be considered to be incapable of self-preservation just because they are in a wheelchair or use assistive walking devices such as a cane, a walker, or crutches. Rather it is the intent to address emergency care centers that receive patients who have been rendered incapable of self-preservation due to the emergency, such as being rendered unconscious as a result of an accident or being unable to move oneself due to sudden illness.

3.3.152.2* Assembly Occupancy. An occupancy (1) used for a gathering of 50 or more persons for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar uses; or (2) used as a special amusement building, regardless of occupant load.

A.3.3.152.2 Assembly Occupancy. Assembly occupancies might include the following:

- (1) Armories
- (2) Assembly halls
- (3) Auditoriums
- (4) Bowling lanes
- (5) Club rooms
- (6) College and university classrooms, 50 persons and over
- (7) Conference rooms
- (8) Courtrooms
- (9) Dance halls
- (10) Drinking establishments
- (11) Exhibition halls
- (12) Gymnasiums
- (13) Libraries
- (14) Mortuary chapels
- (15) Motion picture theaters
- (16) Museums
- (17) Passenger stations and terminals of air, surface, underground, and marine public transportation facilities
- (18) Places of religious worship
- (19) Pool rooms

- (20) Recreation piers
- (21) Restaurants
- (22) Skating rinks
- (23) Special amusement buildings regardless of occupant load
- (24) Theaters

Assembly occupancies are characterized by the presence or potential presence of crowds with attendant panic hazard in case of fire or other emergency. They are generally open or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. Such buildings are ordinarily occupied by able-bodied persons and are not used for sleeping purposes. Special conference rooms, snack areas, and other areas incidental to, and under the control of, the management of other occupancies, such as offices, fall under the 50-person limitation.

Restaurants and drinking establishments with an occupant load of fewer than 50 persons should be classified as mercantile occupancies.

For special amusement buildings, see 12.4.7 and 13.4.7.

3.3.152.2.1 Multipurpose Assembly Occupancy. An assembly room designed to accommodate temporarily any of several possible assembly uses.

3.3.152.3* Business Occupancy. An occupancy used for account and record keeping or the transaction of business other than mercantile.

A.3.3.152.3 Business Occupancy. Business occupancies include the following:

- (1) Air traffic control towers (ATCTs)
- (2) City halls
- (3) College and university instructional buildings, classrooms under 50 persons, and instructional laboratories
- (4) Courthouses
- (5) Dentists' offices
- (6) Doctors' offices
- (7) General offices
- (8) Outpatient clinics, ambulatory
- (9) Town halls

Doctors' and dentists' offices are included, unless of such character as to be classified as ambulatory health care occupancies. (See 3.3.152.1.)

Birth centers should be classified as business occupancies if they are occupied by fewer than four patients, not including infants, at any one time; do not provide sleeping facilities for four or more occupants; and do not provide treatment procedures that render four or more patients, not including infants, incapable of self-preservation at any one time. For birth centers

occupied by patients not meeting these parameters, see Chapter 18 or Chapter 19, as appropriate.

Service facilities common to city office buildings such as newsstands, lunch counters serving fewer than 50 persons, barber shops, and beauty parlors are included in the business occupancy group.

City halls, town halls, and courthouses are included in this occupancy group insofar as their principal function is the transaction of public business and the keeping of books and records. Insofar as they are used for assembly purposes, they are classified as assembly occupancies.

3.3.152.4* Day-Care Occupancy. An occupancy in which four or more clients receive care, maintenance, and supervision, by other than their relatives or legal guardians, for less than 24 hours per day.

A.3.3.152.4 Day-Care Occupancy. Day-care occupancies include the following:

- (1) Adult day-care occupancies, except where part of a health care occupancy
- (2) Child day-care occupancies
- (3) Day-care homes
- (4) Kindergarten classes that are incidental to a child day-care occupancy
- (5) Nursery schools

In areas where public schools offer only half-day kindergarten programs, many child day-care occupancies offer state-approved kindergarten classes for children who need full-day care. Because these classes are normally incidental to the day-care occupancy, the requirements of the day-care occupancy should be followed.

3.3.152.5* Detention and Correctional Occupancy. An occupancy used to house four or more persons under varied degrees of restraint or security where such occupants are mostly incapable of self-preservation because of security measures not under the occupants' control.

A.3.3.152.5 Detention and Correctional Occupancy. Detention and correctional occupancies include the following:

- (1) Adult and juvenile substance abuse centers
- (2) Adult and juvenile work camps
- (3) Adult community residential centers
- (4) Adult correctional institutions
- (5) Adult local detention facilities
- (6) Juvenile community residential centers
- (7) Juvenile detention facilities
- (8) Juvenile training schools

3.3.152.6* Educational Occupancy. An occupancy used for educational purposes through the twelfth grade

by six or more persons for 4 or more hours per day or more than 12 hours per week.

A.3.3.152.6 Educational Occupancy. Educational occupancies include the following:

- (1) Academies
- (2) Kindergartens
- (3) Schools

An educational occupancy is distinguished from an assembly occupancy in that the same occupants are regularly present.

3.3.152.7* Health Care Occupancy. An occupancy used for purposes of medical or other treatment or care of four or more persons where such occupants are mostly incapable of self-preservation due to age, physical or mental disability, or because of security measures not under the occupants' control.

A.3.3.152.7 Health Care Occupancy. Health care occupancies include the following:

- (1) Ambulatory health care facilities
- (2) Hospitals
- (3) Limited care facilities
- (4) Nursing homes

Occupants of health care occupancies typically have physical or mental illness, disease, or infirmity. They also include infants, convalescents, or infirm aged persons.

3.3.152.8* Industrial Occupancy. An occupancy in which products are manufactured or in which processing, assembling, mixing, packaging, finishing, decorating, or repair operations are conducted.

A.3.3.152.8 Industrial Occupancy. Industrial occupancies include the following:

- (1) Dry cleaning plants
- (2) Factories of all kinds
- (3) Food processing plants
- (4) Gas plants
- (5) Hangars (for servicing/maintenance)
- (6) Laundries
- (7) Power plants
- (8) Pumping stations
- (9) Refineries
- (10) Sawmills
- (11) Telephone exchanges

In evaluating the appropriate classification of laboratories, the authority having jurisdiction should treat each case individually based on the extent and nature of the associated hazards. Some laboratories are classified as occupancies other than industrial, for example, a physical therapy laboratory or a computer laboratory.

3.3.152.8.1* General Industrial Occupancy. An in-

dustrial occupancy in which ordinary and low hazard industrial operations are conducted in buildings of conventional design suitable for various types of industrial processes.

A.3.3.152.8.1 General Industrial Occupancy. General industrial occupancies include multistory buildings where floors are occupied by different tenants or buildings suitable for such occupancy and, therefore, are subject to possible use for types of industrial processes with a high density of employee population.

3.3.152.8.2* High Hazard Industrial Occupancy. An industrial occupancy in which industrial operations that include high hazard materials, processes, or contents are conducted.

A.3.3.152.8.2 High Hazard Industrial Occupancy. A high hazard occupancy includes occupancies where gasoline and other flammable liquids are handled, used, or stored under such conditions that involve possible release of flammable vapors; where grain dust, wood flour or plastic dusts, aluminum or magnesium dust, or other explosive dusts are produced; where hazardous chemicals or explosives are manufactured, stored, or handled; where cotton or other combustible fibers are processed or handled under conditions that might produce flammable flyings; and where other situations of similar hazard exist. Chapter 40 and Chapter 42 include detailed provisions on high hazard industrial and storage occupancies.

3.3.152.8.3 Special-Purpose Industrial Occupancy. An industrial occupancy in which ordinary and low hazard industrial operations are conducted in buildings designed for, and suitable only for, particular types of operations, characterized by a relatively low density of employee population, with much of the area occupied by machinery or equipment.

3.3.152.9* Mercantile Occupancy. An occupancy used for the display and sale of merchandise.

A.3.3.152.9 Mercantile Occupancy. Mercantile occupancies include the following:

- (1) Auction rooms
- (2) Department stores
- (3) Drugstores
- (4) Restaurants with fewer than 50 persons
- (5) Shopping centers
- (6) Supermarkets

Office, storage, and service facilities incidental to the sale of merchandise and located in the same building should be considered part of the mercantile occupancy classification.

3.3.152.10 Mixed Occupancy. A multiple occupancy where the occupancies are intermingled.

3.3.152.11 Multiple Occupancy. A building or structure in which two or more classes of occupancy exist.

3.3.152.12* Residential Occupancy. An occupancy that provides sleeping accommodations for purposes other than health care or detention and correctional.

A.3.3.152.12 Residential Occupancy. Residential occupancies are treated as separate occupancies in this Code as follows:

- (1) One- and two-family dwellings (Chapter 24)
- (2) Lodging or rooming houses (Chapter 26)
- (3) Hotels, motels, and dormitories (Chapter 28 and Chapter 29)
- (4) Apartment buildings (Chapter 30 and Chapter 31)

3.3.152.13* Residential Board and Care Occupancy. A building or portion thereof that is used for lodging and boarding of four or more residents, not related by blood or marriage to the owners or operators, for the purpose of providing personal care services.

A.3.3.152.13 Residential Board and Care Occupancy. The following are examples of facilities that are classified as residential board and care occupancies:

- (1) A group housing arrangement for physically or mentally handicapped persons who normally attend school in the community, attend worship in the community, or otherwise use community facilities
- (2) A group housing arrangement for physically or mentally handicapped persons who are undergoing training in preparation for independent living, for paid employment, or for other normal community activities
- (3) A group housing arrangement for the elderly that provides personal care services but that does not provide nursing care
- (4) Facilities for social rehabilitation, alcoholism, drug abuse, or mental health problems that contain a group housing arrangement and that provide personal care services but do not provide acute care
- (5) Assisted living facilities
- (6) Other group housing arrangements that provide personal care services but not nursing care

3.3.152.14 Separated Occupancy. A multiple occupancy where the occupancies are separated by fire resistance-rated assemblies.

3.3.152.15* Storage Occupancy. An occupancy used primarily for the storage or sheltering of goods, merchandise, products, vehicles, or animals.

A.3.3.152.15 Storage Occupancy. Storage occupancies include the following:

- (1) Barns
- (2) Bulk oil storage

- (3) Cold storage
- (4) Freight terminals
- (5) Grain elevators
- (6) Hangars (for storage only)
- (7) Parking structures
- (8) Stables
- (9) Truck and marine terminals
- (10) Warehouses

Storage occupancies are characterized by the presence of relatively small numbers of persons in proportion to the area.

3.3.153 Occupant Characteristics. The abilities or behaviors of people before and during a fire.

3.3.154 Occupant Load. See 3.3.131.2.

3.3.155 Occupiable Story. See 3.3.214.1.

3.3.156 Open-Air Mercantile Operation. An operation conducted outside of all structures, with the operations area devoid of all walls and roofs except for small, individual, weather canopies.

3.3.157 Open Parking Structure. See 3.3.217.7.

3.3.158 Open Structure. See 3.3.217.6.

3.3.159* Outside Stair. A stair with not less than one side open to the outer air.

A.3.3.159 Outside Stair. See 7.2.2.

3.3.160 Panic Hardware. See 3.3.103.2.

3.3.161* Performance Criteria. Threshold values on measurement scales that are based on quantified performance objectives.

A.3.3.161 Performance Criteria. Performance criteria are stated in engineering terms. Engineering terms include temperatures, radiant heat flux, and levels of exposure to fire products. Performance criteria provide threshold values used to evaluate a proposed design.

3.3.162 Permanent Structure. See 3.3.217.8.

3.3.163* Personal Care. The care of residents who do not require chronic or convalescent medical or nursing care.

A.3.3.163 Personal Care. Personal care involves responsibility for the safety of the resident while inside the building. Personal care might include daily awareness by management of the resident's functioning and whereabouts, making and reminding a resident of appointments, the ability and readiness for intervention in the event of a resident experiencing a crisis, supervision in the areas of nutrition and medication, and actual provision of transient medical care.

3.3.164* Photoluminescent. Having the property of emitting light that continues for a length of time after excitation by visible or invisible light has been removed.

A.3.3.164 Photoluminescent. The light source is considered internally illuminated.

3.3.165 Pinrail. A rail on or above a stage through which belaying pins are inserted and to which lines are fastened.

3.3.166* Platform. The raised area within a building used for the presentation of music, plays, or other entertainment.

A.3.3.166 Platform. Platforms also include the head tables for special guests; the raised area for lecturers and speakers; boxing and wrestling rings; theater-in-the-round; and for similar purposes wherein there are no overhead drops, pieces of scenery, or stage effects other than lighting and a screening valance. A platform is not intended to be prohibited from using a curtain as a valance to screen or hide the electric conduit, lighting track, or similar fixtures, nor is a platform prohibited from using curtains that are used to obscure the back wall of the stage; a curtain between the auditorium and the stage (grand or house curtain), a maximum of four leg drops; or a valance to screen light panels, plumbing, and similar equipment from view.

3.3.166.1 Temporary Platform. A platform erected within an area for not more than 30 days.

3.3.167 Plenum. A compartment or chamber to which one or more air ducts are connected and that forms part of the air-distribution system.

3.3.168 Point of Safety. A location that (a) is exterior to and away from a building; or (b) is within a building of any type construction protected throughout by an approved automatic sprinkler system and that is either (1) within an exit enclosure meeting the requirements of this *Code*, or (2) within another portion of the building that is separated by smoke barriers in accordance with Section 8.5, with not less than a ½-hour fire resistance rating, and that portion of the building has access to a means of escape or exit that conforms to the requirements of this *Code* and does not necessitate return to the area of fire involvement; or (c) is within a building of Type I, Type II(222), Type II(111), Type III(211), Type IV, or Type V(111) construction (*see* 8.2.1.2) and is either (1) within an exit enclosure meeting the requirements of this *Code*, or (2) within another portion of the building that is separated by smoke barriers in accordance with Section 8.5, with not less than a ½-hour fire resistance rating, and that portion of the building has access to a means of escape or exit that conforms to the requirements of this *Code* and does not necessitate return to the area of fire involvement.

3.3.169 Previously Approved. That which was acceptable to the authority having jurisdiction prior to the date this edition of the *Code* went into effect.

3.3.170 Private Party Tent. *See* 3.3.222.1.

3.3.171 Professional Engineer. A person registered or licensed to practice engineering in a jurisdiction, subject to all laws and limitations imposed by the jurisdiction.

3.3.172 Prompt Evacuation Capability. *See* 3.3.57.2.

3.3.173* Proposed Design. A design developed by a design team and submitted to the authority having jurisdiction for approval.

A.3.3.173 Proposed Design. The design team might develop a number of trial designs that will be evaluated to determine whether they meet the performance criteria. One of the trial designs will be selected from those that meet the performance criteria for submission to the authority having jurisdiction as the proposed design.

The proposed design is not necessarily limited to fire protection systems and building features. It also includes any component of the proposed design that is installed, established, or maintained for the purpose of life safety, without which the proposed design could fail to achieve specified performance criteria. Therefore, the proposed design often includes emergency procedures and organizational structures that are needed to meet the performance criteria specified for the proposed design.

3.3.174 Proscenium Wall. *See* 3.3.229.2.

3.3.175 Public Way. A street, alley, or other similar parcel of land essentially open to the outside air deeded, dedicated, or otherwise permanently appropriated to the public for public use and having a clear width and height of not less than 3050 mm (120 in.).

3.3.176* Ramp. A walking surface that has a slope steeper than 1 in 20.

A.3.3.176 Ramp. *See* 7.2.5.

3.3.177 Rating.

3.3.177.1 Fire Protection Rating. The designation indicating the duration of the fire test exposure to which a fire door assembly or fire window assembly was exposed and for which it met all the acceptance criteria as determined in accordance with NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, or NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*, respectively.

3.3.177.2 Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have with-

stood a fire exposure as determined by the tests or methods based on tests, prescribed by this *Code*.

3.3.178 Registered Architect. A person licensed to practice architecture in a jurisdiction, subject to all laws and limitations imposed by the jurisdiction.

3.3.179 Registered Design Professional (RDP). An individual who is registered or licensed to practice his/her respective design profession as defined by the statutory requirements of the professional registration laws of the state or jurisdiction in which the project is to be constructed.

3.3.180 Regular Stage. See 3.3.210.2.

3.3.181 Residential Board and Care Occupancy. See 3.3.152.13.

3.3.182 Residential Board and Care Resident. A person who receives personal care and resides in a residential board and care facility.

3.3.183 Residential Occupancy. See 3.3.152.12.

3.3.184 Safe Location. A location remote or separated from the effects of a fire so that such effects no longer pose a threat.

3.3.185 Safety Factor. A factor applied to a predicted value to ensure that a sufficient safety margin is maintained.

3.3.186 Safety Margin. The difference between a predicted value and the actual value where a fault condition is expected.

3.3.187 Sally Port (Security Vestibule). A compartment provided with two or more doors where the intended purpose is to prevent continuous and unobstructed passage by allowing the release of only one door at a time.

3.3.188 Seating.

3.3.188.1* Festival Seating. A form of audience/spectator accommodation in which no seating, other than a floor or ground surface, is provided for the audience/spectators gathered to observe a performance.

A.3.3.188.1 Festival Seating. Festival seating describes situations in assembly occupancies where live entertainment events are held that are expected to result in overcrowding and high audience density that can compromise public safety. It is not the intent to apply the term *festival seating* to exhibitions; sports events; dances; conventions; and bona fide political, religious, and educational events. Assembly occupancies with 1.4 m² (15 ft²) or more per person should not be considered festival seating.

3.3.188.2 Fixed Seating. Seating that is secured to the building structure.

3.3.188.3 Folding and Telescopic Seating. A structure that is used for tiered seating of persons and whose overall shape and size can be reduced, without being dismantled, for purposes of moving or storing.

3.3.188.4 Smoke-Protected Assembly Seating. Seating served by means of egress that is not subject to smoke accumulation within or under the structure.

3.3.189 Self-Closing. Equipped with an approved device that ensures closing after opening.

3.3.190* Self-Luminous. Illuminated by a self-contained power source and operated independently of external power sources.

A.3.3.190 Self-Luminous. An example of a self-contained power source is tritium gas. Batteries do not qualify as a self-contained power source. The light source is typically contained inside the device.

3.3.191* Self-Preservation (Day-Care Occupancy). The ability of a client to evacuate a day-care occupancy without direct intervention by a staff member.

A.3.3.191 Self-Preservation (Day-Care Occupancy). Examples of clients who are incapable of self-preservation include infants, clients who are unable to use stairs because of confinement to a wheelchair or other physical disability, and clients who cannot follow directions or a group to the outside of a facility due to mental or behavioral disorders. It is the intent of this *Code* to classify children under the age of 24 months as incapable of self-preservation. Examples of direct intervention by staff members include carrying a client, pushing a client outside in a wheelchair, and guiding a client by direct hand-holding or continued bodily contact. If clients cannot exit the building by themselves with minimal intervention from staff members, such as verbal orders, classification as incapable of self-preservation should be considered.

3.3.192 Sensitivity Analysis. See 3.3.12.1.

3.3.193 Separate Atmosphere. See 3.3.20.2.

3.3.194 Separated Occupancy. See 3.3.152.14.

3.3.195 Severe Mobility Impairment. The ability to move to stairs but without the ability to use the stairs.

3.3.196 Single-Station Alarm. See 3.3.9.1.

3.3.197 Slow Evacuation Capability. See 3.3.57.3.

3.3.198 Smoke Alarm. See 3.3.9.2.

3.3.199 Smoke Barrier. See 3.3.23.2.

3.3.200 Smoke Compartment. See 3.3.35.2.

3.3.201 Smoke Detector. A device that detects visible or invisible particles of combustion. [72:1.4]

3.3.202* Smoke Partition. A continuous membrane that is designed to form a barrier to limit the transfer of smoke.

A.3.3.202 Smoke Partition. A smoke partition is not required to have a fire resistance rating.

3.3.203* Smokeproof Enclosure. A stair enclosure designed to limit the movement of products of combustion produced by a fire.

A.3.3.203 Smokeproof Enclosure. For further guidance, see the following publications:

- (1) ASHRAE *Handbook and Product Directory—Fundamentals*
- (2) *Design of Smoke Management Systems*, by Klote and Milke
- (3) NFPA 105, *Standard for the Installation of Smoke Door Assemblies*

3.3.204 Smoke-Protected Assembly Seating. See 3.3.188.4.

3.3.205 Special Amusement Building. See 3.3.27.10.

3.3.206 Special Inspection. Services provided by a qualified person, retained by the owner and approved by the authority having jurisdiction, who observes the installation and witnesses the pretesting and operation of the system or systems.

3.3.207 Special-Purpose Industrial Occupancy. See 3.3.152.8.3.

3.3.208 Specification.

3.3.208.1* Design Specification. A building characteristic and other conditions that are under the control of the design team.

A.3.3.208.1 Design Specification. Design specifications include both hardware and human factors, such as the conditions produced by maintenance and training. For purposes of performance-based design, the design specifications of interest are those that affect the ability of the building to meet the stated goals and objectives.

3.3.208.2 Input Data Specification. Information required by the verification method.

3.3.209 Staff (Residential Board and Care). Persons who provide personal care services, supervision, or assistance.

3.3.210 Stage. A space within a building used for entertainment and utilizing drops or scenery or other stage effects.

3.3.210.1 Legitimate Stage. A stage with a height greater than 15 m (50 ft) measured from the lowest

point on the stage floor to the highest point of the roof or floor deck above.

3.3.210.2 Regular Stage. A stage with a height of 15 m (50 ft) or less measured from the lowest point on the deck above.

3.3.211 Stakeholder. An individual, or representative of same, having an interest in the successful completion of a project.

3.3.212 Standpipe System. See 3.3.218.2.

3.3.213 Storage Occupancy. See 3.3.152.15.

3.3.214 Story. The portion of a building located between the upper surface of a floor and the upper surface of the floor or roof next above.

3.3.214.1* Occupiable Story. A story occupied by people on a regular basis.

A.3.3.214.1 Occupiable Story. Stories used exclusively for mechanical equipment rooms, elevator penthouses, and similar spaces are not occupiable stories.

3.3.215 Street. A public thoroughfare that has been dedicated for vehicular use by the public and can be used for access by fire department vehicles.

3.3.216* Street Floor. A story or floor level accessible from the street or from outside a building at ground level, with the floor level at the main entrance located not more than three risers above or below ground level and arranged and utilized to qualify as the main floor.

A.3.3.216 Street Floor. Where, due to differences in street levels, two or more stories are accessible from the street, each is a street floor. Where there is no floor level within the specified limits for a street floor above or below ground level, the building has no street floor.

3.3.217* Structure. That which is built or constructed.

A.3.3.217 Structure. The term *structure* is to be understood as if followed by the words *or portion thereof*. (See also *Building*, A.3.3.27.)

3.3.217.1 Air-Inflated Structure. A structure whose shape is maintained by air pressure in cells or tubes forming all or part of the enclosure of the usable area and in which the occupants are not within the pressurized area used to support the structure.

3.3.217.2* Air-Supported Structure. A structure whose shape is maintained by air pressure and in which occupants are within the elevated pressure area.

A.3.3.217.2 Air-Supported Structure. A cable-restrained air-supported structure is one in which the uplift is resisted by cables or webbing that is anchored

by various methods to the membrane or that might be an integral part of the membrane. It is not a tensioned-membrane structure.

3.3.217.3 Limited Access Structure. A structure or portion of a structure lacking access openings.

3.3.217.4 Membrane Structure. A building or portion of a building incorporating an air-inflated, air-supported, tensioned-membrane structure; a membrane roof; or a membrane-covered rigid frame to protect habitable or usable space.

3.3.217.5 Multilevel Play Structure. A structure that consists of tubes, slides, crawling areas, and jumping areas that is located within a building and is used for climbing and entertainment, generally by children.

3.3.217.6* Open Structure. A structure that supports equipment and operations not enclosed within building walls.

A.3.3.217.6 Open Structure. Open structures are often found in oil refining, chemical processing, or power plants. Roofs or canopies without enclosing walls are not considered an enclosure.

3.3.217.7 Open Parking Structure. A parking structure that, at each parking level, has wall openings open to the atmosphere, for an area of not less than 0.13 m² (1.4 ft²) for each linear 305 mm (12 in.) of its exterior perimeter. Such openings are distributed over at least 40 percent of the building perimeter or uniformly over two opposing sides. Interior wall lines and column lines are at least 20 percent open, with openings distributed to provide ventilation.

3.3.217.8 Permanent Structure. A building or structure that is intended to remain in place for a period of more than 180 consecutive days.

3.3.217.9 Temporary Structure. A building or structure not meeting the definition of *permanent structure*. (See also 3.3.217.8.)

3.3.217.10 Tensioned-Membrane Structure. A membrane structure incorporating a membrane and a structural support system such as arches, columns and cables, or beams wherein the stresses developed in the tensioned membrane interact with those in the structural support so that the entire assembly acts together to resist the applied loads.

3.3.217.11* Underground Structure. A structure or portions of a structure in which the floor level is below the level of exit discharge.

A.3.3.217.11 Underground Structure. In determining openings in exterior walls, doors or access panels are permitted to be included. Windows are also permitted to be included if they are openable or provide a breakable glazed area.

3.3.217.12 Water-Surrounded Structure. A structure fully surrounded by water.

3.3.218 System.

3.3.218.1 Elevator Evacuation System. A system, including a vertical series of elevator lobbies and associated elevator lobby doors, an elevator shaft(s), and a machine room(s), that provides protection from fire effects for elevator passengers, people waiting to use elevators, and elevator equipment so that elevators can be used safely for egress.

3.3.218.2 Standpipe System. An arrangement of piping, valves, hose connections, and allied equipment installed in a building or structure, with the hose connections located in such a manner that water can be discharged in streams or spray patterns through attached hose and nozzles, for the purpose of extinguishing a fire, thereby protecting a building or structure and its contents in addition to protecting the occupants. This is accomplished by means of connections to water supply systems or by means of pumps, tanks, and other equipment necessary to provide an adequate supply of water to the hose connections. [14:1.4].

3.3.219 Temporary Platform. See 3.3.166.1.

3.3.220 Temporary Structure. See 3.3.217.9.

3.3.221 Tensioned-Membrane Structure. See 3.3.217.10.

3.3.222* Tent. A temporary structure, the covering of which is made of pliable material that achieves its support by mechanical means such as beams, columns, poles, or arches, or by rope or cables, or both.

A.3.3.222 Tent. A tent might also include a temporary tensioned-membrane structure.

3.3.222.1 Private Party Tent. A tent erected in the yard of a private residence for entertainment, recreation, dining, a reception, or similar function.

3.3.223 Thermal Barrier. See 3.3.23.3.

3.3.224 Tower. An enclosed independent structure or portion of a building with elevated levels for support of equipment or occupied for observation, control, operation, signaling, or similar limited use.

3.3.225 Uncertainty Analysis. See 3.3.12.2.

3.3.226 Underground Structure. See 3.3.217.11.

3.3.227 Verification Method. A procedure or process used to demonstrate or confirm that the proposed design meets the specified criteria.

3.3.228 Vertical Opening. An opening through a floor or roof.

3.3.229 Wall.

3.3.229.1 Fire Barrier Wall. A wall, other than a fire wall, that has a fire resistance rating.

3.3.229.2 Proscenium Wall. The wall that separates the stage from the auditorium or house.

3.3.230 Water-Surrounded Structure See 3.3.217.12.

3.3.231 Weathered-Membrane Material. See 3.3.135.4.

3.3.232 Yard. An open, unoccupied space other than a court, unobstructed from the ground to the sky on the lot on which a building is situated.

CHAPTER 4

General

The subjects addressed in Chapter 4 were formerly part of Chapter 1, General, in editions prior to 2000. Current NFPA style and format policies dictate that Chapter 1, now titled Administration, include only title, scope, purpose, application, equivalency, units and formulas, and enforcement sections. All other general provisions are contained in Chapter 4, General.

Within Chapter 4, Sections 4.1, 4.2, and 4.3 address goals, objectives, and assumptions and apply to prescriptive-based and performance-based life safety designs.

Section 4.4 offers building designers and owners the prerogative of following the prescriptive requirements of the *Code* or developing an acceptable performance-based design, in accordance with Chapter 5 and in careful consultation with the authority having jurisdiction, or AHJ.

Section 4.5 includes fundamental requirements that present a qualitative summary of what the other specific requirements, in total, are supposed to achieve.

Section 4.6 presents the philosophy associated with enforcement of the *Code*—namely, who enforces it and when it applies to special conditions. Paragraph 4.6.10.2 mandates a warrant of fitness for buildings that have utilized the performance-based option. The warrant of fitness verifies for the AHJ that the terms and conditions that were part of the performance-based design have not been modified to the point that the building is unsafe.

Section 4.7 presents the operational details associated with emergency egress and relocation drills.

Section 4.8 rounds out the chapter by presenting emergency plan requirements.

Section 4.1* Goals

A.4.1 The goals in Section 4.1 reflect the scope of this *Code* (see Section 1.1). Other fire safety goals that are outside the scope of this *Code* might also need to be considered, such as property protection and continuity of operations. Compliance with this *Code* can assist in meeting goals outside of the *Code*'s scope.

The goals in Section 4.1 apply regardless of whether the prescriptive-based option of 4.4.1(1) and 4.4.2 or the performance-based option of 4.4.1(2) and 4.4.3 is used. For prescriptive-based life safety systems, compliance with the specifications of Chapter 4 and Chapters 6 through 42 provides a level of life safety that meets the goals of Section 4.1. For performance-based life safety systems, compliance with the goals needs to be demonstrated in the required documentation package with consideration to not only the goals but also the objectives (see Section 4.2) and performance criteria (see Section 5.2) associated with specific design fire scenarios (see Section 5.5).

4.1.1* Fire and Similar Emergency.

The goal of this *Code* is to provide an environment for the occupants that is reasonably safe from fire and similar emergencies by the following means:

A.4.1.1 Reasonable safety risk is further defined by subsequent language in this *Code*.

(1)* Protection of occupants not intimate with the initial fire development

A.4.1.1(1) The phrase “intimate with the initial fire development” refers to the person(s) at the ignition source or

first materials burning, not to all persons within the same room or area.

- (2) Improvement of the survivability of occupants intimate with the initial fire development

4.1.2* Crowd Movement.

An additional goal is to provide for reasonably safe emergency crowd movement and, where required, reasonably safe nonemergency crowd movement.

A.4.1.2 An assembly occupancy is an example of an occupancy where the goal of providing for reasonably safe emergency and nonemergency crowd movement has applicability. A detention or correctional occupancy is an example of an occupancy where emergency and nonemergency crowd movement is better addressed by detention and correctional facilities specialists than by this *Code*.

An example of a requirement for nonemergency crowd movement appears in 12.2.5.4.3 and 13.2.5.4.3, which apply to assembly occupancies, where access and egress routes are required to be maintained so that crowd management, security, and emergency medical personnel are able to move to any individual at any time without undue hindrance. However, almost all other occupancy chapters remain silent on the subject of nonemergency crowd movement—some because the committee made a conscious decision to omit such information, others, because the subject has not been discussed at technical committee meetings. For example, the detention and correctional occupancies chapters deliberately remain silent on the subject because the movement of residents in occupancies where security concerns are paramount is best addressed by professionals in the daily operation of such facilities. It is important to note that, per the purpose statement in Section 1.2, the minimum requirements of this *Code* were developed with due regard for function. The *Code* endeavors to avoid requirements that might interfere with the normal use and occupancy of a building.

Section 4.2 Objectives

As in the case of application of the goals of Section 4.1, the objectives of Section 4.2 apply regardless of whether the prescriptive-based option of 4.4.1(1) and 4.4.2 or the performance-based option of 4.4.1(2) and 4.4.3 is used. For prescriptive-based life safety systems, compliance with the specifications of Chapter

4 and Chapters 6 through 42 provides a level of life safety that meets the objectives of Section 4.2. For performance-based life safety systems, compliance with the objectives needs to be demonstrated in the required documentation with consideration to not only the objectives but also the goals (see Section 4.1), and performance criteria (see Section 5.2) associated with specific design fire scenarios (see Section 5.5).

The objectives present requirements that must be satisfied to achieve the goals of Section 4.1. Objectives are stated in more specific terms than goals and tend to be more quantitative than qualitative. The goals of Section 4.1 are general enough to apply to numerous NFPA documents. The objectives of Section 4.2 are more specific to the *Life Safety Code* itself. Goals and objectives, taken together, form the initial targets at which a performance-based life safety system can take aim. The goals and objectives alone do not provide sufficient detail to develop and measure the performance of a design. Rather, the performance criteria and other elements of Chapter 5, Performance-Based Option, are needed to flesh out the subject in sufficient detail.

4.2.1 Occupant Protection.

A structure shall be designed, constructed, and maintained to protect occupants who are not intimate with the initial fire development for the time needed to evacuate, relocate, or defend in place.

4.2.2 Structural Integrity.

Structural integrity shall be maintained for the time needed to evacuate, relocate, or defend in place occupants who are not intimate with the initial fire development.

4.2.3 Systems Effectiveness.

Systems utilized to achieve the goals of Section 4.1 shall be effective in mitigating the hazard or condition for which they are being used, shall be reliable, shall be maintained to the level at which they were designed to operate, and shall remain operational.

Section 4.3* Assumption

The protection methods of this *Code* assume a single fire source.

A.4.3 Additional assumptions that need to be identified for a performance-based design are addressed in Chapter 5.

For the user of the traditional, prescriptive, specification-based requirements, the single fire source assumption is a piece of explanatory material and not a requirement. The assumption explains that the *Code* authors developed the requirements with the challenge of a single fire source in mind. Thus, most occupancy chapters require a minimum of two means of egress; if one is blocked by the single fire, then the other should be available for egress. Had the *Code* been written to protect against fires that begin in two locations, then it probably would be common to find occupancy chapter requirements for a minimum of three means of egress. Historically, the *Code's* approach to protecting against a single source fire has proved to meet society's expectations.

Section 4.4 Life Safety Compliance Options

4.4.1 Options.

Life safety meeting the goals and objectives of Section 4.1 and Section 4.2 shall be provided in accordance with either of the following:

- (1) Prescriptive-based provisions per 4.4.2
- (2) Performance-based provisions per 4.4.3

Code editions prior to 2000 required compliance with the prescriptive, specification-based requirements and offered some additional design flexibility via the equivalency concept contained in Section 1.4. The current edition offers the new option of designing the life safety systems, *in toto*, using a performance-based approach. Both the prescriptive-based and performance-based options are tied to the goals and objectives of Sections 4.1 and 4.2, respectively.

The prescriptive-based and performance-based options are offered as equivalent, with neither option designated as the preferred method. Given that performance-based design is new to most *Code* users and that it is complicated to use, most traditional buildings will probably continue to be designed and built to comply with the prescriptive requirements. The performance-based approach will be reserved for use on large, complicated structures where the additional costs associated with such a design can be offset by savings on prescriptive features that can be omitted from the design. The performance-based option also is to be used for innovative designs that are likely to be prohibited by the prescriptive requirements. For example, many years ago, before atria were specifically addressed in the *Code*, a designer proposing to build an atrium building would

likely have been challenged by the authority having jurisdiction who might view the atrium as a hole in the building's floors through which smoke and other products of combustion could be spread. In subsequent editions of the *Code*, the inclusion of provisions for atria showed that, with full building sprinkler and smoke control systems, the atrium could be turned into a fire and life safety asset—one that serves as a smoke dispersion and accumulation chamber early in the fire so as to permit exit access through the atrium. The performance-based approach offers a host of new tools that are used to prove the efficacy of unique designs and unusual, functionally dictated spaces.

4.4.2 Prescriptive-Based Option.

4.4.2.1 A prescriptive-based life safety design shall be in accordance with Chapter 1 through Chapter 4, Chapter 6 through Chapter 11, and the applicable occupancy chapter, Chapter 12 through Chapter 42.

A prescriptive-based life safety design is the traditional norm. Each applicable requirement is met individually, and the resultant level of life safety is deemed to meet the goals and objectives of Sections 4.1 and 4.2, respectively. The requirements are chosen, depending on occupancy classification, from a wide host of possible *Code* chapters, namely, any and all chapters except Chapter 5, Performance-Based Option.

4.4.2.2 Where specific requirements contained in Chapter 11 through Chapter 42 differ from general requirements contained in Chapter 1 through Chapter 4, and Chapter 6 through Chapter 10, the requirements of Chapter 11 through Chapter 42 shall govern.

The *Life Safety Code* is formatted such that Chapters 1 through 4 and 6 through 10 contain administrative provisions and fundamental requirements establishing minimum acceptable criteria for all types of occupancies. Chapters 12 through 42 of the *Code* establish criteria for life safety based upon the characteristic needs of specific occupancies. Chapter 11 further modifies those provisions if unusual situations exist or the building is windowless, underground, or a high-rise. Where requirements differ between the general provisions of Chapters 1 through 4 and 6 through 10 and the more specific provisions of Chap-

ters 11 through 42, the requirements contained in Chapters 11 through 42 take precedence.

To avoid conflicts, if an occupancy chapter exempts itself from a requirement of a core chapter, the core chapter will usually specify that the deviation from the requirement is allowed. For example, although 7.2.2.3.3.1 requires treads of stairs and landing floors to be solid, 7.2.2.3.3.4 permits noncombustible, grated stair treads and landings in various specified occupancies, including industrial occupancies as provided in Chapter 40. Paragraph 40.2.2.3.1(1) confirms the exemption for noncombustible, grated stair treads and landings in industrial occupancies.

4.4.3 Performance-Based Option.

A performance-based life safety design shall be in accordance with Chapter 1 through Chapter 5.

A performance-based life safety design is exempt from the myriad prescriptive, specification-based requirements of the *Code*, but must meet the administrative and general requirements of Chapters 1 through 4. The design must adhere to the definitions of Chapter 3 so that the authority having jurisdiction that judges the performance of the design can communicate with the designer in terminology that is common to all *Code* users. More important, the performance-based design must meet the provisions contained in Chapter 5, Performance-Based Option. Chapter 5 contains a limited number of prescriptive provisions that have been retained from Chapter 7, Means of Egress, for applicability to the performance-based design. See Section 5.3.

Section 4.5 Fundamental Requirements

Section 4.5 outlines the fundamental concepts that are addressed in detail by the requirements contained in the other chapters of the *Code*. The fundamental concepts briefly detailed in this section apply both to prescriptive-based and performance-based life safety designs. Achieving the life safety fundamentals helps to ensure a reasonable level of life safety in building design and arrangement. The following are the fundamentals:

- (1) Provide for adequate safety without dependence on any single safeguard

- (2) Provide an appropriate degree of life safety considering the size, shape, and nature of the occupancy
- (3) Provide for backup or redundant egress arrangements
- (4) Ensure that the egress paths are clear, unobstructed, and unlocked
- (5) Ensure that the exits and egress routes are clearly marked to avoid confusion and provide the cues needed for their effective use
- (6) Provide adequate lighting
- (7) Ensure prompt occupant response by providing early warning of fire
- (8) Ensure the suitable enclosure of vertical openings
- (9) Ensure compliance with applicable installation standards
- (10) Maintain all required features in proper working order

4.5.1 Multiple Safeguards. The design of every building or structure intended for human occupancy shall be such that reliance for safety to life does not depend solely on any single safeguard. An additional safeguard(s) shall be provided for life safety in case any single safeguard is ineffective due to inappropriate human actions or system failure.

4.5.2 Appropriateness of Safeguards.

Every building or structure shall be provided with means of egress and other safeguards of the kinds, numbers, locations, and capacities appropriate to the individual building or structure, with due regard to the following:

- (1) Character of the occupancy
- (2) Capabilities of the occupants
- (3) Number of persons exposed
- (4) Fire protection available
- (5) Height and type of construction of the building or structure
- (6) Other factors necessary to provide occupants with a reasonable degree of safety

4.5.3 Means of Egress.

4.5.3.1 Number of Means of Egress. Two means of egress, as a minimum, shall be provided in every building or structure, section, and area where size, occupancy, and arrangement endanger occupants attempting to use a single means of egress that is blocked by fire or smoke. The two means of egress shall be arranged to minimize the possibility that both might be rendered impassable by the same emergency condition.

4.5.3.2 Unobstructed Egress. In every occupied building or structure, means of egress from all parts of the building shall be maintained free and unobstructed. No lock or fastening shall be permitted that prevents free escape from the inside of any building other than in health care occupancies and detention and correctional occupancies where staff are continually on duty and effective provisions are made to remove occupants in case of fire or other emergency. Means of egress shall be accessible to the extent necessary to ensure reasonable safety for occupants having impaired mobility.

4.5.3.3 Awareness of Egress System. Every exit shall be clearly visible, or the route to reach every exit shall be conspicuously indicated. Each means of egress, in its entirety, shall be arranged or marked so that the way to a place of safety is indicated in a clear manner.

4.5.3.4 Lighting. Where artificial illumination is needed in a building or structure, egress facilities shall be included in the lighting design.

4.5.4* Occupant Notification.

In every building or structure of such size, arrangement, or occupancy that a fire itself might not provide adequate occupant warning, fire alarm facilities shall be provided where necessary to warn occupants of the existence of fire.

A.4.5.4 Fire alarms alert occupants to initiate emergency procedures, facilitate orderly conduct of fire drills, and initiate response by emergency services.

4.5.5 Vertical Openings.

Every vertical opening between the floors of a building shall be suitably enclosed or protected, as necessary, to afford reasonable safety to occupants while using the means of egress and to prevent the spread of fire, smoke, or fumes through vertical openings from floor to floor before occupants have entered exits.

4.5.6 System Design/Installation.

Any fire protection system, building service equipment, feature of protection, or safeguard provided for life safety shall be designed, installed, and approved in accordance with applicable NFPA standards.

4.5.7 Maintenance.

Whenever or wherever any device, equipment, system, condition, arrangement, level of protection, or any other feature is required for compliance with the provisions of this *Code*, such device, equipment, system, condition, arrangement, level of protection, or other feature shall thereafter be maintained unless the *Code* exempts such maintenance.

Section 4.6 General Requirements

4.6.1 Authority Having Jurisdiction.

The authority having jurisdiction (AHJ) is the person or office enforcing the *Code*. In cases where the *Code* is to be legally enforced, the AHJ is usually a fire marshal or building official. The AHJ can also be a safety office, insurance engineering department, accreditation service, other agency, or specified personnel within those groups, especially where the *Code* is to be enforced at other than a governmental level. It is common for multiple authorities having jurisdiction to review the same project while enforcing this *Code* and/or other codes. For example, under the *Code* several agencies—such as state and local fire marshals; federal, state, and local health care licensing agencies; Joint Commission on Accreditation of Healthcare Organizations (JCAHO) accreditation personnel; insurance inspectors; and building inspectors—perform inspections in health care facilities.

4.6.1.1 The authority having jurisdiction shall determine whether the provisions of this *Code* are met.

4.6.1.2 Any requirements that are essential for the safety of building occupants and that are not specifically provided for by this *Code* shall be determined by the authority having jurisdiction.

The provisions of Section 4.6 give the authority having jurisdiction the final determination of whether adequate life safety is provided in a building. When the authority having jurisdiction determines that the *Code* has not specifically addressed a particular life safety situation, the authority can supplement the requirements in the *Code* to address the situation. The power to supplement requirements is an important responsibility, because the *Code* cannot anticipate every type of building and occupancy configuration.

4.6.1.3 Where it is evident that a reasonable degree of safety is provided, any requirement shall be permitted to be modified if, in the judgment of the authority having jurisdiction, its application would be hazardous under normal occupancy conditions.

The provision of 4.6.1.3 gives the authority having jurisdiction latitude in permitting a requirement to

be modified if the strict enforcement of the provision would otherwise create more of a hazard and, thus, less overall life safety than is achieved by modification. For example, the *Code* requires an exit sign at an exit and, via the provisions of 7.10.1.2, requires that the sign be readily visible from any direction of exit access. If the exit door in question is installed in the plane of a corridor wall, the exit sign would need to be positioned perpendicular to the corridor wall. If there is limited headroom at the door, perhaps due to a ceiling projection such as a beam running across the corridor at that point, the exit sign might create the potential for occupants to bump their heads. This provision permits the authority having jurisdiction to allow the exit sign to be mounted flush against the corridor wall based on judgment that a reasonable degree of safety is provided.

4.6.2 Previously Approved Features.

Where another provision of this *Code* exempts a previously approved feature from a requirement, the exemption shall be permitted even where the following conditions exist:

- (1) The area is being modernized, renovated, or otherwise altered.
- (2) A change of occupancy has occurred, provided that the feature's continued use is approved by the authority having jurisdiction.

The term *previously approved* is defined in 3.3.169 as that which was acceptable to the authority having jurisdiction prior to the date this edition of the *Code* went into effect. In a relatively few cases, the responsible technical committees have earmarked specific features that can be continued in use if such features were previously approved. For example, in 40.2.2.8, regarding existing, previously approved escalators in industrial occupancies, the message to the current AHJ is that if an AHJ in an earlier time judged the escalator as adequate for use within the means of egress, the escalator should continue to be approved for use. The AHJ who gave the original approval had detailed criteria in the *Code* at that time. The criteria no longer exist because new escalators are not permitted to comprise any of the required means of egress. The current AHJ is expected to continue recognizing the earlier approval. However, if there is a change of occupancy, the previously approved feature must also receive the current approval of the AHJ because the feature that had been acceptable in the

original occupancy might not be acceptable for the new occupancy. See 4.6.2(2).

Contrast the preceding example with the treatment of existing stairs in 7.2.2.1.2(2) where *approved, existing noncomplying stairs* are recognized in lieu of stairs complying with the detailed criteria of 7.2.2. The term *approved existing*, which is different from the term *previously approved*, is defined in 3.3.60.1 as that which is already in existence on the date this edition of the *Code* goes into effect and is acceptable to the AHJ. In this case, it does not matter how an earlier AHJ ruled on the acceptability of the stair. The current AHJ must evaluate the noncomplying stair and determine for himself/herself whether it is acceptable for continued use.

4.6.3* Historic Buildings.

The provisions of this *Code* shall be permitted to be modified by the authority having jurisdiction for buildings or structures identified and classified as historic buildings or structures where it is evident that a reasonable degree of safety is provided.

Rather than providing historic buildings with a blanket exemption from *Code* requirements, the provision of 4.6.3 reinforces the concept that existing buildings, as well as new construction, need to meet minimum life safety criteria. This provision permits the authority having jurisdiction to offer some leniency — as long as the AHJ judges that a reasonable degree of safety is provided, compliance with modified requirements is adequate.

Historic buildings might have numerous design defects, such as open stair shafts or highly combustible interior finishes. Rather than waiving requirements, the authority having jurisdiction might require that the facility attain a level of safety equivalent or nearly equivalent to that mandated by the *Code*. For example, the AHJ might require the use of sprinkler systems, smoke detection systems, voice alarm systems for staged evacuation, smoke control systems, or other appropriate features to overcome the existing life safety defects. The use of such alternatives could raise the building's life safety to levels many times greater than that which previously existed, without requiring the rebuilding of the structure to the *Code's* specification-based requirements, which might destroy the historical character of the structure.

A.4.6.3 See A.4.6.4.

4.6.4* Modification of Requirements for Existing Buildings.

Where it is evident that a reasonable degree of safety is provided, the requirements for existing buildings shall be permitted to be modified if their application would be impractical in the judgment of the authority having jurisdiction.

A.4.6.4 In existing buildings, it is not always practical to strictly apply the provisions of this *Code*. Physical limitations can cause the need for disproportionate effort or expense with little increase in life safety. In such cases, the authority having jurisdiction should be satisfied that reasonable life safety is ensured.

In existing buildings, it is intended that any condition that represents a serious threat to life be mitigated by the application of appropriate safeguards. It is not intended to require modifications for conditions that do not represent a significant threat to life, even though such conditions are not literally in compliance with the *Code*.

An example of what is intended by 4.6.4 would be an historic ornamental guardrail baluster with spacing that does not comply with the 100-mm (4-in.) requirement. Because reducing the spacing would have minimal impact on life safety but could damage the historic character of the guardrail, the existing spacing might be approved by the authority having jurisdiction.

The provisions of 4.6.4 give the authority having jurisdiction some leeway in applying the *Code* to existing buildings. The *Code* recognizes that there might be situations where applying the requirements to existing situations is not practical, so this provision gives the authority having jurisdiction the authority to modify those requirements. However, the *Code* re-emphasizes that a reasonable degree of safety must be provided.

4.6.5 Time Allowed for Compliance.

A limited but reasonable time, commensurate with the magnitude of expenditure, disruption of services, and degree of hazard, shall be allowed for compliance with any part of this *Code* for existing buildings.

In some cases, appreciable costs—in terms of actual monetary expenditures and disruption of daily activities—might be involved in immediately bringing an existing building into *Code* compliance. Where this

is true, it is appropriate for the operator or owner of the facility to formulate a schedule, approved by the authority having jurisdiction, that allows suitable periods of time for correcting various deficiencies. However, the degree of hazard is an important consideration in this instance; if the degree of hazard is serious enough, it might be necessary to close the building to occupancy while renovations are made to bring the building features associated with the serious hazard into compliance. Once the building is reoccupied, the AHJ might allow some reasonable, additional time for bringing the remaining deficient features into code compliance with the requirements that apply specifically to existing buildings.

4.6.6 Referenced Publications.

Existing buildings or installations that do not comply with the provisions of the standards referenced in this document (see *Chapter 2*) shall be permitted to be continued in service, provided that the lack of conformity with these standards does not present a serious hazard to the occupants as determined by the authority having jurisdiction.

The *Code* mandates that the fire and life safety systems used for compliance are to be installed in accordance with the requirements of more than 50 NFPA codes and standards and more than a dozen documents developed by other organizations. Mandatorily referenced documents are listed in *Chapter 2* and cite a specific edition.

In recognition that it is impractical to expect systems to be continually upgraded to meet the newest edition of an installation standard, the *Code* allows the authority having jurisdiction to permit continued use of systems whose lack of compliance with the referenced standards does not present a serious hazard.

4.6.7 Additions.

Additions shall conform to the provisions for new construction.

Although an addition must conform to the requirements for new construction, the existing portion of the building is generally permitted to conform to the requirements for existing buildings. The exceptions to this rule involve assembly and mercantile occupan-

cies. For example, mercantile occupancies further subclassify the occupancy into a Class A, Class B, or Class C occupancy, based on the floor area used for sales purposes. If consideration of the combined space created by the addition and the existing portion of the building results in a reclassification (for example, from Class C to Class B or from Class B to Class A), the existing portion of the building must also meet the requirements applicable to new construction. See 36.1.1.3.3 and 37.1.1.3.3.

For assembly occupancies, the same concept exists, but its application criteria are specified differently, given that assembly occupancies no longer use the subclassification scheme (that is, Class A, Class B, and Class C). The existing portion of the assembly occupancy building is required to meet the provisions that apply to new construction under either of the following conditions (see 13.1.1.6):

- (1) The occupant load of the combined space created by the addition and the existing assembly area increases from less than 500 to more than 500 so as to require a third exit.
- (2) The occupant load of the combined space created by the addition and the existing assembly area increases from less than 1000 to more than 1000 so as to require a fourth exit.

4.6.8* Modernization or Renovation.

Any alteration or any installation of new equipment shall meet, as nearly as practicable, the requirements for new construction. Only the altered, renovated, or modernized portion of an existing building, system, or individual component shall be required to meet the provisions of this *Code* that are applicable to new construction. If the alteration, renovation, or modernization adversely impacts required life safety features, additional upgrading shall be required. Except where another provision of this *Code* exempts a previously approved feature from a requirement, the resulting feature shall be not less than that required for existing buildings. Existing life safety features that do not meet the requirements for new buildings, but that exceed the requirements for existing buildings, shall not be further diminished.

A.4.6.8 The following is an example of what is intended by 4.6.8. In a hospital that has 1830-mm (72-in.) wide corridors, such corridors cannot be reduced in width, even though the provisions for existing hospitals do not require 1830-mm (72-in.) wide corridors. However, if a hospital has 3050-mm (120-in.) wide corridors, they are permitted to be reduced to 2440 mm (96 in.) in width, which is the requirement for new construction. If the hospital corridor is 915 mm (36

in.) wide, it would have to be increased to 1220 mm (48 in.). If alterations require replacement of a portion of a hospital corridor wall, such portion of the corridor would not be required to be increased to 2440 mm (96 in.) in width, unless it was practical to do so.

Only those existing building features, systems, or components undergoing alteration must conform with the *Code* provisions applicable to new construction. For example, in an occupancy that requires 1-hour fire resistance-rated corridors for new construction but permits existing ½-hour fire resistance-rated corridors to remain in use, a renovation project is undertaken to replace existing doors in the corridor walls. There is no requirement that the renovation project be expanded in scope to include replacing the existing, code-complying, ½-hour fire resistance-rated corridor walls with walls having the minimum 1-hour fire resistance rating required for new construction.

Conformance with the provisions applicable to new construction might not be practical if the existing structure involved cannot reasonably accommodate the feature required for new construction. For example, a hospital might have an existing corridor 1.8 m (6 ft) wide that, if replaced according to specifications for new construction, would be required to be 2.4 m (8 ft) wide. However, if the building's column spacing is 2.1 m × 2.1 m (7 ft × 7 ft), there is no easy and effective way to achieve a 2.4-m (8-ft) corridor width. The authority having jurisdiction must judge whether a 1.8-m (6-ft) wide or even a 2.1-m (7-ft) wide corridor is adequate or whether additional provisions are required to permit a corridor less than 2.4 m (8 ft) in width to be rebuilt.

Where renovations or alterations are made, they must comply with the requirements for new construction to the extent practicable. For example, it is practicable to install carpeting meeting the requirements for new interior floor finish. However, where a corridor wall is to be rebuilt, widening the corridor to meet the minimum width requirements for new corridors might not be practicable, but rebuilding the corridor to meet the required fire resistance rating for new construction most likely will be practicable.

Another example is the installation of a new smoke barrier in an existing hospital. A smoke barrier can be made that meets nearly all the requirements for a new smoke barrier. However, if the corridor across which the smoke barrier extends is not sufficiently wide to install two 1055-mm (41.5-in.) clear width doors, the requirement for such doors would

have to be modified. The authority having jurisdiction might permit a set of doors or possibly a single door of a width that the corridor could accommodate. The requirement to perform renovations that meet as nearly as practicable the requirements for new construction might seem arbitrary, but it is necessary to allow evaluation on a case-by-case basis.

The last sentence of 4.6.8 captures an important, but elusive, concept. In applying the requirements for new construction to a renovated component or system, it is important to compare the requirements for new construction to those for existing buildings. This comparison ensures that the level of safety afforded by compliance with the requirement for new construction is not less than that provided by complying with the corresponding requirement applicable to existing buildings. For example, Chapter 28, which applies to new hotels/dormitories, includes no requirement for smoke barriers because all new hotels/dormitories must either be protected by automatic sprinklers or provide direct exterior exit access from all guest rooms. During renovation of a floor in an existing, nonsprinklered hotel that utilizes inside corridors for exit access from guest rooms, the absence of a requirement for smoke barriers in Chapter 28 (see 28.3.7) must not be applied to the existing building. Rather, the requirements of 29.3.7 for cross-corridor smoke barriers apply. See also A.1.3 for another example of the same concept.

4.6.9 Provisions in Excess of Code Requirements.

Nothing in this *Code* shall be construed to prohibit a better type of building construction, an additional means of egress, or an otherwise safer condition than that specified by the minimum requirements of this *Code*.

Although the *Life Safety Code* is a minimum-requirement code, it does not prohibit the use of a design that exceeds the provisions of the *Code*. Although, in practice, economic considerations usually discourage the use of a design that exceeds minimum requirements, there have been instances where money was saved or additional money generated when *Code* provisions were exceeded. For example, a hotel was constructed with full automatic sprinkler protection, although such protection was not required by the code in effect at the time. Sprinklering the building permitted a third stairway to be eliminated because of the increased travel distance allowed in a sprinklered building. The construction cost of the stair was saved,

and additional revenue-producing guest rooms were built in the space that the stair otherwise would have occupied.

4.6.10 Conditions for Occupancy.

4.6.10.1 No new construction or existing building shall be occupied in whole or in part in violation of the provisions of this *Code*, unless the following conditions exist:

- (1) A plan of correction has been approved.
- (2) The occupancy classification remains the same.
- (3) No serious life safety hazard exists as judged by the authority having jurisdiction.

From an enforcement standpoint, 4.6.10.1 is probably one of the most important in the *Code*, because it states that a building, whether new or existing, cannot be occupied if it is in violation of the provisions of the *Code*.

Because the *Code* applies retroactively, 4.6.10.1 prohibits the use of existing, nonconforming facilities. However, 4.6.10.1 does permit the building to continue to be used, provided that the occupancy classification remains the same and there is no serious life safety hazard, as judged by the authority having jurisdiction, that would constitute an imminent threat. Such permission does not exempt the building from compliance with the *Code*. A limited but reasonable time (see 4.6.5), for bringing the building into compliance with the *Code* to the extent deemed necessary by the AHJ under 4.6.4 must be established and fulfilled.

4.6.10.2 Where compliance with this *Code* is effected by means of a performance-based design, the owner shall annually certify compliance with the conditions and limitations of the design by submitting a warrant of fitness acceptable to the authority having jurisdiction. The warrant of fitness shall attest that the building features, systems, and use have been inspected and confirmed to remain consistent with design specifications outlined in the documentation required by Section 5.8 and that such features, systems, and use continue to satisfy the goals and objectives specified in Section 4.1 and Section 4.2. (*See Chapter 5.*)

Traditional, specification-based life safety systems rely on the combined effect of all required features, systems, and arrangements to provide the intended level of life safety. This overlap of protection schemes

and the resulting redundancy in protection methods, which are mandated by the prescriptive requirements, have historically provided flexibility for a building to undergo changes in how its space is configured and used. For example, a business occupancy floor arranged to provide executives with private offices could be renovated by removing the office walls, installing modular furniture and cubicles, and creating an open-office floor plan for use by telemarketers. The occupancy would remain a business occupancy and little, if anything, would be necessary to retain the level of life safety that existed prior to the renovation.

However, had the original executive office floor been designed using the performance-based option, the removal of office walls would need to be analyzed with respect to its effect on the life safety systems. The performance-based design might have been based on a scenario in which a fire would not propagate beyond one of the private offices due to fire-rated compartmentation. Removing the office walls and creating an open floor plan would result in the loss of the performance-based design's compartmentation premise. Further analysis would be needed to determine whether the original life safety systems continued to meet the goals and objectives after the renovation.

Although the example cited in this commentary centers on a substantial renovation that involves removal of office walls, subtle changes that “creep” into a building over time might also adversely affect a life safety system designed using the performance-based option. For this reason, 4.6.10.2 requires annual certification via a warrant of fitness.

The provisions of 4.6.10.2 are positioned here in Chapter 4 in the hope that the requirement will be noticed and enforced. Had the requirement appeared in Chapter 5, Performance-Based Option, it might have gone unnoticed after the performance-based design is completed and the certificate of occupancy issued.

4.6.11 Construction, Repair, and Improvement Operations.

4.6.11.1* Buildings or portions of buildings shall be permitted to be occupied during construction, repair, alterations, or additions only where required means of egress and required fire protection features are in place and continuously maintained for the portion occupied or where alternative life safety measures acceptable to the authority having jurisdiction are in place.

A.4.6.11.1 Fatal fires have occurred when, for example, a required stair has been closed for repairs or removed for

rebuilding, or when a required automatic sprinkler system has been shut off to change piping.

The provisions of 4.6.11.1 help to control a relatively common practice—the occupation of completed portions of a partially completed structure. The *Code* permits such occupation if certain conditions are met. For example, the *Code* requires that egress features for the portion occupied be complete and maintained to be usable. In many cases, the egress facilities, although completed, are not usable because they are blocked with stored building materials and equipment needed for the ongoing construction, or doors are locked to limit access to parts of the building still under construction. In such cases, occupancy should be prohibited.

The *Code* also requires that fire protection features be in place and be continuously maintained. The incidence of fire is more frequent, and therefore more likely, during construction, repairs, and alterations. Extra caution and concern need to be exercised to ensure adequate egress capacity and arrangement during periods of construction in any occupied building.

Paragraph 4.6.11.1 recognizes that in lieu of strict adherence to the egress and fire protection features, alternative life safety measures might make the building safe enough to be occupied. As usual, it is the authority having jurisdiction who is charged with judging whether the alternative measures provide an acceptable remedy. Paragraph 4.6.11.1 is conceptually similar to 4.6.10.1.

4.6.11.2* In buildings under construction, adequate escape facilities shall be maintained at all times for the use of construction workers. Escape facilities shall consist of doors, walkways, stairs, ramps, fire escapes, ladders, or other approved means or devices arranged in accordance with the general principles of the *Code* insofar as they can reasonably be applied to buildings under construction.

A.4.6.11.2 See also NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*.

4.6.11.3 Flammable or explosive substances or equipment for repairs or alterations shall be permitted in a building while the building is occupied if the condition of use and safeguards provided do not create any additional danger or impediment to egress beyond the normally permissible conditions in the building.

4.6.12* Changes of Occupancy.

In any building or structure, whether or not a physical alteration is needed, a change from one occupancy classification

to another shall be permitted only where such a building, structure, or portion thereof conforms with the requirements of this *Code* that apply to new construction for the proposed new use or, where specifically permitted elsewhere in the *Code*, existing construction features shall be permitted to be continued in use in conversions.

A.4.6.12 Examples of changes from one occupancy subclassification to another subclassification of the same occupancy could include a change from a Class B to a Class A mercantile occupancy. Hospitals and nursing homes are both health care occupancies and are defined separately, but they are not established as separate suboccupancies; thus, a change from one to the other does not constitute a change of occupancy subclassification.

For example, a building was used as a hospital but has been closed for four years. It is again to be used as a hospital. As long as the building was not used as another occupancy during the time it was closed, it would be considered an existing hospital.

Hotels and apartments, although both residential occupancies, are treated separately, and a change from one to the other constitutes a change of occupancy.

In addition to requiring that the provisions for new construction be applied to an existing building upon change of occupancy, former editions of the *Code* required that the provisions for new construction be applied upon change from one occupancy subclassification to another subclassification of the same occupancy. Although the provision is no longer contained in 4.6.12, the concept has not been lost and is addressed in the appropriate individual occupancy chapters. For example, 18.1.1.4.5 and 19.1.1.4.5 mandate that a change from one health care occupancy subclassification to another requires compliance with the requirements for new construction. Subitems 18.1.1.4.5(2) through (4) and 19.1.1.4.5(2) through (4) then allow that any of the following changes do not constitute a change of occupancy or occupancy subclassification:

- (1) From a hospital to a nursing home
- (2) From a nursing home to a hospital
- (3) From a hospital or nursing home to a limited care facility
- (4) From a hospital or nursing home to an ambulatory health care facility

Similarly, in 36.1.1.4 and 37.1.1.4, which apply to mercantile occupancies, a change from Class C to Class A or Class B, or from Class B to Class A, must meet the provisions applicable to new construction, but a change from Class A to Class B or Class C, or

from Class B to Class C, is permitted to comply with the requirements applicable to existing mercantile occupancies.

4.6.13 Maintenance and Testing.

4.6.13.1 Whenever or wherever any device, equipment, system, condition, arrangement, level of protection, or any other feature is required for compliance with the provisions of this *Code*, such device, equipment, system, condition, arrangement, level of protection, or other feature shall thereafter be continuously maintained in accordance with applicable NFPA requirements or as directed by the authority having jurisdiction.

Paragraph 4.6.13.1 emphasizes the importance of maintaining items required by the *Code*. It is useless to have an egress door that will not open, a self-closing device that does not close the door, or a sprinkler system with no water.

4.6.13.2* Existing life safety features obvious to the public, if not required by the *Code*, shall be either maintained or removed.

A.4.6.13.2 Examples of such features include automatic sprinklers, fire alarm systems, standpipes, and portable fire extinguishers. The presence of a life safety feature, such as sprinklers or fire alarm devices, creates a reasonable expectation by the public that these safety features are functional. When systems are inoperable or taken out of service but the devices remain, they present a false sense of safety. Also, before taking any life safety features out of service, extreme care needs to be exercised to ensure that the feature is not required, was not originally provided as an alternative or equivalency, or is no longer required due to other new requirements in the current *Code*. It is not intended that the entire system or protection feature be removed. Instead, components such as sprinklers, initiating devices, notification appliances, standpipe hose, and exit systems should be removed to reduce the likelihood of relying on inoperable systems or features.

The *Code* directs that nonrequired life safety features that are obvious to the public are to be either maintained or removed to prevent false expectations or a false sense of security by building occupants. For example, if the water supply to a nonrequired wet standpipe system were permanently shut off because the system piping leaked but the hose and nozzle for occupant use were left attached to the standpipe, an

occupant could be endangered while attempting to use the system. If the nonrequired standpipe system were turned off and abandoned, it would be necessary, as a minimum, to remove all hoses and nozzles and to place prominent signage at each outlet station advising that the system is out of service. The standpipe system piping, however, would not have to be removed.

4.6.13.3 Equipment requiring periodic testing or operation to ensure its maintenance shall be tested or operated as specified elsewhere in this *Code* or as directed by the authority having jurisdiction.

4.6.13.4 Maintenance and testing shall be performed under the supervision of a responsible person who shall ensure that testing and maintenance are made at specified intervals in accordance with applicable NFPA standards or as directed by the authority having jurisdiction.

Section 4.7* Fire Drills

A.4.7 The purpose of emergency egress and relocation drills is to educate the participants in the fire safety features of the building, the egress facilities available, and the procedures to be followed. Speed in emptying buildings or relocating occupants, while desirable, is not the only objective. Prior to an evaluation of the performance of an emergency egress and relocation drill, an opportunity for instruction and practice should be provided. This educational opportunity should be presented in a nonthreatening manner, with consideration to the prior knowledge, age, and ability of audience.

The usefulness of an emergency egress and relocation drill and the extent to which it can be performed depends on the character of the occupancy.

In buildings where the occupant load is of a changing character, such as hotels or department stores, no regularly organized emergency egress and relocation drill is possible. In such cases, the emergency egress and relocation drills are to be limited to the regular employees, who can, however, be thoroughly schooled in the proper procedure and can be trained to properly direct other occupants of the building in case of emergency evacuation or relocation. In occupancies such as hospitals, regular employees can be rehearsed in the proper procedure in case of fire; such training always is advisable in all occupancies whether or not regular emergency egress and relocation drills can be held.

Subsections 4.7.1 through 4.7.6 and the associated material from Annex A serve as a primer on how to

conduct an emergency egress and relocation drill. The ___7 section, Operating Features, of some of the occupancy chapters provides emergency egress and relocation drill details that directly correlate a drill with the characteristics of the occupancy. An understanding of how the drill details have been matched to the needs of the occupants can be gained by comparing 14.7.1 (new educational occupancies) with 18.7.1 (new health care occupancies).

4.7.1 Where Required.

Emergency egress and relocation drills conforming to the provisions of this *Code* shall be conducted as specified by the provisions of Chapter 11 through Chapter 42, or by appropriate action of the authority having jurisdiction. Drills shall be designed in cooperation with the local authorities.

4.7.2* Drill Frequency.

Emergency egress and relocation drills, where required by Chapter 11 through Chapter 42 or the authority having jurisdiction, shall be held with sufficient frequency to familiarize occupants with the drill procedure and to establish conduct of the drill as a matter of routine. Drills shall include suitable procedures to ensure that all persons subject to the drill participate.

A.4.7.2 If an emergency egress and relocation drill is considered merely as a routine exercise from which some persons are allowed to be excused, there is a grave danger that, in an actual emergency, the evacuation and relocation will not be successful. However, there might be circumstances under which all occupants do not participate in an emergency egress and relocation drill, for example, infirm or bedridden patients in a health care occupancy.

4.7.3 Orderly Evacuation.

When conducting drills, emphasis shall be placed on orderly evacuation rather than on speed.

4.7.4* Simulated Conditions.

Drills shall be held at expected and unexpected times and under varying conditions to simulate the unusual conditions that can occur in an actual emergency.

A.4.7.4 Fire is always unexpected. If the drill is always held in the same way at the same time, it loses much of its value. When, for some reason during an actual fire, it is not possible to follow the usual routine of the emergency egress and relocation drill to which occupants have become accustomed, confusion and panic might ensue. Drills should be carefully planned to simulate actual fire conditions. Not only

should drills be held at varying times, but different means of exit or relocation areas should be used, based on an assumption that fire or smoke might prevent the use of normal egress and relocation avenues.

4.7.5 Relocation Area.

Drill participants shall relocate to a predetermined location and remain at such location until a recall or dismissal signal is given.

4.7.6* A written record of each drill shall be completed by the person responsible for conducting the drill and maintained in an approved manner.

A.4.7.6 The written record required by this paragraph should include such details as the date, time, participants, location, and results of that drill.

Section 4.8 Emergency Plan

4.8.1 Where Required. Emergency plans shall be provided as follows:

- (1) Where required by the provisions of Chapter 11 through Chapter 42
- (2) Where required by action of the authority having jurisdiction

4.8.2 Plan Requirements.

4.8.2.1 Emergency plans shall include the following:

- (1) Procedures for reporting of emergencies
- (2) Occupant and staff response to emergencies
- (3) Design and conduct of fire drills
- (4) Type and coverage of building fire protection systems
- (5) Other items required by the authority having jurisdiction

4.8.2.2 Required emergency plans shall be submitted to the authority having jurisdiction for review.

4.8.2.3 Emergency plans shall be reviewed and updated as required by the authority having jurisdiction.

The requirement for an emergency plan can take two forms:

- (1) An occupancy chapter can require an emergency plan. For example, see 18.7.1.1 and 18.7.2.2, applicable to new health care occupancies.
- (2) The authority having jurisdiction can require such plans in accordance with 4.8.1(2).

No one generic emergency plan can adequately address the needs of all buildings. The AHJ has great latitude in requirements that will result in the creation and upkeep of an emergency plan tailored to the needs of the facility.

CHAPTER 5

Performance-Based Option

Chapter 5 of this *Code* provides a performance-based alternative to the prescriptive provisions. This performance-based option outlines a process that can be used to determine whether the building design satisfies the fire safety goals and objectives specified in the *Code*. This chapter is not intended to replace the prescriptive *Code*; however, it can be used instead of the prescriptive requirements. The performance-based option provides for design flexibility.

Examples of performance-based design include the development of fire safety designs for unique architectural problems not anticipated by the current *Code*. The performance-based option requires the designer and the authority having jurisdiction (AHJ) to agree on the interpretation of the *Code* in terms of goals, objectives, desired levels of safety, appropriate fire scenarios, assumptions, and safety factors. The performance-based option in this chapter addresses these issues explicitly while also presenting information regarding the selection of appropriate calculation methods and input values. Additionally, this chapter outlines a documentation procedure that improves the transmission of information from the designer to the AHJ, thereby aiding in the approval of safe, cost-effective designs.

Many of the concepts in this chapter have never been addressed in earlier codes or standards. For this reason, simple illustrative examples are provided to give the user a better idea of the concepts being discussed. The examples are generally based on specific building occupancies, but the concepts and ideas presented should be applicable across a range of occupancies.

Section 5.1 General Requirements

5.1.1* Application.

The requirements of this chapter shall apply to life safety systems designed to the performance-based option permitted by 4.4.1 and 4.4.3.

A.5.1.1 Chapter 5 of this *Code* provides requirements for the evaluation of a performance-based life safety design. The evaluation process is summarized in Figure A.5.1.1.

Code Criteria. On the left side of Figure A.5.1.1 is input from the *Code*. The life safety goals have been stated in Section 4.1. The objectives necessary to achieve these goals are stated in Section 4.2. Section 5.2 specifies the measures that are to be used to determine whether the objectives have been met.

Input. At the top of Figure A.5.1.1 is the input necessary to evaluate a life safety design.

The design specifications are to include certain retained prescriptive requirements as specified in Section 5.3. All assumptions about the life safety design and the response of the building and its occupants to a fire are to be clearly stated as indicated in Section 5.4. Scenarios are used to assess the adequacy of the design. Eight sets of initiating events are specified for which the ensuing outcomes are to be satisfactory.

Performance Assessment. Appropriate methods for assessing performance are to be used per Section 5.6. Safety factors are to be applied to account for uncertainties in the assessment as stated in Section 5.7. If the resulting predicted outcome of the scenarios is bounded by the performance criteria, the objectives have been met and the life safety design is considered to be in compliance with this *Code*. Although not part of this *Code*, a design that fails to comply

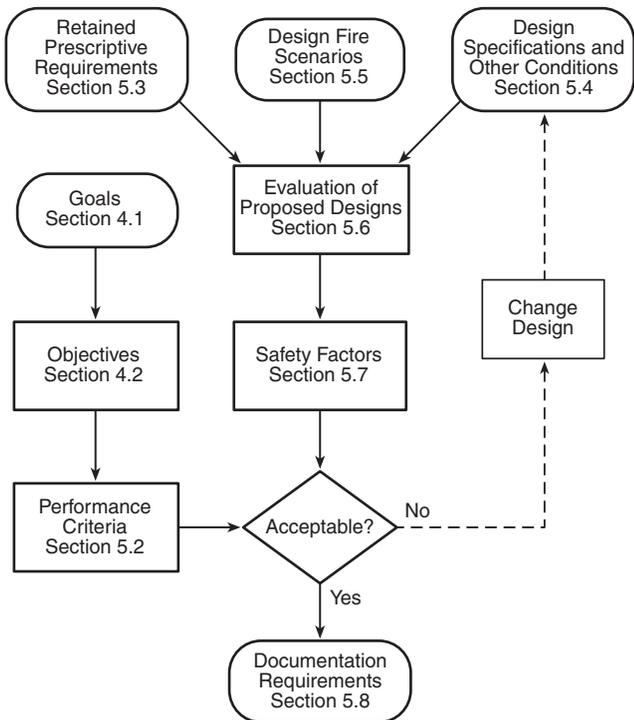

FIGURE A.5.1.1 Performance-Based Life Safety Code Compliance Process.

can be changed and reassessed as indicated on the right side of Figure A.5.1.1.

Documentation. The approval and acceptance of a life safety design are dependent on the quality of the documentation of the process. Section 5.8 specifies a minimum set of documentation that is to accompany a submission.

The performance option of this Code establishes acceptable levels of risk to occupants of buildings and structures as addressed in Section 1.1. While the performance option of this Code does contain goals, objectives and performance criteria necessary to provide an acceptable level of risk to occupants, it does not describe how to meet the goals, objectives, and performance criteria. Design and engineering are needed to develop solutions that meet the provisions of Chapter 5. The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* provides a framework for these assessments. Other useful references include the *Australian Fire Engineering Guidelines* and the *British Standard Firesafety Engineering in Buildings*.

Exhibit 5.1 provides a design tool for guidance through a performance-based design. This guide follows the same pattern as Figure A.5.1.1, with the Code-

specified goals, objectives, and criteria on the left side of the chart, but it goes into more detail on how the general and specific requirements included in this Code are used to formulate the various aspects of the design input. Several aspects of the design input are covered in various sections of this chapter, while others are developed or determined by the design team on the basis of the proposed building design. Once completed, the design input is then used with the chosen verification methods to obtain design output, to which a safety factor is applied. After applying the safety factor, the output can be compared to the fire safety criteria to determine whether the design passes or fails, after which the building design either is submitted for approval or is reevaluated after modifications are made to satisfy the criteria.

5.1.2 Goals and Objectives.

The performance-based design shall meet the goals and objectives of this Code in accordance with Section 4.1 and Section 4.2.

5.1.3 Qualifications.

The performance-based design shall be prepared by a registered design professional.

The qualifications needed by designers who develop performance-based designs are varied. Currently no certification or credential exists that formally identifies an individual as being capable of adequately developing performance-based designs. The best a code can do is to require performance-based designs to be prepared by a registered design professional. It is then left to the states and other governmental bodies to regulate what each registered design profession is permitted to do.

5.1.4* Independent Review.

The authority having jurisdiction shall be permitted to require an approved, independent third party to review the proposed design and provide an evaluation of the design to the authority having jurisdiction.

A.5.1.4 A third-party reviewer is a person or group of persons chosen by the authority having jurisdiction to review proposed performance-based designs.

The owner or developer may include a fee for third-party review in the budget for a performance-based

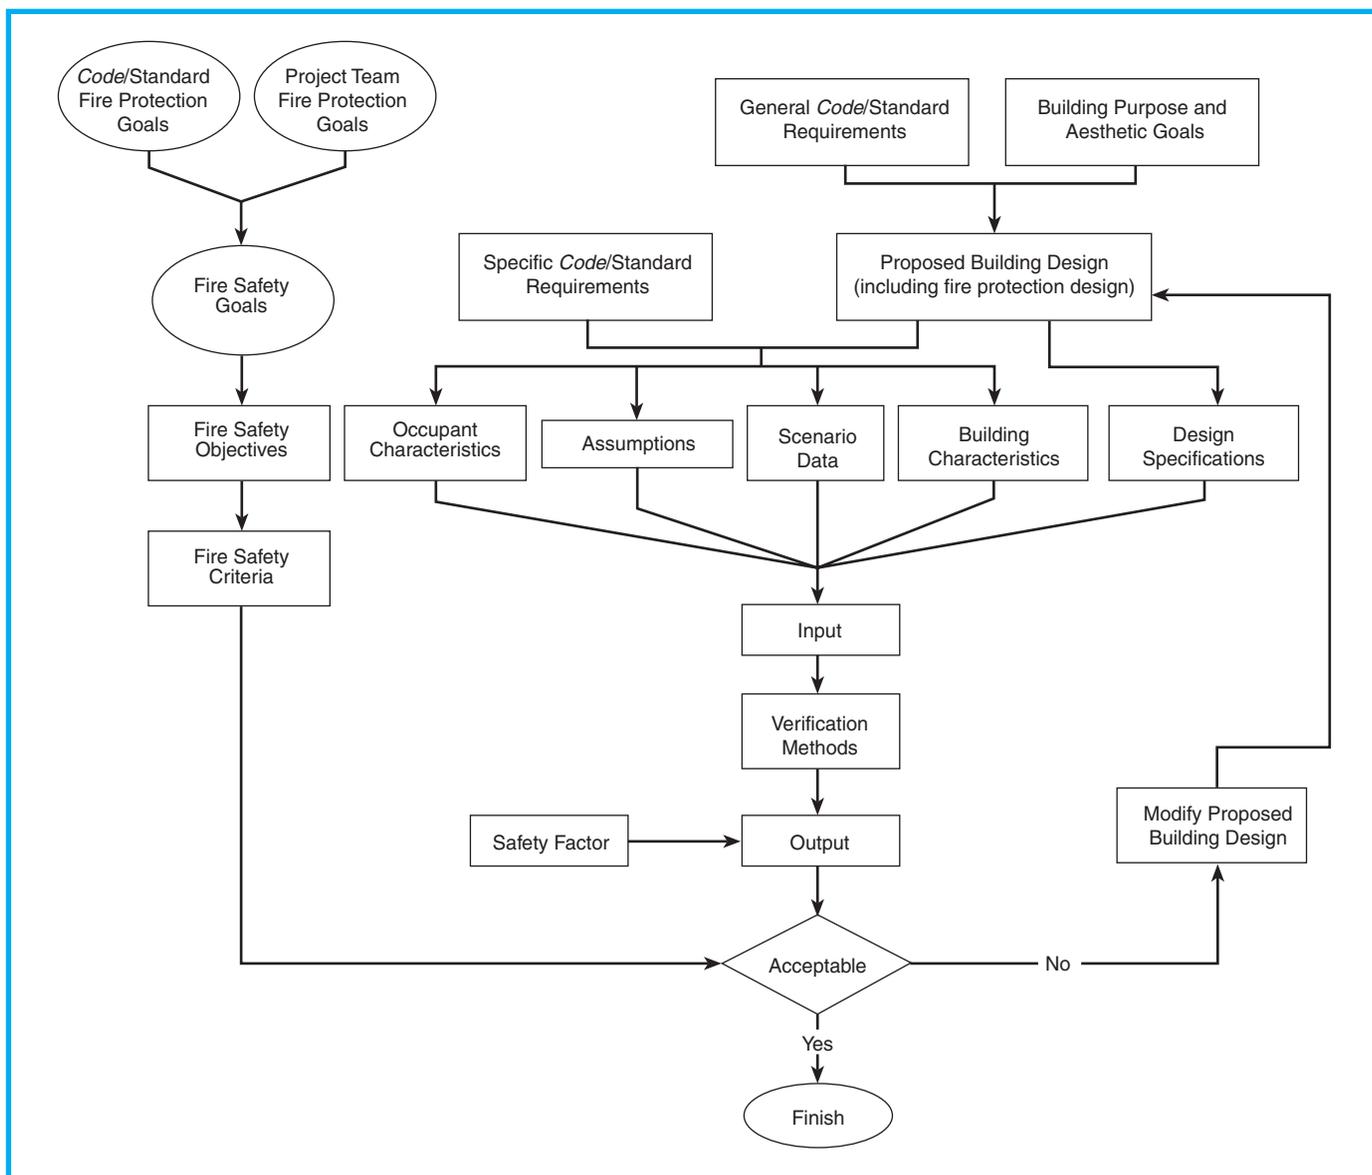

Exhibit 5.1 Performance-based design process.

project. This fee does not indicate that the third-party reviewer is responsible or beholden to the owner. The owner provides the funds for the authority having jurisdiction to hire a third-party reviewer, who then provides all findings to the AHJ.

5.1.5 Sources of Data.

Data sources shall be identified and documented for each input data requirement that must be met using a source other than a design fire scenario, an assumption, or a building design specification. The degree of conservatism reflected

in such data shall be specified, and a justification for the source shall be provided.

5.1.6 Final Determination.

The authority having jurisdiction shall make the final determination as to whether the performance objectives have been met.

5.1.7* Maintenance of Design Features.

The design features required for the building to continue to meet the performance goals and objectives of this Code shall

be maintained for the life of the building. Such performance goals and objectives shall include complying with all documented assumptions and design specifications. Any variations shall require the approval of the authority having jurisdiction prior to the actual change. (*See also 4.6.10.2.*)

A.5.1.7 Continued compliance with the goals and objectives of the *Code* involves many factors. The building construction—including openings, interior finish, and fire- and smoke-resistive construction—and the building and fire protection systems need to retain at least the same level of performance as is provided for the original design parameters. The use and occupancy should not change to the degree that assumptions made about the occupant characteristics, combustibility of furnishings, and existence of trained personnel are no longer valid. In addition, actions provided by other personnel, such as emergency responders, should not be diminished below the documented assumed levels. Also, actions needed to maintain reliability of systems at the anticipated level need to meet the initial design criteria.

The long-term maintenance of a performance-based design is an issue that has been deemed noteworthy, but for which a general solution has not been identified due to the limited experience with performance-based designs to date. Long-term maintenance is essentially a management-of-change issue. On approval of the performance-based (building) design, it becomes a *de facto* building-specific code. As such, the provisions of the design must be maintained for the lifetime of the building. New Zealand has dealt with this issue by using independent qualified persons (IQPs) who certify annually whether a building remains compliant after a certificate of occupancy has been issued.

Example: Maintenance of Design Features

In 5.1.7, the *Code* requires that the design features of the building be maintained for the life of the building. The design features that might be modified include the following:

- (1) Occupancy and use of the structure
- (2) Design specifications
- (3) Assumptions made by the design team regarding the building conditions, emergency response personnel, or staff assistance
- (4) Characteristics of the building and occupants

The following example shows how great an impact a minor change can have on the design input of a performance-based design. The example does not

involve a change in the occupancy of the building, but simply a change in building use. The building in question is an educational facility, originally designed and used as a high school but being modified for use as a kindergarten through grade 3 grammar school.

This type of change in building use does not require major modifications to the building structure; however, the shops and labs in the high school would have to be converted into spaces that normally are used in an elementary school, such as classrooms, offices, or storage space. Outside of these modified spaces, the design specifications remain the same. Additionally, many of the assumptions remain unchanged, such as the worst-case time for ignition, the ambient temperature, or the status of the ventilation system. However, changes are required in the characteristics used as design input.

The designer overseeing the change in building use needs to re-evaluate occupant characteristics, based on the fact that the building was designed with the typical occupant falling into the 14- to 18-year-old category. Now the typical occupant age will range from about 4 to 8 years of age. This change may lead to differences in movement speed, reaction time, and type of reaction. Additionally, the designer might have to make modifications in the location and number of occupants considered in the evaluation, based on the new use. Additional changes would have to be made regarding the need for, and level of, staff assistance.

Modifications might also be required in building characteristics, such as the fuel load. The change in building use could lead to differences in the amount and type of fuel. More items geared toward young children might or might not mean more, faster-burning materials. The building might no longer contain shop or lab areas, which act as a fire hazard, but it might have additional storage space, which can add significantly to the fuel load. The designer should investigate the impact of the different fuel loads in the two building uses.

Based on the specific building, there may be additional factors that have to be modified in the design input before the building is re-evaluated. No matter how small the modification might be, the building stakeholders should ensure that the building performance remains at a level that meets the performance goals and objectives. This investigation might simply entail verifying that the new value for part of the design input is still within the allowable range, or it might entail a complete re-evaluation of the structure. In either case, the authority having jurisdiction needs to be consulted before any changes are made.

5.1.8 Definitions.

A list of terms used in this chapter follows:

- (1) **Alternative Calculation Procedure.** See 3.3.10.
- (2) **Data Conversion.** See 3.3.39.
- (3) **Design Fire Scenario.** See 3.3.80.1.
- (4) **Design Specifications.** See 3.3.208.1.
- (5) **Design Team.** See 3.3.44.
- (6) **Exposure Fire.** See 3.3.67.
- (7) **Fire Model.** See 3.3.77.
- (8) **Fire Scenario.** See 3.3.80.
- (9) **Fuel Load.** See 3.3.131.1.
- (10) **Incapacitation.** See 3.3.116.
- (11) **Input Data Specification.** See 3.3.208.2.
- (12) **Occupant Characteristics.** See 3.3.153.
- (13) **Performance Criteria.** See 3.3.161.
- (14) **Proposed Design.** See 3.3.173.
- (15) **Safe Location.** See 3.3.184.
- (16) **Safety Factor.** See 3.3.185.
- (17) **Safety Margin.** See 3.3.186.
- (18) **Sensitivity Analysis.** See 3.3.12.1.
- (19) **Stakeholder.** See 3.3.211.
- (20) **Uncertainty Analysis.** See 3.3.12.2.
- (21) **Verification Method.** See 3.3.227.

Section 5.2 Performance Criteria

5.2.1 General.

A design shall meet the objectives specified in Section 4.2 if, for each design fire scenario, assumption, and design specification, the performance criterion in 5.2.2 is met.

5.2.2* Performance Criterion.

Any occupant who is not intimate with ignition shall not be exposed to instantaneous or cumulative untenable conditions.

A.5.2.2 One of the following methods can be used to avoid exposing occupants to untenable conditions.

Method 1. The design team can set detailed performance criteria that ensure that occupants are not incapacitated by fire effects. The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* describes a process of establishing tenability limits.

The guide references D. A. Purser, “Toxicity Assessment of Combustion Products,” Chapters 2–8, *SFPE Handbook of Fire Protection Engineering*, National Fire Protection Association, Quincy, MA, 1995, which describes a fractional effective dose (FED) calculation approach also contained in the 1996 edition of NFPA 269, *Standard Test Method for Developing Toxic Potency Data for Use in Fire*

Hazard Modeling. FED addresses carbon monoxide, hydrogen cyanide, carbon dioxide, hydrogen chloride, hydrogen bromide, and anoxia effects. It is possible to use the test data, combined with laboratory experience, to estimate the FED value that leads to the survival of virtually all people. This value is about 0.8.

There is a relationship between exposures leading to death and those leading to incapacitation. Kaplan (Kaplan et al., *Journal of Fire Science*, 2:286–305 (1984)) found that rodent susceptibility is similar to that of humans and that for the narcotic gases, CO and HCN, incapacitation occurs at one-third to one-half of the lethal exposure. Gann (Gann et al., *Fire and Materials* 18:193 (1994)) found that carbon monoxide dominates the lethality of fire smoke, since most fire deaths occur remote from the fire room, in fires that have proceeded past flashover. Thus, if an FED value of 0.8 were used for a nonlethal exposure, an FED of 0.3 would be reasonable for a nonincapacitating exposure.

If the authority having jurisdiction or the design professional is concerned with potential toxic fire effects other than those addressed by the FED procedure as documented, the calculation procedure can be expanded by adding additional terms to the FED equation, with each term expressed as a ratio. The numerator of the ratio is the cumulative exposure to that fire effect, measured as an integral of the product of instantaneous exposure (concentration for toxic products) and time. The denominator of the ratio is the quantity of cumulative exposure for which FED equals the chosen threshold value (that is, 0.8 or 0.3) based on that fire effect alone.

ASTM is actively considering standards that would extend the list of toxic fire effects with standard values.

If the authority having jurisdiction or the design professional is concerned with potential fire effects other than toxicity, the calculation procedure can be modified to include other fire effects, such as thermal effects.

For buildings where an unusually large fraction of the occupants are especially vulnerable, the calculation procedure should be modified to use FED values lower than 0.8 or 0.3.

Method 2. For each design fire scenario and the design specifications, conditions, and assumptions, the design team can demonstrate that each room or area will be fully evacuated before the smoke and toxic gas layer in that room descends to a level lower than 1830 mm (72 in.) above the floor. The timing of such an evacuation means that no occupant is exposed to fire effects. Such an evacuation requires calculation of the locations, movement, and behavior of occupants, because fire effects and occupants are kept separate by moving the occupants. A level of 1525 mm (60 in.) is often used in calculations, but at that level, a large fraction of the population would not be able to stand, walk, or run normally and still avoid inhalation of toxic gases.

They would have to bend over or otherwise move their heads closer to the floor level.

Method 3. For each design fire scenario and the design specifications and assumptions, the design team can demonstrate that the smoke and toxic gas layer will not descend to a level lower than 1830 mm (72 in.) above the floor in any occupied room. The advantage of this procedure is that it conservatively requires that no occupant need be exposed to fire effects, regardless of where occupants are or where they move. This removes the need to make any calculations regarding occupants, including their behavior, movement locations, pre-fire characteristics, and reactions to fire effects. This procedure is even more conservative and simpler than the procedure in Method 2, because it does not allow fire effects in occupied rooms to develop to a point where people could be affected at any time during the fire.

Method 4. For each design fire scenario and the design specifications and assumptions, the design team can demonstrate that no fire effects will reach any occupied room. The advantage of this procedure is that it removes the need to make any calculations regarding occupants, including their behavior, movement, locations, pre-fire characteristics, and reactions to fire effects. A further advantage is that it also removes the need for some of the modeling of fire effects, because it is not necessary to model the filling of rooms, only the spread of fire effects to those rooms. This procedure is even more conservative and simpler than the procedures in Methods 2 and 3, because it does not allow any fire effects in occupied rooms.

The methods described in A.5.2.2 provide an indication of the variety of ways of demonstrating that a proposed design meets the performance criteria and, therefore, the objectives. The Methods also illustrate how different approaches can result in different margins of safety. Specifically, Methods 2, 3, and 4 are all similar in their approach—they deal with smoke filling of a room. Method 2 concentrates on evacuating people before the smoke level reaches 1830 mm (72 in.) above the floor. This method presumes that the smoke will eventually reach a lower level and could, therefore, expose people crawling under the smoke layer. This method results in a relatively small margin of safety. Method 3 has a presumably more proactive design in that it intends to prevent the smoke layer from descending any lower than 1830 mm (72 in.) above the floor. This method intends to prevent exposure to occupants without their leaving the room, unless they are taller than 1830 mm (72 in.) and unwilling or unable to bend over. This method produces a greater margin of safety than that of the

second method. The margin of safety for Method 4 is the greatest—excluding the room of fire origin—because it requires the proposed design to prevent smoke from reaching any occupied room.

Three additional points are relevant to these methods. The first is that the final performance criteria might be the result of an agreement with the authority having jurisdiction, who might require or accept a different threshold other than the 1830-mm (72-in.) threshold cited. In both Methods 2 and 3, a value of 2135 mm (84 in.), 1980 mm (78 in.), or 1525 mm (60 in.) could have been justified instead, based on the use of different fractions of the population requiring protection—given that some people are taller than 1830 mm (72 in.)—or different safety margins on the uncertainty calculation of the smoke layer height. The threshold for smoke layer height, and many others, needs to be a subject of discussion before the performance-based design is begun.

The second point is that Method 4 presumes that the room of fire is unoccupied. Depending on the facility and the scenario, this might not be a reasonable assumption. If it is not, the criteria for safety for the room of fire origin need to be set separately.

The final point, outlined in the following discussion, is provided to demonstrate the differences among Methods 2, 3, and 4 with respect to the level of analysis required, not with regard to their use as a specification for performing an analysis or determining whether the design meets the performance criterion for the method. Depending on the method selected for use in the evaluation, the designer needs to perform different types and levels of analysis. If it is decided to use Method 2, which states that the smoke and toxic gas will not descend to a level lower than 1830 mm (72 in.) before the area is fully evacuated, the designer needs to model both the fire and smoke spread in the building to determine the time each space becomes untenable. Additionally, the designer needs to model each occupant's egress from the building, determining the times at which each space is occupied or fully evacuated. The models and the levels of fire and smoke spread and occupant egress can then be compared to determine if the toxic gas level and smoke descend beyond the specified level before the area is fully evacuated. This analysis path requires detailed modeling of both the toxic gas spread and the evacuation of the occupants. Care must be taken to ensure that the modeling is completed conservatively and accurately, because Method 2 does not provide a large margin for error inherent in the design.

If Method 3, which states that the smoke and toxic gas layer will not descend below 1830 mm (72 in.) in any occupied room, is selected, the analysis becomes both less complicated and more conservative. After determining each occupied space in the building, including spaces that will be occupied during occupant egress, the analysis will consist of a determination of when and whether the smoke and toxic gas layer will descend below the specified level in these areas. While the design still needs a detailed analysis of the fire and the spread of the products of combustion to determine the level of filling in each occupied area, such an analysis need not consider the building occupants or any actions they might take before or during the emergency.

If the stakeholders wish to design the building to satisfy Method 4, which states that no fire effects will reach any occupied area, the analysis becomes even less complicated and more conservative than that of Method 3. The designer should evaluate the building for each fire scenario to determine only if the smoke and toxic products of combustion will spread beyond the room of origin to occupied areas. This process often requires less complicated design tools and verification methods, because the rate and degree of smoke movement in the building is irrelevant as long as the designer can determine whether the smoke or toxic gas will travel into occupied areas.

- (1) Changes in level in means of egress—7.1.7
- (2) Guards—7.1.8
- (3) Doors—7.2.1
- (4) Stairs—7.2.2, excluding the provisions of 7.2.2.5.1, 7.2.2.5.2, 7.2.2.6.2, 7.2.2.6.3 and 7.2.2.6.4
- (5) Ramps—7.2.5, excluding the provisions of 7.2.5.3.1, 7.2.5.5, and 7.2.5.6.1
- (6) Fire escape ladders—7.2.9
- (7) Alternating tread devices—7.2.11
- (8) Capacity of means of egress—Section 7.3, excluding the provisions of 7.3.3 and 7.3.4
- (9) Impediments to egress—7.5.2
- (10) Illumination of means of egress—Section 7.8
- (11) Emergency lighting—Section 7.9
- (12) Marking of means of egress—Section 7.10

The prescriptive provisions listed in 5.3.2 for the means of egress do not readily lend themselves to performance-based calculation. However, these aspects cannot be excluded from the design. Therefore, these prescriptive provisions are retained for performance-based designs. For example, prescriptive exit sign requirements help to assure the effectiveness of the means of egress; emergency lighting along the egress path provides prescriptive reliability for the illumination needed for effective exiting. A rationale for retaining these prescriptive requirements is that existing models of evacuation behavior are not sophisticated enough to quantify the effect of signs or lighting on the speed and effectiveness of exiting behavior.

Section 5.3 Retained Prescriptive Requirements

5.3.1* Systems and Features.

All fire protection systems and features of the building shall comply with applicable NFPA standards for those systems and features.

A.5.3.1 This requirement applies both to systems and features required by the *Code* that reference applicable standards and to any additional systems or features included in the design at the discretion of the design team. The referenced standards are hereby expected to state maintenance, testing, and other requirements needed to provide positive assurance of an acceptable level of reliability. The referenced standards themselves might be prescriptive- or performance-based.

5.3.2 Means of Egress.

The design shall comply with the following requirements in addition to the performance criteria of Section 5.2 and the methods of Section 5.4 through Section 5.8:

5.3.3 Equivalency.

Equivalent designs for the features covered in the retained prescriptive requirements mandated by 5.3.2 shall be addressed in accordance with the equivalency provisions of Section 1.4.

Section 5.4 Design Specifications and Other Conditions

5.4.1* Clear Statement.

Design specifications and other conditions used in the performance-based design shall be clearly stated and shown to be realistic and sustainable.

A.5.4.1 The design specifications and other conditions form the input to evaluation of proposed designs (*see Section 5.6*). Where a specification or condition is not known, a reasonable estimation is permitted. However, the design team must take

steps to ensure that the estimation is valid during the life of the building. Any estimations need to be documented. (See Section 5.8.)

An example of an estimation could be a material property value needed as input by a computer fire model. Typically, computer fire models allow a single value to be input for material properties. However, if the material property varies with temperature, there is a question as to which single value adequately characterizes the material. The single value used to estimate the behavior of the material over the entire temperature range that might be experienced during the course of a fire needs to be conservatively selected and documented.

5.4.2 Assumptions and Design Specifications Data.

5.4.2.1 Each assumption and design specification used in the design shall be accurately translated into input data specifications, as appropriate for the calculation method or model.

The documentation of the performance-based analysis needs to clearly indicate the process for converting assumptions and design specifications into input data specifications. In some cases, the conversion process is straightforward. For example, room dimensions are explicitly stated in the design specification and can be used as input data without modification. However, if the designer assumes that a certain material will be the fuel consumed by the fire, then the process of converting that assumption into a heat release rate curve, a mass loss curve, toxic potency values, flame spread rate, or other data for modeling needs to be described.

Example: Design Specifications

The source of much of the input data for the verification methods is the design specifications for the building. The design specifications are to include all the information from the building design that affects the ability of the building to meet the stated goals and objectives. In addition to the building plans and drawings, the design specification information is to be presented for use by the designer and the authority having jurisdiction. Both parties then review the information and implement it as input data specifications. To give an impression of the type of information that should be included with the design specifications, a simple example—based upon a hypothetical, four-story business occupancy building—is pre-

sented. This example building plan is shown in Exhibit 5.2, which is not drawn to scale. The fire protection and egress features for the building are not designed to meet the prescriptive Code requirements, with the exception of those items listed in 5.3.2. Additionally, the building has not been analyzed using the methods in Chapter 5. To conserve time and space, the systems, features, and construction details specified in this example are not explained in full detail, since this information is available from a variety of other sources. However, when completing an

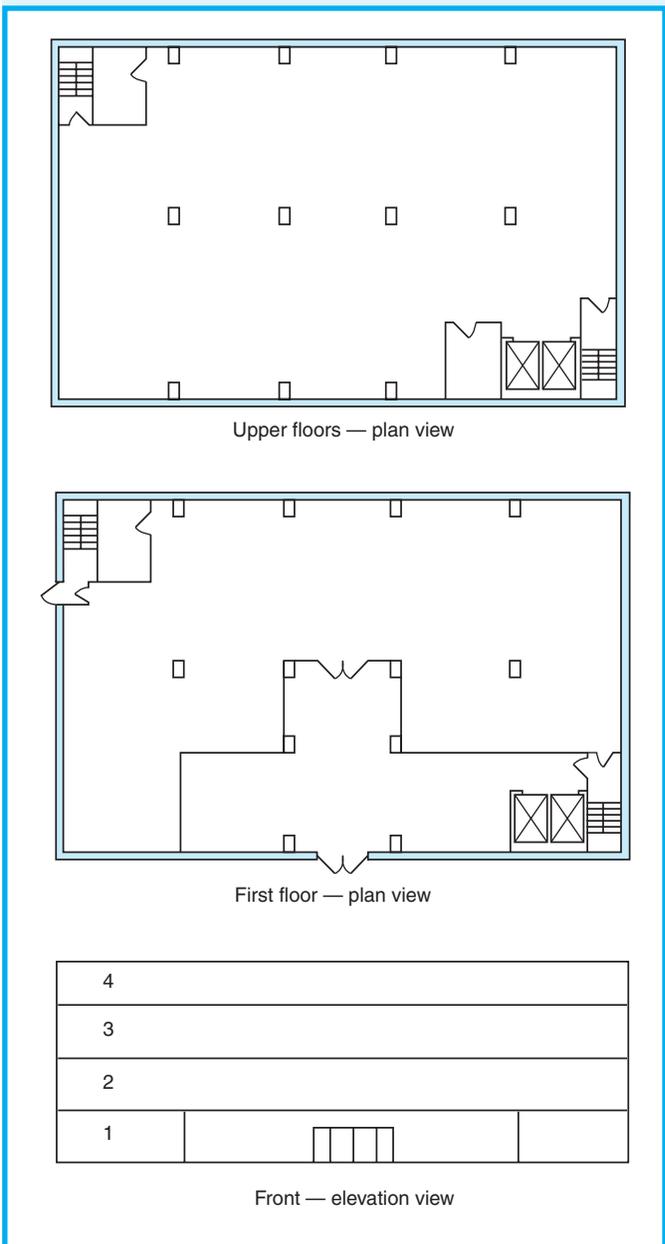

Exhibit 5.2 Four-story business occupancy building.

actual performance-based design, detailed information on each system and construction feature, such as an automatic sprinkler system or a fire barrier wall, needs to be compiled and presented for use by the designer and the authority having jurisdiction.

A description of the layout and dimensions of the building is to be developed. This description is to include a breakdown of each area to be considered in the performance-based design, as well as a description of the building as a whole.

Building footprint—30 m × 76 m (100 ft × 250 ft)

Building height—15 m (50 ft)

Story height (top of floor slab to bottom of slab on next floor)—3660 mm (144 in.)

Floor height (below false ceiling)—3050 mm (120 in.)

Steel frame construction (interior columns)—W8 × 28 steel columns protected by two layers of gypsum wallboard—total 25 mm (1 in.) thick; include design and construction details for column protection

Poured on deck concrete slab—150 mm (6 in.) thick, supported by prefabricated joists

Interior finish material—gypsum wallboard

Ceiling construction—include design and fabrication details for ceiling construction and materials

Automatic sprinkler system—installed throughout per NFPA 13, *Standard for the Installation of Sprinkler Systems*¹; include all specifications for the sprinkler system normally included in a prescriptive system design (for example, information relative to design density, RTI, spacing)

Alarm system—initiation by means of waterflow alarm incorporated into sprinkler system that operates when flow of water is equal to or greater than that from single sprinkler; waterflow alarm activates evacuation signal designed per NFPA 72, *National Fire Alarm Code*²; include all specification and design information for alarm system normally provided for a prescriptive design

HVAC system—designed and installed per NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*³, and applicable regional plumbing and mechanical code

Stairs

Two exit stair enclosures located in opposite corners of building

Stair enclosures—3050 mm × 7620 mm (120 in. × 300 in.)

Stair riser height—150 mm (6 in.)

Stair tread depth—305 mm (12 in.)

Stair clear width—1220 mm (48 in.)

Stairs enclosed with 2-hour fire resistance-rated barrier walls (provide design and construction details)

1 ½-hour fire protection-rated, self-closing, 810-mm (32-in.) clear width doors

Elevators

Two 3660 mm × 3660 mm (144 in. × 144 in.) elevators separated from rest of building by 2-hour fire resistance-rated barrier walls (provide design and construction details)

Elevator installation per ASME A17.1, *Safety Code for Elevators and Escalators*⁴

Storage room—located on upper floors next to elevator lobby

Dimensions—6100 mm × 7620 mm (240 in. × 300 in.)

Nonbearing walls constructed of gypsum wallboard mounted on metal studs

810-mm (32-in.) clear width self-closing door

Rest room—located adjacent to second stair enclosure

Dimensions—4570 mm × 7620 mm (180 in. × 300 in.)

Nonbearing walls constructed of gypsum wallboard mounted on metal studs

810-mm (32-in.) clear width self-closing door

Entranceway (ground floor)

Separated from remainder of first floor by 2-hour fire resistance-rated barrier walls (provide design and construction details)

Two main doors for entry into office space on ground floor—1 ½-hour fire protection-rated, self-closing, 1015-mm (40-in.) clear width

Two exterior exit doors off lobby—self-closing, 1015-mm (40-in.) clear width

Dimensions indicated on drawing

Emergency lighting and marking of the means of egress—specify details and design per Code's prescriptive requirements.

Example: Assumptions

In addition to compiling building specifications, a variety of assumptions need to be made by the de-

signer in developing a performance-based design. These assumptions are to remain constant and consistent throughout the analysis of the building. This example is included to provide information relating to the type of assumptions that might be made on a hypothetical 15-story hotel occupancy building. Similar to the design specifications, this information is provided in a list format. Certain assumptions made by the design team can be included with different sections of the design input, such as assumptions regarding the location of the occupants, which would be included with the occupant characteristics. Additionally, any assumptions that do not remain constant across the various scenarios cannot be classified as assumptions—they instead become scenario-related data. The breakdown of information should be agreed on with the AHJ before a design is submitted.

Status of Ventilation System. Information relating to the ventilation system and its status at the time of ignition should be included among the assumptions. While the design and construction information pertaining to the ventilation system would be included in the design specifications, the assumptions relating to this system would relate purely to its status at the time of the fire—mainly whether it was on or off. Additionally, information relating to whether the ventilation system would remain on throughout the fire scenarios—or whether an automatic device would shut down the system—could be included in this data. This example assumes that the ventilation system is on and operating normally at time of ignition.

Ambient Temperature. Ambient temperature is based on the anticipated condition of the building at the time of ignition. For most modern buildings, ambient temperature is dependent on the occupancy classification, since many buildings now incorporate heating/ventilation systems that maintain a constant temperature. This example has an ambient temperature of 21°C (70°F).

Ignition Time. Assume worst-case time of day for the various fire scenarios. In the case of a hotel, the worst-case time is in the evening or very early morning hours, when the occupants are expected to be sleeping.

Egress Paths. Assumptions are to be made regarding the condition of the egress ways and whether they are clear of debris. These assumptions are generally dependent on the anticipated use of the building, as certain building types are more likely than others to have objects stored or placed in the egress paths. In this example, the assumption that each stairway is

clear of clutter and debris is based on daily verification by a hotel employee. However, the lobby area—which might be used as a primary means of egress—is often cluttered with items such as luggage or chairs, and the designer needs to estimate a usable egress width.

Mobility Impairment. Assume one mobility-impaired occupant per floor of the structure. The mobility impairments affect the occupant characteristics of these individuals. The actual number of mobility-impaired individuals using the building might be based on one of the following:

- (1) The severity of the impairments
- (2) Local jurisdictional requirements
- (3) Selection by the design team based on the location of the structure and the anticipated clientele
- (4) The number of rooms properly equipped to house mobility-impaired individuals

Occupant Age Distribution. Assumptions regarding the age distribution of occupants are to be made. Tests have shown that groups of occupants separated by age have different movement speeds, and the design team needs to conservatively estimate the number of middle-aged adults, elderly, and children who will be located within the structure.

System Performance. Assume that all systems perform as designed unless the scenario specifically mandates a system failure.

Egress Path Selection. Assume that all occupants attempt to egress via the exit most familiar to them or that they will attempt to use the path followed when entering the building. Since most occupants will probably have used the elevator, assume occupants will use the first exit stair encountered in moving toward the elevators.

Fire Fighter Staging. Depending on the time passed to fire fighter arrival, assume that the speed of occupant movement on stairs will be reduced by half for the stairs that the fire department uses as a staging area.

5.4.2.2 Any assumption and design specifications that the design analyses do not explicitly address or incorporate and that are, therefore, omitted from input data specifications shall be identified, and a sensitivity analysis of the consequences of that omission shall be performed.

The term *design analyses* as used in 5.4.2.2 means the baseline analyses of the proposed design. The design

analyses are compiled into a report and submitted to the authority having jurisdiction for approval. Design specifications and assumptions would not be included in the baseline analyses if, for example, the designer originally considered incorporating an automatic suppression system into the building design or designing the building to rely on manual suppression if a fire occurs. In such a case, the designer would perform an analysis on each of those options and include in the proposed design the one that best satisfies the performance criteria at the lowest cost. The rejected option would be included as an appendix in the submittal to the AHJ. The appendix would indicate why the rejected option was not included in the analyses, as well as how the building performance would change if the rejected option were to be incorporated into the design.

5.4.2.3 Any assumption and design specifications modified in the input data specifications, because of limitations in test methods or other data-generation procedures, shall be identified, and a sensitivity analysis of the consequences of the modification shall be performed.

For example, new and innovative designs for detection systems, suppression systems, or overall building layout and egress systems might be incorporated into a performance-based design. Unfortunately, while the design team may feel that these systems and modifications provide a marked improvement in the performance of the building, they might not be quantifiable in the models used to analyze the structure. If the design specifications and assumptions are such that they cannot be directly implemented into a model, the design team needs to provide justification for selection of input values to be used for the specifications and assumptions. This justification needs to include the following:

- (1) A detailed description of the new or modified system
- (2) Rationale behind its selection for incorporation into the building design
- (3) Reason for not incorporating specifications and assumptions directly into the model input
- (4) Anticipated level of performance
- (5) Improvements expected from the system
- (6) Means of specifying input values in the input data specifications

Due to the level of uncertainty involved in this type of input data specification development, the de-

sign team needs to perform a sensitivity analysis on any of the input values formulated using this procedure. An example of a type of system whose design specification cannot be directly incorporated into the input data specifications is a new detection and alarm system that has not been fully tested in the arrangement and layout of the proposed building. If the design team can provide justification that the model cannot accurately predict the system's performance, then modifications should be made to the input data specification to account for the differences in the results of the analysis and the performance of the system.

5.4.3 Building Characteristics.

Characteristics of the building or its contents, equipment, or operations that are not inherent in the design specifications, but that affect occupant behavior or the rate of hazard development, shall be explicitly identified.

Building characteristics that are not classified as design specifications tend to be limited to particular spaces within the building, occupancy- or purpose-driven, or long-term or transitory adjustments by occupants to problems in the functionality of the basic design. The building characteristics depend largely on the materials used to decorate and furnish the building and on the anticipated layout of such materials. The identification of building characteristics needs to take into account the intended use of the building and potential aging effects on the materials used. The identification of building characteristics of concern requires considerable experience with the hazard-related consequences of both typical and problematic operations in occupancies of the type proposed.

Examples of building characteristics include the anticipated layout, fuel load, and burning characteristics of a work area composed of cubicles in a business occupancy. In addition to the flammability characteristics of the interior lining materials of a structure, an additional modification could be included with the building characteristics to account for the potential buildup of combustible dust or hydrocarbon residue on the material in an industrial complex. Buildings in which there is a high rate of occupant turnover and movement, such as educational facilities or dormitories, might include doors—and more important, fire doors—that are routinely blocked open allowing the uninhibited passage of smoke and other fire prod-

ucts of combustion. Designers of a mercantile occupancy might deliberately or inadvertently create a maze-like effect, which not only affects evacuation times, but might also lead to anxiety and confusion in the occupants during an emergency.

Example: Building Characteristics

The description of the building characteristics is to include all of the information related to the building and its various contents and features that is not included with the design specifications. Various examples of building characteristics are provided in this commentary. However, this example includes a more detailed example of the type of items that should be included with the building characteristics when developing a performance-based design. Additionally, this example presents differences in, and modifications that would be required for, the building characteristics if the intended use is changed from a business occupancy to a mercantile occupancy. The different occupancy types can lead to large differences in the smoke production and spread throughout the structure, as well as differences in evacuation time. The designer needs to carefully select and document the characteristics of the specific building. The designer also needs to use conservative estimates of the various building characteristics, particularly if there is a possibility that the owner might change the building type or occupancy.

The building in question is a three-story office building that is being converted into a three-level department store. The following provides a description of the building characteristics that might be used in the original performance-based design for the business occupancy.

Office Space. The space is divided throughout by work cubicles. A base case office setup for cubicle arrangement is to be specified. Arrangements are to be analyzed using sensitivity analysis to determine allowable level of variance in office setup.

Fuel Load. The fuel load is dependent on office setup. A fixed fuel load is to be used, as limited types of materials are available for consumption. The fuel load will consist of materials such as office furniture, computers, cubicle finishing materials, and paper. Tests that measure the burning rate of office cubicles and different office setups are to be consulted to determine the total combined fuel load. The flammability of each potential fuel item in the area of ignition is to be estimated. Other potential sources of fuel in a

business occupancy include the interior finish materials and paper or office equipment in storage areas.

The flammability information for the fuel sources, such as the heat release rate, rate of flame spread, and mass loss rate, can be determined from several sources. The flammability data for the fuels in question might be available in typical fire protection texts, such as the *NFPA Fire Protection Handbook*⁵, the *SFPE Handbook of Fire Protection Engineering*⁶, and Drysdale's *An Introduction to Fire Dynamics*⁷. This information can also be estimated using the results from small-scale tests, such as those from a cone calorimeter or a LIFT apparatus. A more accurate determination of the flammability characteristics can be produced in large-scale testing of the fuels in question. This is not to suggest that the designer conduct large-scale testing of the anticipated fuel sources for each design; however, a review of large-scale tests completed on items similar to those in question at fire testing labs such as the National Institute of Standards and Technology (NIST) Building and Fire Research Laboratory might provide accurate estimates of the required material properties. NIST has compiled this research in reports available for downloading on its web site or at its research library, such as *A Survey of Fuel Loads in Contemporary Office Buildings*⁸ by Caro and Milke. The flammability of the specific items in question should be documented as accurately as possible.

Egress Paths. Despite the variability of the office setup, business occupancies typically will have clear, fixed paths of egress. The egress paths will generally consist of a perimeter loop around the office core, along with multiple aiseways leading from the interior offices to the perimeter loop. Based on the type of business occupying the structure, the designer should determine whether the egress paths are likely to remain clear of clutter and debris. This facet of the building characteristics could also be included with the design assumptions.

Fire Doors. The condition of the fire doors in the structure is to be specified with the building characteristics. Business occupancies generally keep fire doors in the structure closed due to the limited need to block the doors open, since, generally, occupant turnover is not large, and movement of furniture is periodic.

The preceding characteristics are assumptions relating to the building's function. These business occupancy characteristics can be compared to those identified for the department store to determine which characteristics can be replaced with new values

for the new occupancy. Generally, some differences exist; if the new characteristics vary significantly, the designer might have to re-evaluate the performance of the structure completely. The following presents the types of information that are to be included with the building characteristics for the renovated mercantile occupancy spaces.

Mercantile Space. As in the case of the business occupancy, a base case setup of the mercantile space is to be specified. However, a mercantile occupancy generally modifies the arrangement and setup of the building contents more frequently than a business occupancy does, based on the type of store involved. The design is to be sufficiently robust so that almost every typical arrangement of the mercantile occupancy is allowed, with the exception of extreme cases utilizing highly volatile or flammable substances.

Fuel Load. The fuel load for a mercantile occupancy is based primarily on the intended merchandise. The fuel load could consist of items ranging from electronics, plastics, and food products to wood materials, upholstered furniture, and seasonal decorations. The fuel load can vary greatly depending on the type of store and even the time of year. The design is to be based on the worst-case fuel load that the designer feels might be in the building at any time.

Egress Paths. Many mercantile establishments either inadvertently or deliberately create maze-like paths that run through the store. While such paths might keep shoppers in the store for longer periods, causing them to view more of the merchandise, they will also cause longer evacuation times and can lead to anxiety during emergencies. Additionally, due to restocking operations and the moving of merchandise, the egress paths and aiseways in a mercantile occupancy might be partially or fully blocked.

Fire Doors. Mercantile occupancies are frequently moving items and storing contents and may have large occupant loads moving between different spaces. These effects might result in the fire doors within the structure being blocked open, potentially allowing smoke and other products of combustion to spread uninhibited throughout the structure. The evaluation should consider this issue, or the designer should take steps to ensure that the fire doors remain closed.

5.4.4* Operational Status and Effectiveness of Building Features and Systems.

The performance of fire protection systems and building features shall reflect the documented performance and reliability

of the components of those systems or features, unless design specifications are incorporated to modify the expected performance.

A.5.4.4 Systems addressed by this requirement include automatic fire suppression systems and fire alarm systems. Performance issues that need to be documented might include response time indexes, discharge densities, and distribution patterns. Calculations should not include an unlimited supply of extinguishing agent if only a limited supply will be provided in the actual structure or building.

Subsection 5.4.4 and its annex language are meant to help ensure that the performance-based design analysis is realistic and reflects the anticipated operation of the systems. In other words, the analysis must consider that the systems installed in buildings are limited—not like Hollywood guns that never run out of bullets. Designers need to make sure that the analysis deals with the systems in a practical manner and is representative of how the systems will be installed in the building.

Subsection 5.4.4 addresses inherent performance limitations rather than reliability concerns, which are separately addressed in 5.5.3.8 through mandatory analysis of scenarios with systems and features rendered unavailable. For example, there are different modes of fire detection (such as ionization smoke detectors, photoelectric smoke detectors, fixed-temperature heat detectors, and rate-of-rise heat detectors) that provide different speeds of response to different fire scenarios. Also, automatic fire sprinklers use varying design densities of different agents, resulting in different speeds and degrees of effectiveness, depending on fire scenario. Fire doors are rated for different duration and are expected to withstand different levels of heat impact before failing. Additionally, fire barrier walls are expected to exhibit various performance levels, particularly if one extends from the floor to the roof while another extends to a level below the roof.

5.4.5 Occupant Characteristics.

5.4.5.1* General. The selection of occupant characteristics to be used in the design calculations shall be approved by the authority having jurisdiction and shall provide an accurate reflection of the expected population of building users. Occupant characteristics shall represent the normal occupant profile, unless design specifications are used to modify the expected occupant features. Occupant characteristics shall not vary across fire scenarios except as authorized by the authority having jurisdiction.

A.5.4.5.1 Examples of design features that might be incorporated to modify expected occupant characteristics include training, use of staff to assist with notification and movement, or type of notification appliance used.

5.4.5.2* Response Characteristics. The basic response characteristics of sensibility, reactivity, mobility, and susceptibility shall be evaluated. Such evaluation shall include the expected distribution of characteristics of a population appropriate to the use of the building. The source of data for these characteristics shall be documented.

A.5.4.5.2 The four basic characteristics—sensibility, reactivity, mobility, and susceptibility—comprise a minimum, exhaustive set of mutually exclusive performance characteristics of people in buildings that can affect a fire safety system’s ability to meet life safety objectives. The characteristics are briefly described as follows.

- (1) *Sensibility – to physical cues.* Ability to sense the sounding of an alarm; can also include discernment and discrimination of visual and olfactory cues in addition to auditory emanations from the fire itself.
- (2) *Reactivity – ability to interpret correctly cues and take appropriate action.* Can be function of cognitive capacity, speed of instinctive reaction, or group dynamics; might need to consider reliability or likelihood of a wrong decision, as in situations where familiarity with the premises influences wayfinding.
- (3) *Mobility—speed of movement.* Determined by individual capabilities as well as crowding phenomena such as arching at doorways.
- (4) *Susceptibility—to products of combustion.* Metabolism, lung capacity, pulmonary disease, allergies, or other physical limitations that affect survivability in a fire environment.

In application, as with the use of computer evacuation models, assumptions can address a larger number of factors that are components of these basic performance characteristics. Examples follow:

- (1) *Alertness:* Awake/asleep, can depend on time of day
- (2) *Responsiveness:* Ability to sense cues and react
- (3) *Commitment:* Degree to which occupant is committed to an activity underway before the alarm
- (4) *Focal point:* Point at which an occupant’s attention is focused, for example, to front of classroom, stage, or server in business environment
- (5) *Physical and mental capabilities:* Can affect ability to sense, respond, and react to cues; might be related to age or disability
- (6) *Role:* Can determine whether occupant will lead or follow others
- (7) *Familiarity:* Can depend on time spent in building or participation in emergency training

- (8) *Social affiliation:* Extent to which an occupant will act/react as an individual or as a member of a group
- (9) *Condition:* Over the course of the fire, the effects—both physiological and psychological—of the fire and its combustion products on each occupant

5.4.5.3 Location. It shall be assumed that, in every normally occupied room or area, at least one person shall be located at the most remote point from the exits.

All occupant locations at the beginning of the fire must be specified. This information is critical for egress analysis, since travel distances to the exits must be known. Depending on the scenarios of interest, conditions within selected egress paths must be analyzed. However, the conditions in the room of fire origin always need to be determined.

5.4.5.4* Number of Occupants. The design shall be based on the maximum number of people that every occupied room or area is expected to contain. Where the success or failure of the design is contingent on the number of occupants not exceeding a specified maximum, operational controls shall be used to ensure that the maximum number of occupants is not exceeded.

A.5.4.5.4 The number of people expected to be contained in a room or area should be based on the occupant load factor specified in Table 7.3.1.2 or other approved sources.

An example of another approved source for occupant load factors might be zoning regulations. Also, the authority having jurisdiction might specify a higher occupant load than that given in Table 7.3.1.2 to provide an additional safety margin.

Example: Response Characteristics, Location, and Number of Occupants

The occupant characteristics specified for a performance-based design need to provide an accurate representation of the abilities and behaviors of the building occupants before and during a fire. This information is critical to a performance-based design if the design is to be based on and compared with Method 2 of A.5.2.2. This criterion selection requires that each room or area be fully evacuated before the smoke layer in that room descends below 1830 mm (72 in.) above the floor. To show that each space is clear before the smoke layer reaches this level, the designer must document the spread of fire, its products of combustion, and the movement of people

throughout the building during the emergency as accurately as possible using current verification methods. To model the evacuation of the building, characteristics of the occupants of that building must be formulated. The overall function of occupant characteristics is the estimation of the time required to evacuate the building. Therefore, the designer also needs to formulate response characteristics, which dictate how the occupants perceive the fire threat, the time required to respond to this threat, and the time to evacuate the building once the decision has been made to leave. Additionally, the designer needs to determine the number and location of people occupying the structure at the time of the fire initiation. Staff assistance and emergency response, which also have an impact on evacuation time, are presented in separate examples in this chapter.

This example presents a sample of occupant characteristics that could be used as the basis for an egress analysis. It is critical that the designer account for pre-movement activities when completing an egress analysis, as occupants will often spend as much time, if not far more, deciding and preparing to leave than actually moving through the building.⁹ The list of occupant characteristics is based on a hypothetical, three-story apartment building as shown in Exhibit 5.3. This building has two enclosed exit stairs located in the opposite corners of the structure. The stair on the bottom right-hand side of Exhibit 5.3 is assumed to be the main, front stairway for the structure—the egress path most familiar to the majority of the people in the building. The building is laid out

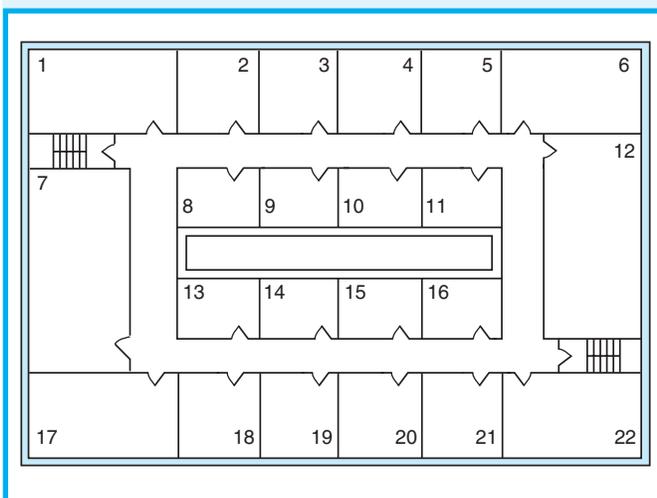

Exhibit 5.3 Three-story apartment building—typical floor, plan view.

such that there are 16 one-bedroom apartments and 6 three-bedroom apartments.

16 small apartments

Single bedroom

Two people per apartment

Two mobility-impaired people (walking disabled) per floor. Base case locations, apartments 3 and 14—subject to sensitivity analysis.

Large apartments

Three bedrooms

Three apartments with two adults and two children; three apartments with two adults and three children; base case locations, five-person apartments 7, 12, and 17. Distribution of four- and five-person apartments subject to sensitivity analysis.

Notification Time. Notification time is the time from ignition until the sounding of the alarm. Notification time is dependent on the fire scene and design specification of the detection and alarm system.

Reaction Time. Assume everyone in the building is sleeping at the time of alarm. This state of sensibility presents a delay in the reaction time of the occupants. Additionally, average reaction time is highly influenced by the performance of the detection and alarm system. Tests have shown that the performance of an alarm system and the occupants' attitude to the sounding of the alarm have a dramatic effect on the average delay time.¹⁰ The average reaction time of adult occupants is determined on the basis of the condition of occupants at the time of alarm (sleeping), design features and audibility of the alarm system, and any local regulation relating to delay times to be used in egress analysis. This example assumes that children will not react and prepare to evacuate without prompting from adults; therefore, only an estimate for adults is to be provided. The predicted range of reaction time is to be provided.

Pre-Evacuation Time. An additional factor that needs to be considered when performing egress analyses is activities that occupants engage in before leaving the building. These activities range from gathering children or pets to getting dressed and packing up valuable belongings. The climate of the building location might factor into the delay time, as occupants are more reluctant to go outside in particularly cold weather, and—before they do—more time will be spent finding and donning jackets and other clothing. In the case of mobility-impaired individuals who require mobility aids, delay time will also in-

clude the time required to find, gather, and begin using these devices. An average time for pre-evacuation activities is to be specified for each of the apartment groups. For this example, the apartments housing two adults and no children have pre-evacuation times based on the time required to get dressed, gather items such as a jacket, keys, shoes, and wallet, and then begin to egress the building. An additional amount of time should be added for those apartments housing mobility-impaired individuals. For those apartments housing children, an additional time factor should be added for the time required to get the children together, dressed, and ready to move out of the building. Information on reaction time and pre-evacuation activities is critical for the completion of an accurate egress analysis. This information can be found in the NFPA *Fire Protection Handbook*, *The SFPE Handbook of Fire Protection Engineering*, or tests such as those cited in the Proulx and Fahy paper¹⁰.

In summary, the following pre-evacuation times are also to be included in the egress analysis:

- (1) Adult apartments pre-evacuation time—provide predicted range based on specific occupant characteristics and available literature and test data
- (2) Adult apartments for mobility-impaired individuals pre-evacuation time—provide predicted range
- (3) Apartments with children pre-evacuation time—provide predicted range

Travel Time. The final component of an egress analysis is the calculation of the time required for occupants to leave the structure once they begin to evacuate. This travel time is primarily based on the location of the occupants and the speed at which they can navigate through the building. Depending on the structure in question, the occupants' ability to move might be affected by crowding phenomena and unfamiliarity with the structure. Other factors that influence travel time are as follows:

- (1) Families remain in a group throughout evacuation and move at the speed of the slowest member.
- (2) Occupants have varied familiarity with the structure.
- (3) Occupants egress via the most familiar path, unless fire or products of combustion block that path. Assume occupants from apartments 1, 2, 3, 7, 8, 9, and 17 attempt to use the stairway in the upper left-hand corner of exhibit 5.3, while the rest of the occupants use the stairway in the bottom right-hand corner of the exhibit.

Occupant movement speeds are available from several sources, including the NFPA *Fire Protection Handbook*, *SFPE Handbook of Fire Protection Engineering*, and Fruin's *Pedestrian Planning and Design*¹¹, or from tests on different samples of the population.

Movement speeds for the following are to be included in the egress analysis:

- (1) Adults on floor—provide predicted range based upon available literature and test data
- (2) Adults on stairs—provide predicted range
- (3) Families with children on floor—provide predicted range
- (4) Families with children on stairs—provide predicted range
- (5) Mobility-impaired adults on floor—provide predicted range
- (6) Mobility-impaired adults on stairs—provide predicted range

$$\text{Egress time} = t_n + t_r + t_p + t_t$$

where:

t_n = notification time

t_r = reaction time

t_p = pre-evacuation time

t_t = travel time

5.4.5.5* Staff Assistance. The inclusion of trained employees as part of the fire safety system shall be identified and documented.

A.5.4.5.5 For example, in hospitals, staff characteristics such as number, location, quality, and frequency of training should be considered.

Example: Staff Assistance

Certain occupancies or building types might require that staff assistance be provided during the evacuation procedure in order for the occupants to evacuate the building safely. The assistance of trained staff in public places such as department stores, shopping malls, theaters, arenas, or similar buildings can help occupants unfamiliar with the building find emergency exits, accelerating their departure and reducing the overall evacuation time. However, it is important that staff members who are accounted for in a design be properly trained and drilled so that they are familiar with their role in the evacuation of the building.

Other examples of occupancies where staff assistance might be required are nursing homes, hospitals, and residential board and care facilities. In facilities housing the elderly or mentally or physically impaired individuals, occupants might be slow to react to warning or alarm systems as well as slow in moving. Depending on the severity of the impairment of the occupants, evacuation time might be extremely prolonged without the incorporation of staff assistance. Take, for example, a nursing home that houses nonambulatory occupants incapable of self-preservation: Impairments of the occupants might range from the inability to hear an alarm, to comprehend the significance of an alarm, to the inability to walk unassisted or the inability to move at all without the use of a wheelchair. Due to the varied nature of the occupants in such a setting, the designer will most likely be unable to predict the types of impairments that the occupants of that building will have at any specific time.

The hypothetical building in question for this example is a two-story nursing home, with 6 occupant rooms, an entrance/waiting room, a desk/office area, and a cafeteria/lounge on the first floor; and 12 occupant rooms on the second floor. Exhibit 5.4 shows a plan view for each floor.

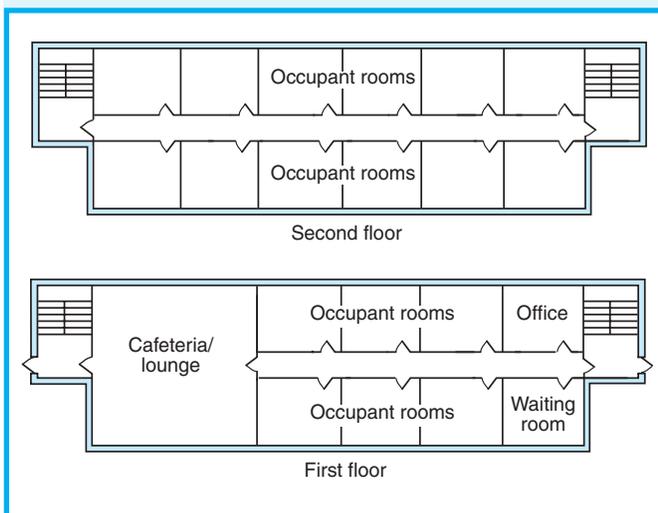

Exhibit 5.4 Two-story nursing home.

There are a total of 18 rooms, each housing 2 occupants. This equates to a total permanent occupancy of 36 patients. These people might suffer from a variety of impairments, which will greatly affect their ability to egress the building in a timely manner in the event of an emergency. This example assumes

that any occupant confined to a wheelchair is housed on the ground floor. The occupant characteristics for this building are not discussed in detail for this example, as occupant characteristics and their impact were addressed in the commentary to A.5.4.5.4. However, this example briefly presents the impact of staff assistance on the various time components that can be used to determine the total egress time.

It is assumed that the occupants of the building are sleeping. Because there is a fairly high likelihood that some of the occupants of this building are hearing impaired or might be unable to comprehend and react to an alarm, the reaction time for this component of the population could be infinite. Additionally, elderly occupants might take more time getting dressed and preparing to leave, further lengthening the pre-evacuation time. There is a high likelihood that some of the occupants of this structure suffer from mobility or mental impairments, which would also affect their travel time. Some of the occupants might be unable to move without assistance, so their travel time will be infinite, while others might simply move at a very slow pace.

Staff assistance can be factored into a design to negate some of the effects of various impairments on egress time. The actual level of staff required in a structure of this type might be restricted by local jurisdictions and individual company specifications. For this example, it is assumed that the building is staffed full time with three nurses, seven aides, and a desk clerk. Two of the nurses and four of the aides are located on the second floor. The designer should work with the building owner and stakeholders to develop a written facility fire safety plan that outlines each person's responsibility in the event of a fire. For this example, it is assumed that upon alarm and confirmation of a fire, the desk clerk is to notify and interact with the fire department, while the nurses and aides help the occupants to evacuate the building.

The designer must make certain assumptions regarding the facility staff and the degree to which they will affect the occupant response characteristics and evacuation. There must be a basis for each assumption made by the designer regarding staff assistance, and each should be documented. Assumptions might include the following:

- (1) All patients are under 24-hour supervision and their location is always known.
- (2) Wheelchair-bound patients are located on the first floor only, and the occupants either are seated in, or located near, their wheelchairs.

- (3) The facility has an emergency evacuation plan that is practiced twice a year.
- (4) Each nurse and aide is assigned a patient or group of patients who they must ensure escapes safely from the building.
- (5) Upon hearing an alarm, the staff verifies that there is a fire, then notifies each of the occupants and proceeds to take the following actions:
 - a. The staff closes the door to each room upon leaving to prevent smoke from entering that room.
 - b. The staff begins helping those in need of assistance in moving through the building.

The effects of staff assistance on the time to evacuation can be stated with each component of the egress analysis time, based on the assumptions made. The first component of the egress time calculation is the time to notification. This component is generally based on the sounding of the alarm, but one of the assumptions for this example is that the staff verifies a fire before helping to notify the occupants. This action introduces a time delay in the notification time. The second and third components of the egress time calculation are the reaction and pre-evacuation times. As previously discussed, these times might be dramatically affected by hearing, mental, or physical impairments. When the staff is notifying the occupants of the fire, they need to ensure that each occupant capable of evacuating without assistance begins to react, or staff is to help them to begin evacuating the structure. This might include getting each occupant dressed and prepared to leave, as well as placing the occupants into wheelchairs if necessary.

The delay estimate for staff assistance must include consideration of the fact that each member of the staff might be responsible for more than one person and that there might be delays associated with each person. For the example presented here, the average staff member is assigned three or four people, and an average delay developed depends on the anticipated level of impairment associated with each person. These actions introduce further delays in the reaction and pre-evacuation activities.

Finally, the staff aids the occupants in moving through the building. This might include wheeling them out of the building, walking next to them throughout the egress process, or simply directing them out of the building. Initially, estimates are to be made for each of these delays, and these estimates are to be confirmed by the evacuation drills.

5.4.6 Emergency Response Personnel.

Design characteristics or other conditions related to the availability, speed of response, effectiveness, roles, and other characteristics of emergency response personnel shall be specified, estimated, or characterized sufficiently for evaluation of the design.

Depending on the design in question, it might be desirable to omit the operations of emergency response personnel. If this is the case, this assumption is to be documented as part of the final design.

Example: Emergency Response Personnel

Depending on the type of occupancy and the use of the building, the designer might wish to incorporate the actions of emergency personnel into the evaluation of the structure. The design team needs to make many assumptions regarding the time to arrival and overall capabilities of the response personnel, and these assumptions must be incorporated into the design documentation. The designer cannot simply assume that the fire department will arrive 30 seconds after the initial fire alarm and suppress the fire immediately upon arrival. This example is provided to present the type of questions that should be addressed regarding emergency response personnel, as well as some of the assumptions that might be made.

The facility in this example is an industrial occupancy located on the outskirts of a suburban town. The facility manufactures plastic products and runs two shifts per day. There are two buildings on the campus: One houses the administrative personnel and design team offices as well as a cafeteria and lounge; the other is where all of the manufacturing takes place. The processes used in manufacturing the product are hazardous and involve the use of toxic and flammable chemicals. The town has two full-time fire stations, both with the same resources. One is located 5 miles from the facility; the other is 10 miles from the facility.

When determining what assumptions can be made about the emergency response personnel, it might be useful for the designer to develop a list of questions to ask the owner and authority having jurisdiction or fire department representative on the design team. The answers to such questions can help assess what level of dependence the design should have on the arrival of the fire department. The following are sample questions:

- (1) Is there a fire brigade on site?
- (2) What is this brigade's level of training?

- (3) What is the estimated response time of the local fire department?
- (4) How many response personnel will respond with the first arriving company? Second arrival?
- (5) Is the local fire department familiar with and trained to respond to emergencies at the facility?
- (6) When an alarm is sounded, does the signal go straight to the local fire department or to a security station on site? Who will assess the situation before calling the local fire department?
- (7) What types of hazards exist on site? Where are they located?
- (8) Do these hazards pose health threats to the surrounding community? To the employees? To the fire fighters?
- (9) Does the local fire department have the equipment to respond to the types of fire incidents that could develop?
- (10) Does the municipality or the plant supply this equipment?
- (11) If supplied by the company, is this equipment stored on site?
- (12) What type of access does the fire department have to the site?
- (13) How long will it take the fire fighters to set up for suppression efforts at a range of locations on the campus?

All assumptions regarding the fire department's response time need to be verified as feasible by the fire department. The overall intention of these questions regarding the fire department and its capabilities is to determine the time to arrival, the time to agent application, and the time to suppression, which can then be incorporated into the building evaluation. These various times should take into consideration not just the fire department, but also the building, as the designer should be aware that certain building designs present more challenging situations than do others. When emergency response personnel are to be an important part of the fire safety design, the designer needs to try to make the building as friendly to the fire department as possible. To facilitate this process, the designer should consult with the fire department early in and throughout the process to ensure that the design is optimized for fire-fighting operations and that any assumptions made regarding the fire department are accurate.

5.4.7* Post-Construction Conditions.

Design characteristics or other conditions related to activities during the life of a building that affect the ability of the

building to meet the stated goals and objectives shall be specified, estimated, or characterized sufficiently for evaluation of the design.

A.5.4.7 Design proposals need to state explicitly any design specifications or estimations regarding building fire safety plans, inspection programs, or other ongoing programs whose performance is necessary for the building, when occupied and operational, to meet the stated goals and objectives. Programs of interest include any maintenance, training, labeling, or certification programs required to ensure operational status or reliability in building systems or features.

Subsection 5.4.7 relates to the management-of-change issues discussed in 5.1.7. One design characteristic that typically changes post-construction is the fuel load. The design basis fuel load must anticipate such changes, no matter what their size. Increased quantities of fuel load that involve materials that are easier to ignite and that involve higher and faster growing heat release rates, with higher smoke generation rates, could have a significant impact on the performance-based design. Neither the designer nor the authority having jurisdiction will want to re-analyze the design's acceptability fully whenever post-construction conditions change slightly. To avoid that need while retaining safety, the designer must use assumptions that are more conservative than the conditions actually anticipated, and also identify those conditions of greatest sensitivity that must be maintained or re-analyzed.

5.4.8 Off-Site Conditions.

Design characteristics or other conditions related to resources or conditions outside the property being designed that affect the ability of the building to meet the stated goals and objectives shall be specified, estimated, or characterized sufficiently for evaluation of the design.

Off-site conditions are considered to be outside the property line and out of the control of the owner/operator. One example of an off-site condition is the status of the public water main. If the fire protection design relies on a sprinkler system fed by the public water main, then the analysis should consider the possibility that the public water main won't deliver the required amount of water.

5.4.9* Consistency of Assumptions.

The design shall not include mutually inconsistent assumptions, specifications, or statements of conditions.

A.5.4.9 The design elements required to be excluded by 5.4.9 include those about the interrelations between the performance of building elements and systems, occupant behavior, or emergency response actions that conflict with each other. For each fire scenario, care needs to be taken to ensure that conflicts in actions do not occur. Typical conflicts could include (1) assuming a fire door will remain closed during the fire to contain smoke while this same door is used by occupants during egress from the area, and (2) assuming fire apparatus will arrive immediately from a distant location to provide water to fire department connections and similar situations.

For example, an assumption that compartmentation blocking the passage of fire and smoke will be maintained at the door to a stairwell cannot be paired with an assumption that evacuation through that door will extend over many minutes.

5.4.10* Special Provisions.

Additional provisions that are not covered by the design specifications, conditions, estimations, and assumptions provided in Section 5.4, but that are required for the design to comply with the performance objectives, shall be documented.

A.5.4.10 The provisions required by 5.4.10 to be documented include those that are in excess of basic requirements covered by referenced codes and standards, typical design requirements, and operating procedures. It includes provisions such as more frequent periodic testing and maintenance to increase the reliability of fire protection systems, redundant systems to increase reliability, on-site guard service to enhance detection of fires and aid in fire response procedures, staff training, availability and performance of emergency response personnel, and other factors.

Section 5.5* Design Fire Scenarios

A.5.5 Design fire scenarios define the challenge a building is expected to withstand. Design fire scenarios capture and limit value judgments on the type and severity of the fire challenge to which a proposed fire safety system needs to respond. The system includes any and all aspects of the proposed design that are intended to mitigate the effects of a fire, such as egress system, automatic detection and suppression, barriers, staff training, and placement of manual extinguishers.

Design fire scenarios come from two sources: those that are specified in paragraphs 5.5.3.1 through 5.5.3.8, and those that are developed by the design team based on the unique characteristics of the building as required by 5.5.2. In most, if not all, cases, more than one design fire scenario will be developed to meet the requirements of 5.5.2.

Once the set of design fire scenarios is established, both those specified by 5.5.3.1 through 5.5.3.8 and those that are developed as required by 5.5.2, they need to be quantified into a format that can be used for the evaluation of proposed designs. The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* outlines a process and identifies tools and references that can be used at each step of this process.

5.5.1 Approval of Parameters.

The authority having jurisdiction shall approve the parameters involved in design fire scenarios. The proposed design shall be considered to meet the goals and objectives if it achieves the performance criteria for each required design fire scenario. (See 5.5.3.)

5.5.2* Evaluation.

Design fire scenarios shall be evaluated using a method acceptable to the authority having jurisdiction and appropriate for the conditions. Each design fire scenario shall be as challenging as any that could occur in the building, but shall be realistic, with respect to at least one of the following scenario specifications:

- (1) Initial fire location
- (2) Early rate of growth in fire severity
- (3) Smoke generation

A.5.5.2 The protection systems and features used to meet the challenge of the design fire scenario should be typical of, and consistent with, those used for other similar areas of the building. They should not be designed to be more effective in the building area addressed than in similar areas not included and that are, therefore, not explicitly evaluated.

Section A.5.5 indicates that 5.5.2 will typically force one or more scenarios to be considered in addition to the eight specified in 5.5.3.1 through 5.5.3.8. The specified scenarios are to be considered for all performance-based designs, but they do not necessarily represent a comprehensive set of scenarios. There may be additional scenarios truly unique to the proposed facility that need to be analyzed. The intent of including nonspecific scenarios (as opposed to the specific scenarios of 5.5.3) is to capture those scenarios where (see 5.5.2) initial fire location, early rate of growth in fire severity, or smoke generation poses a greater problem than those conditions captured by the scenarios in 5.5.3. However, there are also other conditions that may require development of scenarios—overcrowding of a specific space being just one example. Additional scenarios might also be specified

by the authority having jurisdiction to account for an historical, local fire that the AHJ is determined will not recur.

The following suggests how suitable scenarios may be developed.

Introduction. To provide a comprehensive design (that is, to demonstrate how the fire safety system will respond to a variety of fires), more than one scenario should be considered. It is suggested that, at a minimum, the following three types of scenarios be considered:

- (1) High-frequency, low-consequence (typical)
- (2) Low-frequency, high-consequence (high-challenge)
- (3) Special problems

Scenario (1) is used to demonstrate that the fire safety system can manage fires that start as relatively small fires but are frequent (for example, a wastebasket fire). Scenario (2) should present a greater challenge to the fire safety system (for example, fire in an egress path). The intent is to consider a larger fire but not one that is so unrealistically large that it ensures the proposed design (or any other) will not perform adequately. The first two scenario types tacitly assume that the fire safety system will function

as designed. However, Scenario (3) is included to account for those situations in which some aspect of the fire safety system might be compromised (for example, improperly closed valve on a sprinkler system, detection/alarm system temporarily out of service, multiple ignitions as characteristic of an arson fire, degradation of egress system after an earthquake or other natural disaster). Scenario (3) can also be used to consider the reliability of the fire safety system design.

Commentary Table 5.1 provides general scenarios—those that may be experienced by most, if not all, occupancies. Commentary Table 5.1 presents examples of typical and high-challenge fires, based on slow-, moderate-, and fast-developing fires that expose people in the room of origin who are not intimate with ignition and when the room of origin is unoccupied. The table also presents examples of special problem fires for these same individuals.

The leftmost column of Commentary Table 5.1 indicates a general fire type, characterized by the rate at which a potential fire hazard might develop. Fire development is defined by a heat release rate curve. An additional factor in defining the type of fire is the peak heat release rate, which must be severe enough to challenge the fire safety system but not so severe that no design can effectively reduce the hazards of

Commentary Table 5.1 General Scenarios

Fire Type	Scenario	
	Occupant in Room of Fire Origin but Not Intimate	Room of Fire Origin Normally Unoccupied
Slow-developing fire	<ul style="list-style-type: none"> • Cigarette ignition of upholstered furniture • Electrical ignition of small appliance or lighting, or overloaded outlet 	<ul style="list-style-type: none"> • Overloaded or failed wiring igniting switch gear, electrical devices, or insulation, followed by ignition of wooden structural members
Moderate-developing fire	<ul style="list-style-type: none"> • Kitchen/cooking fire • Trash can fire • Open flame ignition of upholstered furniture 	<ul style="list-style-type: none"> • Wildland or exposure fire (e.g., from a neighboring building or parked car) • Lightning-induced ignition of building roof • Laundry room fire
Fast-developing fire	<ul style="list-style-type: none"> • Flammable liquids 	<ul style="list-style-type: none"> • Flammable liquid storage
Shielded from systems, or other problems present	<ul style="list-style-type: none"> • Fire with impaired “first line of defense” • Shielded flaming fires; limited fuel and larger 	<ul style="list-style-type: none"> • External trash collection or trash chute fire • Flammable liquid storage • Room of fire origin door open • Fire in egress path

the postulated fires. The peak heat release rate is a function of the amount of fuel of the first item ignited, if the fire doesn't spread beyond it, or the maximum amount of fuel within the room of origin (that is, the room goes to flashover).

Scenario Components. At a minimum, a fire scenario consists of the following:

- (1) Ignition factors (source, location, and material; other items ignited if applicable)
- (2) At least one heat release rate curve (HRRC)
- (3) Occupant locations (see 5.4.5.3)
- (4) Occupant characteristics (see 5.4.5.2)
- (5) Special factors (shielded, systems unreliable, open door)

Ignition Factors. Ignition factors include the source of ignition; the material that is first ignited and, if it is a solid, where it is ignited; and whether other items are also ignited. Ignition factors to consider when constructing these aspects of the scenario are shown in Commentary Table 5.2.

Ignition Sources. Ignition sources are of primary interest when considering the frequency of design fires. Possible sources of ignition include the following:

- (1) Smoking
- (2) Open flame
- (3) Electrical source
- (4) Incendiary
- (5) Hot surface
- (6) Spontaneous combustion
- (7) Radiant source

Various electrical ignition scenarios are possible and historical data should be consulted to determine which is most appropriate for the occupancy being considered. In addition to smoking-related ignitions and open flames, another example of incendiary ignition would be a “runaway” industrial reaction. Hot surfaces are most often associated with either cooking (stoves, hot plates) or industrial processes (engines, furnaces). Spontaneous combustion is essentially an uncontrolled exothermic chemical reaction, due to either a buildup of flammable vapors (for example, due to improper storage or decomposition) or accidental mixing of reactive chemicals (for example, some cleaning fluids). A common radiant source is a portable heater.

First Item Ignited. The first item ignited is somewhat dependent on the ignition source. For example, an overheated electrical wire is most likely to ignite its

Commentary Table 5.2 Ignition Factors

Ignition Source	First Item Ignited	Second Item Ignited
Cigarette	Electrical equipment ¹	Structural assembly ²
Electrical lighting	Wiring	Library book stack
Incendiary	Seating	Merchandise display
Spontaneous combustion	Sets and decorations	Carpets
Stove/hot plate	Exhibit displays	Curtains
Process-inherent ³	Upholstered furniture	
	Electrical appliance	
	Trash	
	Ordinary combustibles ⁴	
	Gas leaks	
	Flammable liquids	
	Mattress	
	Medical equipment	

¹Includes, but is not limited to, dust collectors, uninterruptible power supplies, generators, HVAC equipment, dryers, and freezers

²Consists of exterior/interior wall or ceiling finish, wall studs, ceiling joists, and insulation

³Applies primarily to industrial settings

⁴Includes mixtures of paper, common plastics, and other materials

own insulation; cooking fires usually ignite items close to the flames, not structural assemblies (for example, wall or ceiling finish materials). The first item ignited is of interest for two reasons. First, it may pose either a thermal or a nonthermal hazard by itself (an example is an occupied mattress or the toxic products resulting from its combustion). Second, the first item might ignite a second item that poses an additional or greater hazard. Examples of second items include merchandise, structural assemblies, and carpets capable of releasing toxic combustion products. There may be no need to consider the second item column of Commentary Table 5.2 if the first item ignited presents enough of a hazard by itself. Certain types of upholstered furniture fall into this category because of the toxic combustion products they release and their relatively high heat release rate.

Second Item Ignited. Ignition of a second item is important in scenarios involving flashover or where structural stability is an issue. Ignition of a second item should be reflected in the heat release rate curve for the room of origin. Ignition of a second item can have two effects on the room heat release rate curve:

- (1) The peak heat release rate might be increased.
- (2) The growth phase of the fire might be accelerated.

The possibility of both phenomena occurring might be applicable to certain scenarios (for example, if the second item involves flammable liquids or gases).

Heat Release Rate Curves. Heat release rate curves can be constructed by referring to *The SFPE Handbook of Fire Protection Engineering* and Drysdale's *An Introduction to Fire Dynamics*.

Special Factors. There are several additional factors that might be critical to the development of scenarios.

(a) *Ignition Location.* The location of the point of ignition can affect the eventual course and spread of a fire. In some cases, specifying a location also implies additional items in the scenario. For example, a kitchen fire could actually be a cooking fire that involves a burner igniting loose clothing or a grease fire igniting "ordinary" combustibles nearby.

(b) *Fire Spread.* With regard to fire spread, the point of ignition is significant because it might, in part, determine the severity of the fire. An aspect of this issue is the availability of oxygen. If the first item ignited is an upholstered chair, two different scenarios result depending on whether the ignition

location is on the outside (for example, by a wastebasket fire) or on the inside (for example, a cigarette between a seat cushion and the arm of the chair). In the former case, a flaming fire is likely to occur; in the latter, a smoldering fire with copious amounts of products of combustion results. Additionally, the point of origin might be conducive to localized flashover. Localized flashover has been observed in experiments involving bunk beds and desks with enclosed leg wells (modesty panels). These geometries tend to concentrate heat energy such that an intense fire is created in a relatively small area.

(c) *Relative Location.* Relative location is somewhat related to the localized flashover. These fires are characterized by the ignition point being shielded from fire protection systems. The problem is that the initial fire development is not sensed by the fire detection system. This results in a larger fire at the time of detection and a commensurate decrease in the time to evacuate. A common scenario involving shielded fires is a fire in warehouse rack storage.

(d) *Interference with Evacuation.* The loss or degradation of any one egress path (for example, when a fire originates in some aspect of the egress system) can place a significant burden on the fire safety system of a facility. If more than two exits exist, the loss of one will have a lesser impact than if only one or two exits are initially available. If a fire originates in a location shared by more than one egress path (for example, where two egress paths merge into a single corridor or a dead-end corridor), the impact is greater than if the fire originates in one of several parallel egress routes.

(e) *Compartmentation Barriers.* This situation involves the fire breaching a barrier or originating in a concealed space or on an exterior surface. When the fire breaches a barrier, the potential for a severe fire increases. The problem with fire originating in a concealed space or an exterior surface is similar to that addressed in item (c), "relative location" (fire shielded from detection or suppression systems).

General Design Scenarios. The general scenarios shown in Commentary Table 5.3 are recommended as a starting point since they encompass the issues addressed in earlier commentary. For those instances where Commentary Table 5.3 does not apply, a process is provided for selecting components for site-specific scenarios that address the concepts of these general scenarios.

Development of Scenarios. The following are steps for use in specifying fire scenarios.

Commentary Table 5.3 General Design Scenarios

Typical Scenario	High-Challenge Scenario	Special Problem Scenario
Fast growth in room contents	Flammable liquids in means of egress	Ordinary fire in typical unoccupied room with sprinklers or detectors out of commission
Ordinary fire in attic or “challenging” concealed space	Largest room fire, fastest growth consistent with use; worst occupant characteristics	
Ordinary fire in typical occupied room with people not intimate with ignition	Worst flame spread fire, if area critical to egress; or flammable room linings or decorations	
Slow-developing fire in typical occupied room with worst case occupant characteristics		

(a) Common scenarios can be specified partly through routine statistical analysis of fire experience in similar buildings. An advantage of common or typical scenarios is that they provide a good picture of what the building’s performance will usually be if fire occurs. Such scenarios also tend to fit easily within the scope of available fire models and calculation methods. This means the authority having jurisdiction can review the results for these scenarios to obtain a basic sense of the building’s level of safety and the appropriateness of the calculations.

(b) High-challenge scenarios are any scenarios that pose unusual fire challenges to the building design. High-challenge scenarios can be developed by refining common scenarios (for example, changing the area of fire origin) to create a greater challenge. Also, high-challenge scenarios can be developed by reducing the challenge in scenarios previously identified as beyond the design expectations (that is, too severe to use as the basis for evaluation).

The following are illustrative techniques for developing high-challenge scenarios from common scenarios.

(a) Change the area of fire origin. Consider an area (for example, bedrooms) where occupants are likely to be particularly vulnerable. Consider an area (for example, concealed spaces, external surfaces) where fire can develop outside the effective range of key fire protection features (such as detectors or sprinklers). Consider an area (for example, egress corridors) that is critical to occupant movement to safety.

(b) Increase the initial size or speed of the development of the fire. This might be done by adjusting

the parameters in a fire growth model (for example, increasing the alpha value in a *t*-squared modeled fire; reflecting a fast or ultra-fast fire; increasing the peak heat release rate value for the fire) or by increasing the assumed room fuel load or decreasing the space between major combustible items.

(c) Assume common degradations in design assumptions. For example, assume the doors are blocked open, allowing the passage of fire effects to secondary spaces; or assume an unlimited oxygen supply for fire growth that could result from open doors, broken windows, or other circumstances.

(d) Increase the toxicity or yields of products of combustion.

Developing high-challenge scenarios from scenarios beyond design expectations involves less-challenging quantitative assumptions. For example, if the bomb used in the New York City World Trade Center incident of 1993 is deemed too severe for a high-rise office building, how small a bomb would constitute an appropriate high-challenge test? Or, if the *Code* cannot assure protection of occupants who are intimate with initial fire development, how close can occupants be and not be considered intimate?

5.5.3* Required Design Fire Scenarios.

Design fire scenarios shall comply with the following:

- (1) Scenarios selected as design fire scenarios shall include, but shall not be limited to, those specified in 5.5.3.1 through 5.5.3.8.
- (2) Design fire scenarios demonstrated by the design team to the satisfaction of the authority having jurisdiction as inappropriate for the building use and conditions shall not be required to be evaluated fully.

A.5.5.3 It is desirable to consider a wide variety of different fire scenarios to evaluate the complete life safety capabilities of the building or structure. Fire scenarios should not be limited to a single or a couple of worst-case fire scenarios.

The descriptive terms used to indicate the rate of fire growth for the scenarios are intended to be generic. Use of *t*-squared fires is not required for any scenario.

Example: Exemptions from Required Design Fire Scenarios

One or more of the required scenarios might not be applicable. For instance, if the designer is analyzing a building that serves primarily as a warehouse but also has limited office space, and that building does not have any concealed wall or ceiling spaces, then design fire scenario 4 might not be applicable.

Another example of a situation in which one of the required scenarios might not apply to a particular design is a building isolated from any possible exposure to outside fire sources, which eliminates the need to evaluate the building using design fire scenario 7. The possible ignition or fuel sources for an exposure fire might include trees or vegetation, cars, delivery trucks, or dumpsters. If the designer can show the authority having jurisdiction that the building is designed such that there would be no vegetation around the perimeter, no personnel or delivery vehicles could park next to or even within a certain distance of the building, and no man-made flammable objects would be placed around the perimeter of the building, then this scenario might not be applicable.

Each of the theoretical examples would be very rare, and justifying the inappropriateness of any of the scenarios can be very difficult for the designer. The majority of buildings to which one or more of the required scenarios do not apply will generally be very specialized cases, such as an aircraft hangar with no concealed spaces or a research lab with no external fuel sources that could lead to an exposure fire. If the designer believes that one or more of the scenarios do not apply to the building in question, the designer should consult the authority having jurisdiction early in the evaluation process and provide written justification on why these do not apply.

5.5.3.1* Design Fire Scenario 1. Design fire scenario 1 shall be as follows:

- (1) It is an occupancy-specific fire representative of a typical fire for the occupancy.
- (2) It explicitly accounts for the following:
 - (a) Occupant activities

- (b) Number and location
- (c) Room size
- (d) Furnishings and contents
- (e) Fuel properties and ignition sources
- (f) Ventilation conditions
- (g) Identification of the first item ignited and its location

A.5.5.3.1 Scenario 1. An example of such a scenario for a health care occupancy would involve a patient room with two occupied beds with a fire initially involving one bed and the room door open. This is a cursory example in that much of the explicitly required information indicated in 5.5.3.1 can be determined from the information provided in the example. Note that it is usually necessary to consider more than one scenario to capture the features and conditions typical of an occupancy.

The idea behind design fire scenario 1 is to ensure that the types of fires most likely in a given occupancy type—that is, the statistically most significant scenarios—are considered in the design analysis. These scenarios have a great degree of variety, from the small fires experienced weekly at aluminum rolling mills to the kitchen fires in high-rise apartment buildings (that is, residences).

5.5.3.2* Design Fire Scenario 2. Design fire scenario 2 shall be as follows:

- (1) It is an ultrafast-developing fire, in the primary means of egress, with interior doors open at the start of the fire.
- (2) It addresses the concern regarding a reduction in the number of available means of egress.

A.5.5.3.2 Scenario 2. Examples of such scenarios are a fire involving ignition of gasoline as an accelerant in a means of egress, clothing racks in corridors, renovation materials, or other fuel configurations that can cause an ultrafast fire. The means of egress chosen is the doorway with the largest egress capacity among doorways normally used in the ordinary operation of the building. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be open throughout the building.

Design fire scenario 2 is intended to provide information on the maximum potential spread of fire effects, mostly smoke and toxic products. It answers the question, “What is the maximum extent of smoke that may be experienced if an egress path is blocked?”

5.5.3.3* Design Fire Scenario 3. Design fire scenario 3 shall be as follows:

- (1) It is a fire that starts in a normally unoccupied room, potentially endangering a large number of occupants in a large room or other area.
- (2) It addresses the concern regarding a fire starting in a normally unoccupied room and migrating into the space that potentially holds the greatest number of occupants in the building.

A.5.5.3.3 Scenario 3. An example of such a scenario is a fire in a storage room adjacent to the largest occupiable room in the building. The contents of the room of fire origin are specified to provide the largest fuel load and the most rapid growth in fire severity consistent with the normal use of the room. The adjacent occupiable room is assumed to be filled to capacity with occupants. Occupants are assumed to be somewhat impaired in whatever form is most consistent with the intended use of the building. At ignition, doors from both rooms are assumed to be open. Depending on the design, doorways connect the two rooms or they connect via a common hallway or corridor.

For purposes of this scenario, an occupiable room is a room that might contain people, that is, a location within a building where people are typically found.

5.5.3.4* Design Fire Scenario 4. Design fire scenario 4 shall be as follows:

- (1) It is a fire that originates in a concealed wall or ceiling space adjacent to a large occupied room.
- (2) It addresses the concern regarding a fire originating in a concealed space that does not have either a detection system or a suppression system and then spreading into the room within the building that potentially holds the greatest number of occupants.

A.5.5.3.4 Scenario 4. An example of such a scenario is a fire originating in a concealed wall- or ceiling-space adjacent to a large, occupied function room. Ignition involves concealed combustibles, including wire or cable insulation and thermal or acoustical insulation. The adjacent function room is assumed to be occupied to capacity. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be open throughout the building.

5.5.3.5* Design Fire Scenario 5. Design fire scenario 5 shall be as follows:

- (1) It is a slowly developing fire, shielded from fire protection systems, in close proximity to a high occupancy area.
- (2) It addresses the concern regarding a relatively small ignition source causing a significant fire.

A.5.5.3.5 Scenario 5. An example of such a scenario is a cigarette fire in a trash can. The trash can is close enough to room contents to ignite more substantial fuel sources but is not close enough to any occupant to create an intimate-with-ignition situation. If the intended use of the property

involves the potential for some occupants to be incapable of movement at any time, the room of origin is chosen as the type of room likely to have such occupants, filled to capacity with occupants in that condition. If the intended use of the property does not involve the potential for some occupants to be incapable of movement, the room of origin is chosen to be an assembly or function area characteristic of the use of the property, and the trash can is placed so that it is shielded by furniture from suppression systems. At ignition, doors are assumed to be open throughout the building.

5.5.3.6* Design Fire Scenario 6. Design fire scenario 6 shall be as follows:

- (1) It is the most severe fire resulting from the largest possible fuel load characteristic of the normal operation of the building.
- (2) It addresses the concern regarding a rapidly developing fire with occupants present.

A.5.5.3.6 Scenario 6. An example of such a scenario is a fire originating in the largest fuel load of combustibles possible in normal operation in a function or assembly room, or in a process/manufacturing area, characteristic of the normal operation of the property. The configuration, type, and geometry of the combustibles are chosen so as to produce the most rapid and severe fire growth or smoke generation consistent with the normal operation of the property. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be closed throughout the building.

This scenario includes everything from a big couch fire in a small dwelling to a rack fire in combustible liquids stock in a big box retail store.

The Dupont Plaza Hotel fire of 1986 in San Juan, Puerto Rico, is an example of a design fire scenario 6. The storage of chairs was part of the normal operating procedures of the hotel. The location and potential heat release of the chairs were evidently considered a small threat due to the lack of an ignition source. Unfortunately, a source was supplied with tragic results.

5.5.3.7* Design Fire Scenario 7. Design fire scenario 7 shall be as follows:

- (1) It is an outside exposure fire.
- (2) It addresses the concern regarding a fire starting at a location remote from the area of concern and either spreading into the area, blocking escape from the area, or developing untenable conditions within the area.

A.5.5.3.7 Scenario 7. An example of such a scenario is an exposure fire. The initiating fire is the closest and most

severe fire possible consistent with the placement and type of adjacent properties and the placement of plants and combustible adornments on the property. The baseline occupant characteristics for the property are assumed.

This category includes wildlands/urban interface fires and exterior wood shingle problems, where applicable.

5.5.3.8* Design Fire Scenario 8. Design fire scenario 8 shall be as follows:

- (1) It is a fire originating in ordinary combustibles in a room or area with each passive or active fire protection system independently rendered ineffective.
- (2) It addresses concerns regarding the unreliability or unavailability of each fire protection system or fire protection feature, considered individually.
- (3)* It is not required to be applied to fire protection systems for which both the level of reliability and the design performance in the absence of the system are acceptable to the authority having jurisdiction.

A.5.5.3.8 Scenario 8. This scenario addresses a set of conditions with a typical fire originating in the building with any one passive or active fire protection system or feature being ineffective. Examples include unprotected openings between floors or between fire walls or fire barrier walls, failure of rated fire doors to close automatically, shutoff of sprinkler system water supply, nonoperative fire alarm system, inoperable smoke management system, or automatic smoke dampers blocked open. This scenario should represent a reasonable challenge to the other building features provided by the design and presumed to be available.

The concept of a fire originating in ordinary combustibles is intentionally selected for this scenario. This fire, although presenting a realistic challenge to the building and the associated building systems, does not represent the worst-case scenario or the most challenging fire for the building. Examples include the following:

- (1) *A fire originating in ordinary combustibles in the corridor of a patient wing of a hospital.* Staff is assumed not to close any patient room doors upon detection of fire. The baseline occupant characteristics for the property are assumed, and the patient rooms off the corridor are assumed to be filled to capacity. At ignition, doors to patient rooms are not equipped with self-closing devices and are assumed to be open throughout the smoke compartment.
- (2) *A fire originating in ordinary combustibles in a large assembly room or area in the interior of the building.* The automatic suppression systems are assumed to be out of operation. The baseline occupant characteristics for the property are assumed, and the room of origin is assumed to be filled to capacity. At ignition, doors are assumed to be closed throughout the building.

- (3) *A fire originating in ordinary combustibles in an unoccupied small function room adjacent to a large assembly room or area in the interior of the building.* The automatic detection systems are assumed to be out of operation. The baseline occupant characteristics for the property are assumed, the room of origin is assumed to be unoccupied, and the assembly room is assumed to be filled to capacity. At ignition, doors are assumed to be closed throughout the building.

A.5.5.3.8(3) The exemption is applied to each active or passive fire protection system individually and requires two different types of information to be developed by analysis and approved by the authority having jurisdiction. System reliability is to be analyzed and accepted. Design performance in the absence of the system is also to be analyzed and accepted, but acceptable performance does not require fully meeting the stated goals and objectives. It might not be possible to meet fully the goals and objectives if a key system is unavailable, and yet no system is totally reliable. The authority having jurisdiction will determine which level of performance, possibly short of the stated goals and objectives, is acceptable, given the very low probability (that is, the system's unreliability probability) that the system will not be available.

Design fire scenario 8 provides information to the authority having jurisdiction by answering a series of "What if . . . ?" questions. For example, what if the hotel sprinkler system is out of service when a fire occurs? What might be the extent of the fire and smoke and their subsequent effects on the egress system? Similar questions can be posed for other fire protection system components and subsystems.

5.5.4 Design Fire Scenarios Data.

5.5.4.1 Each design fire scenario used in the performance-based design proposal shall be translated into input data specifications, as appropriate for the calculation method or model.

5.5.4.2 Any design fire scenario specifications that the design analyses do not explicitly address or incorporate and that are, therefore, omitted from input data specifications shall be identified, and a sensitivity analysis of the consequences of that omission shall be performed.

Paragraph 5.5.4.2 is included to remind the designer that even if every design fire specification cannot be incorporated into a specific design tool or verification method, each must be addressed in the analysis in

some manner. For example, an evacuation model that does not address crowding or queuing effects does not address the particular delay hazard initiated by design fire scenario 2, which reduces the means of egress from the building. Additionally, many fire effects models do not address barrier breach, and, therefore, fail to incorporate the defining characteristics of design fire scenario 4, a concealed space fire threatening an adjacent, occupied space.

Despite the fact that these models do not incorporate particular aspects of the design fire scenario specifications, those aspects must be addressed in the design, either through conservative assumptions supported by accepted technical resources or test data or by comparative techniques that will conservatively account for these effects. A sensitivity analysis should be performed on the omission of these aspects, as well as the techniques used to account for that omission.

5.5.4.3 Any design fire scenario specifications modified in input data specifications, because of limitations in test methods or other data-generation procedures, shall be identified, and a sensitivity analysis of the consequences of the modification shall be performed.

Paragraph 5.5.4.3 essentially expresses the same concern as 5.5.4.2; however, the concern arises more from a limitation in available data than from a limitation of the model. Typically, both types of limitations will be present. When analyzing design fire scenario 2, there may not be a model available that accounts for crowding or queuing, or there may be only a model that assumes uniform speeds and sizes of occupants due to lack of data on expected ranges of occupant characteristics. These effects will tend to produce results for an estimated speed of evacuation, in the absence of turbulence, that are unrealistically fast. Additionally, in regard to design fire scenario 4, there may be no model to determine time to barrier breach and insufficient data on burn-through or failure behavior of the materials and assemblies proposed in the design.

Section 5.6* Evaluation of Proposed Designs

A.5.6 The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* outlines a process for evaluating whether trial designs meet the performance criteria during the design fire scenarios.

The procedures described in Sections 5.2 and 5.4 identify required design fire scenarios among the design fire scenarios within which a proposed fire safety design is required to perform and the associated untenable conditions that are to be avoided in order to maintain life safety. Section 5.6 discusses methods that form the link from the scenarios and criteria to the goals and objectives.

Assessment methods are used to demonstrate that the proposed design will achieve the stated goals/objectives, by providing information indicating that the performance criteria of Section 5.2 can be adequately met. Assessment methods are permitted to be either tests or modeling.

Tests. Test results can be directly used to assess a fire safety design when they accurately represent the scenarios developed by using Section 5.4 and provide output data matching the performance criteria in Section 5.2. Because the performance criteria for this *Code* are stated in terms of human exposure to lethal fire effects, no test will suffice. However, tests will be needed to produce data for use in models and other calculation methods.

Standardized Tests. Standardized tests are conducted on various systems and components to determine whether they meet some predetermined, typically prescriptive criteria. Results are given on a pass/fail basis: The test specimen either does or does not meet the pre-established criteria. The actual performance of the test specimen is not usually recorded.

Scale. Tests can be either small, intermediate, or full scale. Small-scale tests are used to test activation of detection and suppression devices and the flammability and toxicity of materials. Usually, the item to be tested is placed within the testing device or apparatus. Intermediate-scale tests can be used to determine the adequacy of system components—for example, doors and windows—as opposed to entire systems. The difference between small- and intermediate-scale tests is usually one of definition provided by those conducting the test. Full-scale tests are typically used to test building and structural components or entire systems. The difference between intermediate- and large-scale tests is also subject to the definition of those performing the test. Full-scale tests are intended to most closely depict performance of the test subject as installed in the field, that is, most closely represent-real world performance.

Full-scale building evacuations can provide information on how the evacuation of a structure is likely to occur for an existing building with a given population without subjecting occupants to the real physical or psychological effects of a fire.

Data Uses. The data obtained from standardized tests have three uses for verification purposes. First, the test results can be used instead of a model. This use is typically the role of full-scale test results. Second, the test results can be used as a basis for validating the model. The model predictions match well with the test results. Therefore, the model can be used in situations similar to the test scenario.

Third, the test results can be used as input to models. This is typically the use of small-scale tests, specifically flammability tests.

Start-Up Test. Start-up test results can be used to demonstrate that the fire safety system performs as designed. The system design might be based on modeling. If the start-up test indicates a deficiency, the system needs to be adjusted and retested until it can be demonstrated that the design can meet the performance criteria. Typically, start-up tests apply only to the installation to which they are designed.

Experimental Data. Experimental data from nonstandardized tests can be used when the specified scenario and the experimental setup are similar. Typically, experimental data are applicable to a greater variety of scenarios than are standardized test results.

Human and Organizational Performance Tests. Certain tests determine whether inputs used to determine human performance criteria remain valid during the occupancy of a building. Tests of human and organizational performance might include any of the following:

- (1) Measuring evacuation times during fire drills
- (2) Querying emergency response team members to determine whether they know required procedures
- (3) Conducting field tests to ensure that emergency response team members can execute tasks within predetermined times and accuracy limits.

Design proposals should include descriptions of any tests needed to determine whether stated goals, objectives, and performance criteria are being met.

Modeling. Models can be used to predict the performance criteria for a given scenario. Because of the limitations on using only tests for this purpose, models are expected to be used in most, if not all, performance-based design assessments.

Fire models do not model fires: they model the effects of a (user) specified fire—that is, a heat release rate curve is input. For ease, the term *fire model* will be used instead of the more accurate *fire effects model*.

The effect of fire and its toxic products on the occupants can be modeled, as can the movement and behavior of occupants during the fire. The term *evacuation model* will be used to describe models that predict the location and movements of occupants, and the term *tenability model* will be used to describe models that predict the effects on occupants of specified levels of exposure to fire effects.

Types of Fire Models. Fire models are used to predict fire-related performance criteria. Fire models can be either probabilistic or deterministic. Several types of deterministic models are available: computational fluid dynamics (CFD or field) models, zone models, purpose-built models, and hand calculations. Probabilistic fire models are also available but are less likely to be used for this purpose.

Probabilistic fire models use the probabilities as well

as the severity of various events as the basis of evaluation. Some probabilistic models incorporate deterministic models, but this is not a requirement. Probabilistic models attempt to predict the likelihood or probability that events or severity associated with an unwanted fire will occur or they predict the “expected” loss, which can be thought of as the probability-weighted average severity across all possible scenarios. Probabilistic models can be manifested as fault or event trees or other system models that use frequency or probability data as input. These models tend to be manifested as computer software, but this is not a requirement. Furthermore, the discussion that follows under “Sources of Models” can also be applied to probabilistic models, although it concentrates on deterministic models.

CFD models provide the most accurate predictions of all the deterministic models, because they divide a given space into thousands of smaller volumes. However, since they are still models, they are not absolute in their depiction of reality. In addition, they are much more expensive to use because they are computationally intensive. Because of their expense, complexity, and intensive computational needs, CFD models require much greater scrutiny than do zone models. It is much more difficult to provide multiple runs of CFD models to check sensitivity to a variety of factors such as design fire cell resolution and ventilation.

Zone models are more widely used than CFD models because they provide reasonably accurate predictions in much less time. It is much easier to assess the sensitivity of different parameters with zone models because they generally run much faster and the output is much easier to interpret. Prediction of fire growth and spread has a large number of variables associated with it. Consequently, the zone models, with their crudeness and speed, have advantages over the more complex CFD models.

Purpose-built models (also known as stand-alone models) are similar to zone models in their ease of use. However, purpose-built models do not provide a comprehensive model. Instead, they predict the value of one variable of interest. For example, such a model can predict the conditions of a ceiling jet at a specified location under a ceiling, but a zone model would “transport” those conditions throughout the enclosure.

Purpose-built models might or might not be manifested as computer software. Models that are not are referred to as hand calculations. These purpose-built models are, therefore, simple enough that the data management capabilities of a computer are not necessary. Many of these calculations are found in the *SFPE Handbook of Fire Protection Engineering*.

Types of Evacuation Models. Three categories of evacuation models can be considered: single-parameter estimation methods, movement models, and behavioral simulation models.

Single-parameter estimations are generally used for

simple estimates of movement time. They are usually based on equations derived from observations of movement in nonemergency situations. They can be hand calculations or simple computer models. Examples include calculation methods for flow times based on widths of exit paths and travel times based on travel distances. Sources for these methods include the *SFPE Handbook of Fire Protection Engineering* and the *NFPA Fire Protection Handbook*.

Movement models generally handle large numbers of people in a network flow similar to water in pipes or ball bearings in chutes. They tend to optimize occupant behavior, resulting in predicted evacuation times that can be unrealistic and far from conservative. However, they can be useful in an overall assessment of a design, especially in early evaluation stages where an unacceptable result with this sort of model indicates that the design has failed to achieve the life safety objectives.

Behavioral simulation models take into consideration more of the variables related to occupant movement and behavior. Occupants are treated as individuals and can have characteristics assigned to them uniquely, allowing a more realistic simulation of the design under consideration. However, given the limited availability of data for the development of these models, for their verification by their authors, or for input when using them, their predictive reliability is questionable.

Tenability Models. In general, tenability models will be needed only to automate calculations for the time-of-exposure effect equations referenced in A.5.2.2.

Other Models. Models can be used to describe combustion (as noted, most fire models only characterize fire effects), automatic system performance, and other elements of the calculation. There are few models in common use for these purposes, so they are not described further here.

Sources of Models. Compendia of computer fire models are found in Friedman's *Survey of Computer Models for Fire and Smoke* and the *SFPE Computer Software Directory*. Within these references are models that were developed by the Building Fire Research Laboratory of National Institute of Standards and Technology, which can be downloaded from the Internet at <http://www.bfrl.nist.gov/864/fmabs.html>. Evacuation models in all three categories are discussed in the *SFPE Handbook of Fire Protection Engineering* and the *NFPA Fire Protection Handbook*.

Validation. Models undergo limited validation. Most can be considered demonstrated only for the experimental results they were based on or the limited set of scenarios to which the model developers compared the model's output, or a combination of both.

The Society of Fire Protection Engineers has a task group that independently evaluates computer models. In January 1998, they finished their first evaluation and had chosen a second model for evaluation. Until more models can be independently evaluated, the model user has to rely on the

available documentation and previous experience for guidance regarding the appropriate use of a given model.

The design professional should present the proposal, and the authority having jurisdiction, when deciding whether to approve a proposal, should consider the strength of the evidence presented for the validity, accuracy, relevance, and precision of the proposed methods. An element in establishing the strength of scientific evidence is the extent of external review and acceptance of the evidence by peers of the authors of that evidence.

Models have limitations. Most are not user-friendly. For that reason, experienced users are able to construct more reasonable models and better interpret output than are novices. For these reasons, the third-party review and equivalency sections are provided. This is not meant to discourage the use of models, only to indicate that they should be used with caution by those well-versed in their nuances.

Input Data. The first step in using a model is to develop the input data. The heat release rate curve specified by the user is the driving force of a fire effects model. If this curve is incorrectly defined, the subsequent results are not usable. In addition to the smoldering and growth phases that will be specified as part of the scenario definition, two additional phases are needed to complete the input heat release rate curve—steady burning and burnout.

Steady burning is characterized by its duration, which is a function of the total amount of fuel available to be burned. In determining the duration of this phase, the designer needs to consider how much fuel has been assumed to be consumed in the smoldering and growth phases and how much is assumed to be consumed in the burnout phase that follows. A common assumption is that the burnout phase is the mirror image of the preceding phases, with a reversed heat release rate curve and the same amount of fuel consumed in the burnout phase as in the growth phase. Depending on the assumptions made regarding the amount of fuel consumed during burnout, the time at which this phase starts is likely to be easy to determine.

The preceding discussion assumes that the burning objects are solid (for example, tables and chairs). If liquid or gaseous fuels are involved, the shape of the curve will be different. For example, smoldering is not relevant for burning liquids or gases, and the growth period is very short, typically measured in seconds. Peak heat release rate can depend primarily on the rate of release, on the leak rate (gases and liquid sprays), or on the extent of spill (pooled liquids). The steady burning phase is once again dependent upon the amount of fuel available to burn. Like the growth phase, the burnout phase is typically short (for example, closing a valve), although it is conceivable that longer times might be appropriate, depending on the extinguishment scenario.

Material properties are usually needed for all fuel items, both initial and secondary, and the enclosure surfaces of involved rooms or spaces.

For all fires of consequence, it is reasonable to assume that the fire receives adequate ventilation. If there is insufficient oxygen, the fire will not be sustained. An overabundance of oxygen is only a concern in special cases (for example, hermetically sealed spaces) when a fire might not occur due to dilution of the fuel (that is, a flammable mixture is not produced). Therefore, given that the scenarios of interest will occur in nonhermetically sealed enclosures, it is reasonable to assume that adequate ventilation is available and that, if a fire starts, it will continue to burn until it either runs out of fuel or is extinguished by other means. The only variable that might need to be assumed is the total vent width.

Maximum fire extent is affected by two geometric aspects: burning object proximity to walls and overall enclosure dimensions.

Conservatively, when a fire is “against a wall” or “in a corner,” the effective heat release of the fire can be doubled and quadrupled, respectively. For the burning object to be considered against the wall or in the corner, it needs to be either touching the enclosure surface or within 51 mm (2 in.) of the surface. The reasoning behind this convention is that a wall effectively cuts the fire plume in half, whereas a corner results in one quarter of the plume if the burning object is closer to the center of the room. Conceptually, the same amount of combustible vapors are produced, regardless of the burning object’s position, but the presence of walls/corners results in a smaller volume in which to burn them. In other words, walls and corners effectively concentrate the flammable vapors resulting from pyrolysis of the fuel.

The room dimensions affect the time required for a room to flashover. For a given amount and type of fuel, under the same ventilation conditions, a small room will flashover before a large room. In a large room with a small amount of fuel, a fire will behave as if it is burning outside—that is, adequate oxygen for burning and no concentration of heat exist. If the fuel package is unchanged but the dimensions of the room are decreased, the room will begin to have an affect on the fire, assuming adequate ventilation. The presence of the relatively smaller enclosure results in the buildup of a hot layer of smoke and other products of combustion under the ceiling. This buildup, in turn, feeds more heat back to the seat of the fire, which results in an increase in the pyrolysis rate of the fuel and thus increases the amount of heat energy released by the fire. The room enclosure surfaces themselves also contribute to this radiation feedback effect.

Probabilistic data are expressed as either a frequency (units of inverse time) or a probability (unitless, but applicable to a stated period of time). An example of the former is the expected number of failures per year and the range of the latter is between zero and one, inclusive. Probabilities can be either objective or subjective. Subjective probabilities express a degree of belief that an event will occur. Objective

probabilities are based on historical data and can be expressed as a reliability of an item such as a component or a system.

5.6.1 General.

A proposed design’s performance shall be assessed relative to each performance objective in Section 4.2 and each applicable scenario in 5.5.3, with the assessment conducted through the use of appropriate calculation methods. The authority having jurisdiction shall approve the choice of assessment methods.

The verification process starts with the submittal of a proposed design to the authority having jurisdiction. If the AHJ does not consider itself qualified to perform an adequate review of the performance-based design, the AHJ might specify a qualified third-party reviewer. The owner typically incurs the expense associated with the third-party review process.

The first step of the verification process is to identify the goals and the objectives relating to those goals. Attention must be paid to both those objectives that apply to the facility as a whole and those that apply to only limited aspects of the facility. The AHJ’s purpose in this review is to determine whether the designer/owner’s objectives are commensurate with the community’s objectives. Next, the AHJ reviews the performance criteria that relate to each of the objectives, for consistency and reasonableness—Do they form a comprehensive package? Are they realistic? The next step involves the characteristics of whatever is being protected—people, property, and so on. Once again, a comprehensive, cohesive set of assumptions is sought.

Essentially, this means that the logic flow and justification for the choices made are sound; the links between the components are checked to ensure that the design process flows—objectives are to be met by demonstrating that criteria have been achieved through the judicious use of verification methods. Assumptions need to be reasonable, consistent, comprehensive, cohesive, and supported by adequate references.

Presumably, the designer’s proposal “ensures” that all criteria are met for all scenarios. Ultimately, the AHJ is interested in determining whether the designer did a credible job so that the predicted results provide a sufficient margin of safety to permit the design to be approved. Because of the complexity of this issue, many discussions can be anticipated between the AHJ, the designer, and, if used, the third-party reviewer.

5.6.2 Use.

The design professional shall use the assessment methods to demonstrate that the proposed design will achieve the goals and objectives, as measured by the performance criteria in light of the safety margins and uncertainty analysis, for each scenario, given the assumptions.

The choice of which model to select depends on the objectives, the performance criteria to be predicted, and the scenarios to be considered. The model selected should use most, if not all, of the input data specifications and must produce design output that can be directly compared to the performance criteria selected as a baseline for the analysis. Two criteria are usually of greatest interest: upper layer temperature and the height of the smoke layer interface. If the objective is to reduce property damage in a telephone vault, then a purpose-built model that predicts smoke filling is adequate. If the objective is the life safety of those not intimate with the fire—both within the room of origin and along adjacent egress paths—in a rectilinear room, then a zone model is adequate. If life safety is the objective and the fire occurs in a more geometrically challenging configuration (for example, an amusement park fun house or enclosed amusement ride), then a field model is appropriate. If the effects on occupants are to be estimated, an evacuation or toxicity model needs to be used.

5.6.3 Input Data.

5.6.3.1 Data. Input data for computer fire models shall be obtained in accordance with ASTM E 1591, *Standard Guide for Data for Fire Models*. Data for use in analytical models that are not computer-based fire models shall be obtained using appropriate measurement, recording, and storage techniques to ensure the applicability of the data to the analytical method being used.

5.6.3.2 Data Requirements. A complete listing of input data requirements for all models, engineering methods, and other calculation or verification methods required or proposed as part of the performance-based design shall be provided.

Documentation of the assumptions made by the model user while developing the input data is critical. If the model user does not explicitly state the values used and the references from which they are taken, the credibility of the analysis is decreased.

5.6.3.3* Uncertainty and Conservatism of Data. Uncertainty in input data shall be analyzed and, as determined appropriate by the authority having jurisdiction, addressed through the use of conservative values.

A.5.6.3.3 Procedures used to develop required input data need to preserve the intended conservatism of all scenarios and assumptions. Conservatism is only one means to address the uncertainty inherent in calculations and does not remove the need to consider safety factors, sensitivity analysis, and other methods of dealing with uncertainty. The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* outlines a process for identifying and treating uncertainty.

5.6.4* Output Data.

The assessment methods used shall accurately and appropriately produce the required output data from input data based on the design specifications, assumptions, and scenarios.

A.5.6.4 An assessment method translates input data, which might include test specifications, parameters or variables for modeling, or other data, into output data, which are measured against the performance criteria. Computer fire models should be evaluated for their predictive capability in accordance with ASTM E 1355, *Standard Guide for Evaluating the Predictive Capability of Fire Models*.

The design team selects verification methods that produce output data that can be directly compared to the performance criteria. Any additional output data needs to be included with the analysis results and submitted to the authority having jurisdiction for review.

5.6.5 Validity.

Evidence shall be provided to confirm that the assessment methods are valid and appropriate for the proposed building, use, and conditions.

If the chosen assessment method is a computer model, then the validity of the model, with regard to the scenario being modeled, might be in question. By choosing a particular model, the designer is tacitly assuming that the model is valid for the particular scenario. Two situations are possible: Either the assumption is correct (and there's nothing to worry about) or the assumption is not correct. If the assumption is not correct, this does not immediately invalidate the entire analysis. Part of the argument for using

a particular model is that it is the only tool available (that is, constrained by available resources) that can be used. If a sensitivity analysis is also performed, this will go a long way in demonstrating that a range of conditions has been considered and the “real” answer has been adequately bounded by the results of the sensitivity analysis.

Section 5.7* Safety Factors

Approved safety factors shall be included in the design methods and calculations to reflect uncertainty in the assumptions, data, and other factors associated with the performance-based design.

A.5.7 The assessment of precision required in 5.8.2 will require a sensitivity and uncertainty analysis, which can be translated into safety factors.

Sensitivity Analysis. The first run a model user makes should be labeled as the base case, using the nominal values of the various input parameters. However, the model user should not rely on a single run as the basis for any performance-based fire safety system design. Ideally, each variable or parameter that the model user made to develop the nominal input data should have multiple runs associated with it, as should combinations of key variables and parameters. Thus, a sensitivity analysis should be conducted that provides the model user with data that indicate how the effects of a real fire might vary and how the response of the proposed fire safety design might also vary.

The interpretation of a model’s predictions can be a difficult exercise if the model user does not have knowledge of fire dynamics or human behavior.

In addition to justification of the base case input data specification values, the design team should include an allowable range of values determined using a sensitivity analysis. The design team should investigate the effects of varying key components and variables independently and in combination and document the effects of this variation.

Reasonableness Check. The model user should first try to determine whether the predictions actually make sense, that is, whether they do not upset intuition or preconceived expectations. Most likely, if the results do not pass this test, an input error has been committed.

Sometimes the predictions appear to be reasonable but are, in fact, incorrect. For example, a model can predict higher temperatures farther from the fire than closer to it.

The values themselves might be reasonable, for example, they are not hotter than the fire, but they do not “flow” down the energy as expected.

A margin of safety can be developed using the results of the sensitivity analysis in conjunction with the performance criteria to provide the possible range of time during which a condition is estimated to occur.

Safety factors and margin of safety are two concepts used to quantify the amount of uncertainty in engineering analyses. Safety factors are used to provide a margin of safety and represent, or address, the gap in knowledge between the theoretically perfect model—reality—and the engineering models that can only partially represent reality.

Safety factors can be applied either to the predicted level of a physical condition or to the time at which the condition is predicted to occur. Thus, a physical or a temporal safety factor, or both, can be applied to any predicted condition. A predicted condition (that is, a parameter’s value) and the time at which it occurs are best represented as distributions. Ideally, a computer fire model predicts the expected or nominal value of the distribution. Safety factors are intended to represent the spread of these distributions.

Given the uncertainty associated with data acquisition and reduction, and the limitations of computer modeling, any condition predicted by a computer model can be thought of as an expected or nominal value within a broader range. For example, an upper layer temperature of 600°C (1110°F) is predicted at a given time. If the modeled scenario is then tested (that is, full-scale experiment based on the computer model’s input data), the actual temperature at that given time could be 640°C or 585°C (1185°F or 1085°F). Therefore, the temperature should be reported as 600°C + 40°C/–15°C (1110°F + 70°F/–25°F) or a range of 585°C to 640°C (1085°F to 1185°F).

Ideally, predictions are reported as a nominal value, a percentage, or an absolute value. As an example, an upper layer temperature prediction could be reported as “600°C (1110°F), 30°C (55°F)” or “600°C (1110°F), 5 percent.” In this case, the physical safety factor is 0.05 (that is, the amount by which the nominal value should be degraded and enhanced). Given the state-of-the-art of computer fire modeling, this is a very low safety factor. Physical safety factors tend to be on the order of tens of percent. A safety factor of 50 percent is not unheard of.

Part of the problem in establishing safety factors is that it is difficult to state the percentage or range that is appropriate. These values can be obtained when the computer model predictions are compared to test data. However, using computer fire models in a design mode does not facilitate this comparison, because (1) the room being analyzed has not been built yet and (2) test scenarios do not necessarily depict the intended design.

A sensitivity analysis should be performed based on the

assumptions that affect the condition of interest. A base case that uses all nominal values for input parameters should be developed. The input parameters should be varied over reasonable ranges and the variation in predicted output should be noted. This output variation can then become the basis for physical safety factors.

The temporal safety factor addresses the issue of when a condition is predicted and is a function of the rate at which processes are expected to occur. If a condition is predicted to occur 2 minutes after the start of the fire, this can be used as a nominal value. A process similar to that already described for physical safety factors can also be employed to develop temporal safety factors. In this case, however, the rates (for example, of heat release and toxic product generation) will be varied instead of absolute values (for example, material properties).

The margin of safety can be thought of as a reflection of societal values and can be imposed by the authority having jurisdiction for that purpose. Because the time for which a condition is predicted will most likely be the focus of the authority having jurisdiction (for example, the model predicts that occupants will have 5 minutes to safely evacuate), the margin of safety will be characterized by temporal aspects and tacitly applied to the physical margin of safety.

Escaping the harmful effects of fire (or mitigating them) is, effectively, a race against time. When assessing fire safety system designs based on computer model predictions, the choice of an acceptable time is important. When an authority having jurisdiction is faced with the predicted time of untenability, a decision needs to be made regarding whether sufficient time is available to ensure the safety of building occupants. The authority having jurisdiction is assessing the margin of safety. Is there sufficient time to get everyone out safely? If the authority having jurisdiction feels that the predicted egress time is too close to the time of untenability, the authority having jurisdiction can impose an additional period of time that the designer will have to incorporate into the system design. In other words, the authority having jurisdiction can impose a greater margin of safety than that originally proposed by the designer.

Section 5.8 Documentation Requirements

5.8.1* General.

All aspects of the design, including those described in 5.8.2 through 5.8.14, shall be documented. The format and content of the documentation shall be acceptable to the authority having jurisdiction.

A.5.8.1 The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* describes the documentation that should be provided for a performance-based design.

Proper documentation of a performance design is critical to the design acceptance and construction. Proper documentation will also ensure that all parties involved understand what is necessary for the design implementation, maintenance, and continuity of the fire protection design. If attention to details is maintained in the documentation, there should be little dispute during approval, construction, start-up, and use.

Poor documentation could result in rejection of an otherwise good design, poor implementation of the design, inadequate system maintenance and reliability, and an incomplete record for future changes or for testing the design forensically.

5.8.2* Technical References and Resources.

The authority having jurisdiction shall be provided with sufficient documentation to support the validity, accuracy, relevance, and precision of the proposed methods. The engineering standards, calculation methods, and other forms of scientific information provided shall be appropriate for the particular application and methodologies used.

A.5.8.2 The sources, methodologies, and data used in performance-based designs should be based on technical references that are widely accepted and used by the appropriate professions and professional groups. This acceptance is often based on documents that are developed, reviewed, and validated under one of the following processes:

- (1) Standards developed under an open consensus process conducted by recognized professional societies, codes or standards organizations, or governmental bodies
- (2) Technical references that are subject to a peer review process and published in widely recognized peer-reviewed journals, conference reports, or other publications
- (3) Resource publications such as the *SFPE Handbook of Fire Protection Engineering*, which are widely recognized technical sources of information

The following factors are helpful in determining the acceptability of the individual method or source:

- (1) Extent of general acceptance in the relevant professional community. Indications of this acceptance include peer-reviewed publication, widespread citation in the technical literature, and adoption by or within a consensus document.
- (2) Extent of documentation of the method, including the analytical method itself, assumptions, scope, limitations, data sources, and data reduction methods.
- (3) Extent of validation and analysis of uncertainties. This includes comparison of the overall method with experimental data to estimate error rates as well as analysis of the uncertainties of input data, uncertainties and limi-

tations in the analytical method, and uncertainties in the associated performance criteria.

- (4) Extent to which the method is based on sound scientific principles.
- (5) Extent to which the proposed application is within the stated scope and limitations of the supporting information, including the range of applicability for which there is documented validation. Factors such as spatial dimensions, occupant characteristics, and ambient conditions, can limit valid applications.

In many cases, a method will be built from, and will include, numerous component analyses. These component analyses should be evaluated using the same factors that are applied to the overall method as outlined in items (1) through (5).

A method to address a specific fire safety issue, within documented limitations or validation regimes, might not exist. In such a case, sources and calculation methods can be used outside of their limitations, provided that the design team recognizes the limitations and addresses the resulting implications.

The technical references and methodologies to be used in a performance-based design should be closely evaluated by the design team and the authority having jurisdiction, and possibly by a third-party reviewer. The strength of the technical justification should be judged using criteria in items (1) through (5). This justification can be strengthened by the presence of data obtained from fire testing.

5.8.3 Building Design Specifications.

All details of the proposed building design that affect the ability of the building to meet the stated goals and objectives shall be documented.

5.8.4 Performance Criteria.

Performance criteria, with sources, shall be documented.

5.8.5 Occupant Characteristics.

Assumptions about occupant characteristics shall be documented.

5.8.6 Design Fire Scenarios.

Descriptions of design fire scenarios shall be documented.

5.8.7 Input Data.

Input data to models and assessment methods, including sensitivity analyses, shall be documented.

5.8.8 Output Data.

Output data from models and assessment methods, including sensitivity analyses, shall be documented.

5.8.9 Safety Factors.

The safety factors utilized shall be documented.

5.8.10 Prescriptive Requirements.

Retained prescriptive requirements shall be documented.

5.8.11* Modeling Features.

A.5.8.11 Documentation for modeling should conform to ASTM 1472, *Standard Guide for Documenting Computer Software*, although most, if not all, models were originally developed before this standard was promulgated.

5.8.11.1 Assumptions made by the model user, and descriptions of models and methods used, including known limitations, shall be documented.

5.8.11.2 Documentation shall be provided to verify that the assessment methods have been used validly and appropriately to address the design specifications, assumptions, and scenarios.

5.8.12 Evidence of Modeler Capability.

The design team's relevant experience with the models, test methods, databases, and other assessment methods used in the performance-based design proposal shall be documented.

5.8.13 Performance Evaluation.

The performance evaluation summary shall be documented.

5.8.14 Use of Performance-Based Design Option.

Design proposals shall include documentation that provides anyone involved in the ownership or management of the building with notification of the following:

- (1) Approval of the building as a performance-based design with certain specified design criteria and assumptions
- (2) Need for required re-evaluation and reapproval in cases of remodeling, modification, renovation, change in use, or change in established assumptions

CHAPTER 6

Classification of Occupancy and Hazard of Contents

Chapter 6 addresses the following considerations needed for accurately determining which *Code* provisions apply to a specific building:

- (1) Classification of occupancy
- (2) Choice of treating multiple occupancies as either mixed occupancies or separated occupancies
- (3) Categorization of the relative hazard presented by the contents or use of the building

Proper classification of the occupancy is crucial; since the *Code* is not a “one size fits all” document, the selection of the proper occupancy is of paramount importance to ensure that the correct chapters and sections of the *Code* are used. The occupancy classification scheme uses general descriptions of each occupancy (for example, assembly, educational, day care, or health care). The annex text that accompanies each of the occupancy classifications provides lists of the most common building uses for each classification.

Occupancy classification of a building often encompasses more than one category. It is common for multiple occupancy types to coexist within a single building. For example, a hotel often consists of a multiple occupancy that includes hotel, assembly, mercantile, and business occupancies. Paragraph 6.1.14.1.1 permits multiple occupancies to be treated as either mixed occupancies or separated occupancies.

Hazard of contents, as addressed in Section 6.2, describes the relative hazard associated with the contents and operational aspects of the building. *Hazard of contents* is a relative term that is used to describe the potential threat to occupants from a fire that occurs in a given occupancy type.

Section 6.1 Classification of Occupancy

Each of the occupancy groupings addressed by Chapter 6 was developed to reflect the design features, usage patterns, and unique life safety needs of occupants who are characteristic of a given occupancy. This approach was used to assess the degree to which the features contained in the core chapters need to be combined to achieve the minimum level of life safety necessary for an occupancy. It is extremely important that the correct occupancy classification be made, because the *Code* requirements differ for each type of occupancy. Improper classification might result in an inadequate level of life safety or overspending on nonrequired items. The occupancy groupings are as follows:

(a) *Assembly*. Assembly occupancies generally contain large numbers of people who are unfamiliar with the space and are therefore subject to indecision regarding the best means of egress in an emergency.

(b) *Educational*. Educational occupancies primarily include the large numbers of young people found in school buildings.

(c) *Day-Care*. Day-care occupancies contain both young and adult occupants who are under the supervision of adults other than their relatives or legal guardians. In cases where day-care occupancies cater to preschool age children, the occupants might need to be carried out of the facility during evacuation.

(d) *Health Care*. Health-care occupancies are characterized by occupants who are incapable of self-preservation. In a health care occupancy, the occu-

pants may not be able to use exits, regardless of the number of exits provided. Occupants might be immobile, connected to monitoring equipment, debilitated, or recovering from surgery; or they might be disabled in some other way. The *Code*, in this instance, calls for a defend-in-place design strategy that uses horizontal movement and compartmentation. It recognizes that the occupants are to be provided enough protection to enable them to survive the fire by remaining in the structure, at least temporarily.

(e) *Ambulatory Health Care*. Ambulatory health care occupancies are similar to health care occupancies in that the occupants are generally incapable of self-preservation, in this case as a result of the treatment provided. Also, ambulatory health care occupancies operate on an outpatient basis, so no individual patient occupies the building for a period of 24 hours or more.

(f) *Detention and Correctional*. Detention and correctional occupancies, as in the case of health care occupancies, house occupants who are incapable of self-preservation. In detention and correctional occupancy, however, the incapability for self-preservation is due to the security imposed on the occupants. Because doors are not unlocked to allow free egress to the public way, the defend-in-place design strategy is used.

(g) *Residential*. Residential occupancies are characterized by occupants who are asleep for a portion of the time they occupy the building. The sleeping that takes place is for normal restorative rest as opposed to the sleeping that takes place in a hospital or residential board and care facility where caretakers are present. Sleeping occupants might be unaware of an incipient fire and might be trapped before egress can occur. This occupancy group is further divided into one- and two-family dwellings, lodging and rooming houses, hotels and dormitories, and apartment buildings. Each occupancy in the group has characteristic needs that differ from the others. For this reason, separate chapters of the *Code* address each of these subgroups.

(h) *Residential Board and Care*. Residential board and care occupancies, as in the case of residential occupancies, provide sleeping accommodations. However, the residents also receive personal care services by caretakers who live with the residents. Personal care includes assistance with many of the activities of daily living, such as bathing and dressing. Personal care does not include medical care.

(i) *Mercantile*. Mercantile occupancies, as in the case of assembly occupancies, are characterized by

large numbers of people who gather in a space that is relatively unfamiliar to them. In addition, mercantile occupancies often contain sizable quantities of combustible contents and use circuitous egress paths that are deliberately arranged to force occupants to travel around displays of materials that are available for sale.

(j) *Business*. Business occupancies generally have a lower occupant density than mercantile occupancies, and the occupants are usually more familiar with their surroundings. However, confusing and indirect egress paths are often developed due to office layouts and the arrangement of tenant spaces. The *Code* requirements for such occupancies address the needs of visitors unfamiliar with the building.

(k) *Industrial*. Industrial occupancies expose occupants to a wide range of processes and materials of varying hazard. Special-purpose industrial occupancies, which are characterized by large installations of equipment that dominate the space, are addressed separately from general-purpose industrial facilities, which have higher densities of human occupancy.

(l) *Storage*. Storage occupancies are characterized by relatively low human occupancy in comparison to building size, and by varied hazards associated with the materials stored.

6.1.1 General.

6.1.1.1 Occupancy Classification. The occupancy of a building or structure, or portion of a building or structure, shall be classified in accordance with 6.1.2 through 6.1.13. Occupancy classification shall be subject to the ruling of the authority having jurisdiction where there is a question of proper classification in any individual case.

Because the appropriate occupancy classification is not always easily determined, the *Code* assigns the authority having jurisdiction the responsibility of determining whether the designer, owner's representative, or other applicable person has correctly classified the occupancy.

6.1.1.2 Special Structures. Occupancies in special structures shall conform to the requirements of the specific occupancy chapter, Chapter 12 through Chapter 42, except as modified by Chapter 11.

The provision of 6.1.1.2 clarifies that placing an occupancy in a special structure—such as a windowless,

underground, water-surrounded, or high-rise building—does not create a unique occupancy. Rather, the occupancy is classified as one of those addressed by Chapters 12 through 42. Chapter 11 is then consulted to find any permitted modifications that apply to the structure.

6.1.2 Assembly.

For requirements, see Chapter 12 and Chapter 13.

6.1.2.1* Definition—Assembly Occupancy. An occupancy (1) used for a gathering of 50 or more persons for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar uses; or (2) used as a special amusement building, regardless of occupant load.

A.6.1.2.1 Assembly Occupancy. Assembly occupancies might include the following:

- (1) Armories
- (2) Assembly halls
- (3) Auditoriums
- (4) Bowling lanes
- (5) Club rooms
- (6) College and university classrooms, 50 persons and over
- (7) Conference rooms
- (8) Courtrooms
- (9) Dance halls
- (10) Drinking establishments
- (11) Exhibition halls
- (12) Gymnasiums
- (13) Libraries
- (14) Mortuary chapels
- (15) Motion picture theaters
- (16) Museums
- (17) Passenger stations and terminals of air, surface, underground, and marine public transportation facilities
- (18) Places of religious worship
- (19) Pool rooms
- (20) Recreation piers
- (21) Restaurants
- (22) Skating rinks
- (23) Special amusement buildings regardless of occupant load
- (24) Theaters

Assembly occupancies are characterized by the presence or potential presence of crowds with attendant panic hazard in case of fire or other emergency. They are generally or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. Such buildings are ordinarily occupied by able-bodied persons and are not used for sleeping purposes. Spe-

cial conference rooms, snack areas, and other areas incidental to, and under the control of, the management of other occupancies, such as offices, fall under the 50-person limitation.

Restaurants and drinking establishments with an occupant load of fewer than 50 persons should be classified as mercantile occupancies.

For special amusement buildings, see 12.4.7 and 13.4.7.

Subpart (2) of 6.1.2.1 clarifies that a special amusement building is an assembly occupancy, even if the occupant load is fewer than 50 persons. If this were not the case, the house of horror amusement building at a carnival, for example, could be treated as a business occupancy, because it does not have the minimum 50-person occupant load typically associated with an assembly occupancy, and the necessary level of life safety might not be provided. As an assembly occupancy, a special amusement building is subject to the provisions of Chapter 12 or 13. Because such buildings purposely confound the egress path and further confuse the occupants with sound and lighting effects, they need to meet the special requirements of 12.4.7 or 13.4.7.

For other than special amusement buildings, the threshold at which an assembly use becomes an assembly occupancy is the 50-person occupant load.

6.1.2.2 Small Assembly Uses. Occupancy of any room or space for assembly purposes by fewer than 50 persons in another occupancy and incidental to such other occupancy shall be classified as part of the other occupancy and shall be subject to the provisions applicable thereto.

Note that 6.1.2.2 refers to small assembly *uses* and not to small assembly *occupancies*. Small assembly uses are considered part of the predominant occupancy. Except for special amusement buildings, as addressed in 6.1.2.1, there are no assembly occupancies with occupant loads fewer than 50 persons.

6.1.3 Educational.

For requirements, see Chapter 14 and Chapter 15.

6.1.3.1* Definition—Educational Occupancy. An occupancy used for educational purposes through the twelfth grade by six or more persons for 4 or more hours per day or more than 12 hours per week.

A.6.1.3.1 Educational Occupancy. Educational occupancies include the following:

- (1) Academies
- (2) Kindergartens
- (3) Schools

An educational occupancy is distinguished from an assembly occupancy in that the same occupants are regularly present.

6.1.3.2 Other Occupancies. Other occupancies associated with educational institutions shall be in accordance with the appropriate parts of this *Code*.

6.1.3.3 Incidental Instruction. In cases where instruction is incidental to some other occupancy, the section of this *Code* governing such other occupancy shall apply.

Educational occupancies are limited to facilities used for educational purposes through the 12th grade. College classroom buildings do not meet this criterion and are classified as business occupancies. Where the occupant load of a classroom is 50 or more, the appropriate occupancy classification is assembly, regardless of educational grade level.

6.1.4 Day Care.

For requirements, see Chapter 16 and Chapter 17.

6.1.4.1* Definition—Day-Care Occupancy. An occupancy in which four or more clients receive care, maintenance, and supervision, by other than their relatives or legal guardians, for less than 24 hours per day.

A.6.1.4.1 Day-Care Occupancy. Day-care occupancies include the following:

- (1) Adult day-care occupancies, except where part of a health care occupancy
- (2) Child day-care occupancies
- (3) Day-care homes
- (4) Kindergarten classes that are incidental to a child day-care occupancy
- (5) Nursery schools

In areas where public schools offer only half-day kindergarten programs, many child day-care occupancies offer state-approved kindergarten classes for children who need full-day care. Because these classes are normally incidental to the day-care occupancy, the requirements of the day-care occupancy should be followed.

Day-care occupancies have some similarities to educational occupancies. However, in lieu of educational activity with classroom occupants and teachers, there are activities with clients and staff, with staff serving as caretakers. The clients of a day-care occupancy

might be adults. It has become fairly common for elderly adults to attend a day-care facility.

6.1.4.2 Other. (Reserved)

6.1.5 Health Care.

For requirements, see Chapter 18 and Chapter 19.

6.1.5.1* Definition—Health Care Occupancy. An occupancy used for purposes of medical or other treatment or care of four or more persons where such occupants are mostly incapable of self-preservation due to age, physical or mental disability, or because of security measures not under the occupants' control.

A.6.1.5.1 Health Care Occupancy. Health care occupancies include the following:

- (1) Hospitals
- (2) Limited care facilities
- (3) Nursing homes

Occupants of health care occupancies typically have physical or mental illness, disease, or infirmity. They also include infants, convalescents, or infirm aged persons.

Chapters 18 and 19 address hospitals, nursing homes, and limited care facilities as health care occupancies. These subclassifications of health care occupancies are defined in 3.3.112, 3.3.110.2, and 3.3.69.2, respectively. The definitions specify that each type of facility accommodate four or more persons. Because Chapter 24 permits a living unit housing a family and up to three outsiders to be classified as a one-family dwelling, a home with three or fewer persons incapable of self-preservation does not constitute a health care occupancy.

A definition of *birth center* appears in 3.3.24. Also, guidance for whether a birth center is to be classified as a business occupancy or as a health care occupancy is provided in A.6.1.11.1.

6.1.5.2 Other. (Reserved)

6.1.6 Ambulatory Health Care.

For requirements, see Chapter 20 and Chapter 21.

6.1.6.1* Definition—Ambulatory Health Care Occupancy. A building or portion thereof used to provide services or treatment simultaneously to four or more patients that provides, on an outpatient basis, one or more of the following:

- (1) Treatment for patients that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others
- (2) Anesthesia that renders the patients incapable of taking action for self-preservation under emergency conditions without the assistance of others
- (3) Emergency or urgent care for patients who, due to the nature of their injury or illness, are incapable of taking action for self-preservation under emergency conditions without the assistance of others

A.6.1.6.1 Ambulatory Health Care Occupancy. The intent of 6.1.6.1 is not that occupants be considered to be incapable of self-preservation just because they are in a wheelchair or use assistive walking devices such as a cane, a walker, or crutches. It is the intent to address emergency care centers that receive patients who have been rendered incapable of self-preservation due to the emergency, such as being rendered unconscious as a result of an accident or being unable to move oneself due to sudden illness.

Chapters 20 and 21 address the outpatient form of a health care occupancy. The requirements draw heavily from those applicable to business occupancies but supplement them with special provisions that address the fact that some patients in such occupancies are incapable of self-preservation. As is the case with other health care occupancies, the facility must accommodate at least four persons. Subitems (1), (2), and (3) of 6.1.6.1 further define the treatment, care, and initial condition of the patient that can render the patient incapable of self-preservation.

6.1.6.2 Other. (Reserved)

6.1.7 Detention and Correctional.

For requirements, see Chapter 22 and Chapter 23.

6.1.7.1* Definition—Detention and Correctional Occupancy. An occupancy used to house four or more persons under varied degrees of restraint or security where such occupants are mostly incapable of self-preservation because of security measures not under the occupants' control.

A.6.1.7.1 Detention and Correctional Occupancy. Detention and correctional occupancies include the following:

- (1) Adult and juvenile substance abuse centers
- (2) Adult and juvenile work camps
- (3) Adult community residential centers
- (4) Adult correctional institutions
- (5) Adult local detention facilities
- (6) Juvenile community residential centers
- (7) Juvenile detention facilities
- (8) Juvenile training schools

6.1.7.2* Nonresidential Uses. Within detention and correctional facilities, uses other than residential housing shall be in accordance with the appropriate chapter of the *Code*. (See 22.1.2.3 and 23.1.2.3.)

A.6.1.7.2 Chapter 22 and Chapter 23 address the residential housing areas of the detention and correctional occupancy as defined in 3.3.152.5. Examples of uses other than residential housing include gymnasiums or industries.

Chapters 22 and 23 are intended to apply only to those areas of detention and correctional facilities used for occupant housing, such as sleeping and day activity areas. Other occupied spaces within the facility are to receive an occupancy classification representative of their use and are to be regulated by the applicable provisions of Chapters 12 through 21 and Chapters 24 through 42. For example, cafeterias are regulated using the assembly occupancy chapters, and metal shops follow the requirements of the industrial occupancy chapter. The occupancy requirements of those chapters are usually modified due to special security needs.

6.1.8 Residential.

For requirements, see Chapter 24 through Chapter 31.

6.1.8.1 Definition—Residential Occupancy. An occupancy that provides sleeping accommodations for purposes other than health care or detention and correctional.

The residential occupancy subclassifications of one- and two-family dwellings, lodging or rooming houses, hotels, dormitories, and apartment buildings are defined in 6.1.8.1.1 through 6.1.8.1.5.

Although people sleep in health care occupancies and detention and correctional occupancies, they occupy such facilities for other than normal residential purposes. Because the occupants of these facilities are incapable of self-preservation—in one case due to illness or infirmity and, in the other, as a result of security measures—the provisions that apply to normal residential occupancies might not provide the necessary level of life safety. The user is referred to Chapters 18 and 19 for health care occupancies and Chapters 22 and 23 for detention and correctional occupancies. See also 6.1.5 and 6.1.7.

6.1.8.1.1* Definition—One- and Two-Family Dwelling Unit. A building that contains not more than two dwelling units with independent cooking and bathroom facilities.

A.6.1.8.1.1 One- and Two-Family Dwelling. The definition of *one- and two-family dwelling* states that each dwelling unit can be “occupied by members of a single family with not more than three outsiders.” The *Code* does not define the term *family*. The definition of family is subject to federal, state, and local regulations and might not be restricted to a person or a couple (two people) and their children. The following examples aid in differentiating between a single-family dwelling and a lodging or rooming house:

- (1) An individual or a couple (two people) who rent a house from a landlord and then sublease space for up to three individuals should be considered a family renting to a maximum of three outsiders, and the house should be regulated as a single-family dwelling in accordance with Chapter 24.
- (2) A house rented from a landlord by an individual or a couple (two people) in which space is subleased to four or more individuals, but not more than 16, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.
- (3) A residential building that is occupied by four or more individuals, but not more than 16, each renting from a landlord, without separate cooking facilities, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.

6.1.8.1.2 Definition—Lodging or Rooming House. A building or portion thereof that does not qualify as a one- or two-family dwelling, that provides sleeping accommodations for a total of 16 or fewer people on a transient or permanent basis, without personal care services, with or without meals, but without separate cooking facilities for individual occupants.

6.1.8.1.3* Definition—Hotel. A building or groups of buildings under the same management in which there are sleeping accommodations for more than 16 persons and primarily used by transients for lodging with or without meals.

A.6.1.8.1.3 Hotel. So-called apartment hotels should be classified as hotels because they are potentially subject to the same transient occupancy as hotels. Transients are those who occupy accommodations for less than 30 days.

6.1.8.1.4* Definition—Dormitory. A building or a space in a building in which group sleeping accommodations are provided for more than 16 persons who are not members of the same family in one room, or a series of closely associated rooms, under joint occupancy and single management, with or without meals, but without individual cooking facilities.

A.6.1.8.1.4 Dormitory. Rooms within dormitories intended for the use of individuals for combined living and sleeping purposes are guest rooms or guest suites. Examples

of dormitories include college dormitories, fraternity and sorority houses, and military barracks.

6.1.8.1.5 Definition—Apartment Building. A building or portion thereof containing three or more dwelling units with independent cooking and bathroom facilities.

6.1.8.2 Other. (Reserved)

6.1.9 Residential Board and Care.

For requirements, see Chapter 32 and Chapter 33.

6.1.9.1* Definition—Residential Board and Care Occupancy. A building or portion thereof that is used for lodging and boarding of four or more residents, not related by blood or marriage to the owners or operators, for the purpose of providing personal care services.

A.6.1.9.1 Residential Board and Care Occupancy. The following are examples of facilities classified as residential board and care occupancies:

- (1) A group housing arrangement for physically or mentally handicapped persons who normally attend school in the community, attend worship in the community, or otherwise use community facilities
- (2) A group housing arrangement for physically or mentally handicapped persons who are undergoing training in preparation for independent living, for paid employment, or for other normal community activities
- (3) A group housing arrangement for the elderly that provides personal care services but that does not provide nursing care
- (4) Facilities for social rehabilitation, alcoholism, drug abuse, or mental health problems that contain a group housing arrangement and that provide personal care services but do not provide acute care
- (5) Assisted living facilities
- (6) Other group housing arrangements that provide personal care services but not nursing care

The provision of personal care services to residents of residential board and care facilities is an indicator that the residents might have special needs. The requirements of Chapters 20 and 21 credit the combined abilities of staff and residents to evacuate the building or relocate to a point of safety.

6.1.9.2 Other. (Reserved)

6.1.10 Mercantile.

For requirements, see Chapter 36 and Chapter 37.

6.1.10.1* Definition—Mercantile Occupancy. An occupancy used for the display and sale of merchandise.

A.6.1.10.1 Mercantile Occupancy. Mercantile occupancies include the following:

- (1) Auction rooms
- (2) Department stores
- (3) Drugstores
- (4) Restaurants with fewer than 50 persons
- (5) Shopping centers
- (6) Supermarkets

Office, storage, and service facilities incidental to the sale of merchandise and located in the same building should be considered part of the mercantile occupancy classification.

Bulk merchandising retail buildings, which characteristically consist of a warehouse-type building occupied for sales purposes, are a subclass of mercantile occupancy with a greater potential for hazards than more traditional mercantile operations. See also 36.4.5 and 37.4.5.

6.1.10.2 Other. (Reserved)

6.1.11 Business.

For requirements, see Chapter 38 and Chapter 39.

6.1.11.1* Definition—Business Occupancy. An occupancy used for account and record keeping or the transaction of business other than mercantile.

A.6.1.11.1 Business Occupancy. Business occupancies include the following:

- (1) Air traffic control towers (ATCTs)
- (2) City halls
- (3) College and university instructional buildings, classrooms under 50 persons, and instructional laboratories
- (4) Courthouses
- (5) Dentists' offices
- (6) Doctors' offices
- (7) General offices
- (8) Outpatient clinics, ambulatory
- (9) Town halls

Doctors' and dentists' offices are included, unless of such character as to be classified as ambulatory health care occupancies as defined in 3.3.152.1.

Birth centers occupied by fewer than four patients, not including infants, at any one time; not providing sleeping facilities for four or more occupants; and not providing treatment procedures that render four or more patients, not including infants, incapable of self-preservation at any one time should be classified as business occupancies. For birth centers occupied by patients not meeting these parameters, see Chapter 18 or Chapter 19, as appropriate.

Service facilities common to city office buildings such as newsstands, lunch counters serving fewer than 50 persons, barber shops, and beauty parlors are included in the business occupancy group.

City halls, town halls, and courthouses are included in this occupancy group insofar as their principal function is the transaction of public business and the keeping of books and records. Insofar as they are used for assembly purposes, they are classified as assembly occupancies.

Depending on the characteristics of a laboratory, it may be classified as a business occupancy, industrial occupancy, or other occupancy.

Paragraph A.6.1.11.1 also provides guidance for whether a birth center is to be classified as a business occupancy or a health care occupancy. A definition of *birth center* appears in 3.3.24. Also, see A.3.3.24, *Birth Center*.

6.1.11.2 Other. (Reserved)

6.1.12 Industrial.

For requirements, see Chapter 40.

6.1.12.1* Definition—Industrial Occupancy. An occupancy in which products are manufactured or in which processing, assembling, mixing, packaging, finishing, decorating, or repair operations are conducted.

A.6.1.12.1 Industrial Occupancy. Industrial occupancies include the following:

- (1) Dry cleaning plants
- (2) Factories of all kinds
- (3) Food processing plants
- (4) Gas plants
- (5) Hangars (for servicing/maintenance)
- (6) Laundries
- (7) Power plants
- (8) Pumping stations
- (9) Refineries
- (10) Sawmills
- (11) Telephone exchanges

In evaluating the appropriate classification of laboratories, the authority having jurisdiction should treat each case individually based on the extent and nature of the associated hazards. Some laboratories are classified as occupancies other than industrial; for example, a physical therapy laboratory or a computer laboratory.

Industrial occupancy buildings, along with storage occupancy buildings, are more likely than any other

occupancies to have contents with a wide range of hazards.

Depending on the characteristics of a laboratory, it may be classified as a business occupancy, industrial occupancy, or other occupancy.

6.1.12.2 Other. (Reserved)

6.1.13 Storage.

For requirements, see Chapter 42.

6.1.13.1* Definition—Storage Occupancy. An occupancy used primarily for the storage or sheltering of goods, merchandise, products, vehicles, or animals.

A.6.1.13.1 Storage Occupancy. Storage occupancies include the following:

- (1) Barns
- (2) Bulk oil storage
- (3) Cold storage
- (4) Freight terminals
- (5) Grain elevators
- (6) Hangars (for storage only)
- (7) Parking structures
- (8) Stables
- (9) Truck and marine terminals
- (10) Warehouses

Storage occupancies are characterized by the presence of relatively small numbers of persons in proportion to the area.

Storage occupancy buildings, along with industrial occupancy buildings, are more likely than any other occupancies to have contents with a wide range of hazards.

Bulk merchandising retail buildings, which characteristically consist of a warehouse-type building occupied for sales purposes, are a subclass of mercantile occupancy rather than a storage occupancy. See 36.4.5 and 37.4.5.

6.1.13.2 Other. (Reserved)

6.1.14 Multiple Occupancies.

6.1.14.1 General.

6.1.14.1.1 Multiple occupancies shall comply with the requirements of 6.1.14.1 and one of the following:

- (1) Mixed occupancies—6.1.14.3
- (2) Separated occupancies—6.1.14.4

Classifying a building as simply a multiple occupancy is an incomplete classification. Rather, a classification of multiple occupancy needs to include mention of the occupancy types involved. For example, a building with spaces used for storage and spaces used for sales should be classified as a multiple occupancy that is part storage occupancy and part mercantile occupancy.

Once a building is classified as a multiple occupancy and the occupancy types present are enumerated, the provisions of 6.1.14.1.1 are applied. This paragraph offers the option of protecting multiple occupancies via the mixed occupancy requirements of 6.1.14.3 or via the separated occupancy requirements of 6.1.14.4.

If the mixed occupancy option of 6.1.14.3 is chosen for the protection of the multiple occupancy, the *Code* provisions for all occupancy types present must be compared. For each subject area addressed, the more stringent requirement from the applicable occupancy chapters must be identified and followed.

If the separated occupancy option of 6.1.14.4 is chosen for the protection of the multiple occupancy, the *Code* user must identify the appropriate cell or cells of Table 6.1.14.4.1 to determine the minimum hourly fire resistance rating needed between the occupancies. Paragraph 6.1.14.1.3 exempts certain accessory occupancies from the separation requirement.

An example of a multiple occupancy building that is protected as a mixed occupancy is illustrated in Exhibit 6.1. Because the assembly occupancy (that is, the auditorium) shares the internal corridor egress system with the educational occupancy classrooms and shops, separating the subject occupancies from each other is impractical. Therefore, the uses and arrangement lend themselves to using the option of protecting the multiple occupancy via the mixed occupancy requirements of 6.1.14.3.

Assuming that the building depicted in Exhibit 6.1 is new, the requirements of Chapter 12 for new assembly occupancies are compared with those of Chapter 14 for new educational occupancies for each of the subjects addressed by the *Code*. In each case, the more stringent requirement applies to the entire building. For example, the 1830-mm (72-in.) minimum corridor width requirement of 14.2.3.2 for educational occupancies is stricter than the 1120-mm (44-in.) minimum of 12.2.3.8 for assembly occupancies and, thus, applies throughout the floor depicted. The panic hardware requirement of 12.2.2.2.3 for assembly occupancies is identical to that in 14.2.2.2.2 for educational occupancies; therefore, this common requirement applies throughout the mixed occupancy.

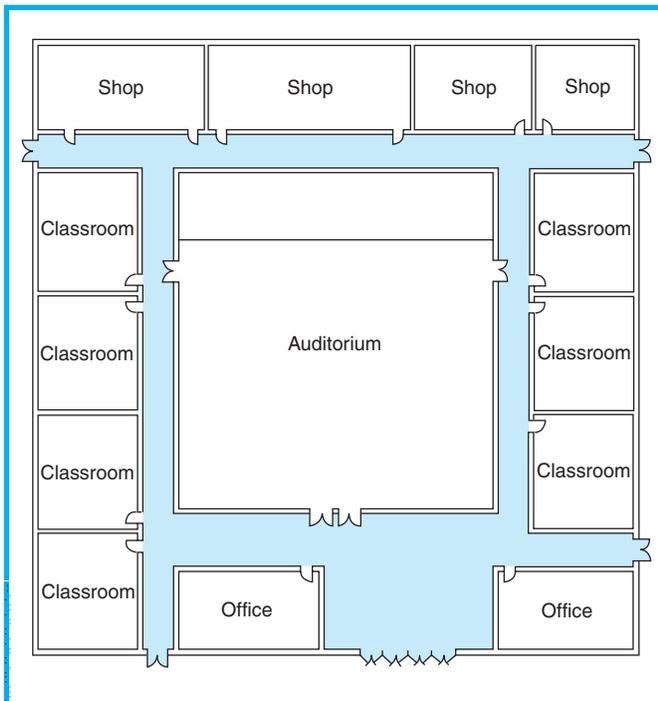

Exhibit 6.1 Multiple occupancy building protected via the mixed occupancies requirements.

With regard to travel distance, in assembly occupancies, travel distance to the nearest exit is limited to a maximum of 61 m (200 ft) in a nonsprinklered building or 76 m (250 ft) in a sprinklered building; educational occupancies are limited to a 46-m (150-ft) travel distance in a nonsprinklered building and 61 m (200 ft) in a sprinklered building. So, the stricter travel distance requirement from the educational occupancies chapter applies.

A simple example of a multiple occupancy building where the subject occupancies can be easily separated from each other is illustrated in Exhibit 6.2. Because each individual-use space is arranged to meet its egress requirements independently of its neighbors, meeting only the requirements that apply to the occupancy of that space can adequately protect each space.

6.1.14.1.2* Where incidental to another occupancy, areas used as follows shall be permitted to be considered part of the predominant occupancy and shall be subject to the provisions of the *Code* that apply to the predominant occupancy:

- (1) Mercantile, business, industrial, or storage use
- (2)* Nonresidential use with an occupant load fewer than that established by Section 6.1 for the occupancy threshold

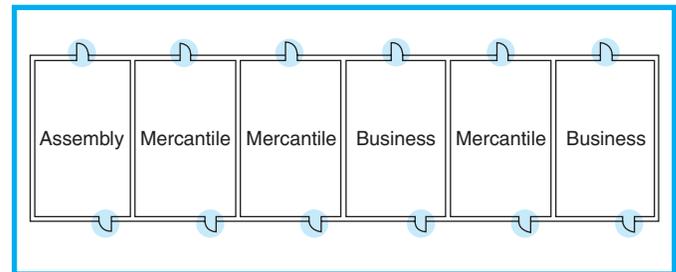

Exhibit 6.2 Multiple occupancy building protected via the separated occupancies requirements.

A.6.1.14.1.2 Examples of uses that might be incidental to another occupancy include the following:

- (1) A newsstand (mercantile) in an office building
- (2) A giftshop (mercantile) in a hotel
- (3) A small storage area (storage) in any occupancy
- (4) Minor office space (business) in any occupancy
- (5) A maintenance area (industrial) in any occupancy

A.6.1.14.1.2(2) Examples of uses that have occupant loads below the occupancy classification threshold levels include the following:

- (1) An assembly use with fewer than 50 persons within a business occupancy
- (2) An educational use with fewer than 6 persons within an apartment building.

Paragraph 6.1.14.1.2 clarifies that some, but not all, incidental uses can be considered part of the predominant occupancy. Incidental residential uses, regardless of the number of persons for whom sleeping accommodations are provided, are to be treated as residential occupancies. For example, if there are sleeping facilities for five fire fighters in a fire station, the *Code* does not permit the building to be classified simply as a storage occupancy. Rather, the proper classification is a multiple occupancy that is part storage occupancy and part residential occupancy (that is, lodging/rooming house). The requirements that apply to both occupancies need to be compared, and the more stringent provisions applied, or the occupancies need to be separated from each other.

In addition, a day-care use with more than three clients is not exempted by either criterion of 6.1.14.1.2. For example, a small day-care center with 14 clients located in a high-rise office building is not permitted to be considered part of the predominant business occupancy. The more stringent of the requirements that apply to day-care occupancies and business occupancies need to be implemented in accordance

with 6.1.14.3, or the occupancies need to be separated from each other in accordance with 6.1.14.4.

If the day-care use in the high-rise office building addressed in the preceding paragraph had only three clients, that number of clients would be less than the threshold number of four clients at which a day-care use becomes a day-care occupancy. The day-care use could, therefore, be classified as incidental to the business occupancy as allowed by 6.1.14.1.2(2).

6.1.14.1.3 The following accessory occupancies shall not be required to be separated from the primary occupancy as required in 6.1.14.4:

- (1) An area used solely as a public dining room having an occupant load of not more than 300 persons and accessory to a retail sales area
- (2) An assembly room not over 70 m² (750 ft²), where not accessory to an occupancy with high hazard contents
- (3) Administrative, clerical, or other office rooms that, in the aggregate, are not more than 25 percent of the principal occupancy, where not accessory to an occupancy with high hazard contents

6.1.14.2 Definitions.

6.1.14.2.1 Multiple Occupancy. A building or structure in which two or more classes of occupancy exist.

6.1.14.2.2 Mixed Occupancy. A multiple occupancy where the occupancies are intermingled.

6.1.14.2.3 Separated Occupancy. A multiple occupancy where the occupancies are separated by fire resistance-rated assemblies.

6.1.14.3 Mixed Occupancies.

6.1.14.3.1 Each portion of the building shall be classified as to its use in accordance with Section 6.1.

6.1.14.3.2 The means of egress facilities, type of construction, protection, and other safeguards in the building shall comply with the most restrictive fire and life safety requirements of the occupancies involved.

6.1.14.4 Separated Occupancies.

6.1.14.4.1 Where separated occupancies are provided, each part of the building comprising a distinct occupancy, as described in this chapter, shall be completely separated from other occupancies by fire-resistive assemblies as specified in 6.1.14.4.2, 6.1.14.4.3, and Table 6.1.14.4.1, unless separation is provided by approved existing separations.

6.1.14.4.2 Occupancy separations shall be classified as 3-hour fire resistance-rated, 2-hour fire resistance-rated, or 1-hour fire resistance-rated, and shall meet the requirements of Chapter 8.

6.1.14.4.3 The fire resistance rating specified in Table 6.1.14.4.1 shall be permitted to be reduced by 1 hour, but in no case shall it be reduced to less than 1 hour, where the building is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

Table 6.1.14.4.1 Required Separation of Occupancies (hours)^a

	Assembly		Day-Care			Ambulatory	Detention	One- & Lodging	Hotels

Storage, High Hazard												

NP = Not permitted

^a The fire resistance rating is permitted to be reduced by 1 hour, but in no case to less than 1 hour, where the building is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

^b The 1-hour reduction due to the presence of sprinklers in accordance with footnote a is not permitted.

6.1.14.4.4 Occupancy separations shall be vertical, horizontal, or both or, when necessary, of such other form as required to provide complete separation between occupancy divisions in the building.

Section 6.2 Hazard of Contents

6.2.1 General.

6.2.1.1 For the purpose of this *Code*, the hazard of contents shall be the relative danger of the start and spread of fire, the danger of smoke or gases generated, and the danger of explosion or other occurrence potentially endangering the lives and safety of the occupants of the building or structure.

The classification of hazard of contents is based on the potential threat to life presented by the contents. A fuel load that might be considered as a *light hazard* in terms of its ease of extinguishment by a sprinkler system might, in fact, produce enough smoke and other products of combustion to threaten the lives of the occupants. In this case, the *Code* requires the material to be classified as *ordinary hazard* contents.

The *Code's* method of classifying hazard of contents is based on life safety. For this reason, the *Code's* provisions are not readily incorporated into the design criteria of other codes where hazard classification is based on property preservation. Many *light hazard* materials, in terms of extinguishment characteristics, are required to be treated as *ordinary hazards* under the *Code*. For example, a business occupancy might be classified as *light hazard* contents by NFPA 13, *Standard for the Installation of Sprinkler Systems*¹, for purposes of sprinkler system design but be considered *ordinary hazard* contents for purposes of applying *Life Safety Code* requirements.

The *Life Safety Code* classifies contents based on the threat of fire, explosions, and other similar events. It does not specifically consider the danger posed by toxic chemical, etiologic contamination, or similar hazards.

6.2.1.2 Hazard of contents shall be determined by the authority having jurisdiction on the basis of the character of the contents and the processes or operations conducted in the building or structure.

6.2.1.3* For the purpose of this *Code*, where different degrees of hazard of contents exist in different parts of a building or structure, the most hazardous shall govern the classification, unless hazardous areas are separated or pro-

tected as specified in Section 8.7 and the applicable sections of Chapter 11 through Chapter 42.

A.6.2.1.3 Under the provision of 6.2.1.3, any violation of the requirements of Chapter 11 through Chapter 42 for separation or protection of hazardous operation or storage would inherently involve violation of the other sections of the *Code*, unless additional egress facilities appropriate to high hazard contents were provided.

The presence of a high hazard contents area on a floor does not have to result in classification of the entire floor as a high hazard contents area if separation or protection is provided in accordance with the requirements of Section 8.7. Once the potential hazard has been mitigated either by automatic sprinkler protection or via isolation from the remainder of the floor by fire resistance-rated construction, the floor is permitted to be treated as an ordinary hazard contents area. For example, in a new hospital, the high hazard contents area created by a soiled-linen storage room is required to be protected by a combination of sprinkler protection and 1-hour fire resistance-rated storage room walls with 45-minute fire protection-rated doors. If the high hazard contents soiled-linen storage room is thus protected, other life safety features are permitted to be provided using the requirements that apply to ordinary hazard contents—not the stricter provisions that apply to occupancies having high hazard contents. For details on the limitations—such as maximum 23-m (75-ft) travel distance—imposed on occupancies having high hazard contents, see Section 7.11.

6.2.2 Classification of Hazard of Contents.

6.2.2.1* The hazard of contents of any building or structure shall be classified as low, ordinary, or high in accordance with 6.2.2.2, 6.2.2.3, and 6.2.2.4.

A.6.2.2.1 These classifications do not apply to the application of sprinkler protection classifications. (*See NFPA 13, Standard for the Installation of Sprinkler Systems.*)

6.2.2.2* Low Hazard. Low hazard contents shall be classified as those of such low combustibility that no self-propagating fire therein can occur.

A.6.2.2.2 Chapter 42 recognizes storage of noncombustible materials as low hazard. In other occupancies it is assumed that, even where the actual contents hazard is normally low, there is sufficient likelihood that some combustible materials or hazardous operations will be introduced in connection

with building repair or maintenance, or some psychological factor might create conditions conducive to panic, so that the egress facilities cannot safely be reduced below those specified for ordinary hazard contents.

Very few occupancies qualify as having low hazard contents. When pressed for an example of low hazard contents, the cautious offer “pig iron ingots stored underwater.” A more realistic and useful example of low hazard contents might be metal parts stored in metal containers on metal—not wood—pallets supported by metal shelving. If the same metal parts stored in metal containers were placed on wood pallets, the pallets would be capable of sustaining a self-propagating fire, and the hazard of contents classification would be ordinary.

6.2.2.3* Ordinary Hazard. Ordinary hazard contents shall be classified as those that are likely to burn with moderate rapidity or to give off a considerable volume of smoke.

A.6.2.2.3 Ordinary hazard classification represents the conditions found in most buildings and is the basis for the general requirements of this *Code*.

The fear of poisonous fumes or explosions is necessarily a relative matter to be determined on a judgment basis. All smoke contains some toxic fire gases but, under conditions of ordinary hazard, there should be no unduly dangerous exposure during the period necessary to escape from the fire area, assuming there are proper exits.

6.2.2.4* High Hazard. High hazard contents shall be classified as those that are likely to burn with extreme rapidity or from which explosions are likely. (*For means of egress requirements, see Section 7.11.*)

A.6.2.2.4 High hazard contents include occupancies where flammable liquids are handled or used or are stored under

conditions involving possible release of flammable vapors; where grain dust, wood flour or plastic dust, aluminum or magnesium dust, or other explosive dusts are produced; where hazardous chemicals or explosives are manufactured, stored, or handled; where cotton or other combustible fibers are processed or handled under conditions producing flammable flyings; and other situations of similar hazard.

Chapter 40 and Chapter 42 include detailed provisions on high hazard contents.

Occupancies containing low hazard or high hazard contents are rare. In deciding which hazard classification applies, users need to ask the following questions:

- (1) Do the contents qualify for a low hazard classification?
- (2) Do the contents qualify for a high hazard classification?

If the answer to each of these questions is no, then the hazard of contents classification is ordinary.

Once an ordinary hazard of contents classification is made, the application of *Code* requirements becomes simple, because the vast majority of the provisions are written to apply to ordinary hazard contents without mentioning ordinary hazard specifically. Generally, specialized requirements apply to high hazard contents, such as those in Section 7.11, and the few exceptions for which application is limited to low hazard contents, such as the unlimited travel distance permitted in low hazard storage occupancies by Table 42.2.6.

CHAPTER 7

Means of Egress

The earliest editions of the *Life Safety Code* were titled the *Building Exits Code*. This title made it evident that one of the main themes addressed in the *Code* was that sufficient exits are needed to allow building occupants to leave a building safely during a fire.

The term *means of egress* is defined in 3.3.136 as “a continuous and unobstructed way of travel from any point in a building or structure to a public way consisting of three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge.” The concept of the three-part means of egress was codified in the *Code* in 1956. Since that time, this concept has been well understood and its philosophy has been implemented by code officials and building designers.

This chapter is segmented to describe the key elements that are typical of egress features.

Separation of the means of egress from other use areas is important to ensure a route of safe passage for the occupants. Subsection 7.1.3 establishes a set of basic principles concerning the separation and segregation of exits to achieve this objective.

Section 7.2 establishes criteria applicable to a variety of components that might constitute a part of the means of egress—from doors and stairs (which are permitted by all occupancy chapters) to specialized components such as alternating tread devices (which are permitted by only certain occupancy chapters).

The method used to determine the number of occupants who can safely move through any of these individual components is addressed in Section 7.3, which deals with the capacity of the means of egress. Part of this approach also involves establishing how many people can reasonably be expected to occupy

a given area; Section 7.3 also presents occupant load factors.

Sections 7.4 through 7.7 relate to the number, arrangement, measurement, and discharge of the means of egress. These four sections not only address the proper number of exits and exit access points, they also control the distance to the exits and the placement of the exits with respect to one another.

The illumination of the means of egress, emergency lighting, and the marking of the means of egress with appropriate signage are related topics. The portions of this chapter that address these subjects were written in recognition that simply having enough exits that are properly arranged does not guarantee that the exits are readily apparent in a variety of circumstances. Normal illumination for the means of egress is governed by Section 7.8, while emergency lighting provisions are addressed in Section 7.9. Section 7.10 establishes the requirements for proper marking of the means of egress with various types of exit signs.

Sections 7.11 and 7.12 provide general rules for egress arrangement for high hazard areas and for mechanical equipment rooms.

Section 7.1 General

The purpose of Chapter 7 is to establish minimum requirements for the means of egress for application to all occupancy classifications. In agreement with the 1.3.1 application statement, Chapter 7 presents requirements that apply to both new construction

and existing buildings. Where the requirements of this chapter are unsuitable for a specific occupancy or impose an unreasonable burden on an existing facility, exemptions are provided as part of the text.

Sometimes the exemptions take the form of a concise statement that refers the user to the specific occupancy chapter. Only by consulting the complete text in the specific occupancy chapter does the user learn the details of the exemption from the Chapter 7 requirements. For example, where 7.2.1.5.1 requires that egress doors remain unlocked, 7.2.1.5.3 cues the user to the fact that, for health care occupancies and detention and correctional occupancies, locked doors are permitted under certain conditions. Paragraph 7.2.1.5.3 uses the phrase “where otherwise provided in Chapter 18 through Chapter 23” to refer the user to chapters in which the details of the exemption’s conditions can be found. For example, 18.2.2.2.2(2) permits locked doors in health care occupancies where the clinical needs of the patients require specialized security measures for their safety, with the provision that keys are carried by staff at all times.

In addition to specifying means of egress features that are required to be provided in all occupancies, Chapter 7 presents other features that, although not required, are permitted to be part of the means of egress if specified conditions are met. Recognizing that some provisions detailed in this chapter might not be suitable to a particular occupancy, the *Code* often introduces such features using the language “where permitted in Chapter 11 through Chapter 42.” For example, doors in means of egress can be equipped with the access-controlled entrance and egress locking system addressed in 7.2.1.6.2 only where specifically permitted by an occupancy chapter. New business occupancies are permitted to use such a system via 38.2.2.2.5, which reads “access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.” If an occupancy chapter is silent on the use of access-controlled egress doors, such doors are prohibited within the required means of egress serving that type of occupancy.

Chapter 7 also presents features that are mandatory only when another part of the *Code* specifically requires the use of that component, system, or arrangement. Recognizing that some of the features detailed in this way in Chapter 7 might not be necessary for a particular occupancy, the *Code* often introduces such features using the language “where required in Chapter 11 through Chapter 42.” For example, Section 7.10 provides details for exit signs but does not require such signs. Section 7.10 is written to include all the criteria necessary for providing exit

signs if another part of the *Code*—typically an occupancy chapter—requires exit signs in accordance with Section 7.10. New assembly occupancies require exit signs per 12.2.10.1, which reads “means of egress shall be provided with signs in accordance with Section 7.10.”

Thus, some of the provisions of Chapter 7 are absolute requirements that apply to all occupancies unless specific exemptions are presented; some provisions are permitted to be used only if another part of the *Code*—typically an occupancy chapter—specifically includes language permitting such use; and some provisions apply only where another part of the *Code*—typically an occupancy chapter—specifically includes language requiring the use of that feature.

7.1.1* Application.

Means of egress for both new and existing buildings shall comply with this chapter. (*See also 4.5.3.*)

Means of egress are to comply with the requirements of this chapter and those detailed in the appropriate occupancy chapter. To avoid creating conflicting requirements, the occupancy chapters, Chapters 12 through 42, are permitted to establish provisions or requirements less stringent than those in Chapter 7 only if correlating language is added to the Chapter 7 requirement to which the exemption applies. However, if an occupancy chapter is written to be more stringent than Chapter 7, it only needs to include the stricter requirement. In accordance with 4.4.2.2, where the specific requirements of the occupancy chapters differ from the general requirements contained in Chapters 1 through 4 and Chapters 6 through 10, the more specific occupancy chapter requirements govern. See also the commentary following 4.4.2.2.

A.7.1.1 Portable ladders, rope fire escapes, and similar emergency escape devices can have a useful function in facilitating escape from burning buildings lacking adequate exits of the stairway or other standard type, but they are not the equivalent of standard exits, and their use is not in any way recognized by this *Code* as satisfying the requirements for means of egress. Furthermore, many such devices are of types unsuitable for use by aged or infirm persons or by small children. Therefore, such devices can provide a false sense of security and should not be used as an excuse for not providing standard exit facilities.

The *Code* relies on standard components such as doors, stairs, and ramps to create a reliable means of egress system usable by persons of all ages. Emergency escape devices such as portable ladders and rope fire escapes, for the reasons explained in A.7.1.1, receive no credit toward satisfying *Code* requirements.

7.1.2 Definitions.

The occupants of a building must be protected from obstacles to safe egress. To achieve this goal, the protection of each component in the egress system is to be considered. Clear and concise definitions of the terms in 7.1.2 appear in Chapter 3. These definitions help explain the special features of each component. The term *means of egress* has been used for many years, but it was not until the late 1950s that its definition was expanded to comprise three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge. Prior to that, the term *exit* was used more often than the term *means of egress*, a fact evidenced by the *Code's* original title, the *Building Exits Code*.

The following is a list of terms used in this chapter:

- (1) **Accessible Area of Refuge.** See 3.3.17.1.

For an area of refuge to be considered an accessible area of refuge, it must be capable of being reached by a person in a wheelchair without traveling over stairs or other obstacles. ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*¹, provides additional details on accessible routes. This edition of the *Life Safety Code* references the 1998 edition of ICC/ANSI A117.1, which was processed in an effort to achieve harmony with the *Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities* (ADAAG)². Parallel changes to the ADAAG are being processed via government rule-making procedures.

- (2) **Accessible Means of Egress.** See 3.3.136.1.

A means of egress is considered an accessible means of egress if it meets one of the following criteria:

- (1) A wheelchair-bound person is able to travel unassisted through the exit access, exit, and exit dis-

charge to a public way (that is, ramp-type travel and not stair-type travel if elevation differences are involved), or

- (2) A wheelchair-bound person is able to travel unassisted through that portion of the exit access necessary to reach an area of refuge.

The area of refuge specified in item (2) serves as a temporary haven from the effects of the fire. A person with severe mobility impairment must have the ability to travel from the area of refuge to the public way, although such travel might depend on the assistance of others. If elevation differences are involved, an elevator might be used or the person might be carried on an extra-wide stair. See also 7.5.4.

- (3) **Area of Refuge.** See 3.3.17.
- (4) **Common Path of Travel.** See 3.3.34.
- (5) **Electroluminescent.** See 3.3.52.
- (6) **Elevator Evacuation System.** See 3.3.218.1.
- (7) **Elevator Lobby.** See 3.3.54.
- (8) **Elevator Lobby Door.** See 3.3.47.1.

The terms *elevator evacuation system*, *elevator lobby*, and *elevator lobby door* are defined for purposes of applying 7.2.13. Although elevators are addressed in 7.2.13 as a component of a means of egress system, the restrictions imposed recognize the elevator only as a second means of egress from a tower provided with limited occupant load, sprinkler protection throughout the tower building, and other detailed features. See also 11.3.2.2.2.

- (9) **Exit.** See 3.3.62.

The *exit* is that portion of the means of egress that is separated from other building spaces by enclosing it within construction having the minimum degree of fire resistance specified by 7.1.3.2, with limited openings through the enclosing construction and protection of such openings. The exit might include doors, stairs, ramps, smokeproof enclosures, exit passageways, and outside balconies. In each case, the exit components are required to conform to the *Code* specifications for fire protection, dimensions, and arrangement. In its simplest form, an exit is a doorway or a door opening directly to the exterior at grade. An exit other than a door opening directly to the outside provides a protected path of travel.

In the case of a stairway, the exit includes the

door into the stairway enclosure, the stair enclosure, the stairs and landings inside the enclosure, and the door from the enclosure to the street or exit discharge.

The entrance to an exit is part of the exit and usually consists of a fire protection-rated door assembly that provides a protected entrance into a protected area. A fire door, however, does not always signal an entrance to an exit. A door or fire door between a hotel room and a corridor or a fire door across a corridor or lobby is not part of an exit, unless the corridor or lobby are separated and protected as required for an exit in accordance with 7.1.3.2.

Various building features—where properly arranged and constructed—might constitute an exit. Examples include an exterior exit door, an exit passageway, a horizontal exit, an exit stair, or an exit ramp.

Several types of exits that might occur are shown in Exhibit 7.1 as shaded areas. On the second floor, exits include the following:

- (1) Two exit stairs enclosed by fire-rated barriers, including a rated self-closing door
- (2) A horizontal exit consisting of a fire-rated barrier, including rated self-closing doors, completely dividing the floor into two fire compartments

On the first floor, exits include the following:

- (1) Two doors from the corridor directly to the outside at grade level
- (2) A horizontal exit that is a vertical extension of and therefore similar to the horizontal exit on the second floor
- (3) An exit passageway that connects one of the second floor exit stairs directly with the outside and is separated from the remainder of the floor by fire-rated barriers, including rated self-closing doors

For detailed requirements for a horizontal exit, see 7.2.4. For detailed requirements for an exit passageway, see 7.2.6.

(10) **Exit Access.** See 3.3.63.

The exit access includes the rooms and building spaces people occupy and the doors, aisles, corridors, unenclosed stairs, and unenclosed ramps that are traversed to reach an exit. Spaces constituting exit access are shown in Exhibit 7.2 as shaded areas. All spaces occupied and traversed in reaching an exit are considered the exit access portion of the means of egress. The shading shown in the figures indicates that exit access comprises more floor area than either

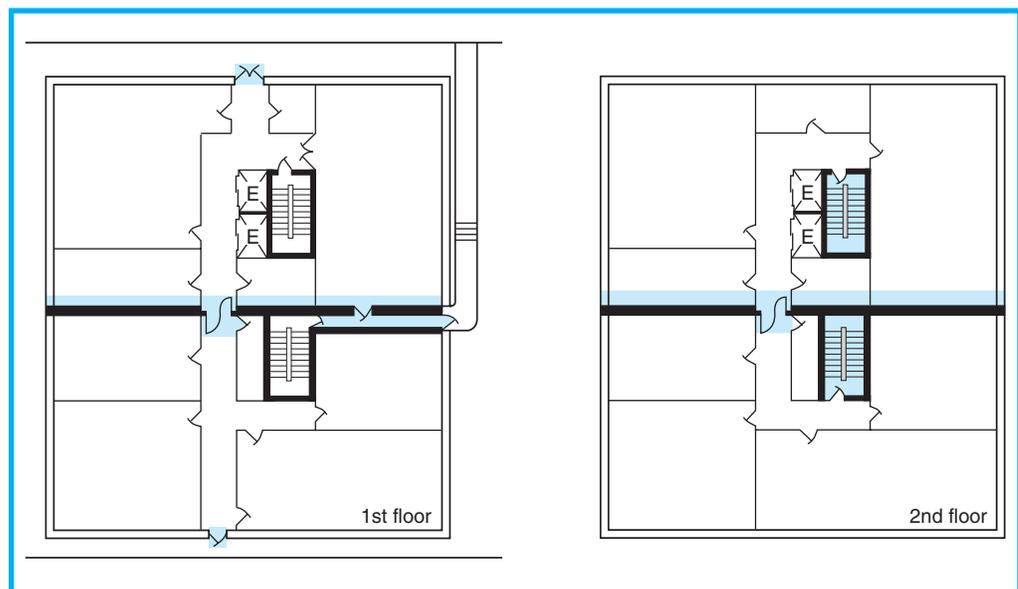

Exhibit 7.1 Various forms of exits.

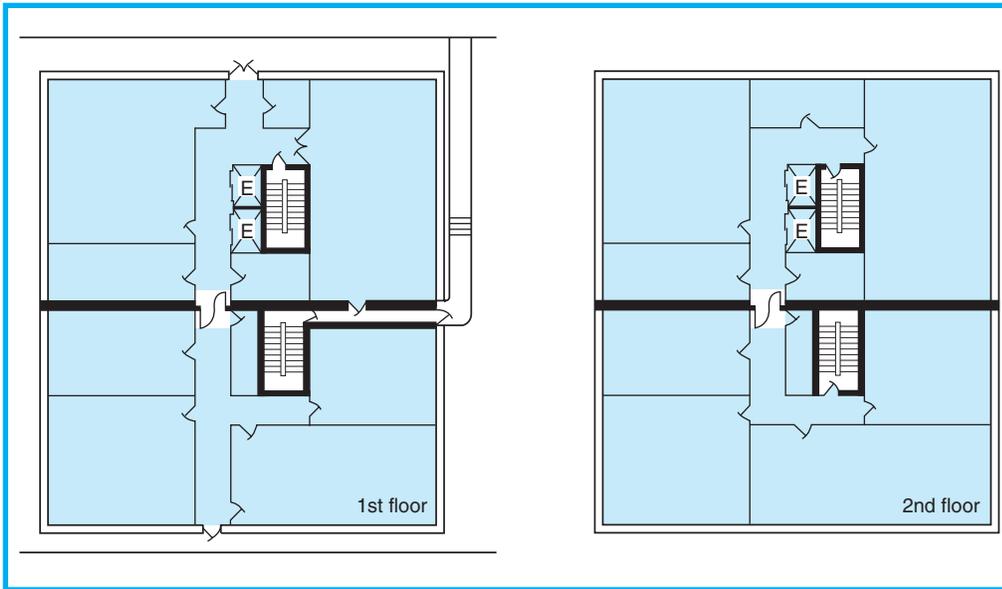

Exhibit 7.2 Spaces constituting exit access.

of the other components of means of egress—the exit and exit discharge.

(11) **Exit Discharge.** See 3.3.64.

Because some exits do not discharge directly into a public way, the exit discharge is defined as providing building occupants with a path of travel from the

termination of an exit to a public way. This path of travel might be inside the building, as permitted by 7.7.2, or outside. Where an exit opens onto an alley, court, or yard, a safe path of travel is to be provided to a public way or some equivalent safe area. This portion of the means of egress is the exit discharge. See also 7.7.1.

Forms of exit discharge are shown in Exhibit 7.3

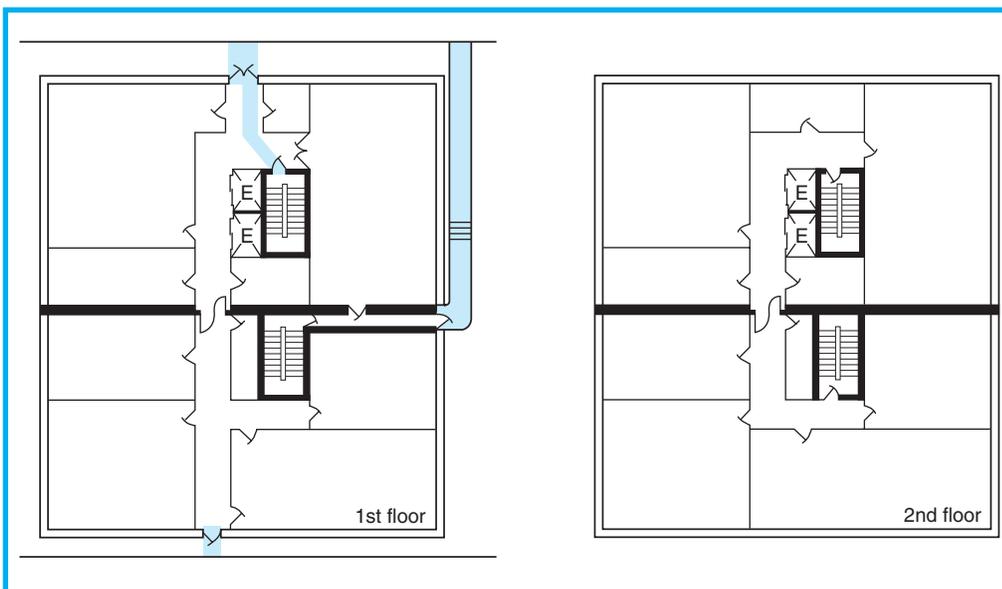

Exhibit 7.3 Spaces constituting exit discharge.

as shaded areas. Because occupants leave the building at the first floor only, no exit discharge occurs on the second floor. The first floor exit discharge includes the following:

- (1) The exterior space beginning at the exit doors from the corridor and continuing to the public way (street)
- (2) The exterior walkway along the side of the building beginning at the door from the exit passage-way and continuing to the public way
- (3) The interior path of travel from the second floor exit stair discharging through a portion of the first floor corridor

A portion of the first floor through which an occupant of the second floor needs to travel is considered exit discharge; yet, an occupant of the first floor who travels across the same space is considered to be within exit access. See also 7.7.2.

(12) **Externally Illuminated.** See 3.3.114.1.

(13) **Horizontal Exit.** See 3.3.62.1.

A horizontal exit is a fire barrier with fire doors that provide passage from one fire compartment of a building to another fire compartment in the same building or in an adjoining building on approximately the same level. Substantial fire separations are required, because the area to which egress is made serves as a temporary safe haven. The horizontal exit might be a combination of a 2-hour fire resistance-rated barrier separating a building into two areas with 1½-hour fire protection-rated door assemblies that allow travel from one side of the barrier to the other; or the horizontal exit might be a bridge or balcony that allows travel to an adjoining building. An example of a horizontal exit is depicted in Exhibit 7.1 by the barrier running across the center of the building and providing a continuous separation from outside wall to opposite outside wall.

Horizontal exits are particularly useful in health care occupancies and in detention and correctional occupancies where they are important components of an effective defend-in-place strategy. Horizontal exits make it possible to move nonambulatory patients horizontally to a temporary safe area rather than vertically down stairs. They also provide added safety to residents of detention and correctional occupancies by allowing those residents to relocate within a building, rather than requiring that they rely on staff to unlock doors to allow them to evacuate to the outside. For details on horizontal exits, see 7.2.4.

(14) **Internally Illuminated.** See 3.3.114.2.

(15) **Means of Egress.** See 3.3.136.

A means of egress, by definition, provides a path of egress travel to a public way. In effect, the *Code* emphasizes the need to move building occupants to a safe place. In means of egress arrangements on university campuses, military bases, resorts, and other large complexes, there are numerous areas a building occupant could reach before reaching a public way that affords the intended level of safety from a building fire. It is the *Code's* intent that occupants be able to move to a safe place from which they can continue to move away from the burning building as necessary. At that safe point, *Code* requirements cease to apply. This concept provides the basis for A.7.8.1.1, which is applicable to illumination of means of egress. The annex text states that the extent to which illumination needs to be provided outside the building—that is, within the exit discharge portion of the means of egress—should be to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated.

From every location in a building, a means of egress or path of travel is required over which a person can move to gain access to the outside or to a place of safety. Any persons who gain entrance to a building usually have available to them that ingress route by which to egress. However, one important consideration makes egressing more than just reversing one's route of entry, especially if emergency conditions exist. This reverse route might consist of features that, though they were not obstacles upon entrance, prove to be such upon egress. For example, a door hinged to swing in the direction of entry can become an obstacle when one attempts to leave the building in the opposite direction. The door swings against the flow of traffic—a flow that, during emergency egress, is greatly increased as compared with the leisurely flow of people entering a building.

A basic principle of the *Code* requires that every component of a means of egress be operable by and under the control of the occupants attempting egress. Where the *Code* makes exemptions to this basic concept—for example, in health care occupancies where locked doors are permitted if it is necessary for the clinical needs of the patients—it does so by substituting requirements adequate to achieve the same level of life safety as would be provided if the means of egress system were fully under the control of the building occupants.

- (16) **Photoluminescent.** See 3.3.164.
 (17) **Ramp.** See 3.3.176.

Requirements for ramps used in a means of egress are found in 7.2.5.

- (18) **Self-Luminous.** See 3.3.190.
 (19) **Severe Mobility Impairment.** See 3.3.195.

See also 7.5.4.1, which requires areas accessible to persons with severe mobility impairment to be provided with accessible means of egress.

- (20) **Smokeproof Enclosure.** See 3.3.203.

7.1.3 Separation of Means of Egress.

See also Section 8.2.

7.1.3.1 Exit Access Corridors. Corridors used as exit access and serving an area having an occupant load exceeding 30 shall be separated from other parts of the building by walls having not less than a 1-hour fire resistance rating in accordance with Section 8.3, unless otherwise permitted by the following:

- (1) This requirement shall not apply to existing buildings, provided that the occupancy classification does not change.
- (2) This requirement shall not apply where otherwise provided in Chapter 12 through Chapter 42.

Paragraph 7.1.3.1 requires protection via fire-rated corridor walls of exit access corridors serving more than 30 occupants. Note that the requirement for the corridor walls to be fire resistance-rated, which is not a requirement for the floor/ceiling or roof/ceiling assemblies forming the top and bottom of the corridor compartment, provides separation only between the corridor and other spaces on the same floor. To provide the necessary degree of separation between the corridor and spaces on floors above or below, one has to rely on, for example, the provisions of Section 8.3, to ensure that the floor is smoke resistant—or the requirements of subsection ____1.6 of an occupancy chapter, to require fire resistance-rated floor construction.

Paragraph 7.1.3.1(1) exempts existing corridors, provided that the occupancy classification does

not change. Therefore, if the occupancy classification of an existing building does change, the 1-hour corridor wall requirement applies, unless the specific occupancy involved has different requirements. Most of the occupancy chapters establish new exit access corridor wall requirements that supersede the requirements of 7.1.3.1. Also, some of the occupancy chapters establish corridor wall requirements for existing buildings. Such provisions usually appear in subsection ____3.6. For example, 14.3.6 addresses special requirements for corridor walls in new educational occupancies. If no special requirements appear in an occupancy chapter, the provisions of 7.1.3.1 prevail.

Paragraph 7.1.3.1 does not require corridors; however, it does require that where corridors do exist and where they serve an area having an occupant load of more than 30 persons, they must be separated from other (that is, noncorridor) spaces on that floor by corridor walls. Section 8.3 regulates the construction of the barrier forming the corridor walls and the opening protection. Wall segments that serve both as a corridor wall and as part of an exit enclosure must meet the more stringent provisions required for the enclosure of exits. Similarly, wall segments that serve both as a corridor wall and enclosure protection of hazardous contents areas must meet the more stringent provisions required for protection from the hazardous contents area.

Exhibit 7.4 is an example of the protection of exit access corridors required by 7.1.3.1. Note the differ-

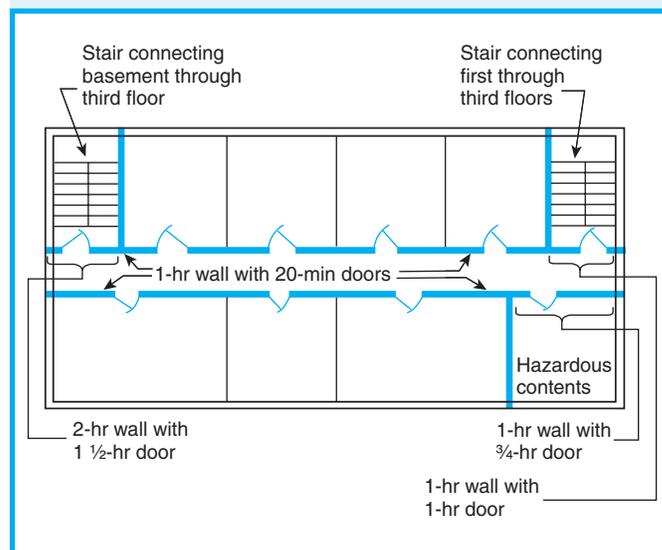

Exhibit 7.4 Protection of exit access corridors.

ence in the required protection for the corridor wall segments serving also as enclosure protection from the hazardous contents area (see Section 8.7) and as part of the enclosure of an exit (see 7.1.3.2).

7.1.3.2 Exits.

7.1.3.2.1 Where this *Code* requires an exit to be separated from other parts of the building, the separating construction shall meet the requirements of Section 8.2 and the following:

- (1)* The separation shall have not less than a 1-hour fire resistance rating where the exit connects three stories or less.

A.7.1.3.2.1(1) In existing buildings, existing walls in good repair and consisting of lath and plaster, gypsum wallboard, or masonry units can usually provide satisfactory protection for the purposes of this requirement where a 1-hour fire resistance rating is required. Further evaluation might be needed where a 2-hour fire resistance rating is required. Additional guidelines can be found in Appendix D of NFPA 914, *Code for Fire Protection of Historic Structures*, and in the *SFPE Handbook of Fire Protection Engineering*.

- (2)* The separation shall have not less than a 2-hour fire resistance rating where the exit connects four or more stories, unless one of the following conditions exists:

- (a) In existing non-high-rise buildings, existing exit stair enclosures shall have not less than a 1-hour fire resistance rating.
- (b) In existing buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, existing exit stair enclosures shall have not less than a 1-hour fire resistance rating.
- (c) One-hour enclosures in accordance with 28.2.2.1.2, 29.2.2.1.2, 30.2.2.1.2, and 31.2.2.1.2 shall be permitted as an alternative to the requirement of 7.1.3.2.1(2).

A.7.1.3.2.1(2) In existing buildings, existing walls in good repair and consisting of lath and plaster, gypsum wallboard, or masonry units can usually provide satisfactory protection for the purposes of this requirement where a 1-hour fire resistance rating is required. Further evaluation might be needed where a 2-hour fire resistance rating is required. Additional guidelines can be found in Appendix D of NFPA 914, *Code for Fire Protection of Historic Structures*, and in the *SFPE Handbook of Fire Protection Engineering*.

- (3) The 2-hour fire resistance-rated separation required by 7.1.3.2.1(2) above shall be constructed of an assembly of noncombustible or limited-combustible materials

and shall be supported by construction having not less than a 2-hour fire resistance rating.

- (4) Openings in the separation shall be protected by fire door assemblies equipped with door closers complying with 7.2.1.8.
- (5)* Openings in exit enclosures shall be limited to doors from normally occupied spaces and corridors and doors for egress from the enclosure, unless one of the following conditions exists:
 - (a) Openings in exit passageways in mall buildings as provided in Chapter 36 and Chapter 37 shall be permitted.
 - (b) In buildings of Type I or Type II construction, existing fire protection-rated doors to interstitial spaces shall be permitted, provided that such spaces meet all of the following criteria:
 - i. The space is used solely for distribution of pipes, ducts, and conduits.
 - ii. The space contains no storage.
 - iii. The space is separated from the exit enclosure in accordance with Section 8.3.
 - (c) Existing openings to mechanical equipment spaces protected by approved existing fire protection-rated doors shall be permitted, provided that the following criteria are met:
 - i. The space is used solely for non-fuel-fired mechanical equipment.
 - ii. The space contains no storage of combustible materials.
 - iii. The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

A.7.1.3.2.1(5) Means of egress from the level of exit discharge is permitted to pass through an exit stair enclosure or exit passageway serving other floors. Doors for convenience purposes and unrelated to egress also are permitted to provide access to and from exit stair enclosures and exit passageways if such doors are from corridors or normally occupied spaces.

- (6) Penetrations into, and openings through, an exit enclosure assembly shall be limited to the following:
 - (a) Doors permitted by 7.1.3.2.1(5)
 - (b) Electrical conduit serving the stairway
 - (c) Required exit doors
 - (d) Ductwork and equipment necessary for independent stair pressurization
 - (e) Water or steam piping necessary for the heating or cooling of the exit enclosure
 - (f) Sprinkler piping
 - (g) Standpipes
 - (h) Existing penetrations protected in accordance with 8.3.5

- (i) Penetrations for fire alarm circuits where the circuits are installed in metal conduit and the penetrations are protected in accordance with 8.3.5.
- (7) Penetrations or communicating openings shall be prohibited between adjacent exit enclosures.

Exits must provide protection from fire originating inside or outside the exit. Protection from fire originating within the enclosure is accomplished by prohibiting use of the enclosure for any purpose that could possibly interfere with the exit functioning as a protected path of travel (see 7.1.3.2.3) and by limiting the combustibility of wall and ceiling interior finish materials within exit enclosures (see 7.1.4). Details on interior wall and ceiling finish are contained in Section 10.2 and subsection 7.3.3 of Chapters 12 through 42. Protection from fire originating outside the exit enclosure is accomplished by separating construction having a specified degree of fire resistance and by careful control of openings into the exit enclosure itself. The only openings permitted in the fire barriers between the exit and the building spaces are those needed to enter the exit from any normally occupied space and those needed to leave the exit to reach the exit discharge. In other words, only openings necessary for an occupant to enter and leave the exit enclosure are permitted.

The degree of fire resistance required depends on the number of stories or floor levels the exit connects, not the height of the building. It is possible to have stairs in a high-rise building connecting only three or fewer stories. In such a case, the enclosing construction is not required to be more than 1-hour fire resistance-rated. See Exhibit 7.5. Where connecting four stories or more, exit stairs must be separated from other spaces within the building by 2-hour fire resistance-rated noncombustible or limited-combus-

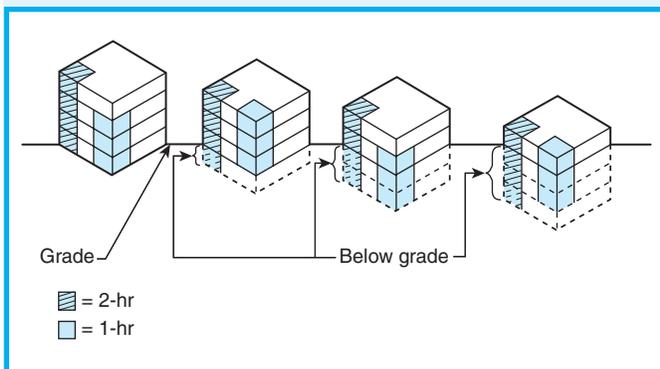

Exhibit 7.5 Required separating construction for exit stairs.

tible construction. Where connecting three or fewer stories, the separation is permitted to be reduced to a minimum 1-hour rating. Via 7.1.3.2.1(2)(a) and 7.1.3.2.1(2)(b), existing exit stair enclosures in existing non-high-rise buildings or in existing sprinklered buildings—regardless of height—are permitted a 1-hour fire resistance rating. As indicated by 7.1.3.2.1(2)(c), some occupancy chapters reduce the 2-hour fire resistance-rated construction requirement to 1 hour—even for new construction—if the building is protected throughout by an approved, supervised automatic sprinkler system. An example can be found in 28.2.2.1.2.

The doors in walls of exit enclosures are to be 1-hour fire protection-rated door assemblies where used in 1-hour fire resistance-rated enclosures, and 1½-hour fire protection-rated door assemblies where used in 2-hour fire resistance-rated enclosures. See Table 8.3.4.2.

If a pair of fire doors opening in the same direction without a center mullion post between the door panels is to be used in an opening in an exit enclosure, it would be prudent to choose a pair of doors listed for use without an overlapping astragal plate. Pairs of doors with an astragal must be arranged to close in a particular sequence to ensure full closure. A coordinator is required to accomplish the sequential closing, and the record of coordinators functioning properly is poor. However, a pair of doors without an astragal could pass considerable smoke through any gap between the meeting edges of the doors and into the exit; therefore, the use of pairs of fire doors opening in the same direction into an exit enclosure should be discouraged.

The only openings permitted in the exit enclosure are for doors providing access into the enclosure from normally occupied spaces and for doors providing egress from the enclosure into the exit discharge. These doors are required to be self-closing fire doors as described in 7.2.1.8. No opening through the exit enclosure walls—including a door—is permitted from storage rooms, closets, boiler rooms, equipment spaces, utility rooms, electrical vaults, or similar spaces that are not normally occupied. Panels providing access to building spaces cannot be installed in the walls or ceilings of exit enclosures, regardless of whether the panels have a fire resistance rating.

Paragraph 7.1.3.2.1(5)(a) permits openings from normally unoccupied spaces within the exit enclosures created by exit passageways in covered mall buildings as detailed in Chapters 36 and 37. By consulting the provisions of 36.4.4.3.7 and 37.4.4.3.7, one

finds that rooms housing building service equipment, service elevators, and janitor closets—spaces not normally occupied—are permitted to open directly onto exit passageways. For an explanation of this deviation from the requirement of 7.1.3.2.1(5), see the commentary following 36.4.4.8(4) and 37.4.4.8(4).

Paragraph 7.1.3.2.1(5)(b) recognizes that, in some existing buildings, it is safe to permit unoccupied rooms to open directly onto an exit stair enclosure. For example, in some existing hospitals, it is common to have interstitial spaces above the ceiling of each floor for purposes of running pipes, ducts, and conduits. The interstitial spaces appear much like separate floors. For example, in an elevation view of a four-story hospital, it would appear that there are eight stories. Every other floor would be occupied by patients, and the alternating “floors” created by the interstitial spaces would house the service pipes, ducts, and conduits. This arrangement is depicted in Exhibit 7.6. Access to the patient floors and to the interstitial space “floors” would be by means of fire-protection rated doors from the stair enclosure. See 7.1.3.2.1(5)(b) for the other criteria necessary to permit the existing situation to be continued in use.

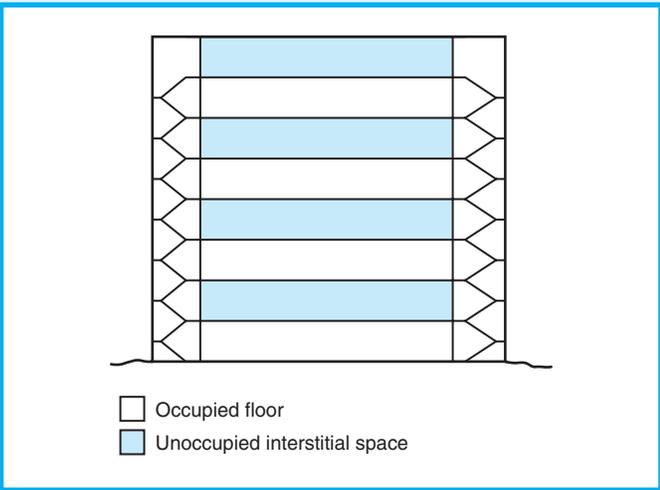

Exhibit 7.6 Unoccupied interstitial spaces with openings to exit stair enclosure.

Exit enclosure penetrations generally are prohibited for new construction. Penetrations are permitted for the following:

- (1) Water and steam piping necessary for the heating and cooling of the exit enclosure
- (2) Electrical conduit serving the exit enclosure
- (3) Fire alarm system circuit wiring installed in metallic conduit and serving the building

- (4) Standpipe and sprinkler piping serving the building

Penetrations for ductwork for pressurization of smokeproof enclosures might be permitted (see 7.2.3), but penetration by other ductwork is prohibited.

Openings to the exterior of the building are not regulated, provided that there is no potential fire exposure from an adjacent source. Such openings need not be protected with fire protection-rated assemblies, because they are not separating the exit from other parts of the building.

7.1.3.2.2 An exit enclosure shall provide a continuous protected path of travel to an exit discharge.

Paragraph 7.1.3.2.2 emphasizes that exit enclosures, and the protection they afford the occupants, must be continuous. It is a fundamental premise that once an occupant has been provided the level of protection afforded by an exit, that level of protection must be maintained to the exit discharge.

This paragraph prohibits an exit stair or exit ramp arrangement that requires a person to leave the exit enclosure, become exposed to conditions on a floor, and then re-enter the exit enclosure to continue moving to the exit discharge. Exhibit 7.7 shows an unacceptable arrangement. The discontinuity of leaving the stair enclosure, then re-entering the stair enclosure to continue moving to the level of exit discharge creates too great a potential for exposing occupants to danger.

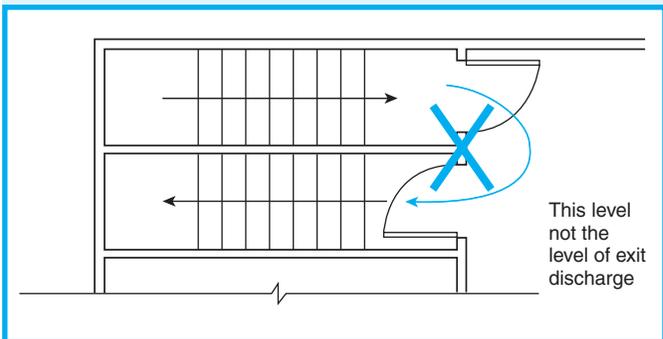

Exhibit 7.7 Unacceptable arrangement for enclosing a stair serving as a required exit.

7.1.3.2.3* An exit enclosure shall not be used for any purpose that has the potential to interfere with its use as an exit and, if so designated, as an area of refuge. (See also 7.2.2.5.3.)

A.7.1.3.2.3 This provision prohibits the use of exit enclosures for storage or for installation of equipment not necessary for safety. Occupancy is prohibited other than for egress, refuge, and access. The intent is that the exit enclosure essentially be “sterile” with respect to fire safety hazards.

Paragraph 7.1.3.2.3 prohibits the use of an exit enclosure for any purpose that could potentially interfere with its use as an exit or as an area of refuge. For example, use of an exit enclosure to house vending machines, copying machines, or storage, or to run electrical distribution wires and cables to areas of the building, is prohibited. Standpipes and emergency lighting that are part of the life safety features are permitted only if their arrangement does not interfere with the passage of people. This limitation covers more than mechanical obstruction of the egress path; it includes any use that could interfere with the use of the exit. See also 7.1.10.1 and 7.2.2.5.3.

The preceding prohibitions also apply to exit passageways because they, too, are exit enclosures.

7.1.4 Interior Finish in Exit Enclosures.

7.1.4.1* Interior Wall and Ceiling Finish in Exit Enclosures. Interior wall and ceiling finish shall be in accordance with Section 10.2. In exit enclosures, interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B.

A.7.1.4.1 See Chapters 12 through 42 for further limitations on interior wall and ceiling finish.

7.1.4.2* Interior Floor Finish in Exit Enclosures. New interior floor finish in exit enclosures, including stair treads and risers, shall be not less than Class II in accordance with Chapter 10.

A.7.1.4.2 See Chapters 12 through 42 for further limitations on interior floor finish.

Paragraph 7.1.4.1 regulates interior wall and ceiling finish within exit enclosures, such as enclosed exit stairs. The intent is to minimize the possibility of fire spreading into and within the exit enclosure. Except as modified by occupancy Chapters 12 through 42, the interior wall and ceiling finish in exit enclosures is required to be either Class A or Class B, as detailed in Section 10.2. Because 7.1.4.1 does not prohibit the use of the provisions of 10.2.8.1, Class C interior wall and ceiling finish would be permitted within an exit enclosure if the enclosure and adjacent areas of the building were protected by automatic sprinklers.

As explained in the commentary following 4.4.2.2, the occupancy chapters can modify the requirements of Chapters 1 through 4 and Chapters 6 through 11. In some cases, the modification results in a more stringent requirement. In others, the result is a relaxation of a base chapter requirement. Interior finish is addressed in detail in Section 10.2, with specific limitations in subsection ____3.3 of the occupancy chapters. For example, for new interior wall and ceiling finish materials in health care occupancies, the requirements of 18.3.3 result in more stringent criteria for wall and ceiling finish within exit enclosures than are required by 7.1.4. Where new interior wall finish nonsprinklered health care occupancy, the requirement is for Class A—not Class B—materials. If the enclosure and adjacent smoke compartments of the building are sprinklered, the requirement is for Class B—not Class C—materials. In this case, the occupancy chapter, considering the needs of its typical occupant group (that is, persons incapable of self-preservation for whom a defend-in-place strategy is employed), tailors its provisions to help achieve the intended minimum level of life safety.

7.1.5* Headroom.

A.7.1.5 For the purpose of this requirement, projections include devices such as lighting equipment, emergency signaling equipment, environmental controls and equipment, security devices, signs, and decorations that are typically limited in area.

7.1.5.1 Means of egress shall be designed and maintained to provide headroom in accordance with other sections of this *Code*, and such headroom shall be not less than 2285 mm (90 in.), with projections from the ceiling not less than 2030 mm (80 in.) nominal above the finished floor, unless otherwise specified in 7.1.5.1.1 and 7.1.5.1.2.

7.1.5.1.1 In existing buildings, the ceiling height shall be not less than 2135 mm (84 in.) from the floor, with projections from the ceiling not less than 2030 mm (80 in.) nominal above the floor.

7.1.5.1.2 Headroom in industrial equipment access areas as provided in 40.2.5.2 shall be permitted.

7.1.5.2 The minimum ceiling height shall be maintained for not less than two-thirds of the ceiling area of any room or space, provided that the ceiling height of remaining ceiling area is not less than 2030 mm (80 in.).

7.1.5.3 Headroom on stairs shall be not less than 2030 mm (80 in.) and shall be measured vertically above a plane parallel to and tangent with the most forward projection of the stair tread.

The minimum 2030-mm (80-in.) clearance that is to be maintained below any projections descending from the minimum ceiling height is intended to be measured as a nominal dimension. Thus, it is the intent of 7.1.5.1 to recognize the clearance provided in passing through the door frame associated with a standard 2030-mm (80-in.) door. Paragraph 7.1.5.3 and the dimensional criteria of 7.2.2.2.1 also allow the 2030-mm (80-in.) minimum headroom height on stairways. Paragraph 7.1.5.3 explains how to measure the headroom on stairs. Headroom measurement is illustrated in Exhibit 7.8. The nominal dimension, 2030 mm (80 in.), is permitted for projections descending from the ceiling and for stairs.

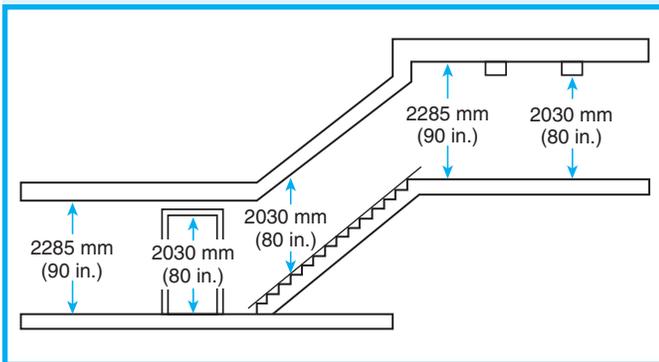

Exhibit 7.8 Headroom measurement.

Earlier editions of the *Code* left unanswered the question of how many 2030-mm (80-in.) projections are too many, so as to leave too little area with at least 2285 mm (90 in.) of headroom height. Since 2000, 7.1.5.2 has required the 2285-mm (90-in.) minimum headroom to be maintained for at least two-thirds of the ceiling area of any room or space.

For industrial occupancies, 40.2.5.2 extends the use of the minimum 2030-mm (80-in.) headroom allowance to industrial equipment access walkways, platforms, ramps, and stairs that serve as a component of the means of egress for not more than 20 people.

7.1.6 Walking Surfaces in the Means of Egress.

7.1.6.1 General.

7.1.6.1.1 Walking surfaces in the means of egress shall comply with 7.1.6.2 through 7.1.6.4.

7.1.6.1.2 Approved, existing walking surfaces shall be permitted.

The vast majority of a building occupant's egress travel time is spent on walking surfaces rather than passing through doors and the other egress components detailed in Section 7.2. Yet, editions of the *Code* prior to 2000 remained silent on the needed characteristics of walking surfaces.

The current provisions applicable to walking surfaces are minimal. They address elevation changes that might cause tripping hazards, maximum slope, and slip resistance that relates to safe use. By addressing for example, slip resistance in the generalized subsection applicable to walking surfaces (see 7.1.6.4), it is no longer necessary to repeat similar provisions for the applicable components of means of egress, such as ramps, stair treads, and landing surfaces. It is expected that the provisions of 7.1.6 will be further expanded for future editions of the *Code*.

7.1.6.2 Changes in Elevation. Abrupt changes in elevation of walking surfaces shall not exceed 6.3 mm ($\frac{1}{4}$ in.). Changes in elevation exceeding 6.3 mm ($\frac{1}{4}$ in.), but not exceeding 13 mm ($\frac{1}{2}$ in.), shall be beveled 1 to 2. Changes in elevation exceeding 13 mm ($\frac{1}{2}$ in.) shall be considered a change in level and shall be subject to the requirements of 7.1.7.

7.1.6.3 Level. Walking surfaces shall be nominally level. The slope of a walking surface in the direction of travel shall not exceed 1 in 20 unless the ramp requirements of 7.2.5 are met. The slope perpendicular to the direction of travel shall not exceed 1 in 48.

7.1.6.4* Slip Resistance. Walking surfaces shall be slip resistant under foreseeable conditions. The walking surface of each element in the means of egress shall be uniformly slip resistant along the natural path of travel.

A.7.1.6.4 The foreseeable slip conditions are those that are likely to be present at the location of the walking surface during the use of the building or area. A foreseeable condition of a swimming pool deck is that it is likely to be wet.

Regarding the slip resistance of treads, it should be recognized that, when walking up or down stairs, a person's foot exerts a smaller horizontal force against treads than is exerted when walking on level floors. Therefore, materials used for floors that are acceptable as slip resistant (as described by ASTM F 1637, *Standard Practice for Safe Walking Surfaces*) provide adequate slip resistance where used for stair treads. Such slip resistance includes the important leading edges of treads, the part of the tread that the foot first contacts during descent, which is the most critical direction of travel. If stair treads are wet, there is an increased danger of slipping, just as there is an increased danger of

slipping on wet floors of similar materials. A small wash or drainage slope on exterior stair treads is, therefore, recommended to shed water. (See *Templer, J. A., The Staircase: Studies of Hazards, Falls, and Safer Design, Cambridge, MA: MIT Press, 1992.*)

7.1.7 Changes in Level in Means of Egress.

7.1.7.1 Changes in level in means of egress shall be achieved by an approved means of egress where the elevation difference exceeds 535 mm (21 in.).

7.1.7.2* Changes in level in means of egress not in excess of 535 mm (21 in.) shall be achieved either by a ramp complying with the requirements of 7.2.5 or by a stair complying with the requirements of 7.2.2.

A.7.1.7.2 Aside from the problems created for persons who are mobility impaired, small changes of elevations in floors are best avoided because of the increased occurrence of missteps where the presence of single steps, a series of steps, or a ramp is not readily apparent. Although small changes of elevation pose significant fall risks in the case of individual movement, they are even more undesirable where crowds traverse the area.

A contrasting marking stripe on each stepping surface can be helpful at the nosing or leading edge so that the location of each step is readily apparent, especially when viewed in descent. Such stripes should be not less than 25 mm (1 in.) but should not exceed 51 mm (2 in.) in width. Other methods could include a relatively higher level of lighting, contrasting colors, contrasting textures, highly prominent handrails, warning signs, a combination thereof, or other similar means. The construction or application of marking stripes should be such that slip resistance is consistent over the walking surface and no tripping hazard is created (see also A.7.2.2.3.3.2). Depending on the distractions of the surroundings, the familiarity of users with a particular small change of level, and especially the number of people that might be in a group traversing the change of level (thereby reducing visibility of the level changes), a strong argument can be made for the elimination of steps and ramps that might pose a risk of missteps.

7.1.7.2.1 Where a ramp is used, the presence and location of ramped portions of walkways shall be readily apparent.

7.1.7.2.2 Where a stair is used, the tread depth of such stair shall be not less than 330 mm (13 in.).

7.1.7.2.3 Tread depth in industrial equipment access areas as provided in 40.2.5.2 shall be permitted.

7.1.7.2.4 The presence and location of each step shall be readily apparent.

Prior to 1988, the *Code* prohibited stairs where changes of elevation were less than 535 mm (21 in.), because steps spanning such small elevation differences often go unnoticed and create conditions conducive to missteps. The minimum 330-mm (13-in.) tread depth and the requirement to make the presence and location of each step readily apparent were established to help reduce missteps. The annex text for 7.1.7.2 provides additional details on stair arrangement to help reduce the problem. Exhibit 7.9 illustrates an arrangement intended to meet the requirements of 7.1.7. In the figure, tread depth has been increased over the usual minimum 280 mm (11 in.) to a minimum of 330 mm (13 in.). The leading edge of each tread has been marked to make its presence and location readily apparent.

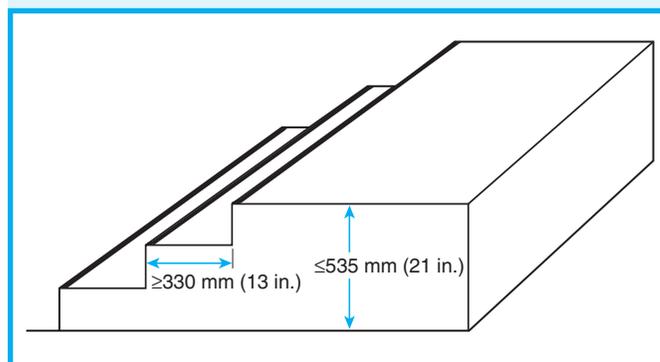

Exhibit 7.9 Special features for stairs involving changes in elevation of 535 mm (21 in.) or less.

Small elevation differences connected by ramps might also go unnoticed and create conditions conducive to missteps. Paragraph 7.1.7.2.1 was added to cover the hazards of trips and other missteps on ramps whose presence is not clear to persons walking in an area where a small change of elevation is otherwise not evident. Although the consequences of a misstep are usually not as severe on ramps as they are on stairs, hazard mitigation is needed.

Single risers and other combinations of a few risers are considered stairs and must meet all the requirements for stairs. Because such risers are considered stairs, handrails are needed along the natural path of egress travel.

7.1.8* Guards.

Guards in accordance with 7.2.2.4 shall be provided at the open sides of means of egress that exceed 760 mm (30 in.) above the floor or grade below.

A.7.1.8 Means of egress components that might require protection with guards include stairs, landings, balconies, corridors, passageways, floor or roof openings, ramps, aisles, porches, and mezzanines.

7.1.9 Impediments to Egress.

Any device or alarm installed to restrict the improper use of a means of egress shall be designed and installed so that it cannot, even in case of failure, impede or prevent emergency use of such means of egress unless otherwise provided in 7.2.1.6 and Chapter 18, Chapter 19, Chapter 22, and Chapter 23.

7.1.10 Means of Egress Reliability.

7.1.10.1* Means of egress shall be continuously maintained free of all obstructions or impediments to full instant use in the case of fire or other emergency.

A.7.1.10.1 A proper means of egress allows unobstructed travel at all times. Any type of barrier including, but not limited to, the accumulations of snow and ice in those climates subject to such accumulations is an impediment to free movement in the means of egress.

For a given occupancy, the combination of requirements contained in Chapters 7 and 8 and in the corresponding occupancy chapter provide for an adequately sized and protected means of egress system. The provision in 7.1.10.1 emphasizes the importance of keeping the egress system usable at all times. In the case of a Class A mercantile occupancy, the minimum 1525-mm (60-in.) exit access aisle width required by 36.2.5.6 and 37.2.5.6 must not, subsequent to receipt of the store's occupancy permit, be filled with mid-aisle displays that reduce the aisle width. Similarly, in a business occupancy with an exit stair of the minimum 1120-mm (44-in.) width required by 7.2.2.2.1, the stair width must not be reduced by the introduction of a mechanized chair lift that is installed, for example, to comply with legislation mandating accessibility for persons with mobility impairments. In an apartment building complex, the required width of the outside exit discharge sidewalk that runs along the side of the building must not be reduced by the presence of a trash dumpster on either a temporary or permanent basis.

Paragraph 7.1.10.1 does not designate responsibility for keeping the means of egress (that is, exit accesses, exits, and exit discharges) free and clear of obstructions. The individuals responsible for each facility—whether managers, owners, or operators—

must make certain that the required egress components are maintained in usable condition. The authority having jurisdiction has the power to enforce this requirement.

7.1.10.2 Furnishings and Decorations in Means of Egress.

Paragraphs 7.1.10.2.1 through 7.1.10.2.3 provide guidance for the interior decoration and maintenance of buildings that serve, for example, as restaurants and theaters, where the mirrored wall surfaces and excessive decoration can camouflage and, in some cases, obstruct exits. For such occupancies, care must be taken to ensure that the required, standard, well-marked exit access that leads to an unobstructed exit is not obscured in the pursuit of period or style authenticity. For example, a restaurant that is heavily decorated with red wall coverings might use green exit signs to help meet the requirements of these paragraphs, despite the fact that Chapter 7 does not specify exit sign color.

7.1.10.2.1 No furnishings, decorations, or other objects shall obstruct exits, access thereto, egress therefrom, or visibility thereof.

7.1.10.2.2 No obstruction by railings, barriers, or gates shall divide the means of egress into sections appurtenant to individual rooms, apartments, or other occupied spaces. Where the authority having jurisdiction finds the required path of travel to be obstructed by furniture or other movable objects, the authority shall be permitted to require that such objects be secured out of the way or shall be permitted to require that railings or other permanent barriers be installed to protect the path of travel against encroachment.

Paragraph 7.1.10.2.2 relates to the arrangement of furniture, as well as to the arrangement of railings, gates, or barriers found in lobbies, foyers, waiting spaces, or staging areas of businesses, hospitals, health care clinics, hotels, and apartments. Because these large spaces are often subdivided by furniture (for example, chairs, tables, and plants) or by railings and gates, furnishings must be prevented from blocking access to exits. This paragraph recommends fastening furnishings so that they are clear of access to exits or placing railings around furnishings to ensure that they are held within a fixed area and cannot be easily

moved or rearranged. The *Code* recognizes the problem created by storage that is placed within the exit access aisles of storage rooms in mercantile occupancies, which is a violation of *Code* requirements. Both Chapters 36 and 37, in accordance with the provisions of 36.2.5.11(4) and 37.2.5.11(4), require fixed barriers to emphasize that such exit access is a specific condition that must be met to permit egress to pass through storerooms.

7.1.10.2.3 Mirrors shall not be placed on exit doors. Mirrors shall not be placed in or adjacent to any exit in such a manner as to confuse the direction of egress.

7.1.11 Sprinkler System Installation.

Where another provision of this chapter requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with the subparts of 9.7.1.1 permitted by the applicable occupancy chapters.

Section 7.2 Means of Egress Components

Many different components of a building or structure are encountered while traversing a means of egress. These components comprise the means of egress and include such items as doors, including necessary hardware; stairs and ramps, including handrails and guards; horizontal exits; exit passageways; and areas of refuge. The composition, properties, use, limits, and function of such components have an effect on the usability of the means of egress system.

Portable ladders, rope ladders, and similar devices are not recognized by the *Code* as providing any portion of the required capacity of a means of egress. In addition, they should not be considered in any way as an upgrade of an inadequate existing means of egress. Although such devices might be used to provide additional safety under emergency conditions, they are unreliable and can lead to a false sense of security. Such devices are often unusable by small children, older people, persons with disabilities, or those who simply have not been trained in their use. See also A.7.1.1.

The components of a means of egress are required to meet certain standards, be built in a prescribed manner, and perform at a level specified by the *Code*. Depending on whether the component is part of the access to an exit, is itself the exit, or is the

exit discharge, the applicable requirements might differ. In most instances, the requirements applicable to a given component are the same regardless of where it is used within the means of egress system. For example, for new stair construction, the riser height must not exceed 180 mm (7 in.), the tread depth must be at least 280 mm (11 in.), and the handrails must be installed at both sides—regardless of where the stairs are placed within the means of egress (unenclosed exit access stairs, enclosed exit stairs, or outside exit discharge stairs).

7.2.1 Doors.

7.2.1.1 General.

Doors serve multiple purposes that relate to the comfort and safety of building occupants and provide protection from the following:

- (1) Weather, drafts, noise, and disturbance from adjoining areas
- (2) Trespass by unauthorized persons
- (3) Fire and smoke, with which this *Code* is concerned

The three broad categories of doors, each providing varying degrees of protection from fire and smoke, are as follows.

(a) *Non-Fire-Rated Door*. A non-fire-rated door is a door such as is used in one- and two-family dwelling construction. While not fire-rated, such doors do provide a limited degree of protection, especially from smoke, if closed.

(b) *Fire-Rated Assembly*. A fire-rated assembly is referred to as a fire door. It has passed the standard fire test for doors, as prescribed by NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*³. A fire door withstands a severe fire and hose stream exposure for the period specified by a *Code* requirement. The fire protection rating specified by the *Code* varies, depending on the uses and occupancy type involved.

(c) *Smoke-Stop Door*. A smoke-stop door is usually of lighter construction than a fire door. Its function is to provide a temporary barrier against the passage of heat, smoke, and gases.

None of these doors will perform satisfactorily if left open during a fire, thus allowing the entry of fire and combustion products into what should be a safer area than the fire area. The history of fires is full of tragic examples of those who died because of an open door. There are also many examples of people saved

because a door was closed. Less frequent, but nonetheless tragic, are those situations in which doors needed for escape were blocked or locked, resulting in dire consequences. Numerous *Code* requirements, particularly those contained in 7.2.1, address these concerns.

Some types of doors that are designed to prevent the spread of fire through wall openings for property protection purposes might be unsuitable for use in means of egress. Certain doors pose the potential for entrapment if they cannot be operated or personal injury if they are used; examples include various rolling-shutter and sliding doors. However, under limited conditions, certain horizontal sliding doors are permitted to be within the exit access path. For example, 7.2.1.4.1.8 is used by 39.2.2.2.7, 40.2.2.2.4, and 42.2.2.2.4 to permit existing sliding doors to be positioned within the exit access path of existing business, industrial, and storage occupancies if additional criteria are met. The provisions help to ensure that the door will be open when conditions in the door's vicinity are tenable for people movement, and closed once it is no longer safe for persons to seek egress via that exit access path.

See also 7.2.1.14 for a specialized form of sliding door that has desirable life safety features.

7.2.1.1.1 A door assembly in a means of egress shall conform to the general requirements of Section 7.1 and to the special requirements of 7.2.1. Such an assembly shall be designated as a door.

Paragraph 7.2.1.1.1 advises that the *Code* uses the term *door* to mean door assembly. Thus, wherever the *Code* refers to a rated door or fire door, it is referring to the entire door assembly. If any single component is not properly provided, installed, and functioning, the assembly is not a fire protection-rated assembly. For example, if a listed fire door leaf and frame are installed with positive latch and hinges but the required self-closing device is omitted, the assembly cannot be considered a fire door and is not considered to have any particular fire protection rating.

7.2.1.1.2 Every door and every principal entrance that is required to serve as an exit shall be designed and constructed so that the path of egress travel is obvious and direct. Windows that, because of their physical configuration or design and the materials used in their construction, have the potential to be mistaken for doors shall be made inaccessible to the occupants by barriers or railings.

The purpose of the barrier rails required by 7.2.1.1.2 is to prevent one from walking through a window. Such barriers are not required to comply with the requirements of 7.2.2.4 applicable to guards. For example, intermediate rails or balusters spaced to meet the 100-mm (4-in.) diameter sphere requirement of 7.2.2.4.5.3 are not needed. A simple barrier rail, without ornamental grille-like fill or closely spaced balusters, will adequately warn occupants to avoid walking into a glass wall or large windowpane.

7.2.1.1.3* For the purposes of Section 7.2, a building shall be considered to be occupied at any time it is open for general occupancy, any time it is open to the public, or at any other time it is occupied by more than 10 persons.

A.7.2.1.1.3 Although 7.2.1.1.3 and 7.2.1.5.1 permit locking of means of egress doors where a building is not considered occupied, the *Code* does not intend to permit occupants to be locked beyond their control in buildings or building spaces, except for detention and correctional occupancies and health care occupancies.

Many industrial, storage, and business occupancy buildings are never open to or accessible to the public; the only occupants are employees and authorized visitors. Therefore, the term *occupied* in 7.2.1.1.3 also includes the condition of being *open for general occupancy*. That is, the facility is *operating or functioning*.

The intent of permitting a building with 10 or fewer occupants to be considered unoccupied—if it is not open for general occupancy and not open to the public—is to allow small security details or small cleaning crews inside a building without applying all the *Code* requirements. This will allow doors to be locked and lights to be turned off without violating the *Code*. The limited number of occupants will use lights as they need them and then turn them off. In the case of security personnel, they will carry their own lights and keys. For example, see the criteria of 7.2.1.5.4 for making a key available to occupants, which is applicable to a special type of key-operated dead bolt lock.

The wording of A.7.2.1.1.3 reiterates that it is not the intent to allow people, no matter how few the number, to be locked in a building without a ready means of egress. Even in detention and correctional facilities, where locked doors are permitted, 24-hour staffing must be provided in sufficient numbers to start the release of locks necessary for emergency evacuation or rescue and initiate other necessary emergency actions within 2 minutes of alarm. See 22.7.1.1(2) and 23.7.1.1(2).

7.2.1.2 Width.

Door width measurements might be used in calculating egress capacity or in determining if a minimum door width requirement is met. Depending on the purpose for which the door width measurement is used, the allowable encroachments on width vary. See commentary to 7.2.1.2.2(3) and 7.2.1.2.3.3.

7.2.1.2.1* Egress Capacity Width. For purposes of calculating capacity, the width of doors shall be measured as follows:

- (1) For new swinging doors, only the width of the doorway when the door is open 90 degrees, as measured in accordance with 7.2.1.2.1(4) and 7.2.1.2.1(5), shall be included.
- (2) For other types of new doors, only the width of the doorway when the door is in the fully open position, as measured in accordance with 7.2.1.2.1(4) and 7.2.1.2.1(5), shall be included.
- (3) For any existing door installation, only the width of the doorway when the door is in the fully open position, as measured in accordance with 7.2.1.2.1(4) and 7.2.1.2.1(5), shall be included.
- (4) For all doors, projections not more than 90 mm (3½ in.) at each side of the doorway at a height of not more than 965 mm (38 in.) shall not be considered a reduction in egress capacity width.
- (5) For swinging doors, egress capacity width shall be measured between the face of the door and the stop.

A.7.2.1.2.1 Figure A.7.2.1.2.1(a) and Figure A.7.2.1.2.1(b) illustrate the method of measuring door width for purposes of calculating egress capacity.

7.2.1.2.2 Clear Width. Clear width shall be measured as follows:

- (1) At the narrowest point in the door opening
- (2) For swinging doors, between the face of the door and the stop
- (3) Without subtracting for the obstructions permitted by 7.2.1.2.3.2 and 7.2.1.2.3.3

The method of measuring clear width required by 7.2.1.2.2 is for purposes of determining the egress capacity of the door, not for meeting minimum door size requirements specified elsewhere in the Code. The egress capacity width will be less than the door leaf width, because deductions in width are made for the stops built into the door frame and for the encroachment created by the thickness of the door where its stile edge extends into the door opening.

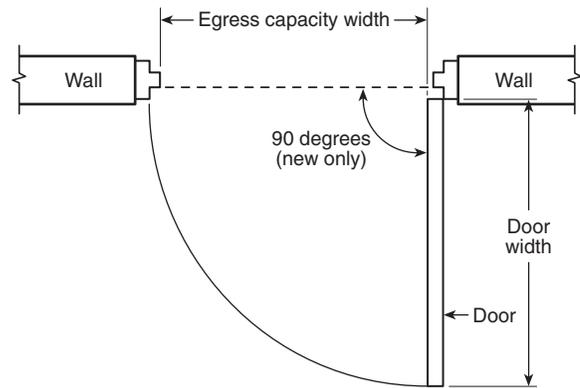

Figure A.7.2.1.2.1(a) Door Width—Egress Capacity.

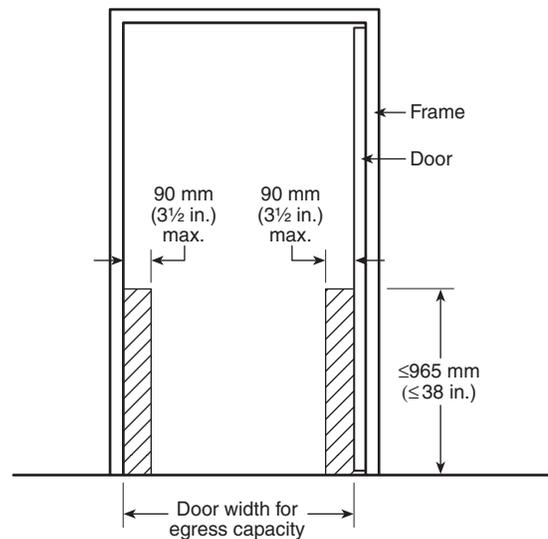

Figure A.7.2.1.2.1(b) Door Width—Egress Capacity with Permitted Obstructions.

The width measurement for new doors that can be opened at least 90 degrees is to be made with the door open 90 degrees. Doors that open more than 90 degrees—permitting the stile edge of the door to move out of the door opening—receive no additional width credit based on the inability of most people to push a door, especially a door with a self-closing device, open more than 90 degrees prior to moving through the door opening. Paragraph 7.2.1.2.1(3) exempts existing doors from the 90-degree criterion. Rather, the egress capacity width measurement for existing doors is made with the door in the fully open position—regardless of whether that position is less than or more than 90 degrees.

Exhibit 7.10 depicts a new door. It also might

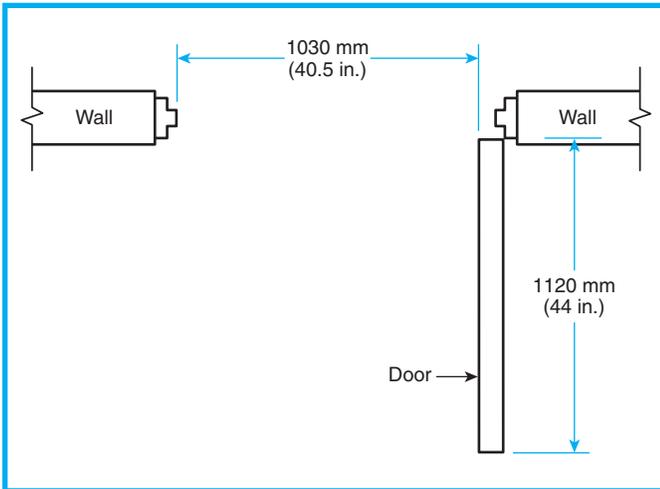

Exhibit 7.10 Egress capacity width for new door open 90 degrees and for existing door that opens 90 degrees.

apply to an existing door that opens exactly 90 degrees. The 1120-mm (44-in.) width door leaf provides approximately 1030 mm (40.5 in.) of egress capacity width, measured in accordance with 7.2.1.2.1(1). Note the reduction in egress width, as compared to the door leaf width, caused by the stop in the door frame at the left of the figure and the stile edge of the door at the right of the figure.

Exhibit 7.11 depicts an existing door that can be opened more than 90 degrees so that the stile edge of the door moves out of the framed door opening. The 1120-mm (44-in.) width door leaf provides approximately 1065 mm (42 in.) of egress capacity width, measured in accordance with 7.2.1.2.1(3). Note the reduction in egress width, as compared to the door leaf width, caused by the stops at each side of the door frame.

Exhibit 7.12 depicts an existing door that can be opened less than 90 degrees due to the presence of

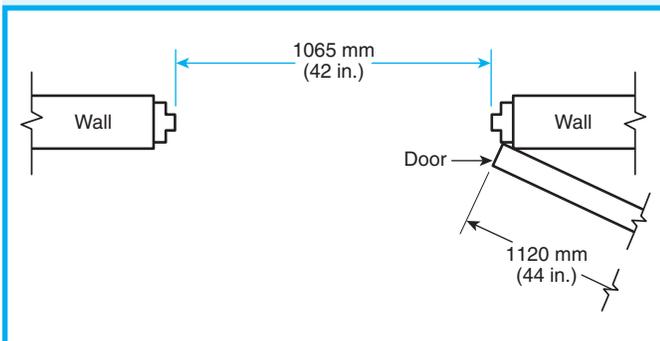

Exhibit 7.11 Egress capacity width for existing door that opens more than 90 degrees.

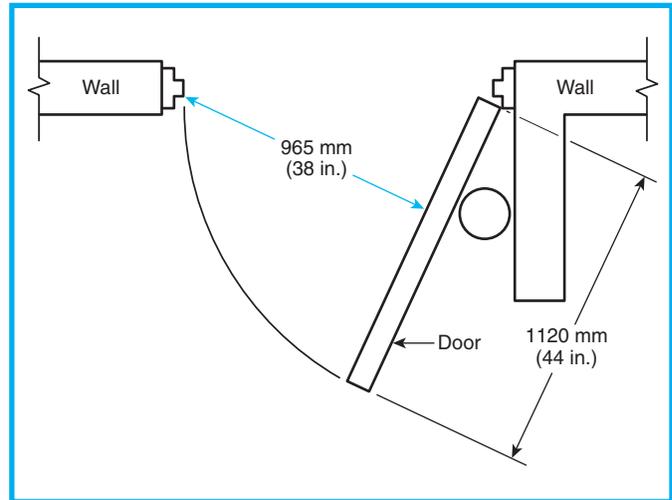

Exhibit 7.12 Egress capacity width for existing door that opens less than 90 degrees.

a pipe column that prevents the door from opening any further. The 1120-mm (44-in.) width door leaf provides approximately 965 mm (38 in.) of egress capacity width, measured in accordance with 7.2.1.2.1(3). Note the reduction in egress width, as compared to the door leaf width, caused by the stop at the left of the figure and the door leaf itself at the right of the figure. The 965-mm (38-in.) dimension is measured to the face of the door at a point where the intersection with the door creates a right angle, thus ensuring that the minimum width is measured.

The wording of 7.2.1.2.1(4) permits projections of not more than 90 mm (3½ in.) at each side of the door, provided that such projections do not extend above 965 mm (38 in.) in height. For example, for a 1015-mm-(40-in.-) width door opening, although there might be only 825 mm (33 in.) of true clear width between the projections near floor level, capacity calculations are permitted that assume an available clear width of 1015 mm (40 in.).

These concepts are illustrated in Figures A.7.2.1.2.1(a) and A.7.2.1.2.1(b).

7.2.1.2.3* Measurement.

A.7.2.1.2.3 Figure A.7.2.1.2.3(a) and Figure A.7.2.1.2.3(b) illustrate the method of measuring clear width for doors.

In cases where a chapter requires a door width, for example, of not less than 915 mm (36 in.), this requirement can be met by a door leaf of the minimum specified width if the term *clear width* does not appear as part of the minimum width requirement. A pair of cross-corridor doors subject to such a requirement would be judged under the following criteria:

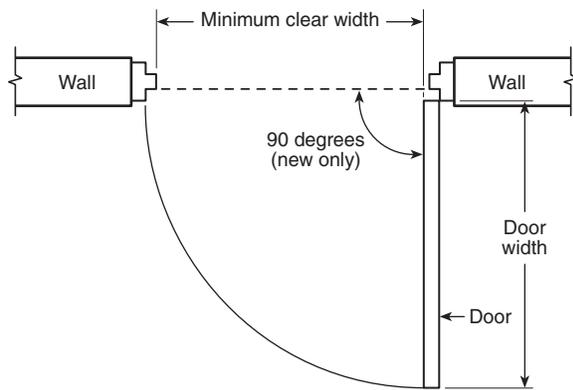

Figure A.7.2.1.2.3(a) Minimum Clear Width.

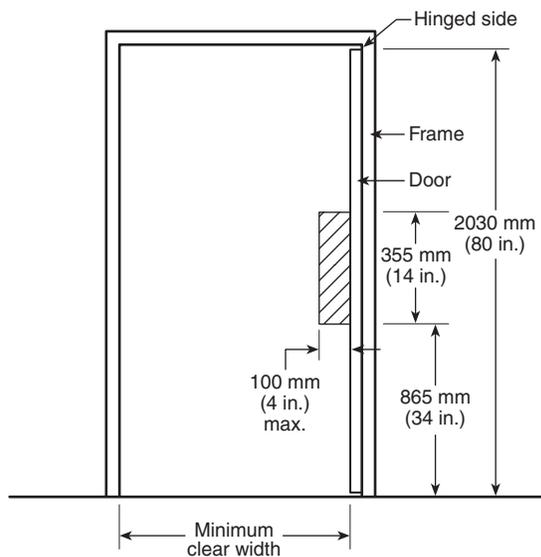

Figure A.7.2.1.2.3(b) Minimum Clear Width with Permitted Obstructions.

- (1) Each door leaf is required to be not less than 915 mm (36 in.) in width.
- (2) The pair of doors is required to provide sufficient, clear, unobstructed width (which will be less than the door leaf width measurement) to handle its assigned occupant load, based on a calculation using the appropriate egress capacity factor in Table 7.3.3.1.

Where swinging doors do not open at least 90 degrees, the clear width of the doorway should be measured between the face of the door and the stop.

It is not the intent to regulate projections above the 2030-mm (80-in.) height.

7.2.1.2.3.1 For purposes of determining minimum door width, the clear width shall be used unless door leaf width is specified.

7.2.1.2.3.2 For swinging doors, projections of not more than 100 mm (4 in.) into the doorway width on the hinge side shall not be considered reductions in width, provided that such projections are for purposes of accommodating panic hardware or fire exit hardware and are located not less than 865 mm (34 in.) above the floor.

7.2.1.2.3.3 Projections exceeding 2030 mm (80 in.) above the floor shall not be considered reductions in width.

Where clear width is to be used to judge whether a Code provision for minimum door width is met, no projections into the clear width within 865 mm (34 in.) of the floor are permitted. Thus, where 7.2.1.2.4 requires door openings to be at least 810 mm (32 in.) in clear width, that full clear width must be available near the floor to accommodate, for example, the width of a wheelchair and the wheelchair user’s arms and hands.

At heights above 865 mm (34 in.), encroachment on clear width is permitted only on the hinge side of the door opening, and then only if the projection into the clear width does not exceed 100 mm (4 in.). The allowance for the projection is intended to permit panic hardware or fire exit hardware—installed at least 100 mm (4 in.) above the minimum 760-mm (30-in.) mounting height—to encroach on clear width. The 100-mm (4-in.) encroachment allowance is likely to be insufficient to exempt the projections created by most hydraulic door closers. Note, however, that projections above the floor of more than 2030 mm (80 in.) are permitted. Thus, for many doors that exceed the minimum, nominal height of 2030 mm (80 in.), the projection created by a door closer is not an issue.

These concepts are illustrated in Figures A.7.2.1.2.3(a) and A.7.2.1.2.3(b).

7.2.1.2.4 Minimum Door Width. Door openings in means of egress shall be not less than 810 mm (32 in.) in clear width, unless one of the following conditions exists:

- (1) Where a pair of doors is provided, not less than one of the doors shall provide not less than an 810-mm (32-in.) clear width opening.
- (2) Exit access doors serving a room not exceeding 70 ft² (6.5 m²) and not required to be accessible to persons with severe mobility impairments shall be not less than 610 mm (24 in.) in door leaf width.
- (3) Doors serving a building or portion thereof not required to be accessible to persons with severe mobility impair-

ments shall be permitted to be 710 mm (28 in.) in door leaf width.

- (4) In existing buildings, the existing door leaf width shall be not less than 710 mm (28 in.).
- (5) Doors in detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23 shall not be required to comply with 7.2.1.2.4.
- (6) Interior doors in dwelling units as otherwise provided in Chapter 24 shall not be required to comply with 7.2.1.2.4.
- (7) A power-operated door leaf located within a two-leaf opening shall be exempt from the minimum 810-mm (32-in.) single-leaf requirement in accordance with 7.2.1.9.1.5.
- (8) Revolving doors as provided in 7.2.1.10 shall be exempt from the minimum 810-mm (32-in.) width requirement.

Generally, various doors are encountered as one travels the means of egress route. Each door opening must provide sufficient clear width to accommodate the number of people expected to pass through that doorway during emergency egress and must meet any absolute minimum widths specified by other provisions of the *Code*. The door width necessary to accommodate a specified number of persons is calculated from the occupant load served and the capacity factors applicable to level egress components, as provided in Table 7.3.3.1. Regardless of the occupant load served and the corresponding calculated minimum usable width required, new door openings generally are not permitted to be less than 810 mm (32 in.) in clear width. Note that a width of 810 mm (32 in.) permits the passage of wheelchairs; however, it might not be adequate for the normal use of the doorway for purposes other than emergency egress. Thus, door widths in excess of those required by the *Code* are often provided voluntarily for purposes of day-to-day function.

If a door in a new business occupancy is to serve 120 occupants, for example, the minimum clear door width calculated from the perspective of occupant load served would be 610 mm (24 in.). However, a door providing only 610 mm (24 in.) of clear width would not satisfy 7.2.1.2.4, which requires that, as a minimum, the door must provide 810 mm (32 in.) of clear width. Because more than one requirement affects door width, a comparison must be made between the calculated minimum width and the more arbitrary minimum width requirement of 7.2.1.2.4. Having performed the comparison, the number that results in the greater width—in this case, the 810 mm (32 in.)—must be used.

Where another *Code* section specifies a width

greater than 810 mm (32 in.), the greater width must be provided. Generally, the greater width is specified in terms of clear width. For example, in new health care occupancies, the minimum width for patient room doors and cross-corridor doors is 1055 mm (41½ in.) in clear width [see 18.2.3.6(1)]. The 1055-mm (41½-in.) minimum clear width requirement unintentionally connotes a precision and accuracy that one might expect resulted from a detailed research program; in reality, it represents an attempt to quantify the clear width realized when a typical 1120-mm (44-in.-) wide door leaf is swung to its fully open position. For many editions of the *Code*, new health care occupancies specified the required minimum as 1120 mm (44 in.) of door leaf width, not of clear opening. If a minimum 1120-mm (44-in.) door leaf had its swing restricted to not more than 90 degrees, it often would provide a clear width opening of less than the 1055 mm (41½ in.) currently required.

The exemptions of 7.2.1.2.4(1) through 7.2.1.2.4(8) modify the minimum 810-mm (32-in.) clear width requirement so as to recognize smaller door widths for the specific situations they address.

Paragraph 7.2.1.2.4(2) permits a small room, likely occupied by only a couple of people and not required to be accessible to people with severe mobility impairments, to use a 610-mm- (24-in.-) width door. This exemption does not specify clear width, so a minimum 610-mm (24-in.) wide door leaf would be sufficient.

Paragraph 7.2.1.2.4(3) also addresses doors serving spaces not required to be accessible to people with severe mobility impairments. In lieu of a room size, the exemption can be applied regardless of occupant load, but the door leaf width must be at least 710 mm (28 in.).

Earlier editions of the *Code* specified that no single door in a doorway is permitted to be less than 710 mm (28 in.) wide. To keep from automatically creating a situation of noncompliance where there had previously been compliance, 7.2.1.2.4(4) exempts existing buildings from the minimum 810-mm (32-in.) clear width requirement if the door width, that is, the leaf width, is at least 710 mm (28 in.).

For security and operations purposes, 7.2.1.2.4(5) permits detention and correctional facilities to have doors of smaller width. See Chapters 22 and 23.

Chapter 24 establishes that doors within dwelling units are within the *means of escape* and not the *means of egress*. It permits such doors, whether new or existing, to be a minimum of 710 mm (28 in.) in leaf width. Paragraph 7.2.1.2.4(6) recognizes this allowance.

It is the intent of the *Code* that a doorway not create a bottleneck in the means of egress. At times, another component of the means of egress might be larger than required, creating the illusion of a bottleneck at an appropriately sized doorway. However, a door opening with a width that is adequate for the occupant load served and with at least a 810-mm (32-in.) clear width is sufficient. A door serving a hallway often is not as wide as the hallway. This is illustrated in Exhibit 7.13. Because operational features of the occupancy, in addition to the occupant load, are considered in determining required corridor width, the corridor might be wider than the exit door serving the corridor. In this example of a new school, the corridor is required by 14.2.3.2 to be 1830 mm (72 in.) wide, as a minimum, and wider only if it serves more than 360 persons. The exit door is required by 7.2.1.2.4 to be 810 mm (32 in.) wide, as a minimum, and wider only if it serves more than 160 persons.

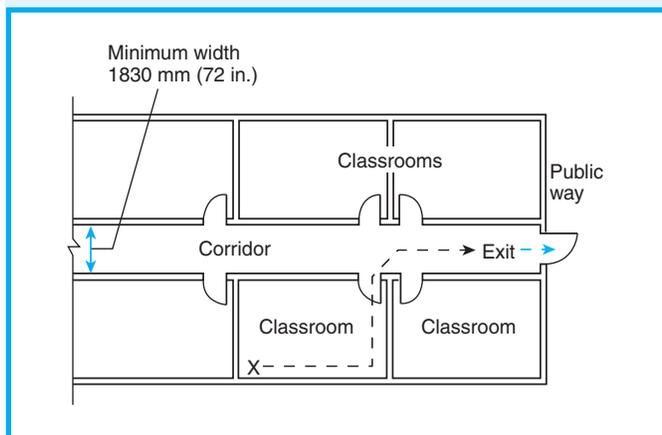

Exhibit 7.13 Exit door width and corridor width relationship.

In a health care facility, the corridor and doorway widths are usually much wider than the occupant load dictates. In this instance, the sizes of the corridor and door openings are governed by the necessity to move patients on gurneys. Patients are often connected to equipment and must be moved horizontally along the means of egress route.

Note that, since the 1997 edition, the *Code* no longer restricts door leaf width to a maximum of 1220 mm (48 in.). Provided that the door and its hardware are maintained in good working order, there is insufficient reason to limit the maximum width of a door.

7.2.1.3 Floor Level.

7.2.1.3.1 The elevation of the floor surfaces on both sides of a door shall not vary by more than 13 mm (½ in.).

7.2.1.3.2 The elevation of the floor surfaces required by 7.2.1.3.1 shall be maintained on both sides of the doorway for a distance not less than the width of the widest leaf.

7.2.1.3.3 Thresholds at doorways shall not exceed 13 mm (½ in.) in height.

7.2.1.3.4 Raised thresholds and floor level changes in excess of 6.3 mm (¼ in.) at doorways shall be beveled with a slope not steeper than 1 in 2.

7.2.1.3.5 In existing buildings where the door discharges to the outside or to an exterior balcony or exterior exit access, the floor level outside the door shall be permitted to be one step lower than that of the inside, but shall be not more than 205 mm (8 in.) lower.

7.2.1.3.6 In existing buildings, a door at the top of a stair shall be permitted to open directly at a stair, provided that the door does not swing over the stair and that the door serves an area with an occupant load of fewer than 50 persons.

The detailed dimensional tolerances specified for thresholds at door openings are intended to permit persons in wheelchairs to move easily through those openings. Arrangements meeting the criteria useful to persons with disabilities provide for the safe use of doors by other occupants.

In earlier editions, the *Code* permitted the floor level outside exterior doors to be one step—up to 205 mm (8 in.)—lower than the floor level inside the door. This was permitted to avoid blocking the outward swing of the door by a buildup of snow or ice. The requirements of 7.2.1.3.1 are practical for new construction because of the importance of avoiding tripping hazards and because other provisions of the *Code* require that the means of egress be maintained free of obstructions and protected from the weather, thus providing for the removal of snow or ice accumulations. Existing buildings continue to be permitted to use one exterior step.

Paragraph 7.2.1.3.6 recognizes an existing situation in which a door at the top of a stair opens directly at the stair without providing a level landing on the stair side of the door opening. In this case, however, the door swings away from the stair, rather than swinging over the stair. See Exhibit 7.14. This is permitted in existing buildings where the area served by the door has an occupant load of fewer than 50 persons. Paragraph 7.2.1.3.6 permits this situation as an exemption to the requirement that there be a level landing on each side of the door that is at least as deep in the direction of stair run as the door is wide. The wording of 7.2.1.3.6 is repeated as 7.2.2.3.2.5 for

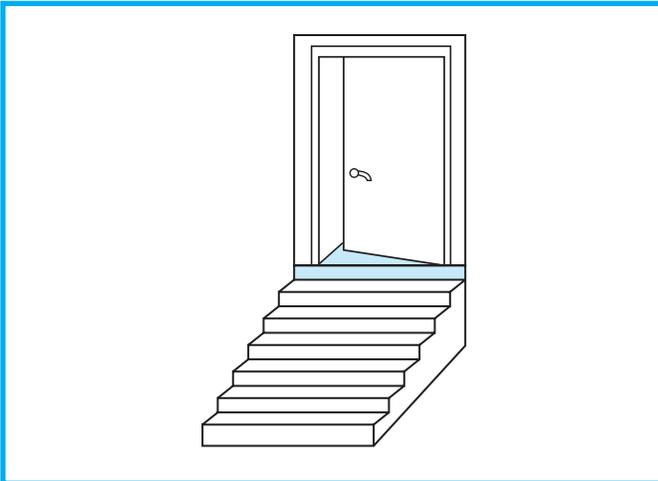

Exhibit 7.14 Door opening directly at the top of a stair, but not swinging over the stair.

consistency. Otherwise, the requirement that stairs have landings at door openings would apply without exemption.

The exemption permitted by 7.2.1.3.6 does not permit the dangerous practice of swinging the door out over the stair, because it would force a person climbing the stairs to reach for the door knob and back away by descending to a tread located a riser or two lower in order to pull the door open while attempting to maintain stability on the stair. Neither does the exemption permit another dangerous practice of opening a door directly at the bottom of a stair without providing a level landing on the stair side of the door opening. Such an action would force a person descending the stair to lean forward and downward to reach the latch release and then push the door open while standing on a tread located one or more risers above the base of the door while attempting to maintain stability on the stair.

7.2.1.4 Swing and Force to Open.

The provisions regulating the direction of door swing appear in Chapter 7 in 7.2.1.4.2, 7.2.1.4.3, and 7.2.4.3.7(1). Paragraph 7.2.1.4.2 requires a door serving a room or area with an occupant load of 50 or more persons to swing in the direction of egress travel. Paragraph 7.2.1.4.3 requires a door used in an exit enclosure or serving a high hazard contents area to swing in the direction of egress travel. Paragraph 7.2.4.3.7(1) requires a swinging fire door used in a horizontal exit to swing in the direction of egress

travel. If none of these three requirements applies, a door is permitted to swing against the direction of egress travel. See commentary following 7.2.1.4.2.

7.2.1.4.1* Any door in a means of egress shall be of the side-hinged or pivoted-swinging type, and shall be installed to be capable of swinging from any position to the full required width of the opening in which it is installed, unless otherwise specified in 7.2.1.4.1.1 through 7.2.1.4.1.8.

A.7.2.1.4.1 Where doors are subject to two-way traffic, or where their opening can interfere with pedestrian traffic, an appropriately located vision panel can reduce the chance of accidents.

Swinging doors in horizontal or vertical rolling partitions complying with the following should be permitted in a means of egress where the following criteria are met:

- (1) The door or doors comply with 7.2.1.4.
- (2) The partition in which the doors are mounted complies with the applicable fire protection rating and closes upon smoke detection or power failure at a speed not exceeding 230 mm/s (9 in./s) and not less than 150 mm/s (6 in./s).
- (3) The doors mounted in the partition are self-closing or automatic-closing in accordance with 7.2.1.8.

Paragraph 7.2.1.4.1 requires that doors within the means of egress be side-hinged or pivoted-swinging. These types of doors are most familiar to the general public, and their operation is readily understood.

Furthermore, 7.2.1.4.1 requires that the door be capable of swinging to the full required width of the opening. The required width is determined by two width considerations. The first consideration involves the width required for egress capacity purposes. For example, if a door in a business occupancy needs to accommodate 180 persons, the applicable capacity factor from Table 7.3.3.1 dictates that a 915-mm (36-in.) opening is to be provided. The second consideration involves the minimum clear width required regardless of occupant load served. For the business occupancy in question, the minimum clear width is specified in 7.2.1.2.4 as 810 mm (32 in.). The required width is the larger of the two widths—in this example, the 915 mm (36 in.) calculated from the egress capacity consideration.

7.2.1.4.1.1 Sliding doors in detention and correctional occupancies as provided in Chapter 22 and Chapter 23, shall be permitted.

7.2.1.4.1.2 Doors in dwelling units as provided in Chapter 24 shall be permitted.

7.2.1.4.1.3 Doors in residential board and care occupancies as provided in Chapter 32 and Chapter 33 shall be permitted.

Some occupancy chapters provide exemptions to the requirement that doors be of the side-hinged or pivoted-swinging type. As referenced in 7.2.1.4.1.1, detention and correctional occupancies allow certain sliding doors because swinging doors can become readily accessible weapons for use by residents against staff. Also, 7.2.1.4.1.2 and 7.2.1.4.1.3 advise that Chapters 24, 32, and 33, which apply to one- and two-family dwellings and residential board and care occupancies, do not require that doors be swinging. These exemptions recognize the smaller numbers of persons using doors within dwellings and the familiarity those occupants have with the operation of other door types, such as sliding doors.

7.2.1.4.1.4 Where permitted in Chapter 12 through Chapter 42, horizontal-sliding or vertical-rolling security grilles or doors that are part of the required means of egress shall be permitted, provided that they meet the following criteria:

- (1) Such grilles or doors shall remain secured in the fully open position during the period of occupancy by the general public.
- (2) On or adjacent to the grille or door, there shall be a readily visible, durable sign in letters not less than 25 mm (1 in.) high on a contrasting background that reads as follows: THIS DOOR TO REMAIN OPEN WHEN THE BUILDING IS OCCUPIED.
- (3) Doors or grilles shall not be brought to the closed position when the space is occupied.
- (4) Doors or grilles shall be operable from within the space without the use of any special knowledge or effort.
- (5) Where two or more means of egress are required, not more than half of the means of egress shall be equipped with horizontal-sliding or vertical-rolling grilles or doors.

Paragraph 7.2.1.4.1.4 allows horizontal sliding or vertical rolling security grilles or doors to be used in lieu of side-hinged or pivoted-swinging type doors, provided that the exception is specifically allowed by the applicable occupancy chapter. This exemption permits the type of security doors and grilles normally found in covered shopping mall buildings. Note that there is a difference between 7.2.1.4.1.4(1)

and 7.2.1.4.1.4(3). Paragraph 7.2.1.4.1.4(1) requires that the door be fully open when the space is occupied by the public, while 7.2.1.4.1.4(3) states that the door cannot be closed when the space is occupied. This allows the common practice of leaving the door partially closed at closing time and other times when restricting entry to the general public is desired. See the explanation of the term *occupied* in 7.2.1.1.3 and its commentary.

The following occupancies allow the use of horizontal sliding or vertical rolling doors complying with 7.2.1.4.1.4. See the referenced paragraphs for additional restrictions, if any, imposed by the occupancy chapter:

- (1) Assembly occupancies (12.2.2.2.2, 13.2.2.2.2)
- (2) Mercantile occupancies (36.2.2.2.6, 37.2.2.2.6)
- (3) Business occupancies (38.2.2.2.6, 39.2.2.2.6)

7.2.1.4.1.5 Horizontal-sliding doors complying with 7.2.1.14 shall be permitted.

Paragraph 7.2.1.4.1.5 recognizes the use of a special form of horizontal sliding door under detailed conditions. One of the characteristic features of this door is the operability in the direction of door travel when a specified force is applied in the direction of occupant travel. See also 7.2.1.14.

7.2.1.4.1.6 Where private garages, business areas, industrial areas, and storage areas with an occupant load not exceeding 10 contain only low or ordinary hazard contents, doors to such areas shall be exempt from the requirement of 7.2.1.4.1.

Paragraph 7.2.1.4.1.6 recognizes that many private garages, small businesses, and industrial and storage buildings typically have only an overhead rolling or horizontal sliding door and no side-hinged door. Provided the maximum 10-person occupant load is not exceeded and there are no high-hazard contents, such doors are allowed to substitute for side-hinged or pivoted-swinging doors.

7.2.1.4.1.7 Revolving doors complying with 7.2.1.10 shall be permitted.

Paragraph 7.2.1.4.1.7 cross-references the provisions of 7.2.1.10, which apply to revolving doors. If this

exemption did not exist, it might be assumed, incorrectly, that revolving doors violate the requirement for doors to be side-hinged or pivoted-swinging.

7.2.1.4.1.8 Existing fusible link–operated horizontal-sliding or vertical-rolling fire doors shall be permitted to be used as provided in Chapter 12 through Chapter 42.

Paragraph 7.2.1.4.1.8 legitimizes provisions of 39.2.2.2.7, 40.2.2.2.4, and 42.2.2.2.4 that permit existing fusible link–operated sliding doors to be positioned within the exit access of existing business, industrial, and storage occupancies if additional criteria are met. These provisions help to ensure that the door is open when conditions in the door’s vicinity are tenable for occupant movement and that it is closed once it is no longer safe for persons to seek egress via that exit access path.

7.2.1.4.2 Doors required to be of the side-hinged or pivoted-swinging type shall swing in the direction of egress travel where serving a room or area with an occupant load of 50 or more, except under the following conditions:

- (1) Doors in horizontal exits shall not be required to swing in the direction of egress travel where permitted by 7.2.4.3.7.1 or 7.2.4.3.7.2.
- (2) Smoke barrier doors shall not be required to swing in the direction of egress travel in existing health care occupancies as provided in Chapter 19.

Ideally, all doors in a means of egress would swing in the direction of egress travel. However, because of operational concerns, there are cases where door swing in the direction of egress travel is not desirable. For example, a classroom door that swings into a corridor serving as an exit access for several classrooms might open against another door or against the flow of people and possibly restrict the width available as corridor exit access. The *Code* recognizes this danger and permits the classroom/corridor door from a room with an occupant load of fewer than 50 persons to swing against the direction of egress travel. This provision limits the number of people using a door that swings against egress travel to that which is safe. The *Code* also recognizes similar constraints with regard to an exterior exit door; although such a door is considered an exit, the *Code* does not require that it swing in the direction of egress travel unless it serves 50 or more occupants.

Exhibit 7.15 illustrates considerations involved in evaluating door swing direction as addressed in

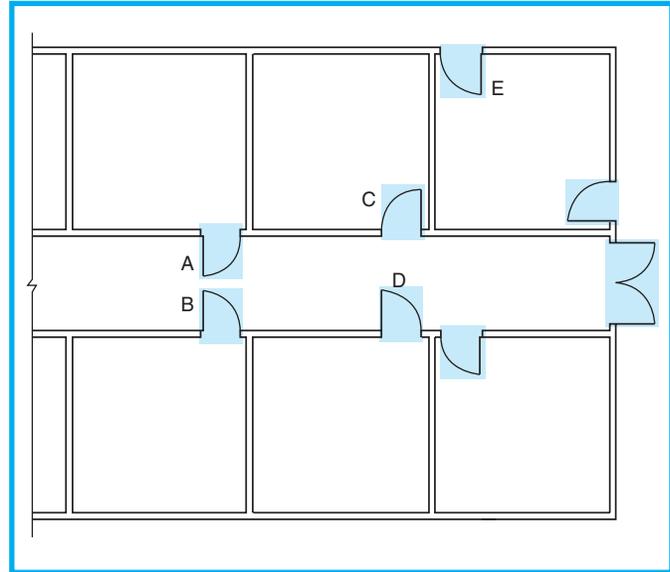

Exhibit 7.15 Door swing considerations.

7.2.1.4.2 and 7.2.1.4.3. Door C is permitted to swing back into the room if the room has an occupant load of fewer than 50 persons and does not have high hazard contents [see 7.2.1.4.3(2)]. Door D must swing in the direction of egress travel if the room has an occupant load of 50 or more. Door E, although it is an exit door, is not used in an exit enclosure [see 7.2.1.4.3(1)], so it is permitted to swing back into the room if the occupant load is less than 50 and the room does not have high hazard contents. Doors A and B are related to the provisions of 7.2.1.4.4. They open into the corridor directly opposite each other. Although this does not violate any *Code* provision, it is preferable that doors not be arranged to swing in a direction that blocks the use of the corridor when both are open.

Paragraph 7.2.1.4.2(1) recognizes that the provisions of 7.2.4.3.7 exempt doors in horizontal exits from having to swing in the direction of egress travel in accordance with specific allowances and conditions for existing health care occupancies and existing detention and correctional occupancies. For these occupancies, staff is expected to be able to control occupant movement at horizontal exit doors to prevent a crowd from pushing against a door that is arranged to open only by swinging back toward the occupants. See 7.2.4.3.7.1. Also see 7.2.4.3.7.2 for an exemption with applicability to any occupancy.

Paragraph 7.2.1.4.2(2) exempts smoke barrier doors from having to swing in the direction of egress travel in existing health care facilities. Such doors usually span the width of a corridor. Because existing

health care occupancies are permitted to have corridors as narrow as 1220 mm (48 in.), it might be impractical to install a pair of doors swinging in opposite directions. The single door recognized by the exception swings in the correct direction for occupants on one side and swings against the direction of egress travel for occupants on the other side. Because staff directs the egress movement necessary during an emergency, the direction of door swing problem is alleviated.

7.2.1.4.3 A door shall swing in the direction of egress travel under either of the following conditions:

- (1) Where the door is used in an exit enclosure, unless the door is the door of an individual living unit that opens directly into an exit enclosure
- (2) Where the door serves a high hazard contents area

Subparagraph 7.2.1.4.3(1) addresses the common design in apartment buildings in which doors from the exit enclosure into apartment units normally swing into the apartment units. This design is common in a three-story, single-exit, garden apartment. The swing of the door in this arrangement is not a significant concern. The exemption also addresses another situation common to hotels where guest room doors frequently open directly into an exit enclosure created to enclose a formerly open stair. Because it is often necessary to use part of the corridor to create a stair landing for the newly enclosed exit stair, the exception offers some relief without compromising safety.

Per 7.2.1.4.3(2), doors to hazardous contents areas must swing in the direction of egress travel. A conflict sometimes arises between this requirement and the desire of those responsible for explosion control—who prefer that doors to areas subject to explosion be required to swing inward to impede spreading the effects of a blast to adjacent rooms and spaces. In new construction, this conflict can usually be resolved if the hazardous contents area can be located on an outside wall of the main building; the required egress doors then open directly to the outside—which is desirable for life safety. This arrangement is also favorable for explosion relief, because it easily allows the doors to swing outward. Subsequently, convenience doors that are not required for egress and that are positioned in partitions separating the hazardous area from the remainder of the building can be permitted to swing toward the hazardous area to help contain the explosion, if so desired. In existing situa-

tions, or where the hazardous area must be located internal to a building and away from exterior walls, the conflict is not easily resolved. The authority having jurisdiction needs to work with the building owner, insurer, and other involved parties to determine how best to reduce the exposure hazard while adequately providing needed life safety to those who work in the hazardous area. See also Section 7.11.

7.2.1.4.4* During its swing, any door in a means of egress shall leave not less than one-half of the required width of an aisle, a corridor, a passageway, or a landing unobstructed and shall project not more than 180 mm (7 in.) into the required width of an aisle, a corridor, a passageway, or a landing, when fully open, unless both of the following conditions are met:

- (1) The door provides access to a stair in an existing building.
- (2) The door meets the requirement that limits projection to not more than 180 mm (7 in.) into the required width of a stair or landing when the door is fully open.

A.7.2.1.4.4 The requirement of 7.2.1.4.4 is not intended to apply to the swing of cross-corridor doors such as smoke barrier doors and horizontal exits.

Doors capable of swinging a full 180 degrees, so that they rest flat against the wall in which the door opening is installed, have a greater utility than doors capable of swinging only 90 degrees. The 180-degree swinging door can be fully opened into a corridor without significant intrusion on corridor width. The 90-degree swinging door, however, might have to open into an unusually wide corridor, be set into an alcove, or otherwise be recessed so as not to exceed the maximum encroachment allowed by 7.2.1.4.4.

Note that 7.2.1.4.4 requires that, during its swing, a door must leave unobstructed at least one-half of the required width of a corridor. Note that this requirement is concerned with the required corridor width, which is not necessarily the same as the actual width. For example, in a corridor that is required to be 1120 mm (44 in.) wide but that is voluntarily constructed to be 1420 mm (56 in.) wide, an 865-mm-(34-in.-) wide door—one that provides the minimum 810-mm (32-in.) clear width required by 7.2.1.2.4—would swing to encroach on 865 mm (34 in.) of the corridor width. Although this encroachment is more than one-half of the *actual* corridor width, it does leave one-half of the *required* corridor width [560 mm (22 in.)] unobstructed. Such an arrangement meets the requirement of 7.2.1.4.4.

Doors that swing within a recessed pocket of the corridor so as not to protrude into the required corridor width provide the best arrangement for clear passage through an exit access corridor. Doors that swing 180 degrees so that they come to rest against a wall and do not extend into more than 180 mm (7 in.) of required corridor width provide an acceptable arrangement. A door that swings 90 degrees so that it comes to rest in the path of travel is considered not to encroach excessively on the exit access corridor width if not more than 180 mm (7 in.) of the required width of the corridor remains obstructed. Additionally, any door swinging into the corridor must leave at least one-half of the required corridor width unobstructed during its entire swing. See Exhibit 7.16.

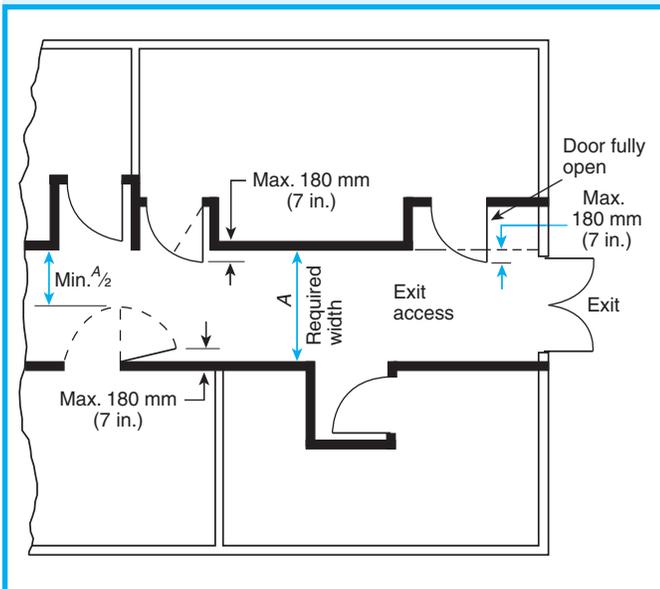

Exhibit 7.16 Door swing into a corridor.

Doors serving as an entrance into an enclosed stair should not unduly block the stair landing or the stairs. Ideally, the door would not reduce the required width either during its swing or while at rest. However, the Code does allow encroachment on the stair landing as shown in Exhibit 7.17. For most stairs, 7.2.2.2.1 requires a 1120-mm (44-in.) clear width. In cases such as these, the $B \geq A/2$ rule shown in Exhibit 7.17 would require that the clearance between the leading edge of the opening door and stair newel post be at least 560 mm (22 in.). However, where the total occupant load of all floors served by the stair is fewer than 50 persons, 7.2.2.2.1 permits a 915-mm-(36-in.-) wide stair; in this case, the $B \geq A/2$ rule would require that the clearance between the leading

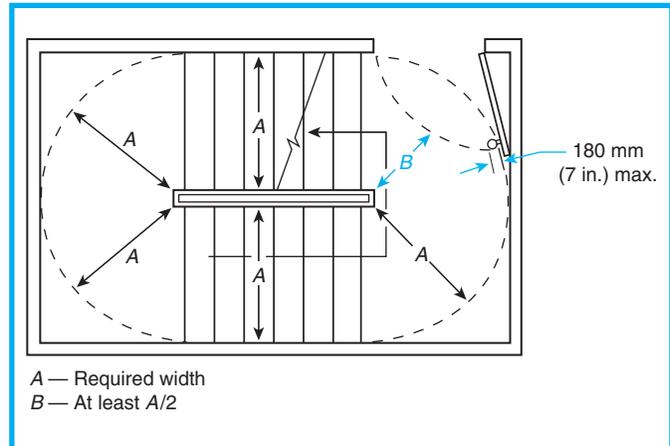

Exhibit 7.17 Minimum required unobstructed clearance with door encroaching on landing in new buildings.

edge of the opening door and stair newel post be at least 455 mm (18 in.).

An acceptable arrangement for a door opening onto a stair landing in an existing building is shown in Exhibit 7.18. In lieu of a $B \geq A/2$ rule, existing stairs are not required to maintain given clearance between the leading edge of the opening door and stair newel post. However, the maximum 180-mm (7-in.) encroachment when the door is fully open still applies.

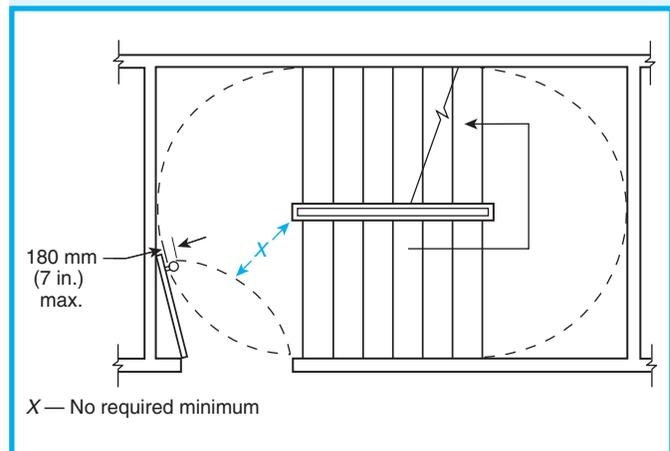

Exhibit 7.18 Encroachment during door swing not limited in existing buildings.

7.2.1.4.5 The forces required to fully open any door manually in a means of egress shall not exceed 67 N (15 lbf) to release the latch, 133 N (30 lbf) to set the door in motion, and 67 N (15 lbf) to open the door to the minimum required width, unless otherwise specified in 7.2.1.4.5.2 through 7.2.1.4.5.5.

7.2.1.4.5.1 The forces specified in 7.2.1.4.5 shall be applied to the latch stile.

7.2.1.4.5.2 Opening forces for interior side-hinged or pivoted-swinging doors without closers shall not exceed 22 N (5 lbf).

7.2.1.4.5.3 The opening force for existing doors in existing buildings shall not exceed 222 N (50 lbf) applied to the latch stile.

7.2.1.4.5.4 The opening forces for horizontal sliding doors in detention and correctional occupancies shall be as provided in Chapter 22 and Chapter 23.

7.2.1.4.5.5 The opening forces for power-operated doors shall be as provided in 7.2.1.9.

The *Code* recognizes that several movements are necessary to move a door from its closed to its fully open position. Paragraph 7.2.1.4.5 identifies each of those movements and limits the force needed to accomplish each. The force required to unlatch the door is limited to 67 N (15 lbf); the force necessary to start the door in motion, or to overcome its inertia, is limited to not more than 133 N (30 lbf); and the force necessary to move the door to its required open position is limited to not more than 67 N (15 lbf).

Care must be taken to ensure that the 133 N (30 lbf) needed to overcome the inertia of a door in a means of egress is not exceeded for doors opening into pressurized stairs. The pressure necessary to protect the stair often might be such that 133 N (30 lbf) is insufficient to open the door. The use of barometric relief dampers or other pressure-regulating methods might be required. See NFPA 92A, *Recommended Practice for Smoke-Control Systems*⁴.

A person with a severe mobility impairment, such as someone who uses a wheelchair, might find it difficult or impossible to exert even the 67 N (15 lbf) specified by 7.2.1.4.5. Specification of a lower operating force for self-closing doors might adversely affect the door closer's ability to perform its intended function of returning an open door to the fully closed and latched position. For interior side-hinged or pivoted-swinging doors without closers, no conflict exists between the needs of a closer and those of a person with physical disabilities. Therefore, 7.2.1.4.5.2 specifies that such doors be operable when no more than 22 N (5 lbf) is applied at the latch stile.

Circumstances such as wet floors, smooth-soled shoes, and light body weight can render many people incapable of exerting 222 N (50 lbf) horizontally. Therefore, the maximum 222-N (50-lbf) operating re-

quirement of earlier editions of the *Code* remains applicable only to existing doors via the provisions of 7.2.1.4.5.3.

Paragraphs 7.2.1.4.5.4 and 7.2.1.4.5.5 address special situations where the operating force requirements of 7.2.1.4.5 cannot be applied. For horizontal sliding doors in detention and correctional occupancies, see 22.2.11.5 and 23.2.11.5. For requirements specific to power-operated doors, see 7.2.1.9.

7.2.1.4.6 Screen doors and storm doors used in a means of egress shall be subject to the requirements for direction of swing that are applicable to other doors used in a means of egress.

Various functional arrangements of screen or storm doors can be provided without allowing a door to swing against the direction of egress travel. A screen or storm door might be permitted to be used in proximity to a doorway with an ordinary door by providing a vestibule of sufficient size to allow the inner door to swing outward without interfering with the operation of the door at the outer end of the vestibule. See Exhibit 7.19.

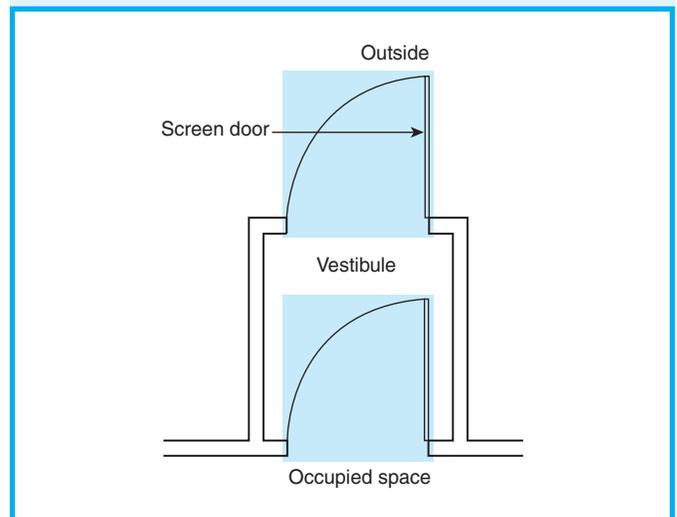

Exhibit 7.19 Arrangement of vestibule leading to screen door complying with 7.2.1.4.6.

7.2.1.5 Locks, Latches, and Alarm Devices.

An increase in thefts, muggings, and similar crimes has led to the practice of providing extra security on

exit doors and the exit access doors to which they lead. Such a practice, particularly where doors to exit stairs and exit discharges are involved, is an open invitation to tragedy in the event of fire or other emergency. The provisions of 7.2.1.5 are aimed at preventing locked doors in means of egress or any other unnecessary interference with the orderly movement of people through doors in the event of fire. The *Code* has attempted to accomplish this objective while maintaining features that are essential to security within the building.

A study of structural fires reported to U.S. fire departments between 1981 and 1985 found that an average of 117 fire deaths a year involved locks or gates that prevented escape.⁵ Most of these deaths occurred in fires in residential occupancies. The report also described a number of incidents, including those that follow.

In a Texas dwelling fire, seven people died when a space heater ignited a sofa. Two of the adults who died were overcome while they struggled to unlock the dead bolt lock on the front door and the security bars.

In another Texas dwelling fire, three people died when a bedridden woman accidentally ignited her bedding with a cigarette. The other two victims died while trying to escape past burglar bars, double-cylinder dead bolt locks, and a security bar on a sliding glass door.

The report also found that makeshift security arrangements, such as windows that had been nailed shut, were factors in more multiple-fatality fires than in cases where more expensive security devices such as security bars and gates were used. The conflict between some security provisions and sound fire safety practices takes many forms. Also see Supplements 1 and 6.

The requirement that doors be easily openable from the egress side is consistent with the concept that all components in the means of egress must be under the control of the occupants. This requirement prohibits the use of key locks or hard-to-use devices, such as door handles or latches covered with glass that has to be broken. Where panic hardware or fire exit hardware is used, no device that might interfere with its operation can be used; however, this does not prevent the use of alarm connections that indicate that the door is in use.

Requirements for doors leading to exits also apply to doors that open to roofs where exit stairs terminate at a recognized roof exit and to exit discharge doors leading to the street or other public way.

7.2.1.5.1 Doors shall be arranged to be opened readily from the egress side whenever the building is occupied.

7.2.1.5.2 Locks, if provided, shall not require the use of a key, a tool, or special knowledge or effort for operation from the egress side.

Paragraph 7.2.1.5.1 establishes the principle that when a building is occupied, doors must be able to be opened easily from the side from which egress is to be made. Paragraph 7.2.1.1.3 defines *occupied* for the purpose of this requirement. Paragraph 7.2.1.5.2 prohibits the installation of locks that require the use of a key to open the door from the inside.

7.2.1.5.3 The requirements of 7.2.1.5.1 and 7.2.1.5.2 shall not apply where otherwise provided in Chapter 18 through Chapter 23.

Paragraph 7.2.1.5.3 cross-references the provisions applicable to health care occupancies and detention and correctional occupancies where doors locked against egress by building occupants are permitted under specific conditions. For examples, see 18.1.1.1.5, 18.2.2.2.2(1), and 18.2.2.2.2(2), 18.2.2.2.4(1), 18.2.2.2.5, and similar provisions in Chapter 19. Also see 22.2.11.2 and 22.2.11.6 through 22.2.11.10, and similar provisions in Chapter 23.

7.2.1.5.4 Exterior doors shall be permitted to have key-operated locks from the egress side, provided that the following criteria are met:

- (1) This alternative is permitted in Chapter 12 through Chapter 42 for the specific occupancy.
- (2) A readily visible, durable sign in letters not less than 25 mm (1 in.) high on a contrasting background that reads as follows is located on or adjacent to the door: THIS DOOR TO REMAIN UNLOCKED WHEN THE BUILDING IS OCCUPIED.
- (3) The locking device is of a type that is readily distinguishable as locked.
- (4) A key is immediately available to any occupant inside the building when it is locked.

7.2.1.5.5 The alternative provisions of 7.2.1.5.4 shall be permitted to be revoked by the authority having jurisdiction for cause.

Paragraph 7.2.1.5.4 is provided for key-operated locks under four conditions—one of which is that the

appropriate occupancy chapter must specifically allow use of the exemption. Compliance with 7.2.1.5.4(3), which requires that the locking device be of a type readily distinguishable as locked, is to be judged by the authority having jurisdiction. Locks specifically designed to meet this requirement often have an indicating window mechanism that displays the word *open* when the device is in the unlocked position and displays the word *locked* when the device is in the locked position.

In permitting up to 10 persons in a locked building, the *Code* does not dismiss them as unimportant. The *Code* recognizes that there are instances where a building must be occupied by security personnel or by janitorial crews when it is locked. Such persons are generally familiar with the premises, and the *Code* requires that they have keys available for egress when necessary. Also see commentary following A.7.2.1.1.3.

The following occupancies allow the use of the key-operated lock addressed by 7.2.1.5.4. Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced within parentheses. For example, in new assembly occupancies, use of a key-operated lock is restricted to the main exit of a building with an occupant load of not more than 500 persons. In addition, the main exit of the building is required to consist of a single door or single pair of doors, and any latch on this door(s) is required to be released by panic hardware.

The occupancies allowing the use of the key-operated lock addressed in 7.2.1.5.4 are as follows:

- (1) Assembly occupancies (12.2.2.2.4, 13.2.2.2.4)
- (2) Mercantile occupancies (36.2.2.2.2, 37.2.2.2.2)
- (3) Business occupancies (38.2.2.2.2, 39.2.2.2.2)

7.2.1.5.6 Where permitted in Chapter 12 through Chapter 42, key operation shall be permitted, provided that the key cannot be removed when the door is locked from the side from which egress is to be made.

Paragraph 7.2.1.5.6 permits the “captive key” hardware, as is permitted in lodging and rooming houses via the provisions of 26.2.3.6. The captive key lock has the potential for misuse and must be used carefully. The design of the lock is such that an occupant could unlock the door from the inside, thus freeing the key; move through the door, taking the key to the outside; lock the door from the outside; and leave the property—potentially leaving others locked in the building. Thus, this lock is permitted limited use within the occupancy chapters.

7.2.1.5.7* Every door in a stair enclosure serving more than four stories, unless permitted by 7.2.1.5.7.2, shall meet one of the following:

- (1) Re-entry from the stair enclosure to the interior of the building shall be provided.
- (2) An automatic release that is actuated with the initiation of the building fire alarm system shall be provided to unlock all stair enclosure doors to allow re-entry.
- (3) Selected re-entry shall be provided in accordance with 7.2.1.5.7.1.

A.7.2.1.5.7 It is intended that the re-entry provisions apply only to enclosed exit stairs, not to outside stairs. This arrangement makes it possible to leave the stairway at such floor if the fire renders the lower part of the stair unusable during egress or if the occupants seek refuge on another floor.

Every door in a stair enclosure serving more than four stories in a new building [see 7.2.1.5.7.2(1)] must be arranged to permit re-entry into the building. However, the *Code* recognizes the need for varying degrees of security and does specify some equivalent alternatives. Stairway doors are permitted to be locked to the stairwell side if arranged to unlock automatically upon initiation of the fire alarm system.

7.2.1.5.7.1 Doors on stair enclosures shall be permitted to be equipped with hardware that prevents re-entry into the interior of the building, provided that the following criteria are met:

- (1) There shall be not less than two levels where it is possible to leave the stair enclosure to access another exit.
- (2) There shall be not more than four stories intervening between stories where it is possible to leave the stair enclosure to access another exit.
- (3) Re-entry shall be possible on the top story or next-to-top story that allows access to another exit.
- (4) Doors allowing re-entry shall be identified as such on the stair side of the door.
- (5) Doors not allowing re-entry shall be provided with a sign on the stair side indicating the location of the nearest door, in each direction of travel, that allows re-entry or exit.

Paragraph 7.2.1.5.7.1 permits some stair enclosure doors, regardless of occupancy, to be locked to prevent re-entry on selected floors. In such instances, there must be at least two levels with unlocked doors providing a way out of the stairway, one of which must be the top floor or the next to top floor; the

other is usually the door at the level of exit discharge. Because the *Code* prohibits more than four floors between floors that provide a way out of the stairway, stair enclosures serving more than six or seven stories must have more than two unlocked re-entry points. This arrangement provides flexibility in buildings that, perhaps for security reasons, need to prevent re-entry on certain floors, while at the same time ensuring that one can re-enter the building without having to travel up or down too many flights of stairs. See Exhibit 7.20. Any door providing a way out of the stair enclosure must be identified as such on the stairwell side.

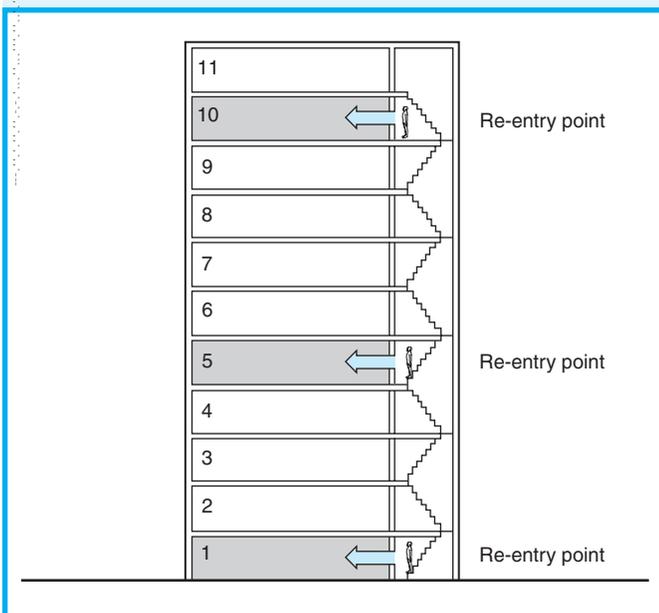

Exhibit 7.20 Stairway re-entry option.

7.2.1.5.7.2 The requirement of 7.2.1.5.7 shall not apply to the following:

- (1) Existing installations as permitted in Chapter 12 through Chapter 42
- (2) Stair enclosures serving a building permitted to have a single exit in accordance with Chapter 11 through Chapter 42
- (3) Stair enclosures in health care occupancies where otherwise provided in Chapter 18
- (4) Stair enclosures in detention and correctional occupancies where otherwise provided in Chapter 22

Paragraph 7.2.1.5.7.2(2) recognizes that re-entry in buildings permitted to have a single exit is not neces-

sary. In most single-exit buildings, the doors from the stairway open directly into the occupant space. Most of the single-exit buildings recognized by the occupancy chapters are no more than four stories in height and are exempt from the stairwell re-entry provisions via the base paragraph of 7.2.1.5.7.

7.2.1.5.8 If a stair enclosure allows access to the roof of the building, the door to the roof either shall be kept locked or shall allow re-entry from the roof.

Paragraph 7.2.1.5.8 was written to prevent building occupants from being trapped on a roof by a locked door that does not permit re-entry into the building. If security concerns, for example, dictate that rooftop doors are to be locked to the outside, then the doors also need to be locked to the inside to prevent unauthorized persons from going to the roof and becoming trapped. Note that there is no requirement that stair enclosure doors provide rooftop access. Heroic helicopter rescues from rooftops of burning buildings are Hollywood movie illusions that seldom happen in real life.

7.2.1.5.9* A latch or other fastening device on a door shall be provided with a releasing device that has an obvious method of operation and that is readily operated under all lighting conditions.

A.7.2.1.5.9 Examples of devices that might be arranged to release latches include knobs, levers, and panic bars. This requirement is permitted to be satisfied by the use of conventional types of hardware, whereby the door is released by turning a lever, knob, or handle or by pushing against a panic bar, but not by unfamiliar methods of operation such as a blow to break glass. The operating devices should be capable of being operated with one hand and should not require tight grasping, tight pinching, or twisting of the wrist to operate.

7.2.1.5.9.1 The releasing mechanism for any latch other than existing installations shall be located not less than 865 mm (34 in.), and not more than 1220 mm (48 in.), above the finished floor.

7.2.1.5.9.2 The releasing mechanism shall open the door with not more than one releasing operation, unless otherwise specified in 7.2.1.5.9.3 and 7.2.1.5.9.4.

Paragraph 7.2.1.5.9 requires that, where a latch or other similar device is provided, the method of opera-

tion of its releasing device must be obvious, even in the dark. The intention of this requirement is that the method of release be one that is familiar to the average person. Generally, a two-step release, such as a knob and an independent slide bolt, is not acceptable. In most occupancies, it is important that a single action unlatch the door. Furthermore, 7.2.1.5.9.1 specifies that the latch release mechanism be located at least 865 mm (34 in.) and not more than 1220 mm (48 in.) above the floor, so that the latch release is located in a position that is neither too low nor too high to be reached by persons in wheelchairs. The maximum mounting height for the latch release also helps to ensure that children can reach the latch. Note that the minimum mounting height is a new *Code* requirement; it is not applicable to existing installations.

7.2.1.5.9.3* Egress doors from individual living units and guest rooms of residential occupancies shall be permitted to be provided with devices, including automatic latching devices, that require not more than one additional releasing operation, provided that such device is operable from the inside without the use of a key or tool and is mounted at a height not exceeding 1220 mm (48 in.) above the finished floor.

A.7.2.1.5.9.3 Examples of devices that, when used with a latch, can be arranged to require not more than one additional releasing operation include night latches, dead bolts, and security chains.

7.2.1.5.9.4 Existing security devices permitted by 7.2.1.5.9.3 shall be permitted to have two additional releasing operations.

7.2.1.5.9.5 Existing security devices permitted by 7.2.1.5.9.3, other than automatic latching devices, shall be located not more than 1525 mm (60 in.) above the finished floor.

Paragraphs 7.2.1.5.9.3 and 7.2.1.5.9.4 recognize the use, in residential living units and hotel guest rooms, of one additional device requiring release in new construction and two additional devices requiring release in existing installations. The exemption in 7.2.1.5.9.5 allows an existing condition to continue where a hotel room door, for example, has hardware arranged such that one operation releases the security chain or bar (that is, night latch), another operation releases the dead bolt (usually via a thumb turn-type knob), and a third operation releases the door latch, usually by turning the door knob or op-

erating the door lever. However, in new installations, if a night latch or security device is installed, one operation would release the security device and a second operation, such as turning the door knob or operating the door lever, would have to release both the dead bolt and normal door latch.

Also, the *Code* prohibits supplemental automatic latching security devices from being located more than 1220 mm (48 in.) above the floor, even in existing buildings (see 7.2.1.5.9.5). This prohibition is intended to prevent children and wheelchair users from being trapped in a space when an automatic latching device that is located above reach range engages, locking the door. Existing security devices that must be physically engaged are permitted in locations not more than 1525 mm (60 in.) above the floor, based on the assumption that the person engaging such a device is present to disengage it when needed.

7.2.1.5.10 Where pairs of doors are required in a means of egress, one of the following criteria shall be met:

- (1) Each leaf of the pair shall be provided with a releasing device that does not depend on the release of one door before the other.
- (2) Approved automatic flush bolts shall be used and arranged such that the following criteria are met:
 - (a) The door leaf equipped with the automatic flush bolts shall have no doorknob or surface-mounted hardware.
 - (b) Unlatching of any leaf shall not require more than one operation.

This requirement of 7.2.1.5.10(1) for independent releasing hardware applies only to pairs of doors in a common door opening where both door leaves are required for means of egress. If a second leaf is provided for a reason other than required egress, that leaf can have a releasing mechanism that requires the egress leaf to be released first. However, in such a case, the leaf not used for egress must be arranged so as not to be mistaken for the egress door.

Paragraph 7.2.1.5.10(2) allows a pair of doors—both a part of the required means of egress—to be placed within a common frame, whereby one leaf has no visible releasing hardware but has approved automatic flush bolts that release that leaf when the other leaf, which has visible hardware, is released. Therefore, the user is directed to the leaf with releasing hardware and disengages the latch on that leaf, and the other leaf automatically unlatches to allow its use if pushed in the direction of door travel.

7.2.1.5.11* Devices shall not be installed in connection with any door on which panic hardware or fire exit hardware is required where such devices prevent or are intended to prevent the free use of the door for purposes of egress, unless otherwise provided in 7.2.1.6.

A.7.2.1.5.11 Examples of devices prohibited by this requirement include locks, padlocks, hasps, bars, chains, or combinations thereof.

It is not the intent of 7.2.1.5.11 to require panic hardware or fire exit hardware; that requirement is made by the various occupancy chapters. Rather, this paragraph requires that where panic hardware or fire exit hardware is installed, no device or arrangement is to interfere with its intended function. The intended function is the release of the latch when pressure—such as that exerted by persons crushing up against the door—is applied to the bar or pad extending across the majority of the door width.

7.2.1.6 Special Locking Arrangements.

The special locking arrangements described in 7.2.1.6 include delayed-egress locks and access-controlled egress doors. See 7.2.1.6.1 and 7.2.1.6.2.

7.2.1.6.1 Delayed-Egress Locks. Approved, listed, delayed-egress locks shall be permitted to be installed on doors serving low and ordinary hazard contents in buildings protected throughout by an approved, supervised automatic fire detection system in accordance with Section 9.6 or an approved, supervised automatic sprinkler system in accordance with Section 9.7, and where permitted in Chapter 12 through Chapter 42, provided that the following criteria are met:

- (1) The doors shall unlock upon actuation of one of the following:
 - (a) An approved, supervised automatic sprinkler system in accordance with Section 9.7
 - (b) Any heat detector
 - (c) Not more than two smoke detectors of an approved, supervised automatic fire detection system in accordance with Section 9.6
- (2) The doors shall unlock upon loss of power controlling the lock or locking mechanism.
- (3)* An irreversible process shall release the lock within 15 seconds, or 30 seconds where approved by the authority having jurisdiction, upon application of a force to the release device required in 7.2.1.5.9 under the following conditions:
 - (a) The force shall not be required to exceed 67 N (15 lbf).
 - (b) The force shall not be required to be continuously applied for more than 3 seconds.
 - (c) The initiation of the release process shall activate an audible signal in the vicinity of the door.
 - (d) Once the door lock has been released by the application of force to the releasing device, relocking shall be by manual means only.

A.7.2.1.6.1(3) It is not the intent to require a direct physical or electrical connection between the door release device and the lock. It is the intent to allow door movement initiated by operating the door release device required in 7.2.1.5.9 as one option to initiate the irreversible process.

Several factors need to be considered in approving an increase in delay time from 15 seconds to 30 seconds. Some of those factors include occupancy, occupant density, ceiling height, fire hazards present, fire protection features provided, and the location of the delayed egress locks. An example of a location where the increase on delay time might not be approved is at an exit stair discharge door.

- (4)* A readily visible, durable sign in letters not less than 25 mm (1 in.) high and not less than 3.2 mm (in.) in stroke width on a contrasting background that reads as follows shall be located on the door adjacent to the release device:

PUSH UNTIL ALARM SOUNDS
DOOR CAN BE OPENED IN 15 SECONDS

A.7.2.1.6.1(4) In the event that the authority having jurisdiction has permitted increased operation time, the sign should reflect the appropriate time.

Delayed-egress locks prevent a door from being opened for 15 or 30 seconds under either nonemergency conditions or those encountered very early in a fire or similar emergency. Delayed-egress locks are to be used only where specifically permitted by the appropriate occupancy chapter. Their use is further limited to buildings protected throughout by either an approved, supervised automatic fire detection system or an approved, supervised automatic sprinkler system. In addition, 7.2.1.6.1(1) requires that the locking devices unlock upon activation of that corresponding detection or sprinkler system. The required detection system provides early warning; the alternately required sprinkler system provides early control of the fire—each to the degree necessary to make tolerable the delay experienced in waiting for the door to be unlocked.

Paragraph 7.2.1.6.1(2) provides a fail-safe feature

where, upon loss of the electrical power that controls the lock, immediate unlocking occurs.

Paragraph 7.2.1.6.1(3) requires that, once the release device is manually activated, the door must unlock within 15 seconds, or 30 seconds with specific permission of the authority having jurisdiction. This action must be irreversible and cannot require the user to maintain pressure on the release device for more than 3 seconds. To provide occupants attempting egress with cues to indicate that the system is functioning, a signal is sounded in the vicinity of the door. Additionally, the signage required by 7.2.1.6.1(4) provides useful, reassuring information.

After the door is physically opened (that is, swung on its hinges away from the door frame), it is permitted to be relocked by manual means only. Relocking generally involves returning the door to its closed and latched position and then resetting the system to engage the lock.

Note that the unlocking required by 7.2.1.6.1(1), (2), and (3) need not automatically open the door. Rather, the door is permitted to remain latched. The unlocking permits the user to open the door immediately by operating the releasing mechanism on the door. Security is not sacrificed. Of course, any exterior exit door is permitted to be locked against building entry at any time.

The following occupancies allow the use of delayed-egress locks in accordance with 7.2.1.6.1. Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced within parentheses. For example, health care occupancies, hotels and dormitories, and apartment buildings permit delayed-egress locks if all the conditions of 7.2.1.6.1 are met and only one such lock is encountered along any natural path of egress travel.

The occupancies permitting delayed egress locks are as follows:

- (1) Assembly occupancies (12.2.2.2.5, 13.2.2.2.5)
- (2) Educational occupancies (14.2.2.2.3, 15.2.2.2.3)
- (3) Day-care centers (16.2.2.2.3, 17.2.2.2.3)
- (4) Health care occupancies [18.2.2.2.4(2), 19.2.2.2.4(2)]
- (5) Ambulatory health care centers (20.2.2.2, 21.2.2.2)
- (6) Lodging and rooming houses (26.2.3.5.2)
- (7) Hotels (28.2.2.2.2, 29.2.2.2.2)
- (8) Apartment buildings (30.2.2.2.2, 31.2.2.2.2)
- (9) Board and care facilities [32.2.2.5.6.1, 32.3.2.2.2(4), 33.2.2.5.6.1, 33.3.2.2.2(4)]
- (10) Mercantile occupancies (36.2.2.2.4, 37.2.2.2.4)
- (11) Business occupancies (38.2.2.2.4, 39.2.2.2.4)

- (12) Industrial occupancies (40.2.2.2.2)
- (13) Storage occupancies (42.2.2.2.2, 42.8.2.2.2)

7.2.1.6.2 Access-Controlled Egress Doors. Where permitted in Chapter 11 through Chapter 42, doors in the means of egress shall be permitted to be equipped with an approved entrance and egress access control system, provided that the following criteria are met:

- (1) One of the following shall be provided:
 - (a) A sensor on the egress side, arranged to detect an occupant approaching doors that are arranged to unlock in the direction of egress upon detection of an approaching occupant or loss of power to the sensor
 - (b) Listed panic hardware or fire exit hardware that, when operated, unlocks the door
- (2) Loss of power to the part of the access control system that locks the doors shall automatically unlock the doors in the direction of egress.
- (3) The doors shall be arranged to unlock in the direction of egress from a manual release device located 1015 mm to 1220 mm (40 in. to 48 in.) vertically above the floor and within 1525 mm (60 in.) of the secured doors.
- (4) The manual release device specified in 7.2.1.6.2(3) shall be readily accessible and clearly identified by a sign that reads as follows: PUSH TO EXIT.
- (5) When operated, the manual release device shall result in direct interruption of power to the lock—independent of the access control system electronics—and the doors shall remain unlocked for not less than 30 seconds.
- (6) Activation of the building fire-protective signaling system, if provided, shall automatically unlock the doors in the direction of egress, and the doors shall remain unlocked until the fire-protective signaling system has been manually reset.
- (7) Activation of the building automatic sprinkler or fire detection system, if provided, shall automatically unlock the doors in the direction of egress, and the doors shall remain unlocked until the fire-protective signaling system has been manually reset.

The access-controlled egress doors addressed by 7.2.1.6.2 are intended to be locked against access from the outside of the building and require a magnetic card or similar instrument for authorized entry. However, such doors are to be arranged to be usable for egress purposes whenever the building is occupied. The reason the *Code* addresses these doors under the subject of special locking arrangements is that such doors generally do not have the door-mounted manual latch/lock release typically installed on a door.

The absence of the door-mounted manual latch/lock release is to prevent a person on the outside from inserting a wire hanger or other tool between the gaps at the door edges to reach the release. Use of access-controlled egress doors requires specific occupancy chapter permission.

The following occupancies allow the use of access-controlled egress doors in accordance with 7.2.1.6.2. Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced within parentheses. For example, the provisions of 36.2.2.2.5 and 37.2.2.2.5, which apply to mercantile occupancies, permit access-controlled egress doors if all conditions of 7.2.1.6.2 are met and the building is protected throughout by an approved, supervised fire detection system or an approved automatic sprinkler system.

The occupancies permitting access-controlled egress doors are as follows:

- (1) Assembly occupancies (12.2.2.2.6, 13.2.2.2.6)
- (2) Educational occupancies (14.2.2.2.3, 15.2.2.2.3)
- (3) Day-care centers (16.2.2.2.3, 17.2.2.2.3)
- (4) Health care occupancies [18.2.2.2.4(3), 19.2.2.2.4(3)]
- (5) Ambulatory health care centers (20.2.2.2, 21.2.2.2)
- (6) Hotels (28.2.2.2.2.3, 29.2.2.2.2.3)
- (7) Apartment buildings (30.2.2.2.2.3, 31.2.2.2.2.3)
- (8) Board and care facilities [32.2.2.5.6.2, 32.3.2.2.2(5), 33.2.2.5.6.2, 33.3.2.2.2(5)]
- (9) Mercantile occupancies (36.2.2.2.5, 37.2.2.2.5)
- (10) Business occupancies (38.2.2.2.5, 39.2.2.2.5)
- (11) Industrial occupancies (40.2.2.2.3)
- (12) Storage occupancies (42.2.2.2.3, 42.8.2.2.2.2)

Paragraph 7.2.1.6.2(1) provides for the door to unlock when either a sensor detects an occupant approaching the door or panic hardware is operated by an occupant. These methods are the normal primary means of releasing the lock to permit occupants to leave the building. If the sensor and the release system fail, the requirements of 7.2.1.6.2(3) through 7.2.1.6.2(5) provide a backup system consisting of a manual lock-release mounted at a usable height in the immediate vicinity of the door opening. The *Code* permits the manual release to be installed as much as 1525 mm (60 in.) from the secured door, recognizing that the glass side lights featured on many of these doors are an impractical place to install a manual release device.

Additionally, 7.2.1.6.2(2) requires a fail-safe fea-

ture to unlock the door immediately upon loss of the electrical power that controls the lock.

Paragraphs 7.2.1.6.2(1) through 7.2.1.6.2(5) work together to help ensure that the door is usable at all times, before and during a fire emergency. Paragraphs 7.2.1.6.2(6) and 7.2.1.6.2(7) provide added assurance that the door is usable under fire emergency conditions. If the building has a fire alarm system, initiation of that system must unlock the door. If the building has either a fire detection system or a sprinkler system, activation of such system must unlock the door.

7.2.1.7 Panic Hardware and Fire Exit Hardware.

The difference between panic hardware and fire exit hardware is that fire exit hardware is tested and listed for use on fire-rated doors; panic hardware is not (see 7.2.1.7.2). As the terms imply, *panic hardware* and *fire exit hardware* are designed for ease of use and functional reliability under conditions that range from an orderly evacuation to that of hurried egress that might accompany a fast-spreading fire.

The provisions of 7.2.1.7 do not require panic hardware; they do, however, set the requirements for such hardware if it is required by the applicable occupancy chapter.

The following occupancies require the use of panic hardware or fire exit hardware. Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced within parentheses.

The occupancies are as follows:

- (1) Assembly occupancies (12.2.2.2.3, 13.2.2.2.3)
- (2) Educational occupancies (14.2.2.2.2, 15.2.2.2.2)
- (3) Day-care centers (16.2.2.2.2, 17.2.2.2.2)

Additionally, 7.11.6, which applies to high hazard contents areas, permits doors from spaces with occupant loads of more than five persons to be provided with a latch or lock only if panic hardware or fire exit hardware is installed to release the latch or lock. Although not required by the other occupancy chapters, panic hardware or fire exit hardware is often used in other occupancies, either because an assembly occupancy is located within the occupancy or because it is used as a means of complying with 7.2.1.5.9.

7.2.1.7.1 Where a door is required to be equipped with panic or fire exit hardware, such hardware shall meet the following criteria:

- (1) It shall consist of a cross bar or a push pad, the actuating portion of which extends across not less than one-half of the width of the door leaf.
- (2) It shall be mounted as follows:
 - (a) New installations shall be not less than 865 mm (34 in.), nor more than 1220 mm (48 in.), above the floor.
 - (b) Existing installations shall be not less than 760 mm (30 in.), nor more than 1220 mm (48 in.), above the floor.
- (3) It shall be constructed so that a horizontal force not to exceed 66 N (15 lbf) actuates the cross bar or push pad and latches.

Panic hardware and fire exit hardware are required to be instantly and easily released. New panic hardware and fire exit hardware installations are to be located 865 mm to 1220 mm (34 in. to 48 in.) above the floor [for existing installations—760 mm to 1220 mm (30 in. to 48 in.)], and the actuating portion is to extend at least one-half the width of the door leaf. Such hardware, where mounted to a door surface, might reduce the usable, clear width of a doorway. Provided that the hardware is installed at least 865 mm (34 in.) above the floor, the provisions of 7.2.1.2.3.2 permit a 100-mm (4-in.) encroachment on clear width without forcing a reduction in reported clear width. Installed below 865 mm (34 in.), the panic hardware or fire exit hardware might create a reduction in clear width sufficient to obstruct wheelchair passage through the opening associated with an 865-mm (34-in.) width door leaf.

The maximum force that the device can require for operation is 67 N (15 lbf). Note that this is the force needed to release the latching device only. The force needed to open the door itself is governed by 7.2.1.4.5.

7.2.1.7.2 Only approved panic hardware shall be used on doors that are not fire doors. Only approved fire exit hardware shall be used on fire doors.

It is not the intent of 7.2.1.7.2 to require the use of panic hardware or fire exit hardware. The two requirements of this paragraph are as follows:

- (1) Only approved hardware is to be used.
- (2) Where such devices are used on fire-rated doors, they must have been tested for use on fire-rated doors.

Fire exit hardware is tested for use on fire-rated doors; panic hardware is not.

7.2.1.7.3 Required panic hardware and fire exit hardware, in other than detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23, shall not be equipped with any locking device, set screw, or other arrangement that prevents the release of the latch when pressure is applied to the releasing device.

7.2.1.7.4 Devices that hold the latch in the retracted position shall be prohibited on fire exit hardware, unless such devices are listed and approved for such purposes.

It is the intent of the *Code* to allow the use of the delayed-egress lock described by 7.2.1.6.1 where panic hardware is required if the applicable occupancy chapter specifically permits its use. In these cases, the bar, which 7.2.1.7.1(1) requires to extend across at least half the door width, serves as the device that initiates the irreversible process that results in the door unlocking within the 15 or 30 seconds specified.

Panic hardware, which is prohibited from being used on fire-rated doors, often features the ability to “dog” the bar in the down position so as to hold the door latch in the retracted position. This latch-retracting feature is generally not available on fire exit hardware, because it would violate the listing of the rated fire door assembly. Rated doors must self-latch upon being brought to the closed position by the required closing device. A latch helps to keep the door closed under the pressures generated by a fire.

7.2.1.8 Self-Closing Devices.

7.2.1.8.1* A door normally required to be kept closed shall not be secured in the open position at any time and shall be self-closing or automatic-closing in accordance with 7.2.1.8.2.

A.7.2.1.8.1 Examples of doors designed to normally be kept closed include those to a stair enclosure or horizontal exit.

7.2.1.8.2 In any building of low or ordinary hazard contents, as defined in 6.2.2.2 and 6.2.2.3, or where approved by the authority having jurisdiction, doors shall be permitted to be automatic-closing, provided that the following criteria are met:

- (1) Upon release of the hold-open mechanism, the door becomes self-closing.

- (2) The release device is designed so that the door instantly releases manually and, upon release, becomes self-closing, or the door can be readily closed.
- (3) The automatic releasing mechanism or medium is activated by the operation of approved smoke detectors installed in accordance with the requirements for smoke detectors for door release service in *NFPA 72®*, *National Fire Alarm Code®*.
- (4) Upon loss of power to the hold-open device, the hold-open mechanism is released and the door becomes self-closing.
- (5) The release by means of smoke detection of one door in a stair enclosure results in closing all doors serving that stair.

Fire doors in a means of egress route should be kept in the closed position, particularly those serving as entrances to a stair enclosure or positioned in a horizontal exit; however, it is in these two locations that doors so often are held open by some type of door-stopping chock to aid in the free flow of normal traffic. This practice establishes conditions conducive to the rapid spread of fire, smoke, and heat to other sections of the building—the very situation that the stringent compartmentation requirements for the exit enclosure intend to prevent.

Recognizing that tampering with the self-closing feature might occur—and in an effort to encourage the use of effective positive measures rather than ineffective prohibitions that often go ignored—the *Code* presents criteria for holding doors in the open position. It permits doors to be held open in buildings that house low or ordinary hazard contents or where the authority having jurisdiction gives approval.

Specific requirements found elsewhere in the *Code* mandate the use of automatic-closing devices rather than making their use an option. For example, 7.2.4.3.10 requires that horizontal exit doors that span a corridor be automatic-closing in accordance with 7.2.1.8. The requirement of 7.2.4.3.10 recognizes that cross-corridor doors without an automatic release feature are often wedged open to facilitate normal pedestrian movement. Such wedges compromise the safety intended to be provided by the horizontal exit door.

The provisions of 7.2.1.8.2 allow for doors to be held open by an automatic-releasing device. The triggering of the automatic release is done through the operation of smoke detectors installed in accordance with the requirements for *smoke detectors for door release service* as specified in *NFPA 72®*, *National Fire Alarm Code®*. Fusible links are not an acceptable trigger in this system, because untenable smoke con-

ditions could easily render an exit enclosure or adjoining fire compartment unusable long before the temperature in the vicinity of the door opening has risen enough to operate the fusible link.

Additionally, loss of power to the device providing the hold-open feature must cause immediate automatic release. A manual method of release is also required. The manual method might involve tugging on the door to cause its release. Therefore, magnetic devices with significant holding forces that are not easily overcome by a deliberate tug on the door cannot be used. Once the hold-open device is released, the self-closing device installed on the door swings the door to its closed position. On a fire protection-rated door, the required door latch then engages.

The doors held open in accordance with the provisions of 7.2.1.8.2 can be arranged to close simultaneously throughout the building or only in the affected zones. Zoning is generally better, because it permits doors in areas unaffected by the emergency to remain open to accommodate normal use. If protecting a room, that room might be considered a zone. If protecting a stair enclosure, the entire stair enclosure is considered a zone, and the signal to close one door in the enclosing walls must close all doors in that stair enclosure.

With the exception of certain hazardous areas where flash fires or explosions could occur, the use of automatic closers in accordance with these provisions is permitted. Use of automatic-closing equipment should be encouraged to prevent doors from being secured open by other means. Wedges, for example, need to be removed before the self-closer installed on the door can move the door to its closed position.

7.2.1.9* Powered Doors.

A.7.2.1.9 Powered doors are divided into two categories—power assisted and power operated. Power-assisted doors that conform to ANSI/BHMA A156.19, *American National Standard for Power Assist & Low Energy Power Operated Doors*, use limited power to operate the door. They require fewer safeguards as compared to full power-operated doors. These door operators are for swinging doors only. Power-operated doors that conform to ANSI/BHMA A156.10, *American National Standard for Power Operated Pedestrian Doors*, require more power to operate the door and require additional safeguards to provide protection against personal injury. Power-operated doors can be swinging, sliding, or folding doors.

7.2.1.9.1* General. Where means of egress doors are operated by power upon the approach of a person or are provided with power-assisted manual operation, the design shall be such that, in the event of power failure, the doors open manually to allow egress travel or close when necessary to safeguard the means of egress.

A.7.2.1.9.1 An example of the type of door addressed by 7.2.1.9.1 is one actuated by a motion-sensing device upon the approach of a person.

7.2.1.9.1.1 The forces required to manually open the doors specified in 7.2.1.9.1 shall not exceed those required in 7.2.1.4.5, except that the force required to set the door in motion shall not exceed 222 N (50 lbf).

7.2.1.9.1.2 The door shall be designed and installed so that, when a force is applied to the door on the side from which egress is made, it shall be capable of swinging from any position to provide full use of the required width of the opening in which it is installed (*see 7.2.1.4*).

7.2.1.9.1.3 A readily visible, durable sign in letters not less than 25 mm (1 in.) high on a contrasting background that reads as follows shall be located on the egress side of each door:

IN EMERGENCY, PUSH TO OPEN

Power-operated sliding doors activated by an automatic mechanism are permitted, provided that their movement can be manually overpowered and the door can be made to swing in the direction of egress travel while still providing the required egress capacity. The feature for manual operation must work at all times, even when other features of the door's mechanism (such as the treadle, the electric eye, or the sliding rail) have failed. Such a door must be arranged so it can be made to swing manually from any position, whether fully or partially closed. Care must be taken to ensure that the enclosing construction of any door pocket does not defeat its ability to swing. Note that the breakaway feature cannot require a force in excess of 222 N (50 lbf).

The sign advising that the door can be pushed open in an emergency provides the user with information that might not be intuitively obvious. Typically, the user sees the door operate under power, which involves the door sliding to the side of the opening. The emergency manual mode of operation often relies on a breakaway feature that permits the door to become side-hinged and swinging when pushed in the direction of egress travel.

7.2.1.9.1.4 Sliding, power-operated doors in exit access serving an occupant load of fewer than 50 that manually open in the direction of door travel with forces not exceeding those required in 7.2.1.4.5 shall not be required to have the swing-out feature required by 7.2.1.9.1.2. The required sign shall be in letters not less than 25 mm (1 in.) high on a contrasting background and shall read as follows:

IN EMERGENCY, SLIDE TO OPEN

Recall that swinging doors, other than those in exit enclosures, serving an occupant load of fewer than 50 persons are permitted to swing against the direction of egress travel. Paragraph 7.2.1.9.1.4 considers a sliding door that can be manually opened with forces not exceeding those required of swinging doors to be equivalent to a door that swings against the direction of egress travel. Again, because the door is power-operated during normal use, a sign must be provided advising the user that force can be used to slide the door to its open position in an emergency mode—that is, on loss of power or equipment malfunction.

7.2.1.9.1.5* In the emergency breakout mode, a door leaf located within a two-leaf opening shall be exempt from the minimum 810-mm (32-in.) single-leaf requirement of 7.2.1.2.4, provided that the clear width of the single leaf is not less than 760 mm (30 in.).

A.7.2.1.9.1.5 Although a single power-operated door leaf located within a two-leaf opening might alone not provide more than 760 mm (30 in.) of clear width in the emergency breakout mode, where both leaves are broken out to become side-hinged, the required egress width is permitted to be provided by the width of the entire opening.

7.2.1.9.1.6 For a biparting sliding door in the emergency breakout mode, a door leaf located within a multiple-leaf opening shall be exempt from the minimum 810-mm (32-in.) single-leaf requirement of 7.2.1.2.4 if a clear opening of not less than 810 mm (32 in.) is provided by all leaves broken out.

Paragraphs 7.2.1.9.1.5 and 7.2.1.9.6 were developed to recognize a design limitation of power-operated doors currently manufactured and widely in use. Power-operated doors that are capable of providing the minimum 810-mm (32-in.) clear width for a single leaf as required by 7.2.1.2.4 generally are not capable of providing the same minimum 810-mm (32-in.) clear width in the emergency breakout mode. As long as there are multiple leaves within a single opening

and each is provided with the breakout feature, the 810-mm (32-in.) single-leaf requirement is relaxed, because the minimum required width can be provided by the entire opening with multiple door leaves broken out.

7.2.1.9.1.7 Doors complying with 7.2.1.14 shall be permitted to be used.

7.2.1.9.1.8 The requirements of 7.2.1.9.1 through 7.2.1.9.1.7 shall not apply in detention and correctional occupancies where otherwise provided in Chapter 22 and Chapter 23.

7.2.1.9.2 Doors Required to Be Self-Closing. Where doors are required to be self-closing and are operated by power upon the approach of a person, or are provided with power-assisted manual operation, they shall be permitted in the means of egress where they meet the following criteria:

- (1) The doors can be opened manually in accordance with 7.2.1.9.1 to allow egress travel in the event of power failure.
- (2) New doors remain in the closed position unless actuated or opened manually.
- (3) When actuated, new doors remain open for not more than 30 seconds.
- (4) Doors held open for any period of time close—and the power-assist mechanism ceases to function—upon operation of approved smoke detectors installed in such a way as to detect smoke on either side of the door opening in accordance with the provisions of *NFPA 72®*, *National Fire Alarm Code®*.
- (5) Doors required to be self-latching are either self-latching or become self-latching upon operation of approved smoke detectors per 7.2.1.9.2(4).
- (6) New power-assisted swinging doors comply with BHMA/ANSI A156.19, *American National Standard for Power Assist and Low Energy Power Operated Doors*.

If a door that is required to be self-closing by a provision of the *Code* is a powered door, the possibility of competing functions creating conflict exists. The intent of the self-closing requirement is to keep the door in its closed position except when someone is moving through the door opening; the intent of a powered door is either to make the door open automatically upon approach of a person or to open via power assist when a limited force is applied against the door. Under fire conditions, boxes falling from shelving, for example, might cause either the approach-actuated powered door or force-actuated power-assist door to open. The provisions of 7.2.1.9.2(4) require that, upon detection of smoke, the

door closes and the power-assist mechanism ceases to function. This requirement emphasizes that the need for the door to be in its closed position is paramount compared to the need to use the door easily under fire conditions.

7.2.1.10 Revolving Doors.

Note that 7.2.1.10.1 applies to all revolving doors, whether they are in the means of egress or not. Paragraph 7.2.1.10.2 applies to revolving doors within required means of egress. Paragraphs 7.2.1.10.3 and 7.2.1.10.4 apply specifically to those revolving doors that are not within the required means of egress.

7.2.1.10.1 Revolving doors, whether used or not used in the means of egress, shall comply with the following:

- (1) Revolving doors shall be capable of being collapsed into a book-fold position, unless they are existing revolving doors approved by the authority having jurisdiction.
- (2) When revolving doors are collapsed into the book-fold position, the parallel egress paths formed shall provide an aggregate width of 915 mm (36 in.), unless they are approved, existing revolving doors.
- (3) Revolving doors shall not be used within 3050 mm (120 in.) of the foot or the top of stairs or escalators.
- (4) A dispersal area acceptable to the authority having jurisdiction shall be located between stairs or escalators and the revolving door.
- (5) The revolutions per minute (rpm) of revolving doors shall not exceed the values in Table 7.2.1.10.1.
- (6) Each revolving door shall have a conforming side-hinged swinging door in the same wall as the revolving door and within 3050 mm (120 in.) of the revolving door, unless one of the following conditions applies:
 - (a) Revolving doors shall be permitted without adjacent swinging doors, as required by 7.2.1.10.1(6), in street floor elevator lobbies, provided that no stairways or doors from other parts of the building discharge through the lobby and the lobby has no occupancy other than as a means of travel between the elevators and street.
 - (b) The requirement of 7.2.1.10.1(6) shall not apply to existing revolving doors where the number of revolving doors does not exceed the number of swinging doors within 6100 mm (240 in.) of the revolving door.

The provisions of 7.2.1.10.1, which apply to revolving doors, address collapsibility, width of egress path, location, speed of rotation, and supplementary

Table 7.2.1.10.1 Revolving Door Maximum Speed

Inside Diameter		Power-Driven Speed Control (rpm)	Manual Speed Control (rpm)
mm	in.		
1980	78	11	12
2135	84	10	11
2285	90	9	11
2440	96	9	10
2590	102	8	9
2745	108	8	9
2895	114	7	8
3050	120	7	8

swinging doors. Paragraphs 7.2.1.10.1(1) and 7.2.1.10.1(2) require collapsibility to provide egress paths, albeit narrow paths, to each side of the center column with attached book-fold position doors. Paragraph 7.2.1.10.1(3), which requires that revolving doors not be used within 3050 mm (120 in.) of the foot or top of stairs or escalators, is meant to prevent the crushing accumulation of occupants if egress travel is slowed at the door. Paragraph 7.2.1.10.1(6) provides redundant egress via a nearby side-hinged swinging door if the revolving door prevents egress upon failure of its emergency features. Paragraph 7.2.1.10.1(6)(a) specifies a safe arrangement under which the additional swinging door is not needed.

7.2.1.10.2 Where permitted in Chapter 12 through Chapter 42, revolving doors shall be permitted as a component in a means of egress, provided that the following criteria are met:

- (1) Revolving doors shall not be given credit for more than 50 percent of the required egress capacity.
- (2) Each revolving door shall not be credited with more than a 50-person capacity or, if of not less than a 2745-mm (108-in.) diameter, a revolving door shall be permitted egress capacity based on the clear opening width provided when collapsed into a book-fold position.
- (3) Revolving doors shall be capable of being collapsed into a book-fold position when a force not exceeding 580 N (130 lbf) is applied to the wings within 75 mm (3 in.) of the outer edge.

The following occupancies allow the use of a revolving door in a means of egress. Additional restrictions that might be imposed by the occupancy chapter are contained in the paragraphs referenced in parentheses.

The occupancies permitting a revolving door within the means of egress are as follows:

- (1) Assembly occupancies (12.2.2.2.7, 13.2.2.2.7)
- (2) Hotels (28.2.2.2.3, 29.2.2.2.3)
- (3) Apartments (30.2.2.2.3, 31.2.2.2.3)
- (4) Existing board and care facilities [33.3.2.2.2(6)]
- (5) Mercantile occupancies (36.2.2.2.8, 37.2.2.2.8)
- (6) Business occupancies (38.2.2.2.8, 39.2.2.2.8)

Revolving doors present the potential for problems when too many people try to use them in too short a period of time. The congestion created by such a situation is one reason why their use is prohibited at the foot or top of stairs. This potential danger is also why they are not permitted to provide more than 50 percent of the required egress capacity. Where revolving doors are used, they each receive credit for a maximum of 50 persons, regardless of the width of the revolving panel.

7.2.1.10.3 Revolving doors not used as a component of a means of egress shall have a collapsing force not exceeding 800 N (180 lbf).

7.2.1.10.4 The requirement of 7.2.1.10.3 shall not apply to revolving doors, provided that the collapsing force is reduced to a force not to exceed 580 N (130 lbf) under the following conditions:

- (1) Power failure, or removal of power to the device holding the wings in position
- (2) Actuation of the automatic sprinkler system, where such a system is provided
- (3) Actuation of a smoke detection system that is installed to provide coverage in all areas within the building that are within 23 m (75 ft) of the revolving doors
- (4) Actuation of a clearly identified manual control switch in an approved location that reduces the holding force to a force not to exceed 580 N (130 lbf)

Note that the provisions of 7.2.1.10.3 apply if the door is not within the required means of egress. The criteria contained in 7.2.1.10.4 need to be satisfied only if the collapsing force is in excess of 800 N (180 lbf) under normal operating conditions.

7.2.1.11 Turnstiles.

The intent of 7.2.1.11 is to provide guidance on how best to place turnstiles in a building, to describe the circumstances under which they are permitted, and to reduce the chances of their improper use during an emergency.

7.2.1.11.1 Turnstiles or similar devices that restrict travel to one direction or are used to collect fares or admission charges shall not be placed so as to obstruct any required means of egress, unless otherwise specified in 7.2.1.11.1.1 and 7.2.1.11.1.2

7.2.1.11.1.1 Approved turnstiles not exceeding 990 mm (39 in.) in height that turn freely in the direction of egress travel shall be permitted where revolving doors are permitted in Chapter 12 through Chapter 42.

7.2.1.11.1.2 Where turnstiles are approved by the authority having jurisdiction and permitted in Chapter 12 through Chapter 42, each turnstile shall be credited for a capacity of 50 persons, provided that such turnstiles meet the following criteria:

- (1) They freewheel in the egress direction when primary power is lost, and freewheel in the direction of egress travel upon manual release by an employee assigned in the area.
- (2) They are not given credit for more than 50 percent of the required egress width.
- (3) They are not in excess of 990 mm (39 in.) in height and have a clear width of not less than 420 mm (16½ in.).

7.2.1.11.2 Turnstiles exceeding 990 mm (39 in.) in height shall meet the requirements for revolving doors in 7.2.1.10.

7.2.1.11.3 Turnstiles located in, or furnishing access to, required exits shall provide not less than 420 mm (16½ in.) clear width at and below a height of 990 mm (39 in.) and at least 560 mm (22 in.) clear width at heights above 990 mm (39 in.).

Generally, turnstiles are installed to prevent or control entry. As such, they are not always suitable for installation in a means of egress. Turnstiles are permitted in means of egress locations where revolving doors are permitted; see the commentary on 7.2.1.10.2 for a list of occupancies that permit revolving doors within the means of egress. The reference in 7.2.1.11 to revolving doors is not meant to imply that there is a relationship between their purpose and that of turnstiles. The revolving door is not meant to restrict traffic in either direction, while the turnstile is often used to do just that, with the restriction or obstruction to traffic movement usually in the direction of building entry. Yet, if a turnstile does not restrict egress, it might be assumed to be the equivalent of a revolving door. At heights not exceeding 990 mm (39 in.), a freewheeling turnstile is not required to provide the collapsibility features required of a revolving door; turnstiles with heights exceeding 990 mm (39 in.) must be provided with all the features applicable to revolving doors.

Some turnstiles do not turn in the direction of entry until coin-operated. Others require no coin for operation and are used simply to count numbers of people. Perhaps the most dangerous are those that do not bar entry but specifically bar egress. This might occur in large mercantile occupancies where turnstiles turn freely on entering but do not turn in the direction of egress, thereby causing patrons to reroute their egress through checkout stands. It is possible that the patrons of places using one-way turnstiles are quite aware of this limitation and know the correct path to take for emergency egress; however, this cannot be relied on, especially if the turnstiles are placed near the exit doors. In emergencies, occupants might head for what appears to be the shortest route to the outside, only to find it blocked by a turnstile preventing movement in that direction.

Some occupancy chapters permit turnstiles to provide a portion of the required egress capacity, provided that they are in strict compliance with the dimensional criteria and performance requirements of 7.2.1.11.1.2. Turnstiles are not permitted to provide more than 50 percent of the required egress capacity, and no single turnstile can be given egress capacity for more than 50 persons.

7.2.1.12 Doors in Folding Partitions. Where permanently mounted folding or movable partitions divide a room into smaller spaces, a swinging door or open doorway shall be provided as an exit access from each such space, unless otherwise specified in 7.2.1.12.1 and 7.2.1.12.2.

7.2.1.12.1 A door or opening in the folding partition shall not be required, provided that all of the following criteria are met:

- (1) The subdivided space is not used by more than 20 persons at any time.
- (2) The use of the space is under adult supervision.
- (3) The partitions are arranged so that they do not extend across any aisle or corridor used as an exit access to the required exits from the story.
- (4) The partitions conform to the interior finish and other requirements of this *Code*.
- (5) The partitions are of an approved type, have a simple method of release, and are capable of being opened quickly and easily by experienced persons in case of emergency.

7.2.1.12.2 Where a subdivided space is provided with not less than two means of egress, the swinging door in the folding partition specified in 7.2.1.12 shall not be required, and one such means of egress shall be permitted to be equipped with a horizontal-sliding door complying with 7.2.1.14.

Although 7.2.1.12.1(3) might appear to contradict the intent of 7.2.1.12.2, it refers to exit access for the rest of the floor, not exit access for the small space created by closing the partition.

7.2.1.13 Balanced Doors. If panic hardware is installed on balanced doors, the panic hardware shall be of the push-pad type, and the pad shall not extend more than approximately one-half the width of the door, measured from the latch side. [See 7.2.1.7.1(1).]

Balanced doors do not have side hinges; instead, they have a pivot point that is set in a small distance. This arrangement helps reduce the force needed to open the door. With balanced doors, where the hinge or pivot point is set in from the edge of the door leaf, care must be taken to position the panic hardware device on the latch side of the pivot point; otherwise, pushing on the bar might actually help to hold the door closed. This arrangement might be effectively accomplished using pushpad panic hardware, which more readily instructs the user where to push. Exhibit 7.21 depicts a balanced door; Exhibit 7.22 illustrates the difference between traditional panic hardware and pushpad panic hardware.

7.2.1.14 Horizontal-Sliding Doors. Horizontal-sliding doors shall be permitted in means of egress, provided that the following criteria are met:

- (1) The door is readily operable from either side without special knowledge or effort.
- (2) The force that, when applied to the operating device in the direction of egress, is required to operate the door is not more than 67 N (15 lbf).
- (3) The force required to operate the door in the direction of door travel is not more than 133 N (30 lbf) to set the door in motion and is not more than 67 N (15 lbf) to close the door or open it to the minimum required width.
- (4) The door is operable using a force of not more than 222 N (50 lbf) when a force of 1100 N (250 lbf) is applied perpendicularly to the door adjacent to the operating device, unless the door is an existing horizontal-sliding exit access door serving an area with an occupant load of fewer than 50.
- (5) The door assembly complies with the fire protection rating, if required, and, where rated, is self-closing or automatic-closing by means of smoke detection in accordance with 7.2.1.8 and is installed in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*.

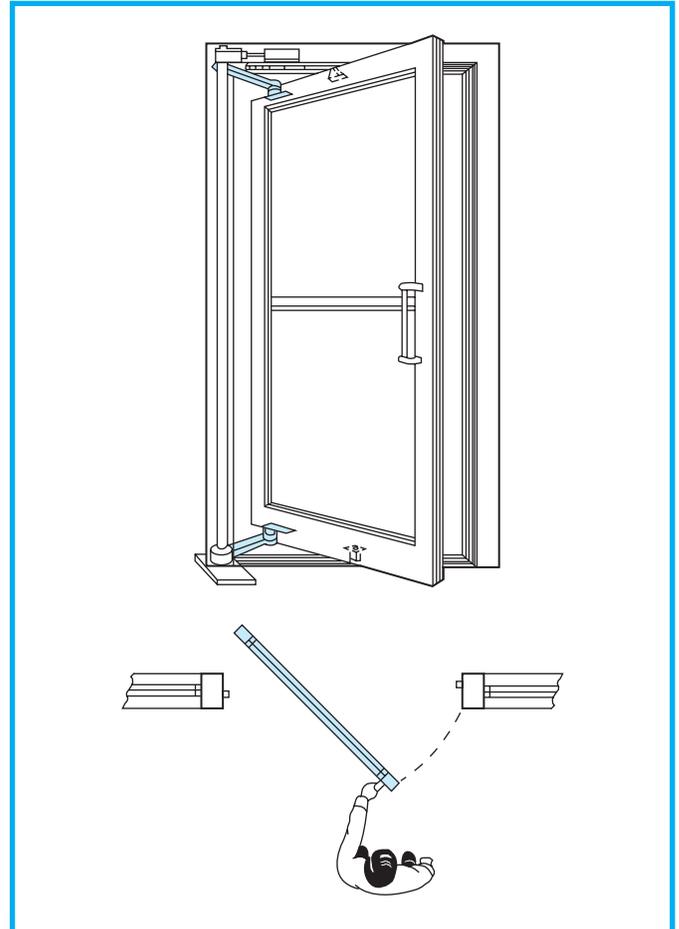

Exhibit 7.21 Balanced door.

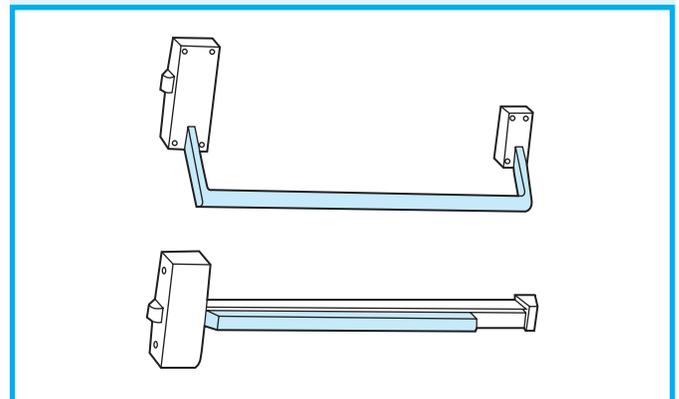

Exhibit 7.22 Traditional panic hardware (top) and pushpad panic hardware (bottom).

The special type of horizontal sliding door addressed by 7.2.1.14 is different from a traditional horizontal sliding door. When force is applied in the direction

of egress travel to the door actuator, the door must slide to the side to allow passage. This concept is illustrated in Exhibit 7.23.

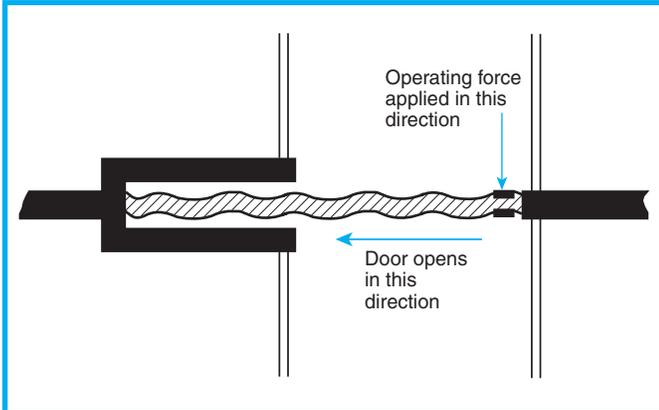

Exhibit 7.23 Horizontal sliding door operation.

Although the provisions of 7.2.1.14 do not require specific occupancy chapter permission for use of horizontal sliding doors, some occupancy chapters impose additional restrictions. For example, 28.2.2.2.4 prohibits the installation of these doors across a corridor in a new hotel or dormitory.

The requirements for the installation of horizontal sliding doors address the following:

- (1) Simple method of operation from either side without special knowledge or effort
- (2) Force necessary to operate the door
- (3) Fire protection rating applicable to door location and purpose
- (4) Automatic-closing means by smoke detection or means for self-closing

The force requirements of 7.2.1.14(3) and (4) help to ensure that the door can be operated if the usual method of operation required by 7.2.1.14(2) fails.

It is important that sliding doors be evaluated for compliance with all the requirements of 7.2.1.14. Traditional sliding doors cannot comply with these requirements; an example of a type of door that can be shown in Exhibit 7.24.

7.2.2 Stairs.

Stairs, whether interior or exterior to a building, serve multiple functions, from allowing normal occupant movement among the floors of a building, to providing emergency egress in case of fire, to facilitating

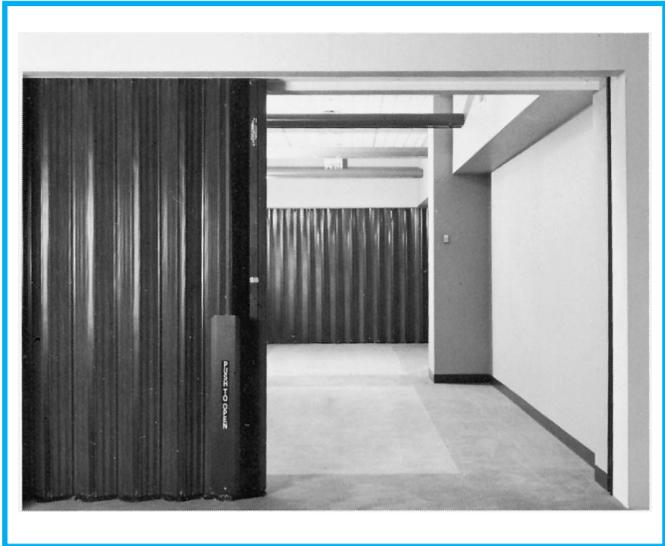

Exhibit 7.24 Horizontal sliding door addressed by 7.2.1.14. (Photo courtesy of Won-Door Corp.)

rescue and fire-control operations conducted by fire fighters.

Stairs are used within any of the three components of a means of egress system, that is, the exit access, the exit, and the exit discharge. The *Code* focuses much attention on stairs to help ensure their effective use during emergency egress. These requirements for emergency egress help to ensure that stairs are also safe to use on a regular basis. As one of the most commonly used building elements on a day-to-day, nonemergency basis, stairs are one of the most common scenes of accidents.

7.2.2.1 General.

7.2.2.1.1 Stairs used as a component in the means of egress shall conform to the general requirements of Section 7.1 and to the special requirements of this 7.2.2 unless otherwise specified in 7.2.2.1.2.

7.2.2.1.2 The requirement of 7.2.2.1.1 shall not apply to the following:

- (1) Aisle stairs in assembly occupancies as provided in Chapter 12 and Chapter 13
- (2) Approved, existing noncomplying stairs

Aisle stairs (that is, stepped aisles) are detailed in 12.2.5.6 and 13.2.5.6.

Although stairs can serve within any of the three components of the means of egress, they are most often located within an exit. To be considered an exit, interior stairs must be separated from the other

spaces on the floor in accordance with 7.1.3.2. Unenclosed interior stairs normally serve as exit access rather than as exits. Where an interior stair connects two or more stories, it creates a vertical opening and must meet the requirements applicable to such, regardless of whether it is an exit. See the vertical opening protection provisions of Section 8.6.

It is sometimes more difficult to determine whether outside stairs are part of the exit access, the exit, or the exit discharge. To be considered an exit, outside stairs need to be separated from the interior of the building by fire-rated construction in accordance with 7.2.2.6.3. Outside stairs adjacent to the building that are unprotected would normally be considered part of the exit access where serving occupants of upper stories, with the user reaching the exit and exit discharge simultaneously at the base of the last stair flight. Where stairs occur in a sidewalk that connects an exit door to a public way, the stairs are part of the exit discharge.

7.2.2.2 Dimensional Criteria.

7.2.2.2.1 Standard Stairs. Stairs shall meet the following criteria:

- (1) New stairs shall be in accordance with Table 7.2.2.2.1(a).
- (2)* Existing stairs shall be permitted to remain in use, provided that they meet the requirements for existing stairs shown in Table 7.2.2.2.1(b).

A.7.2.2.2.1(2) It is the intent of 7.2.2.2.1(2) to permit the use of Table 7.2.2.2.1(b) in existing buildings, even where there is a change in occupancy per 4.6.12. Safety improvements should be made that are reasonable and feasible at minimal cost. Improvements include removal, repair, or replacement of step coverings as described in A.7.2.2.3.5, particularly Figure A.7.2.2.3.5(e), and addition of functional handrails and guardrails in place of or in conjunction with other rails as described in 7.2.2.4.

- (3) Approved existing stairs shall be permitted to be rebuilt in accordance with the following:
 - (a) Dimensional criteria of Table 7.2.2.2.1(b)
 - (b) Other stair requirements of 7.2.2
- (4) The requirements for new and existing stairs shall not apply to stairs located in industrial equipment access areas where otherwise provided in 40.2.5.2.

Tables 7.2.2.2.1(a) and (b) present the required stair geometry for both new and existing stairs.

Editions of the *Code* prior to 1981 required that the height of every riser and the width of every tread

Table 7.2.2.2.1(a) New Stairs

Feature	Dimensional Criteria
Minimum width clear of all obstructions, except projections not more than 114 mm (4½ in.) at or below handrail height on each side	1120 mm (44 in.); 915 mm (36 in.) where total occupant load of all stories served by stairways is fewer than 50
Maximum height of risers	180 mm (7 in.)
Minimum height of risers	100 mm (4 in.)
Minimum tread depth	280 mm (11 in.)
Minimum headroom	2030 mm (80 in.)
Maximum height between landings	3660 mm (144 in.)
Landing	See 7.2.1.3 and 7.2.1.4.4

Table 7.2.2.2.1(b) Existing Stairs

Feature	Dimensional Criteria	
	Class A	Class B
Minimum width clear of all obstructions, except projections not more than 114 mm (4½ in.) at or below handrail height on each side	915 mm (36 in.)	915 mm (36 in.)
Maximum height of risers	190 mm (7½ in.)	205 mm (8 in.)
Minimum tread depth	255 mm (10 in.)	230 mm (9 in.)
Minimum headroom	2030 mm (80 in.)	2030 mm (80 in.)
Maximum height between landings	3660 mm (144 in.)	3660 mm (144 in.)
Landing	See 7.2.1.3 and 7.2.1.4.4	

be so proportioned that the sum of two risers and a tread, exclusive of its nosing or projection, was not less than 610 mm (24 in.) nor more than 635 mm (25 in.). This requirement was deleted because it was based on a 300-year-old French formula in which the inch was a slightly larger unit of measure than it is today. Moreover, people’s feet and stride length—the basis for the formula—were somewhat smaller at that time. Also, the requirement was originally intended only for stairs of moderate steepness or pitch. These

reasons, as well as information gathered by researchers on people movement, explain why the requirement was replaced by requirements that ensure good step geometry.

Because of the hardship and impracticality of rebuilding all existing stairs to the newer requirements, the *Code* permits existing stairs in existing buildings to comply with previous requirements. It also allows existing stairs to be rebuilt to the previous dimensional criteria, because a new stair might not fit in an existing stair enclosure. However, the rebuilt stair utilizing the older geometry must meet all other requirements of 7.2.2, including those relating to handrails. The wording of A.7.2.2.2.1(2) provides guidance for judging the improvements that are reasonable.

Existing stairs are classified as either Class A or Class B, depending on their tread depth and riser height, as shown in Exhibit 7.25. Riser height, tread

depth, and stair width requirements are illustrated for both new and existing stairs. Note that new stairs must have a lower riser height and a greater tread depth than existing stairs.

If the total occupant load of all floors served by the stair is fewer than 50, the minimum width can be reduced from 1120 mm (44 in.) to 915 mm (36 in.). The occupancy chapters applicable to existing buildings specify the class of existing stair that is permitted to be used. For example, 15.2.2.3.2 permits Class A stairs for existing educational occupancies; 15.2.2.3.3 permits existing Class B stairs for existing educational occupancy stairs not used for student access. Also, 17.2.2.3.2 permits Class A stairs for existing day-care occupancies, and 17.2.2.3.3 permits existing Class B stairs for existing day-care occupancy stairs not used for client access. If an occupancy chapter applicable to existing buildings does not specify the class of existing stair that is permitted to be used, either is permitted. A change of occupancy does not require that stairs be rebuilt to meet the requirements applicable to new construction.

See 7.1.7 for special requirements where stairs provide a total elevation change of not more than 535 mm (21 in.).

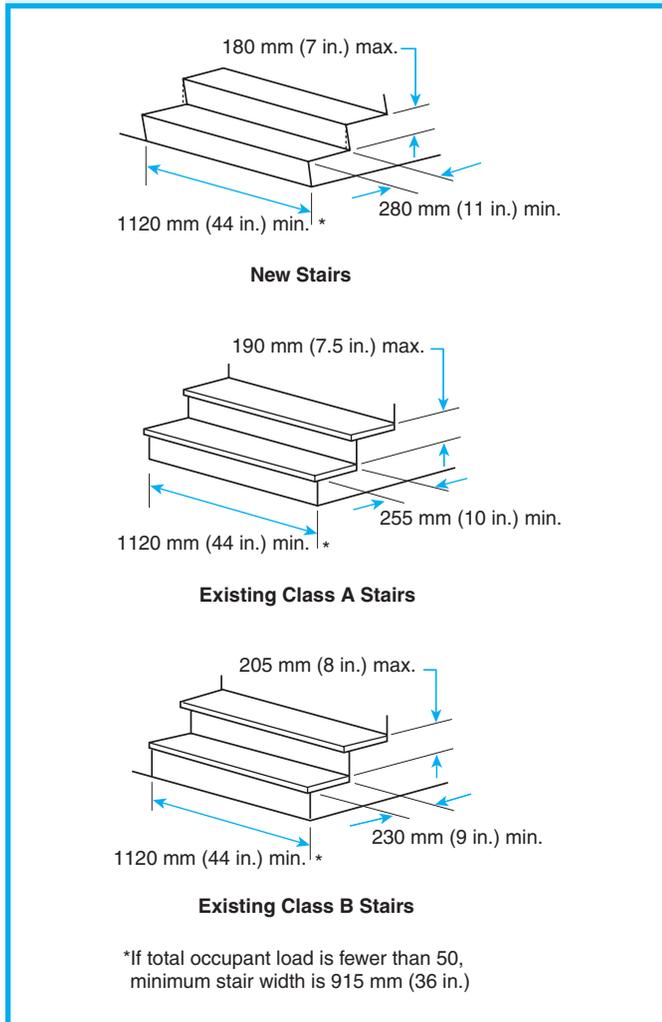

Exhibit 7.25 Stair specifications.

7.2.2.2.2 Curved Stairs.

7.2.2.2.2.1 New curved stairs shall be permitted as a component in a means of egress, provided that the depth of tread is not less than 280 mm (11 in.) at a point 305 mm (12 in.) from the narrower end of the tread and the smallest radius is not less than twice the stair width.

7.2.2.2.2.2 Existing curved stairs shall be permitted as a component in a means of egress, provided that the depth of tread is not less than 255 mm (10 in.) at a point 305 mm (12 in.) from the narrower end of the tread and the smallest radius is not less than twice the stair width.

Paragraph 7.2.2.2.2.1 relates the degree of curvature to the width of the curved stair, as shown in Exhibit 7.26. Dimension B must be at least twice dimension A. Dimension C, the tread depth, is measured at the so-called inner walking line (where feet land when walking on the inner part of the stair); it must be at least 280 mm (11 in.). This relationship of smallest radius to stair width should be based on the actual width of the stair, rather than on the required width only. Otherwise, unsafe conditions toward the outside of wide-curved stairs could be created.

The measurement method for curved stairs that

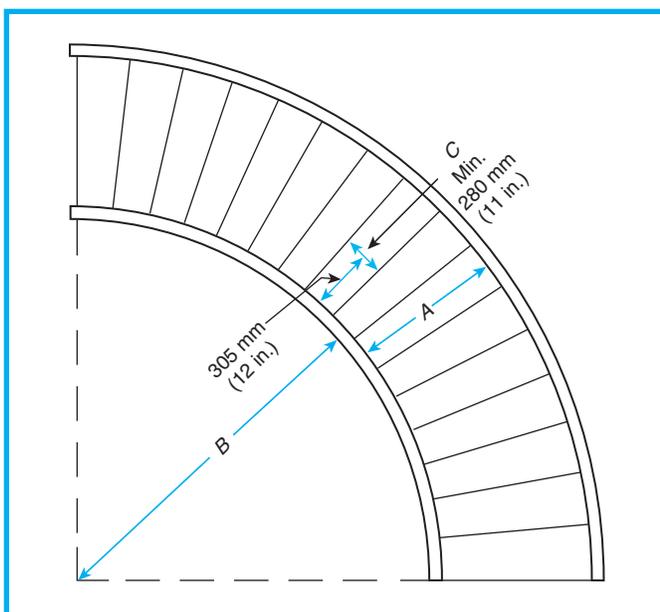

Exhibit 7.26 Curved stairs.

is specified by the *Code* is based on how such stairs are used, with reference to a minimum 280-mm (11-in.) tread depth at the inner walking line. This concept has been used in the *Code's* requirement for winders for some time (see 7.2.2.2.4). With the minimum tread depth stated as a dimension similar to that applicable to other stairs permitted in the required means of egress, it is more evident that curved stairs are an acceptable egress component for any occupancy.

7.2.2.2.3 Spiral Stairs.

7.2.2.2.3.1 Where specifically permitted for individual occupancies by Chapter 12 through Chapter 42, spiral stairs shall be permitted as a component in a means of egress in accordance with 7.2.2.2.3.2 through 7.2.2.2.3.4.

7.2.2.2.3.2 Spiral stairs shall be permitted, provided that the following criteria are met:

- (1) Riser heights shall not exceed 180 mm (7 in.).
- (2) The stairway shall have a tread depth of not less than 280 mm (11 in.) for a portion of the stairway width sufficient to provide egress capacity for the occupant load served in accordance with 7.3.3.1.
- (3) At the outer side of the stairway, an additional 265 mm (10½ in.) of width shall be provided clear to the other handrail, and this width shall not be included as part of the required egress capacity.

- (4) Handrails complying with 7.2.2.4 shall be provided on both sides of the spiral stairway.
- (5) The inner handrail shall be located within 610 mm (24 in.), measured horizontally, of the point where a tread depth of not less than 280 mm (11 in.) is provided.
- (6) The turn of the stairway shall be such that the outer handrail is at the right side of descending users.

7.2.2.2.3.3 Where the occupant load served does not exceed three, spiral stairs shall be permitted, provided that the following criteria are met:

- (1) The clear width of the stairs shall be not less than 660 mm (26 in.).
- (2) The height of risers shall not exceed 240 mm (9½ in.).
- (3) The headroom shall be not less than 1980 mm (78 in.).
- (4) Treads shall have a depth not less than 190 mm (7½ in.) at a point 305 mm (12 in.) from the narrower edge.
- (5) All treads shall be identical.
- (6) Handrails shall be provided on both sides of the stairway.

7.2.2.2.3.4 Where the occupant load served does not exceed five, existing spiral stairs shall be permitted, provided the requirements of 7.2.2.2.3.3(1) through 7.2.2.2.3.3(5) are met.

Spiral stairs can be used only where expressly allowed by the appropriate occupancy chapter. Some occupancy chapters establish additional limitations. For example, in assembly occupancies, spiral stairs are permitted only from lighting and access catwalks, galleries, and gridirons. In apartment buildings, spiral stairs are permitted only within a dwelling unit, not within the common spaces and egress paths serving multiple dwelling units.

The occupancies that permit spiral stairs are as follows:

- (1) Assembly occupancies (12.2.2.3.2.2, 13.2.2.3.2.2)
- (2) Detention and correctional occupancies (22.2.2.3.2, 23.2.2.3.2)
- (3) One- and two-family dwellings (24.2.5.5)
- (4) Apartments (30.2.2.3.3, 31.2.2.3.3)
- (5) Mercantile occupancies (36.2.2.3.2, 37.2.2.3.2)
- (6) Business occupancies (38.2.2.3.2, 39.2.2.3.2)
- (7) Industrial occupancies (40.2.2.3.2)
- (8) Storage occupancies (42.2.2.3.2)

The requirement of 7.2.2.2.3.2 is significant in that it includes a spiral stair geometry that can be used without a prespecified maximum occupant limit. The number of occupants permitted to use a spiral stair depends on how much egress width is provided. The term *egress width* has a specific meaning in this instance. It excludes the narrow part of the tapered

tread that has less than 280 mm (11 in.) of tread depth. It also excludes the outer 265 mm (10 ½ in.) of tread width. Note that handrails are required at both sides. Also, the turn of the stairway must be such that the outer handrail is available to descending users at their right side. These criteria are depicted in Exhibit 7.27. An additional criterion is that the riser height not exceed 180 mm (7 in.), as is required for traditional stairs in accordance with Table 7.2.2.2.1(a).

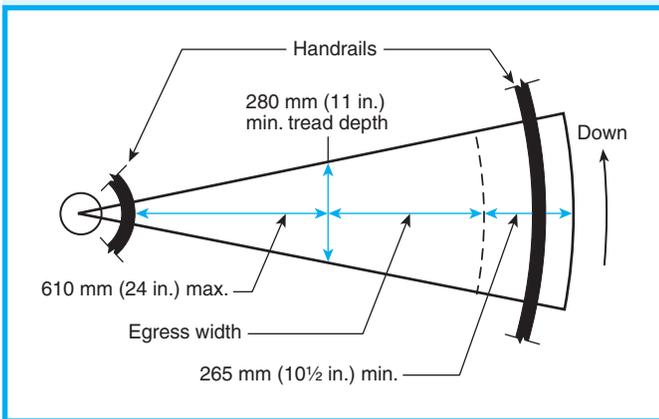

Exhibit 7.27 Spiral stair tread dimensional criteria reflecting the requirements of 7.2.2.2.3.2.

The requirement of 7.2.2.2.3.3 retains the dimensional criteria for spiral stairs from earlier editions of the Code but changes the maximum number of occupants served by the stair from five to three and requires that handrails be provided at both sides of the stair.

The requirement of 7.2.2.2.3.4 applies to existing spiral stairs as well as to those in new dwelling units, guest rooms, and guest suites. The traditional five-person limit and the requirement that a handrail be at the open side have been retained.

7.2.2.2.4* Winders.

A.7.2.2.4 If properly designed and constructed, stairs with winders are not necessarily more dangerous than other stairs. Attention to the following factors helps to make winders generally more effective for egress and safety. Handrails should be continuous, without breaks at newel posts, from story to story. Handrails located at a greater than normal distance from the inner turn of winders can improve safety by constraining stair users to walk on the portion of the treads providing deeper treads, which should have not less

than 280 mm (11 in.) of depth. Combinations of straight flights and winders are best arranged with winders located only below the straight flight. This arrangement is best because the winders provide larger tread dimensions over much of their width than do typical treads on straight flights. A descending person will, thus, be unlikely to experience a reduction of tread depth during descent, a condition of non-uniformity that is best avoided.

7.2.2.2.4.1 Where specified in Chapter 12 through Chapter 42, winders shall be permitted in stairs, provided that they meet the requirements of 7.2.2.2.4.2 and 7.2.2.2.4.3.

7.2.2.2.4.2 New winders shall have a tread depth of not less than 150 mm (6 in.) and a tread depth of not less than 280 mm (11 in.) at a point 305 mm (12 in.) from the narrowest edge.

7.2.2.2.4.3 Existing winders shall be permitted to be continued in use, provided that they have a tread depth of not less than 150 mm (6 in.) and a tread depth of not less than 230 mm (9 in.) at a point 305 mm (12 in.) from the narrowest edge.

A winder is a tapered tread used to change the direction the stair runs. Because winders introduce a variation in the stair geometry and their effective tread depths are less than 280 mm (11 in.), they are suited to limited applications. At one time, the Code prohibited winders. Chapter 7 now sets applicable criteria for winders if the appropriate occupancy chapter specifically permits their use. Other than within dwelling units, the Code limits winders to existing installations. Exhibit 7.28 illustrates the dimensional criteria required.

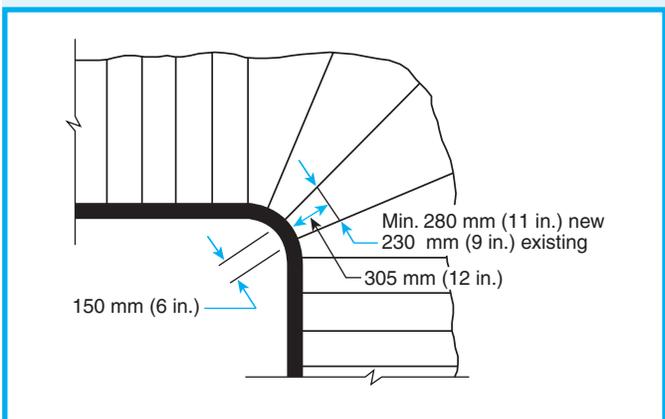

Exhibit 7.28 Acceptable winders.

Some occupancy chapters include additional limitations in addition to the criteria of 7.2.2.2.4. For example, in apartment buildings, winders are permitted to serve only within a living unit and not within the common spaces such as corridors and lobbies.

The occupancies that permit winders are as follows:

- (1) One- and two-family dwellings (24.2.5.5)
- (2) Lodging and rooming houses (26.2.2.4)
- (3) Apartments (30.2.2.3.4, 31.2.2.3.4)
- (4) Board and care facilities (32.2.2.6.2, 33.2.2.6.2)
- (5) Existing mercantile occupancies (37.2.2.3.3)
- (6) Existing business occupancies (39.2.2.3.3)
- (7) Existing industrial occupancies (40.2.2.3.3)
- (8) Existing storage occupancies (42.2.2.3.3, 42.8.2.2.3.2)

7.2.2.3 Stair Details.

7.2.2.3.1 Construction.

7.2.2.3.1.1 All stairs serving as required means of egress shall be of permanent fixed construction, unless they are stairs serving seating that is designed to be repositioned in accordance with Chapter 12 and Chapter 13.

The requirement of 7.2.2.3.1.1 recognizes the functional requirement in theaters, for example, where seating sections are added, removed, or repositioned depending on the specific theatrical production. It is impractical for stairs associated with such seating sections to be of fixed, permanent construction.

7.2.2.3.1.2 Each stair, platform, and landing, not including handrails and existing stairs, in buildings required in this Code to be of Type I or Type II construction shall be of noncombustible material throughout.

The requirement of 7.2.2.3.1.2 covers the combustibility of materials used to construct new stairs. Stairs are permitted to be of combustible construction if the building is permitted to be of Type III, Type IV, or Type V construction as defined in NFPA 220, *Standard on Types of Building Construction*⁷. If the building is required to be of Type I or Type II construction, which limits building materials to those that are noncombustible, the materials used for new stair construction must also be noncombustible.

7.2.2.3.2 Landings.

7.2.2.3.2.1 Stairs shall have landings at door openings, except as permitted in 7.2.2.3.2.5.

7.2.2.3.2.2 Stairs and intermediate landings shall continue with no decrease in width along the direction of egress travel.

7.2.2.3.2.3 In new buildings, every landing shall have a dimension, measured in the direction of travel, that is not less than the width of the stair.

7.2.2.3.2.4 Landings shall not be required to exceed 1220 mm (48 in.) in the direction of travel, provided that the stair has a straight run.

7.2.2.3.2.5 In one- and two-family dwellings and existing buildings, a door at the top of a stair shall be permitted to open directly to the stair, provided that the door does not swing over the stair and the door serves an area with an occupant load of fewer than 50 persons.

Stairs must have landings at door openings. It is unsafe to move through a door opening and immediately begin vertical travel on a stair. Paragraph 7.2.2.3.2.5 provides an exemption to this requirement for dwellings and existing buildings. Exhibit 7.14, associated with the commentary on 7.2.1.3.6, depicts the exemption.

Intermediate stair landings of the minimum depth specified by 7.2.2.3.2.3 serve as effective breaks in runs of stairs, which allows persons who slip or trip to halt their fall. Exhibit 7.29 illustrates the minimum landing depth addressed by 7.2.2.3.2.3 and 7.2.2.3.2.4.

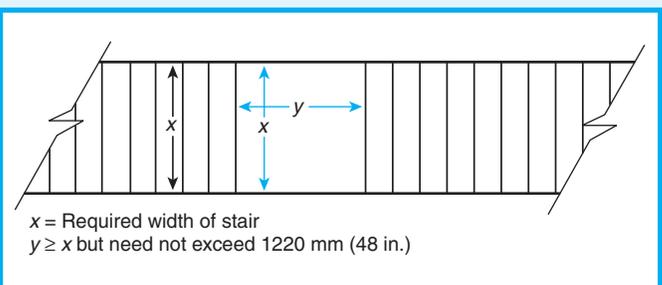

Exhibit 7.29 Uniform width of stairs and intermediate landings.

7.2.2.3.3 Tread and Landing Surfaces.

7.2.2.3.3.1 Stair treads and landings shall be solid, without perforations, unless otherwise permitted in 7.2.2.3.3.4.

7.2.2.3.3.2* Stair treads and landings shall be free of projections or lips that could trip stair users.

A.7.2.2.3.3.2 The tripping hazard referred to in 7.2.2.3.3.2 occurs especially during descent, where the tread walking surface has projections such as strips of high-friction materials or lips from metal pan stairs that are not completely filled with concrete or other material. Tread nosings that project over adjacent treads can also be a tripping hazard. ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, illustrates projecting nosing configurations that minimize the hazard.

Where environmental conditions (such as illumination levels and directionality or a complex visual field that draws a person's attention away from stair treads) lead to a hazardous reduction in one's ability to perceive stair treads, they should be made of a material that allows ready discrimination of the number and position of treads. In all cases, the leading edges of all treads should be readily visible during both ascent and descent. A major factor in injury-producing stair accidents and in the ability to use stairs efficiently in conditions such as egress is the clarity of the stair treads as separate stepping surfaces.

7.2.2.3.3.3 If not vertical, risers on other than existing stairs shall be permitted to slope under the tread at an angle not to exceed 30 degrees from vertical, provided that the projection of the nosing does not exceed 38 mm (1½ in.).

7.2.2.3.3.4 The requirement of 7.2.2.3.3.1 shall not apply to noncombustible grated stair treads and landings in the following occupancies:

- (1) Assembly occupancies as otherwise provided in Chapter 12 and Chapter 13
- (2) Detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23
- (3) Industrial occupancies as otherwise provided in Chapter 40

Solid treads and solid landing floors provide a visual barrier that shields the user's view of the vertical drop beneath the stair. Persons with a fear of high places are more comfortable using such stairs. Grated and expanded metal treads and landings might catch a user's heel and present a tripping hazard. Noncombustible grated stair treads are permitted in areas not accessed by the general public, such as catwalks and gridirons in theaters, resident housing areas in prisons, and factories and other industrial occupancies.

The *Code* does not directly mandate solid risers on stairs. Rather, the requirement that treads be free of projections or lips that could trip stair users is a performance-based provision that indirectly mandates solid risers on egress stairs used in the upward direction. Given that a riser is provided, the maximum slope—established as 30 degrees from the verti-

cal with not more than a 38-mm (1½-in.) nosing projection—is intended to keep an ascending user's toes from becoming caught under the tread if the user has a disability that prevents pulling the foot backwards to clear the lip created by the stair tread. This relatively new provision is not applicable to existing stairs.

7.2.2.3.4* **Tread Slope.** Tread slope shall not exceed 21 mm/m (¼ in./ft) (a slope of 1 in 48).

A.7.2.2.3.4 A small drainage slope for stair treads subject to wetting can improve tread slip resistance (*see also* A.7.2.2.3.3.2). A consistent slope to a side of the stair, where drainage is possible, might be preferable to a front-to-back slope of the treads. Providing a pitch of 10 mm/m to 21 mm/m (⅓ in./ft to ¼ in./ft) aids the shedding of water from a nominally horizontal surface.

Sloping treads are intentionally used to avoid water accumulation on stairs. They might also be unintentionally created where treads erode unevenly through usage or where differential settlement occurs. The limitation in slope is intended to reduce the dimensional nonuniformity of the effective riser heights and to reduce the chance of occupants slipping.

7.2.2.3.5* **Riser Height and Tread Depth.** Riser height shall be measured as the vertical distance between tread nosings. Tread depth shall be measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread's leading edge but shall not include bevelled or rounded tread surfaces that slope more than 20 degrees (a slope of 1 in 2.75). At tread nosings, such bevelling or rounding shall not exceed 13 mm (½ in.) in horizontal dimension.

A.7.2.2.3.5 Figure A.7.2.2.3.5(a), Figure A.7.2.2.3.5(b), Figure A.7.2.2.3.5(c), and Figure A.7.2.2.3.5(d) illustrate the method for measuring riser height and tread depth. Stairs that are covered with resilient floor coverings might need additional tread depth beyond the minimum specified in the *Code*. Any horizontal projection of resilient covering materials beyond the tread nosing and riser, such as carpet and underlayment, can interfere with users' feet and thereby reduce usable tread depth. At the tread nosing, such resilient covering materials might not be capable of providing stable support for users' feet. Generally, effective tread depth is reduced by the uncompressed thickness of such resilient coverings and might be further reduced over time if coverings are not well secured and consequently move forward at the nosings. [*See Figure A.7.2.2.3.5(e).*]

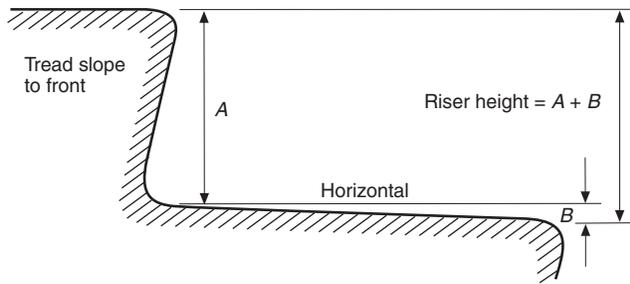

Figure A.7.2.2.3.5(a) Riser Measurement with Tread Slope to Front.

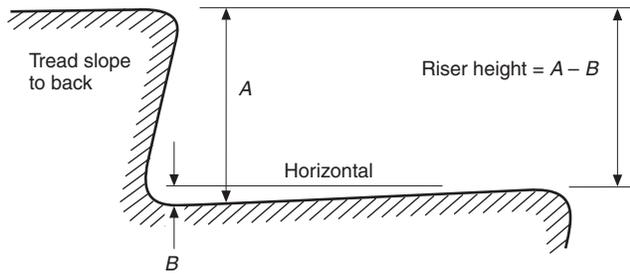

Figure A.7.2.2.3.5(b) Riser Measurement with Tread Slope to Back.

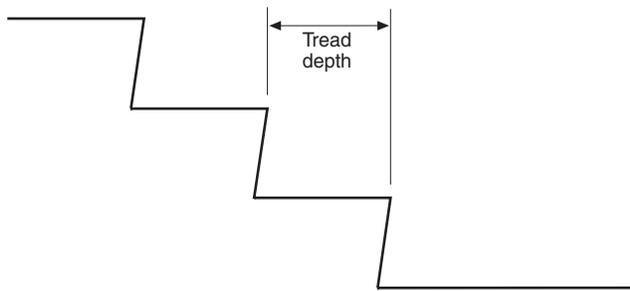

Figure A.7.2.2.3.5(c) Tread Depth.

Measurement of riser and tread dimensions needs to represent the actual heights and depths experienced by those using the stairs. Therefore, the tread dimension is not to include any part of the tread that is not functional for normal foot placement, especially where the tread slopes more than 20 degrees from the horizontal. Normal placement of the foot onto the step nosings results in an initial contact angle of less than 20 degrees. Therefore, any part of the nosing sloping more than an angle of 20 degrees is ineffective and might create a tripping hazard. The limitation of a 13-mm (½-in.) horizontal dimension for beveling

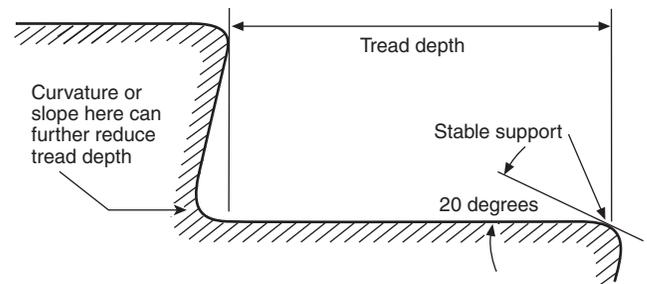

Figure A.7.2.2.3.5(d) Tread Measurement with Stable Support at Leading Edge.

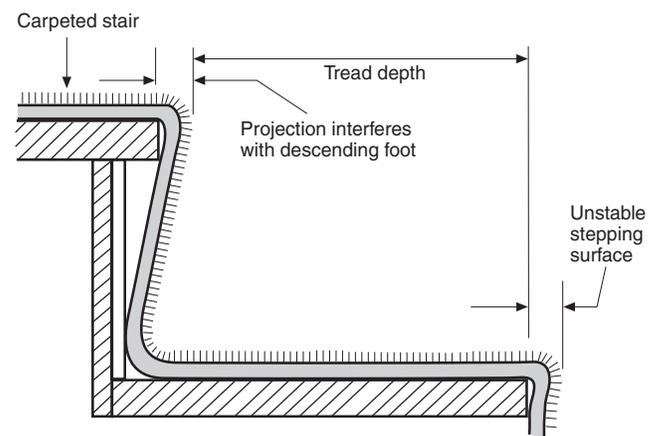

Figure A.7.2.2.3.5(e) Tread Measurement with Unstable Stepping Surface at Leading Edge.

or rounding of the step nosings is also related to tripping hazards. This beveling or rounding also reduces the chance of a slip occurring when the foot initially contacts the nosing during descent of the stair. By following this rule, the designer also achieves acceptable step dimensions while keeping the space used for the stair to a minimum.

Stair designers should keep in mind the possibility that a stair that originally was designed without a resilient covering might someday be carpeted, thereby possibly reducing significantly the effective tread depth of the steps. Designing such stairs to provide slightly more than the minimum required tread depths is especially prudent in these cases. In addition, those responsible for maintaining stairs should keep in mind that the addition of resilient coverings might reduce steps tread dimensions to below the standard, and the dimensions will be further reduced if the coverings are not installed and maintained tight against the underlying steps.

7.2.2.3.6 Dimensional Uniformity.

7.2.2.3.6.1 Variation in excess of 4.8 mm (3/16 in.) in the depth of adjacent treads or in the height of adjacent risers shall be prohibited unless otherwise permitted in 7.2.2.3.6.3.

7.2.2.3.6.2 The tolerance between the largest and smallest riser or between the largest and smallest tread shall not exceed 9.5 mm (3/8 in.) in any flight.

7.2.2.3.6.3 Where the bottom riser adjoins a sloping public way, walk, or driveway having an established grade and serving as a landing, the bottom riser shall be permitted to have a variation in height of not more than 25 mm in every 300 mm (1 in. in every 12 in.) of stairway width.

Many accidents have resulted from irregularities in stair geometry from one step to an adjacent step or over an entire run of stairs. There should be no design irregularities. Variations due to construction are permitted, provided that the variation between adjacent treads or adjacent risers does not exceed 5 mm (3/16 in.) and that the difference between the largest and smallest riser, as well as the difference between the largest and smallest tread, in any flight of stairs does not exceed 10 mm (3/8 in.).

Exhibit 7.30 illustrates a stair that has various nonuniformities or irregularities. Note that the treads are not all uniformly horizontal and the risers are not all vertical. This situation, which illustrates construction errors, is sometimes encountered with cast-in-place concrete stairs. Exhibit 7.30 shows unacceptable nonuniformities of the dimensions measured in accordance with 7.2.2.3.6.1 and 7.2.2.3.6.2. The nonuniformities measured at the backs of the treads and

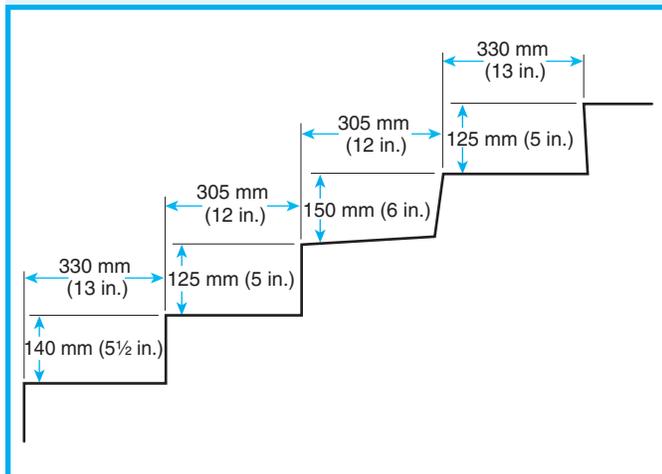

Exhibit 7.30 Variations in tread and riser dimensions.

along the risers might be greater or smaller depending on how the treads and risers slope.

Where the riser at the base of a stair abuts sloping public property, such as a public sidewalk, the building owner usually has no right to alter the grade of the public property. Therefore, 7.2.2.3.6.3 accepts a certain minimum across-the-stair slope not in excess of 1 in 12, as shown in Exhibit 7.31.

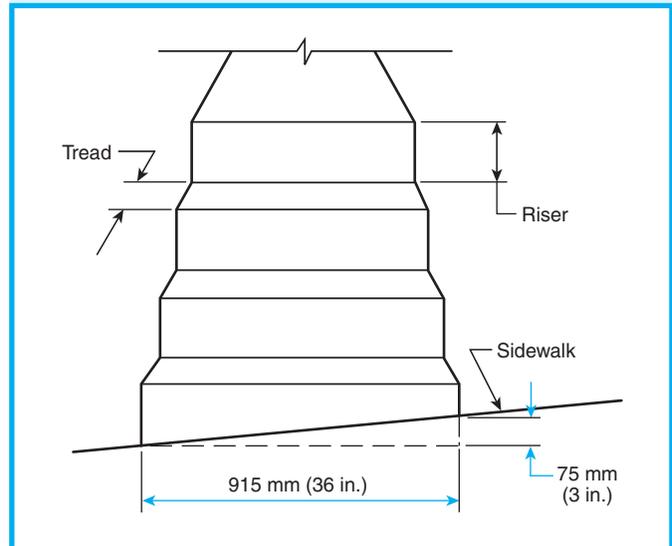

Exhibit 7.31 Permissible across-the-stair slope.

7.2.2.4 Guards and Handrails.

Subsection 7.1.8 requires guards along the open sides of means of egress paths where there is a vertical drop of at least 760 mm (30 in.). This requirement is positioned in the general requirements of Section 7.1 because the open sides of means of egress paths occur in places other than just stairs and ramps.

This requirement for guards at open sides of means of egress has a particular impact on stairs that historically have required only handrails. Guards must be provided on open sides of the stair—including those that “switch back” between adjacent stair flights, regardless of the horizontal distance between those flights. The minimum 1065-mm (42-in.) high guard, used in place of the minimum 865-mm (34-in.) handrail, is needed to prevent the 95 percentile male from falling over the rail upon striking the side of a stair. On switch-back flights of stairs, the required guard is intended to keep a person from falling to the adjacent stair flight. See 7.2.2.4.5 for guard details—especially 7.2.2.4.5.2(3), which permits

existing guards on existing stairs to be a minimum of 760 mm (30 in.) high.

Where the *Code* specifically permits guards to be omitted, such language is provided. For example, in 12.2.11.1.6, which applies to new assembly occupancies, guards are exempted on the audience side of stages; raised platforms; and other raised floor areas, such as runways, ramps, and side stages used for entertainment or presentations. Similarly, permanent guards are not required at vertical openings in the performance area of stages. Nor are guards required in assembly occupancies where the side of an elevated walking surface is required to be open for the normal functioning of special lighting or for the access and use of other special equipment.

NFPA staff members are often asked whether guards can be omitted at the open edge of loading docks. Given that the *Code* provides no specific exemption for loading docks, it is the intent that the general provisions for guards apply. However, Chapter 4 gives the authority having jurisdiction great latitude in making judgment calls where protection equivalent to that required by the *Code* is provided. Examples of judgment calls made by the AHJ are presented in the three scenarios that follow.

Scenario 1. A loading dock is 9140 mm (360 in.) deep [that is, the building wall is set back 9140 mm (360 in.) from the open edge of the dock]. At the open edge of the dock, there is more than 760 mm (30 in.) of vertical drop to the ground below. The egress system relies on passage along the width of the loading dock as part of the exit discharge leading to the public way. A 1120-mm- (44-in.-) wide aisle has been stenciled on the floor running parallel to and adjacent to the building wall. Building management strictly enforces a policy that keeps the aisle clear at all times. The authority having jurisdiction judges that, in traveling along the designated path, the building occupants never come close to the open edge of the dock and, thus, guards are not required.

Scenario 2. The same physical arrangement exists as in scenario 1, but the authority having jurisdiction inspects the facility and finds stacked materials in the designated aisle and across the depth of the loading dock. During emergency egress, the building occupants would need to travel close to the open edge of the dock to get around the stacked materials. The AHJ judges that, in this case, the guard provisions need to be followed.

Scenario 3. The loading dock is only 3050 mm (120 in.) deep. Materials are placed in a haphazard fashion on the dock. There is no designated egress path and,

thus, building occupants can be expected to have to travel near the open edge of the dock. The authority having jurisdiction judges that guards are needed.

7.2.2.4.1 Handrails.

7.2.2.4.1.1 Stairs and ramps shall have handrails on both sides, unless otherwise permitted in 7.2.2.4.1.5 or 7.2.2.4.1.6.

7.2.2.4.1.2 In addition to the handrails required at the sides of stairs by 7.2.2.4.1.1, the following provisions shall apply:

- (1) For new stairs exceeding 1905 mm (75 in.) in width, handrails shall be provided within 760 mm (30 in.) of all portions of the required egress width.
- (2) For existing stairs, handrails shall be provided within 1120 mm (44 in.) of all portions of the required egress width.

7.2.2.4.1.3 Where new intermediate handrails are provided in accordance with 7.2.2.4.1.2, the minimum clear width between handrails shall be 510 mm (20 in.).

7.2.2.4.1.4* The required egress width shall be provided along the natural path of travel.

A.7.2.2.4.1.4 The intent of this provision is to place handrails for the required egress width only, regardless of the actual width. The required egress width is provided along the natural path of travel to and from the building. Examples of this requirement are shown in Figure A.7.2.2.4.1.4. The reduced intermediate handrail spacing of 1525 mm (60 in.) along with a handrail height within the permissible height limits allows users to reach and grasp one handrail. Except as noted in 7.2.2.4.2 and 7.2.2.4.4, handrails are not required on stair landings.

7.2.2.4.1.5 If a single step or a ramp is part of a curb that separates a sidewalk from a vehicular way, it shall not be required to have a handrail.

7.2.2.4.1.6 Existing stairs, existing ramps, stairs within dwelling units and within guest rooms, and ramps within dwelling units and guest rooms shall be permitted to have a handrail on one side only.

Handrails are required on each side of new stairs and ramps, but they are not required on landings, except as noted in 7.2.2.4.2 and 7.2.2.4.4.10. Handrails are also required on at least one side of existing stairs. The handrails provide support for people using stairs and can serve as a guide if smoke enters the stairway

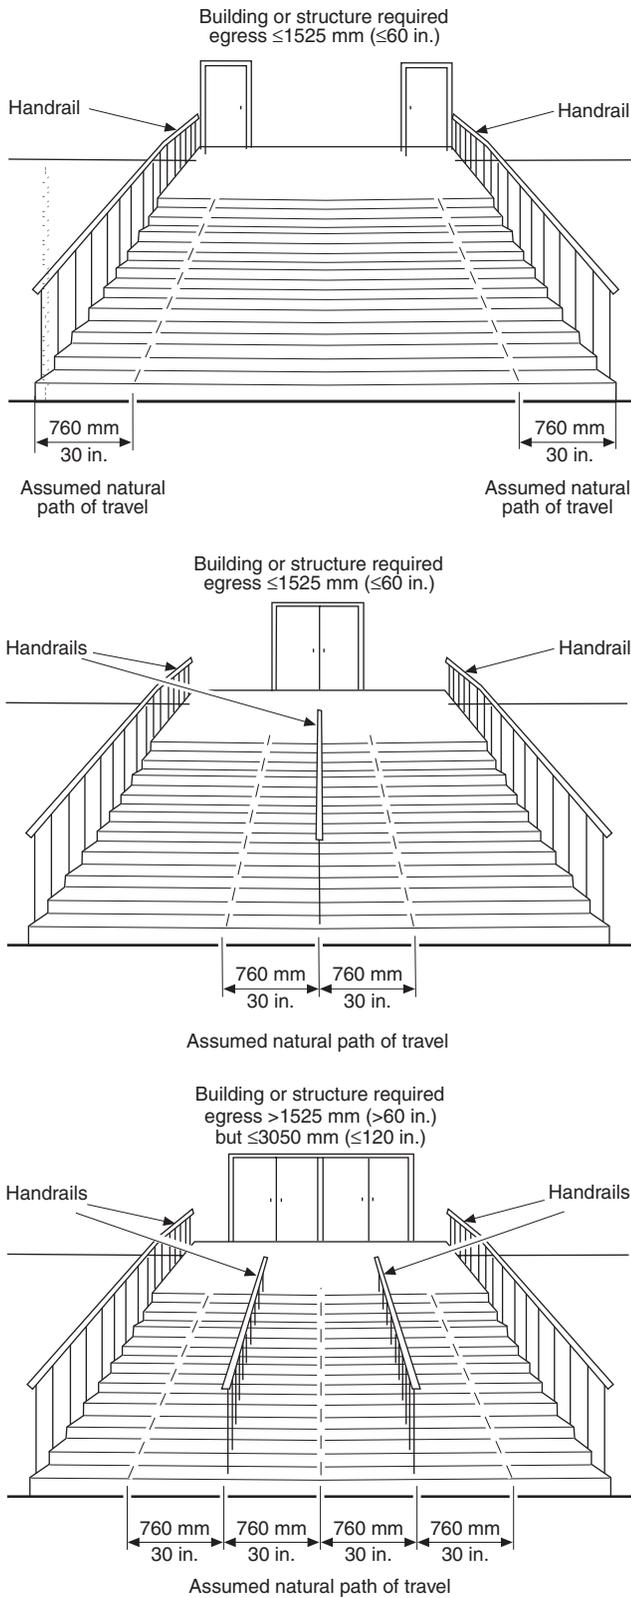

Figure A.7.2.2.4.1.4 Assumed Natural Paths of Travel on Monumental Stairs with Various Handrail Locations.

in a quantity sufficient to obscure vision or if the stair lighting system fails.

For handrails to be effective, they must be within reach of each file of people using the stair. In new stairs wider than 1905 mm (75 in.), handrails need to be provided within 760 mm (30 in.) of all portions of the required egress width; for existing stairs, they must be within 1120 mm (44 in.). The maximum 760-mm (30-in.) distance from a point on a new stair to the nearer handrail is based on the facts that people can only reach approximately 610 mm (24 in.) to the side to grasp a handrail and that a person's arms extend from the side of the body, not from the centerline. Exhibit 7.32 depicts people movement on a stair, seen in overhead plan view. The staggered filling of the stair surfaces is typical of that observed during building evacuation where movement, speed, density, and flow are near optimum for safe, comfortable crowd movement.

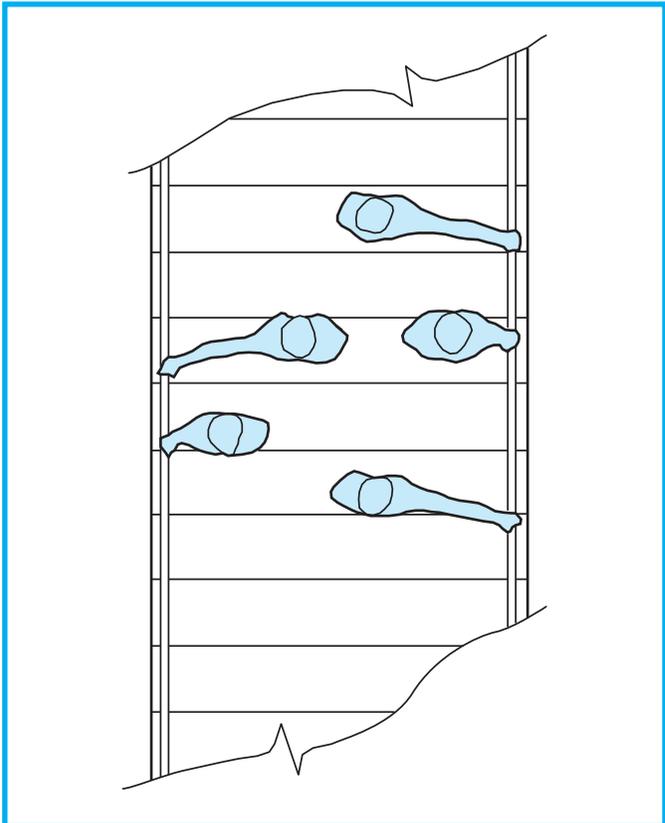

Exhibit 7.32 Overhead plan view of stair with handrails within maximum 760-mm (30-in.) reach.

Paragraph 7.2.2.4.1.2(1) requires intermediate handrails for new stairs that are wider than 1905 mm (75 in.). Paragraph 7.2.2.4.1.2(2) requires intermediate

handrails for existing stairs only where the absence of such an intermediate handrail would allow a person using the stair to be more than 1120 mm (44 in.) from a handrail. Because Table 7.2.2.2.1(b) and 7.3.2.2 permit handrails to project as much as 114 mm (4½ in.) into the stair clear width at each side of the stair, center handrails are needed on existing stairs more than, approximately, 2470 mm (97 in.) wide, or 115 mm + 1120 mm + 1120 mm + 115 mm (4½ in. + 44 in. + 44 in. + 4½ in.), as illustrated in Exhibit 7.33.

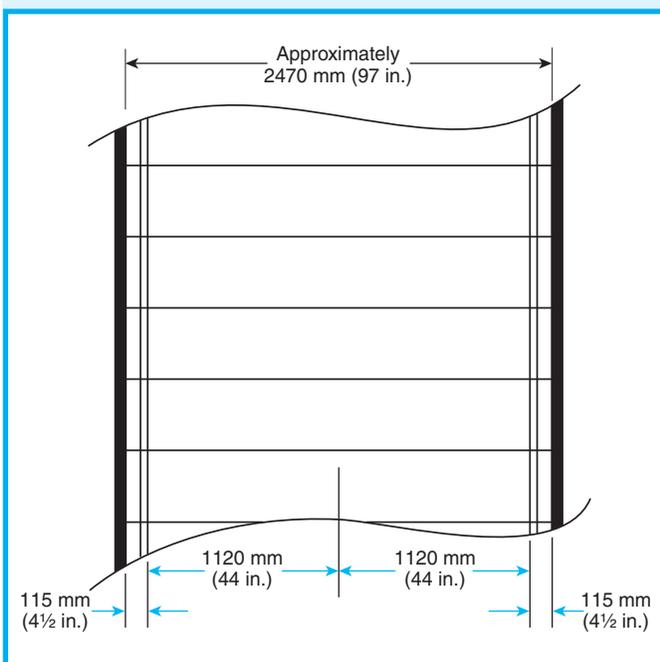

Exhibit 7.33 Maximum required width permitted without center handrail on existing stair.

On monumental stairs, which are characterized by their extreme widths, the required handrails should be located along the normal path of travel to and from the building. Figure A.7.2.2.4.1.4 illustrates the placement of handrails required on monumental stairs. Handrails are provided along the natural paths of travel from the associated doors.

7.2.2.4.2 Continuity. Required guards and handrails shall continue for the full length of each flight of stairs. At turns of new stairs, inside handrails shall be continuous between flights at landings.

It is not the intent of this Code to require handrails on stair landings. However, new interior handrails

on stairs that change direction at a landing must be continuous. See the turn detailed in the plan view of Figure A.7.2.2.4.4.

The commentary following the 7.2.2.4 subsection title explains the need for guards on open sides of stairs where there is at least a 760-mm (30-in.) vertical distance to fall. The 760-mm (30-in.) criterion—considered alone—would seem to exempt the guard from running past the last couple of risers at the base of each stair flight; however, this criterion must be considered in conjunction with 7.2.2.4.2, which mandates that the required guard is to continue for the full length of each flight of stairs.

7.2.2.4.3 Projections. The design of guards and handrails and the hardware for attaching handrails to guards, balusters, or walls shall be such that there are no projections that might engage loose clothing. Openings in guards shall be designed to prevent loose clothing from becoming wedged in such openings.

7.2.2.4.4* Handrail Details.

A.7.2.2.4.4 Figure A.7.2.2.4.4 illustrates some of the requirements of 7.2.2.4.4.

See 12.2.5.6.7 and 13.2.5.6.7 for requirements for handrails on aisle stairs in assembly occupancies.

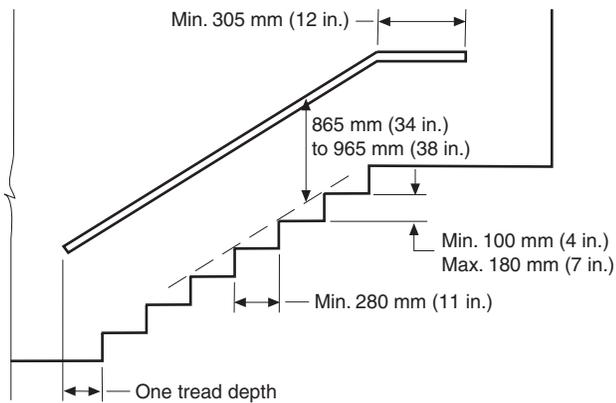

7.2.2.4.4.1 New handrails on stairs shall be not less than 865 mm (34 in.) and not more than 965 mm (38 in.) above the surface of the tread, measured vertically to the top of the rail from the leading edge of the tread.

7.2.2.4.4.2 Existing required handrails shall be not less than 760 mm (30 in.) and not more than 965 mm (38 in.) above the surface of the tread, measured vertically to the top of the rail from the leading edge of the tread.

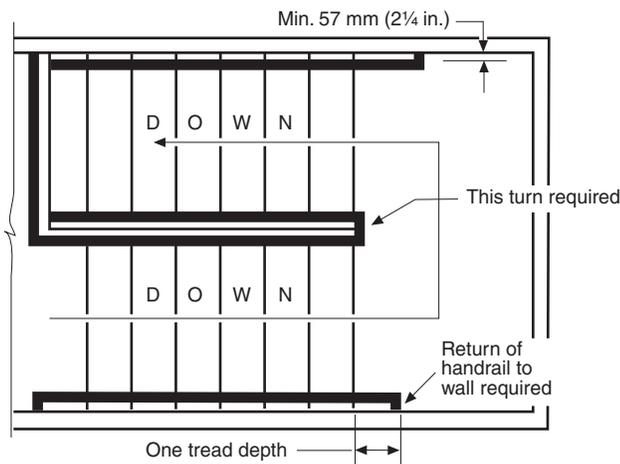

7.2.2.4.4.3 The height of required handrails that form part of a guard shall be permitted to exceed 965 mm (38 in.), but shall not exceed 1065 mm (42 in.), measured vertically to the top of the rail from the leading edge of the tread.

7.2.2.4.4.4* Additional handrails that are lower or higher than the main handrail shall be permitted.

A.7.2.2.4.4.4 Additional handrails, beyond those required by the Code, are permitted at heights other than those stipulated. For example, where children under the age of 5 are major users of a facility, an additional handrail at a height in the range of 710 mm to 810 mm (28 in. to 32 in.) might be useful. Generally, children prefer to use, and can effectively use, handrails that are located at shoulder to head

ELEVATION VIEW (straight stair)

PLAN VIEW (return stair)

Figure A.7.2.2.4.4 Handrail Details.

height due to their developmental characteristics and their less developed balance and walking abilities. At age 3, head height ranges from 890 mm to 1015 mm (35 in. to 40 in.); shoulder height averages 735 mm (29 in.). At age 5, head height ranges from 990 mm to 1170 mm (39 in. to 46 in.); shoulder height ranges from 785 mm to 940 mm (31 in. to 37 in.).

Handrail height was the subject of extensive research by the National Research Council of Canada.

Very high handrails have been tested in field and laboratory conditions. Heights up to about 1065 mm (42 in.) are very effective in helping people stabilize themselves to arrest a fall. Therefore, a guard-height railing that also meets the graspability criteria for

handrails [see 7.2.2.4.4.6] serves well as a handrail also. This dual function is the reason 7.2.2.4.4.3 permits the rail at the top of a 1065-mm (42-in.) high guard to serve as a handrail if it meets the graspability criteria. Three different types of studies of handrail height for stairs all led to the conclusion that the handrail heights previously required by the Code were inadequate. The studies included anthropometric analyses such as illustrated in Exhibit 7.34, field studies of the use of various handrails, and laboratory studies where the functional capability of users to grasp a handrail—as if arresting a fall—could be accurately measured and compared for a range of handrail conditions.

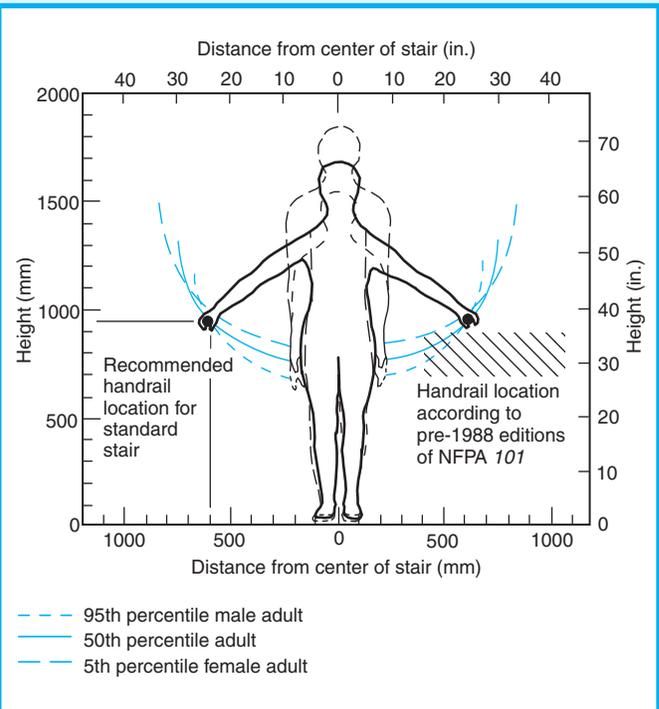

Exhibit 7.34 Anthropometric analysis of reach.

One of the studies leading to the requirement for higher handrails and closer lateral spacing included the anthropometric analysis shown in Exhibit 7.34 of user capability to reach a handrail positioned to the side. The left side of the exhibit shows the recommended height and spacing of handrails; on the right is the location of handrails permitted by pre-1988 editions of the Code. People in the middle of a wide stair will be unable to reach the lower, more distant handrails; therefore, this condition is not desirable when a stair is crowded, as during emergency egress.

The studies included a wide range of ages and

sizes of people, from young children to those in their 70s. Most functional heights—even for elderly persons tested—were in the range of 915 mm to 965 mm (36 in. to 38 in.), and the average height most preferred by elderly persons tested was about 940 mm (37 in.). These studies were reported in “Review of Stair-Safety Research with an Emphasis on Canadian Studies” by Jake Pauls⁸. The recommendation for lower handrails for young children is particularly important for family dwellings and for child day-care facilities.

Exhibit 7.35 is a frame from the documentary film, *The Stair Event*. It shows field testing of an adjustable-height handrail in an aisle stair in Canada’s Edmonton Commonwealth Stadium. Evidence from such field testing, from anthropometric analyses, and from laboratory testing with a range of younger and older adults led to the higher handrail heights first introduced in the 1988 edition of the *Code*. The upper handrail is located 940 mm (37 in.) above tread nosings, which, in the laboratory testing, was the average preferred height for elderly people and an especially effective height for arresting a fall that occurs while descending a stair. The lower railing, provided for children, is approximately 610 mm (24 in.) above the tread nosings. Note that even in this case of ascent, one of the children has chosen to use the higher railing, located at about his shoulder height, in preference to the lower one. A moment after this frame was taken, the smaller of the two boys also chose to use the upper handrail, which was located at about the height of his head. This behavior has been ob-

Exhibit 7.35 Field testing of handrail height. (Photo courtesy of Jake Pauls.)

served in other studies of children; that is, when given a choice of handrail heights, they often select one between shoulder and head height.

7.2.2.4.4.5* New handrails shall be installed to provide a clearance of not less than 57 mm (2¼ in.) between the handrail and the wall to which it is fastened.

A.7.2.2.4.4.5 This 38-mm (1½-in.) clearance assumes that the wall and other surfaces adjacent to the handrail are smooth. Where rough surfaces are used, greater clearances are recommended. Ergonomic studies suggest that not less than 57 mm (2¼ in.) is a more appropriate clearance, even to smooth surfaces. It is important to note that the 90-mm (3½-in.) projection allowance of Table 7.2.2.2.1(a) and Table 7.2.2.2.1(b) and 7.3.2.2 does not prohibit such larger clearances; the 90 mm (3½ in.) refers to stair width required for egress capacity, for example, not the actual width.

7.2.2.4.4.6 Handrails shall include one of the following features:

- (1) A circular cross section with an outside diameter of not less than 32 mm (1¼ in.) and not more than 51 mm (2 in.)
- (2)* A shape that is other than circular with a perimeter dimension of not less than 100 mm (4 in.), but not more than 160 mm (6¼ in.), and with the largest cross-sectional dimension not more than 57 mm (2¼ in.), provided that graspable edges are rounded so as to provide a radius of not less than 3.2 mm (⅛ in.)

A.7.2.2.4.4.6(2) Handrails should be designed so they can be grasped firmly with a comfortable grip and so the hand can be slid along the rail without encountering obstructions. The profile of the rail should comfortably match the hand grips. For example, a round profile such as is provided by the simplest round tubing or pipe having an outside diameter of 38 mm to 51 mm (1½ in. to 2 in.) provides good graspability for adults. Factors such as the use of a handrail by small children and the wall-fixing details should be taken into account in assessing handrail graspability. The most functional as well as the most preferred handrail shape and size is circular with a 38-mm (1½-in.) outside diameter (according to research conducted using adults). Handrails used predominantly by children should be designed at the lower end of the permitted dimensional range.

Handrails are one of the most important components of a stair; therefore, design excesses such as oversized wood handrail sections should be avoided unless there is a readily perceived and easily grasped handhold provided. In handrail design, it is useful to remember at all times the effectiveness of a simple round profile that allows some locking action by fingers as they curl around the handrail.

Perimeter dimension, referred to in 7.2.2.4.4.6(2), is the length of the shortest loop that wraps completely around the railing.

7.2.2.4.4.7 New handrails shall be continuously graspable along their entire length.

In earlier editions of the *Code*, a minimum 38-mm (1 1/2-in.) clearance was required between a new handrail and the wall to which it is fastened. The current provision, as detailed in 7.2.2.4.4.5, increases the required minimum clearance to 57 mm (2 1/4 in.) in recognition that 38 mm (1 1/2 in.) is an inadequate clearance for both a normal grasp and an emergency grasp of the handrail.

Paragraph 7.2.2.4.4.6 introduces a subtle but important requirement for handrails—graspability. People are incapable of exerting sufficient finger pressure to grasp a handrail adequately where using only a *pinch grip*; a *power grip*, where fingers curl around and under a properly shaped and sized railing, is much more effective. Exhibit 7.36 shows examples of acceptable and unacceptable handrails. Example 1 shows a handrail with a shape and an offset from the wall that provides graspability. Example 2 shows a handrail of a size and shape that are unacceptable from a graspability standpoint.

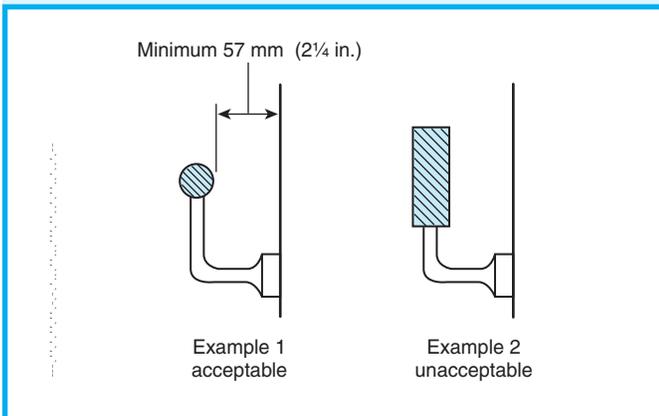

Exhibit 7.36 Handrail graspability features.

Exhibit 7.37 illustrates acceptable, unacceptable, and marginal handrail shapes and sizes based on a Canadian study that used younger and older adults and tested functional capability as well as user preference. The traditional residential handrail, shown at the bottom center, did not perform well in the functional testing; it was not a comfortable shape to grasp in comparison with other shapes. A key difference

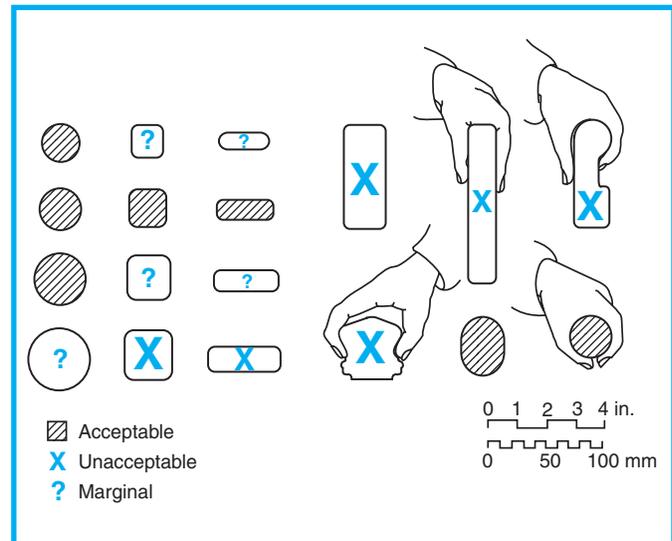

Exhibit 7.37 Acceptable, unacceptable, and marginal handrail shapes.

between the acceptable and unacceptable handrail shapes is the ability to wrap the fingers around the handrail completely to achieve a power grip. Unacceptable shapes permit only a pinch grip, which is ineffective in arresting a fall, even for people with ordinary hand dexterity and strength.

7.2.2.4.4.8 Handrail brackets or balusters attached to the bottom surface of the handrail shall not be considered to be obstructions to graspability, provided that the following criteria are met:

- (1) They do not project horizontally beyond the sides of the handrail within 38 mm (1 1/2 in.) of the bottom of the handrail and provided that, for each additional 13 mm (1/2 in.) of handrail perimeter dimension greater than 100 mm (4 in.), the vertical clearance dimension of 38 mm (1 1/2 in.) is reduced by 3.2 mm (1/8 in.).
- (2) They have edges with a radius of not less than 0.25 mm (0.01 in.).

Paragraph 7.2.2.4.4.8 recognizes that handrail brackets and other forms of support are necessary but need to be designed to permit the hand to slide along the handrail without encountering obstructions that would force the release of one's grip. Exhibit 7.38 shows a handrail that has been positioned above the horizontal extension of the supporting bracket by the required minimum 38 mm (1 1/2 in.). Note how the fingers of the hand have sufficient space to point downward in a natural grasping position without encountering the handrail bracket.

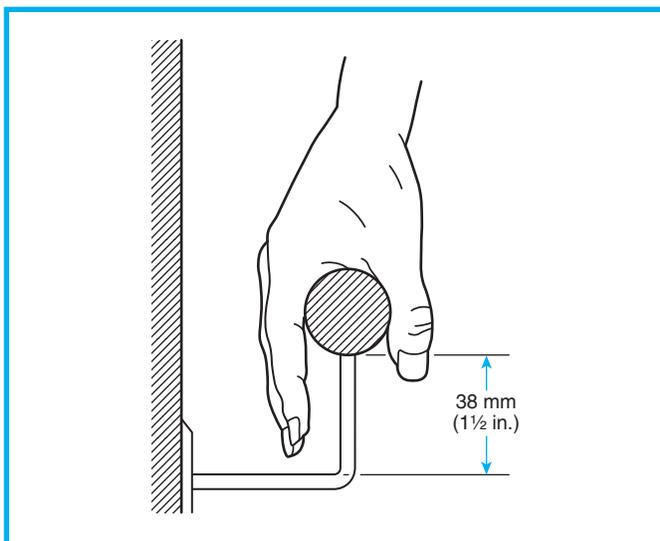

Exhibit 7.38 Minimum clearance to handrail brackets.

7.2.2.4.4.9 New handrail ends shall be returned to the wall or floor or shall terminate at newel posts.

7.2.2.4.4.10 In other than dwelling units, new handrails that are not continuous between flights shall extend horizontally, at the required height, not less than 305 mm (12 in.) beyond the top riser and continue to slope for a depth of one tread beyond the bottom riser.

7.2.2.4.4.11 Within dwelling units, handrails shall extend, at the required height, to at least those points that are directly above the top and bottom risers.

7.2.2.4.5 Guard Details.

7.2.2.4.5.1 The height of guards required in 7.1.8 shall be measured vertically to the top of the guard from the surface adjacent thereto.

7.2.2.4.5.2 Guards shall be not less than 1065 mm (42 in.) high, except as permitted by one of the following:

- (1) Existing guards within dwelling units shall be permitted to be not less than 915 mm (36 in.) high.
- (2) The requirement of 7.2.2.4.5.2 shall not apply in assembly occupancies where otherwise provided in Chapter 12 and Chapter 13.
- (3)* Existing guards on existing stairs shall be permitted to be not less than 760 mm (30 in.) high.

A.7.2.2.4.5.2(3) This reduction in required height applies only to the stair, not to the landings.

7.2.2.4.5.3* Open guards, other than approved, existing open guards, shall have intermediate rails or an ornamental

pattern such that a sphere 100 mm (4 in.) in diameter is not able to pass through any opening up to a height of 865 mm (34 in.), and the following also shall apply:

- (1) The triangular openings formed by the riser, tread, and bottom element of a guardrail at the open side of a stair shall be of such size that a sphere 150 mm (6 in.) in diameter is not able to pass through the triangular opening.
- (2) In detention and correctional occupancies, in industrial occupancies, and in storage occupancies, the clear distance between intermediate rails, measured at right angles to the rails, shall not exceed 535 mm (21 in.).

A.7.2.2.4.5.3 Vertical intermediate rails are preferred to reduce climbability.

The criterion for a 150-mm- (6-in.-) diameter sphere was changed to a 100-mm- (4-in.-) diameter sphere for the 1991 edition of the *Code*. This change was made based on the submission of a proposal that received the backing of the American Academy of Pediatrics. Approximately 950 out of 1000 children under age 10 can pass through a 150-mm (6-in.) wide opening. To prevent small children from falling through guards or being caught in openings, the configuration and construction of a guard must meet certain minimum requirements. Rather than requiring detailed specifications to be met for intermediate rails, the *Code* sets a performance criterion that allows alternative solutions.

Note that the 100-mm- (4-in.-) diameter sphere criterion applies only to the portion of the guard that extends from the walking surface to a height of 865 mm (34 in.), even though the top rail of the guard must extend to a minimum height of 1065 mm (42 in.). See Exhibit 7.39.

7.2.2.5 Enclosure and Protection of Stairs.

7.2.2.5.1 Enclosures.

7.2.2.5.1.1 All inside stairs serving as an exit or exit component shall be enclosed in accordance with 7.1.3.2.

7.2.2.5.1.2 Inside stairs, other than those serving as an exit or exit component, shall be protected in accordance with Section 8.6.

7.2.2.5.1.3 In existing buildings, where a two-story exit enclosure connects the story of exit discharge with an adjacent story, the exit shall be permitted to be enclosed only on the story of exit discharge, provided that not less than 50 percent

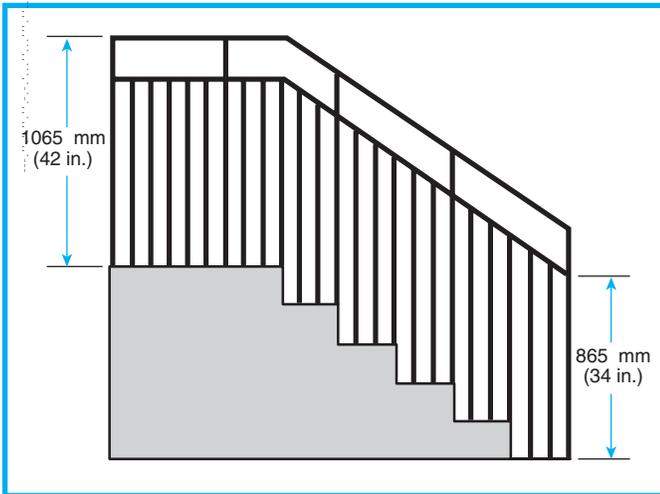

Exhibit 7.39 Height extension for application of 100-mm- (4-in.-) diameter sphere criterion for guards.

of the number and capacity of exits on the story of exit discharge are independent of such enclosures.

Paragraphs 7.2.2.5.1.1 and 7.2.2.5.1.2 emphasize that enclosure protection for stairs depends on whether they serve within an exit or involve a vertical opening between floors. Stairs that are not used as exits but that involve vertical openings are not subject to the requirements of 7.1.3.2; they must be protected in accordance with Section 8.6. Many interior stairs serve as exits and are vertical openings—they must, therefore, meet the requirements of 7.1.3.2 for exits as well as those of Section 8.6. Compliance with Section 8.6 does not ensure compliance with 7.1.3.2. Stairs that are neither within an exit nor part of vertical openings, such as stairs to a platform or stage, or those running between two different floor levels on the same story, would not have to comply with either 7.1.3.2 or Section 8.6.

The provisions of 7.2.2.5.1.3 recognize existing two-story stairs that, rather than being fully enclosed at both the top and bottom, are separated only from the level of exit discharge. Because such a stair is open to another floor, it might compromise the use of the stair enclosure for egress purposes by occupants of the level of exit discharge. The Code requires that at least half of the egress for the level of exit discharge be independent of the stair enclosure. This requirement limits the effect of occupants who are forced to travel into an enclosure that is smoke-filled due to a fire on another floor that is open to the stair.

See Exhibit 7.40. The existing stair connecting the first and second floors, although separated from the first floor, is open to the second floor. This arrangement is permitted because a minimum of 50 percent of the first floor egress can be satisfied independently from use of the stair enclosure via the door that opens directly to the outside at grade level at the right of the figure.

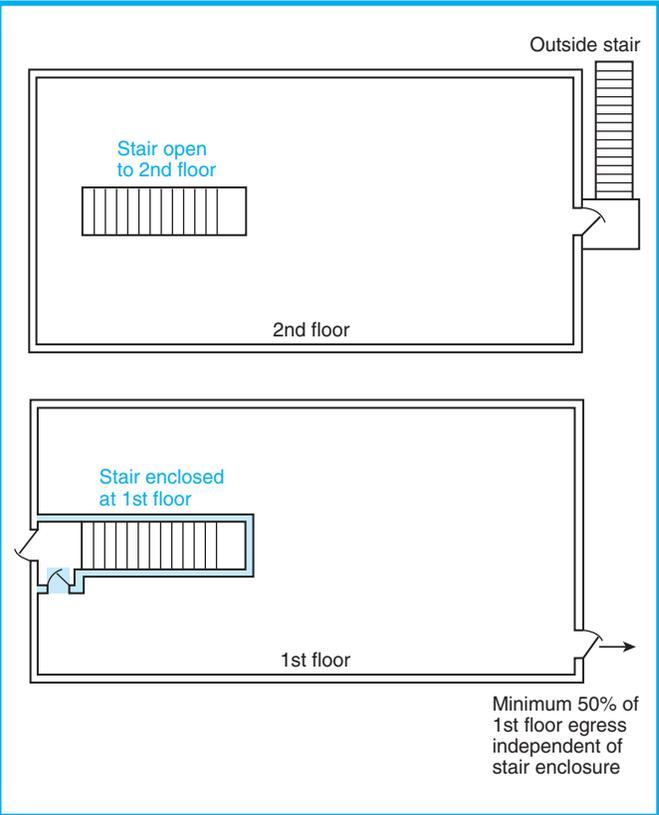

Exhibit 7.40 Partial enclosure of existing stair.

7.2.2.5.2* Exposures.

A.7.2.2.5.2 The purpose of this provision is to protect the exterior wall of a stairway from fires in other portions of the building. If the exterior wall of the stair is flush with the building exterior wall, the fire would need to travel around 180 degrees in order to impact the stair. This has not been a problem in existing buildings, so no protection is required. However, if the angle of exposure is less than 180 degrees, protection of either the stair wall or building wall is required.

Figure A.7.2.2.5.2(a), Figure A.7.2.2.5.2(b), and Figure A.7.2.2.5.2(c) illustrate the requirement, assuming nonrated glass on the exterior wall of the stair is used.

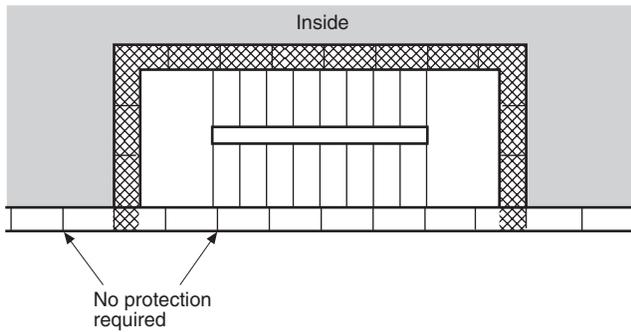

Figure A.7.2.5.2(a) Stairway with Nonrated Exterior Wall in Same Plane as Building Exterior Wall.

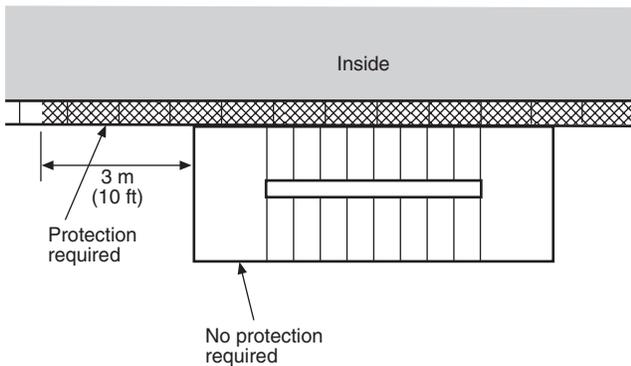

Figure A.7.2.5.2(b) Stairway with Unprotected Exterior Perimeter Protruding Past Building Exterior Wall.

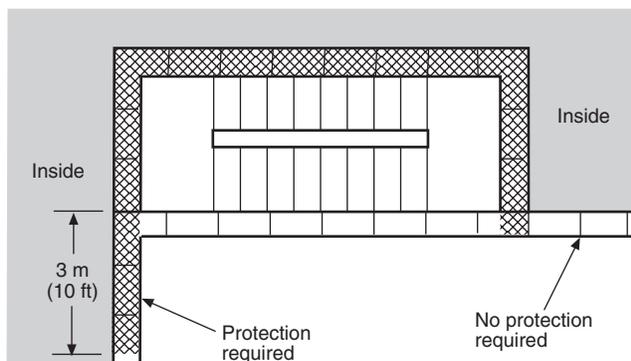

Figure A.7.2.5.2(c) Stairway with Nonrated Exterior Wall Exposed by Adjacent Exterior Wall of Building.

7.2.2.5.2.1 Where nonrated walls or unprotected openings enclose the exterior of a stairway, other than an existing stairway, and the walls or openings are exposed by other parts of the building at an angle of less than 180 degrees, the building enclosure walls within 3050 mm (120 in.) hori-

zontally of the nonrated wall or unprotected opening shall be constructed as required for stairway enclosures, including opening protectives.

7.2.2.5.2.2 Construction shall extend vertically from the ground to a point 3050 mm (120 in.) above the topmost landing of the stairs or to the roofline, whichever is lower.

7.2.2.5.2.3 The fire resistance rating of the separation extending 3050 mm (120 in.) from the stairs shall not be required to exceed 1 hour where openings have not less than a ¾-hour fire protection rating.

Paragraph 7.2.2.5.2 only applies where the stair is required to be enclosed either to create an exit or to protect a vertical opening.

7.2.2.5.3* Usable Space. Enclosed, usable spaces within exit enclosures shall be prohibited, including under stairs, unless otherwise permitted by 7.2.2.5.3.2.

A.7.2.2.5.3 An example of a use with the potential to interfere with egress is storage.

7.2.2.5.3.1 Open space within the exit enclosure shall not be used for any purpose that has the potential to interfere with egress.

7.2.2.5.3.2 Enclosed, usable space shall be permitted under stairs, provided that the following criteria are met:

- (1) The space is separated from the stair enclosure by the same fire resistance as the exit enclosure.
- (2) Entrance to the enclosed, usable space shall not be from within the stair enclosure. (See also 7.1.3.2.3.)

Paragraphs 7.2.2.5.3 and 7.2.2.5.3.1 state that, within an exit enclosure, no enclosed, usable space is permitted, nor is any open space permitted to be used for any purpose that could interfere with the use of the exit enclosure. Per 7.2.2.5.3.2, an enclosed, usable space under a stair is permitted to be considered outside the exit enclosure if the walls and soffits of the enclosed space meet the same protection requirements as the stair enclosure, thereby separating the space from the exit enclosure. See Exhibit 7.41. The door to the space is not permitted to open into the exit enclosure, per 7.1.3.2.1(5).

7.2.2.5.4* Stairway Marking.

A.7.2.2.5.4 Figure A.7.2.5.4 shows an example of a stairway marking sign.

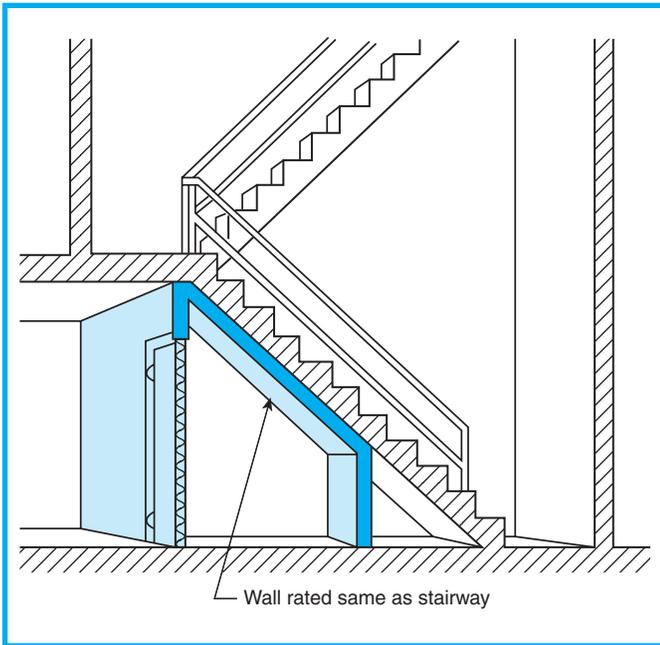

Exhibit 7.41 Enclosed, usable space under flight of stairs.

Figure A.7.2.2.5.4 Example of a Stairway Marking Sign.

7.2.2.5.4.1 Stairs serving five or more stories shall be provided with special signage within the enclosure at each floor landing. The signage shall indicate the floor level, the terminus of the top and bottom of the stair enclosure, and the identification of the stair enclosure. The signage also shall state the floor level of, and the direction to, exit discharge. The signage shall be located inside the enclosure approximately 1525 mm (60 in.) above the floor landing in a position

that is visible when the door is in the open or closed position. The signage shall comply with 7.10.8.1 and 7.10.8.2. The floor level designation shall also be tactile in accordance with ICC/ANSI A117.1 *American National Standard for Accessible and Usable Buildings and Facilities*.

7.2.2.5.4.2 Wherever an enclosed stair requires travel in an upward direction to reach the level of exit discharge, special signs with directional indicators showing the direction to the level of exit discharge shall be provided at each floor level landing from which upward direction of travel is required, unless otherwise provided in 7.2.2.5.4.2(A) and 7.2.2.5.4.2(B), and the following also shall apply:

- (1) Such signage shall comply with 7.10.8.1 and 7.10.8.2.
- (2) Such signage shall be visible when the door is in the open or closed position.

(A) The requirement of 7.2.2.5.4.2 shall not apply where signs required by 7.2.2.5.4.1 are provided.

(B) The requirement of 7.2.2.5.4.2 shall not apply to stairs extending not more than one story below the level of exit discharge where the exit discharge is clearly obvious.

7.2.2.5.4.3 The sign shall be painted or stenciled on the wall or on a separate sign securely attached to the wall.

7.2.2.5.4.4 The stairway identification letter shall be located at the top of the sign in minimum 25-mm (1-in.) high lettering and shall be in accordance with 7.10.8.2.

7.2.2.5.4.5 Roof access or the lack thereof shall be designated by a sign that reads ROOF ACCESS or NO ROOF ACCESS and located under the stairway identification letter. Lettering shall be a minimum of 25 mm (1 in.) high and shall be in accordance with 7.10.8.2.

7.2.2.5.4.6 The floor level number shall be located in the middle of the sign in minimum 125-mm (5-in.) high numbers and shall be in accordance with 7.10.8.2. Mezzanine levels shall have the letter “M” or other appropriate identification letter preceding the floor number, while basement levels shall have the letter “B” or other appropriate identification letter preceding the floor level number.

7.2.2.5.4.7 Identification of the lower and upper terminus of the stairway shall be located at the bottom of the sign in minimum 25-mm (1-in.) high letters or numbers and shall be in accordance with 7.10.8.2.

The provisions of 7.2.2.5.4 require the posting of important information at each floor landing in each stairwell if the stair serves five or more stories. The information is for fire-fighting personnel and building occupants in an emergency. The term *signage* is used to signify that the required information might appear on multiple signs mounted adjacent to each

other. The information most helpful to fire fighters can be put on one sign, and the information most useful to occupants on another. See A.7.2.2.5.4.

The signage must identify the stair, indicate the floor level of the landing and where the stairwell terminates at the top and bottom, and identify and show the direction to the exit discharge. Exhibit 7.42 illustrates the placement required to ensure that the sign is readily visible whether the door is open or closed.

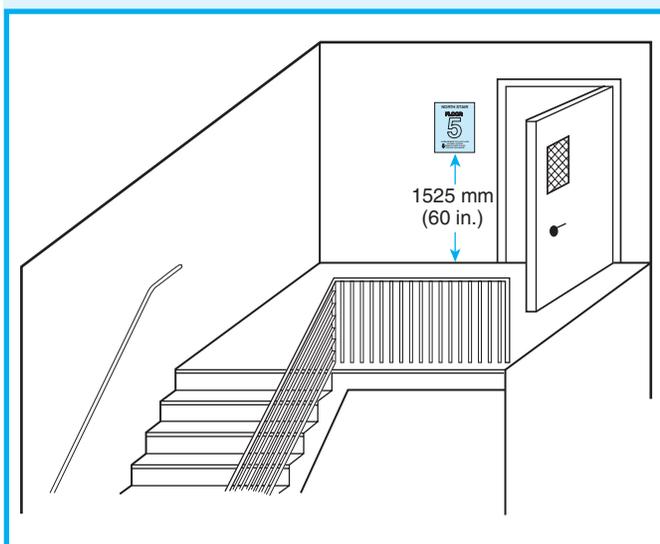

Exhibit 7.42 Stair sign placement.

The indication of the direction to the level of exit discharge can be extremely useful to occupants of a building, especially if they are located below the level of exit discharge. The natural tendency of occupants is to attempt egress by traveling downward in a stair; this is counterproductive where the exit discharge is located on an upper level. Also, many buildings have multiple levels of entrance, which creates confusion with respect to travel direction in a given stair.

The requirements of 7.2.2.5.4 are not exempted for existing buildings, because it is feasible and cost effective to install signs providing the required information. Because stair enclosures are usually not as aesthetically well finished as occupied portions of a building, the requirement for signage is often met by stenciling the information directly onto the walls.

7.2.2.6 Special Provisions for Outside Stairs.

7.2.2.6.1 Access. Where approved by the authority having jurisdiction, outside stairs shall be permitted to lead to roofs

of other sections of a building or an adjoining building where the construction is fire resistive and there is a continuous and safe means of egress from the roof. (See also 7.7.6.)

7.2.2.6.2* Visual Protection. Outside stairs shall be arranged to avoid any impediments to the use of the stairs by persons having a fear of high places. For stairs more than three stories in height, any arrangement intended to meet this requirement shall be not less than 1220 mm (48 in.) in height.

A.7.2.2.6.2 The guards that are required by 7.1.8 and detailed in 7.2.2.4.5 will usually meet this requirement where the stair is not more than three stories high. Special architectural treatment, including application of such devices as metal or masonry screens and grilles, will usually be necessary to comply with the intent of this requirement for stairs over three stories in height.

Outside stairs frequently have an open side. Required rails and guards help to prevent falls but do nothing to shield the user's view of the vertical drop. For outside stairs on high buildings, the fear of height might interfere with the use of such stairs; therefore, 7.2.2.6.2 requires a 1220-mm- (48-in.-) high visual barrier to be provided.

7.2.2.6.3 Separation and Protection of Outside Stairs.

7.2.2.6.3.1 Outside stairs shall be separated from the interior of the building by construction with the fire resistance rating required for enclosed stairs with fixed or self-closing opening protectives, except as follows:

- (1) Outside stairs serving an exterior exit access balcony that has two remote outside stairways or ramps shall be permitted to be unprotected.
- (2) Outside stairs serving not in excess of two adjacent stories, including the story of exit discharge, shall be permitted to be unprotected where there is a remotely located second exit.
- (3) In existing buildings, existing outside stairs serving not in excess of three adjacent stories, including the story of exit discharge, shall be permitted to be unprotected where there is a remotely located second exit.
- (4) The fire resistance rating of a separation extending 3050 mm (120 in.) from the stairs shall not be required to exceed 1 hour where openings have not less than a $\frac{3}{4}$ -hour fire protection rating.
- (5) Outside stairs in existing buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7 shall be permitted to be unprotected.

7.2.2.6.3.2 Wall construction required by 7.2.2.6.3.1 shall extend as follows:

- (1) Vertically from the ground to a point 3050 mm (120 in.) above the topmost landing of the stairs or to the roofline, whichever is lower
- (2) Horizontally for not less than 3050 mm (120 in.)

7.2.2.6.3.3 Roof construction required by 7.2.2.6.3.1 shall meet the following criteria:

- (1) It shall provide protection beneath the stairs.
- (2) It shall extend horizontally to each side of the stair for not less than 3050 mm (120 in.).

Paragraph 7.2.2.6.3 applies only where the outside stair serves as an exit. See the commentary following 7.2.2.

An important consideration is the proximity of outside stairs to openings in the building wall through which fire emerging from the building could render the stairs useless as a means of egress. Protection against such an occurrence is achieved as follows:

- (1) Protection from openings by separation distances
- (2) Protection of openings by fire-rated doors and fire-rated windows, which must be done if the openings are positioned such that the separation distances are less than are required.

The old fire escape arrangement where a window access is positioned immediately below a fire escape landing creates the potential for fire exposure of the fire escape and should, therefore, be avoided. The separation and protection provisions in 7.2.2.6.3 for outside stairs are illustrated in Exhibits 7.43 through 7.45.

In Exhibit 7.43, if openings are within 3050 mm (120 in.) of the outside stairs, they must be protected (see 7.2.2.6.3.2). However, the fire resistance ratings in the 3050-mm (120-in.) extension need not exceed 1 hour, and fire protection rating for the opening need not exceed $\frac{3}{4}$ hour.

In Exhibit 7.44, the fire resistance rating for the walls of the 3050-mm (120-in.) extension is a minimum of 1 hour. The fire resistance rating for the walls within the short dashed lines is based on the number of stories served by the outside stair, the same as for interior stairs.

In Exhibit 7.45, the exemption allowed by 7.2.2.6.3.1(1) is illustrated in the top figure (a). The exemption allowed by 7.2.2.6.3.1(2), which is restricted to stairways serving no more than two adjacent stories, is illustrated in the bottom figure (b). This same figure also illustrates the exemption allowed by 7.2.2.6.3.1(3), though that exemption permits stairways to serve up to three adjacent stories and is restricted to use in existing buildings.

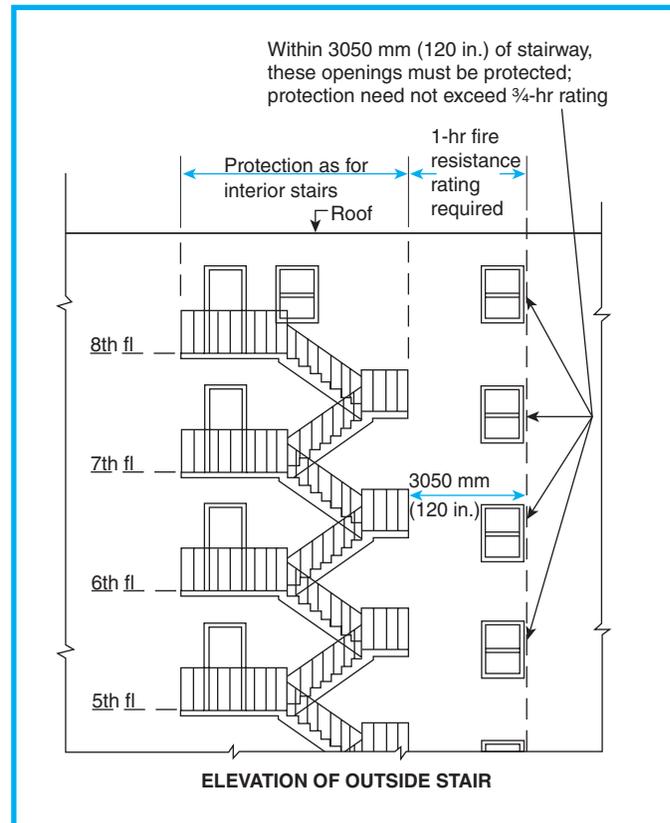

Exhibit 7.43 Protection of openings for outside stairs—Example 1.

7.2.2.6.4 Protection of Openings. All openings below an outside stair shall be protected with an assembly having not less than a $\frac{3}{4}$ -hour fire protection rating as follows:

- (1) Where located in a court, the smallest dimension of which does not exceed one-third its height
- (2) Where located in an alcove having a width that does not exceed one-third its height and a depth that does not exceed one-fourth its height

Exhibit 7.46 illustrates the provisions of 7.2.2.6.4. The bases for the required protection of openings below open, outside stairs discharging to a courtyard are as follows:

- (1) If D or W is less than one-third of H , all openings within the courtyard below the open, outside stairs must be protected.
- (2) If D is greater than one-fourth of H , and W is less than one-third of H , protection is required at openings.

7.2.3 Smokeproof Enclosures.

7.2.3.1 General. Where smokeproof enclosures are required in other sections of this *Code*, they shall comply with 7.2.3, unless they are approved, existing smokeproof enclosures.

A smokeproof enclosure is a stair enclosure designed to limit the infiltration of heat, smoke, and fire gases from a fire in any part of a building. A smokeproof enclosure improves protection against the products of combustion entering the actual stairway enclosure. The *Code* requires the use of smokeproof enclosures in 31.2.11 for existing, nonsprinklered, high-rise apartment buildings.

7.2.3.2 Performance Design. An appropriate design method shall be used to provide a system that meets the definition of smokeproof enclosure. The smokeproof enclosure shall be permitted to be created by using natural ventilation, by using mechanical ventilation incorporating a vestibule, or by pressurizing the stair enclosure.

Paragraph 7.2.3.2 requires that smokeproof enclosures meet the performance criterion contained in the definition of smokeproof enclosure in 3.3.203. Paragraph 7.2.3.2 also specifies three different means of creating smokeproof enclosures, as follows:

- (1) By use of natural ventilation as detailed in 7.2.3.7
- (2) By mechanical ventilation in accordance with 7.2.3.8
- (3) By pressurizing the stair enclosure as outlined in 7.2.3.9

However, the *Code* does not restrict the design to one of the three methods detailed if the design meets the performance requirements and is acceptable to the authority having jurisdiction. This alternative is especially important for existing smokeproof enclosures, because they often do not meet all the specifications that follow.

Exhibit 7.47 illustrates four variations of smokeproof enclosures that meet the specific *Code* criteria contained in 7.2.3.4 through 7.2.3.8. Plan A utilizes an open air vestibule. Plan B shows entrance to the smokeproof enclosure by way of an outside balcony. Plan C provides a stair enclosure entrance common to two buildings or two building areas. In Plan D, smoke and gases entering the vestibule are exhausted by mechanical ventilation. In each case, a double entrance to the stair enclosure with at least one side open or vented is characteristic of the type of con-

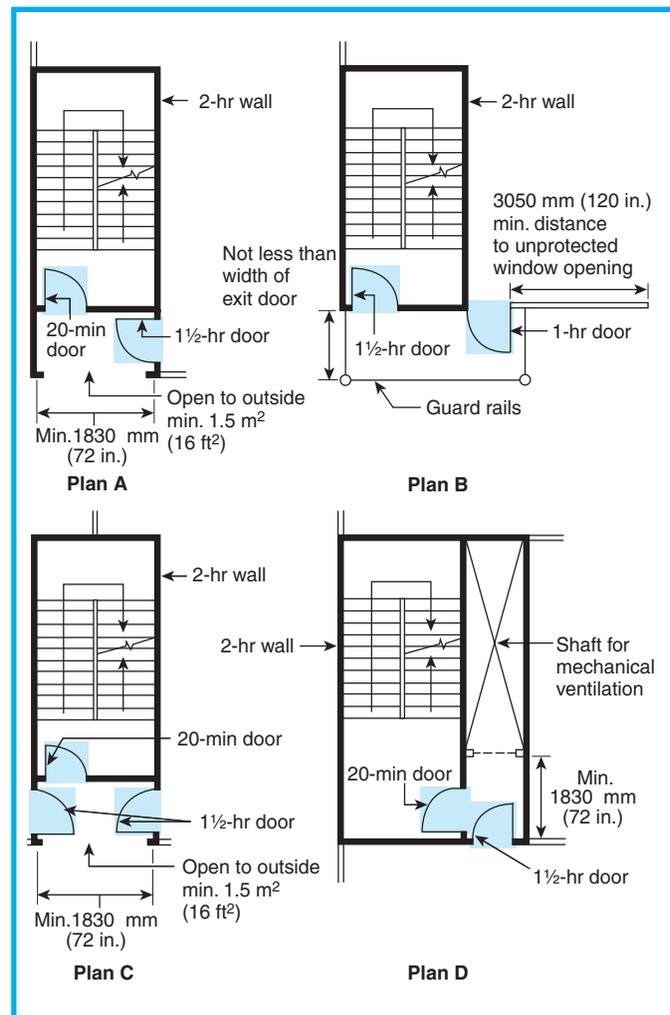

Exhibit 7.47 Four variations of smokeproof enclosures.

struction. Pressurization of the stair enclosure in the event of fire provides an attractive alternative and is a means of eliminating the need for an entrance vestibule.

7.2.3.3 Enclosure. A smokeproof enclosure shall be enclosed from the highest point to the lowest point by barriers having 2-hour fire resistance ratings. Where a vestibule is used, it shall be within the 2-hour-rated enclosure and shall be considered part of the smokeproof enclosure.

7.2.3.4 Vestibule. Where a vestibule is provided, the doorway into the vestibule shall be protected with an approved fire door assembly having a 1 1/2-hour fire protection rating, and the fire door assembly from the vestibule to the smokeproof enclosure shall have not less than a 20-minute fire protection rating. Doors shall be designed to minimize air leakage and shall be self-closing or shall be automatic-clos-

ing by actuation of a smoke detector within 3050 mm (120 in.) of the vestibule door.

Paragraph 7.2.3.3 requires that the smokeproof enclosure and all of its components be within the required 2-hour fire resistance-rated enclosure, with openings therein protected by a door having a 1½-hour fire protection rating. Such an arrangement protects the smokeproof enclosure from the direct attack of fire. However, the door from the vestibule (within the 2-hour rated enclosure) into the actual stairway requires only a 20-minute fire protection rating, because the purpose of this door is to minimize air or smoke leakage.

7.2.3.5 Discharge. Every smokeproof enclosure shall discharge into a public way, into a yard or court having direct access to a public way, or into an exit passageway. Such exit passageways shall be without openings, other than the entrance to the smokeproof enclosure and the door to the outside yard, court, or public way. The exit passageway shall be separated from the remainder of the building by a 2-hour fire resistance rating.

Note that 7.2.3.5 prohibits smokeproof enclosures from discharging through the level of exit discharge. It emphasizes the need for continuity to a public way, the exit discharge that leads to a public way, or an exit passageway that leads to an exit discharge that leads to a public way. Because an exit passageway is an exit, it is permitted to have only those openings necessary for building occupant egress.

7.2.3.6 Access. For smokeproof enclosures other than those consisting of a pressurized stair enclosure complying with 7.2.3.9, access to the smokeproof enclosure stair shall be by way of a vestibule or by way of an exterior balcony.

7.2.3.7 Natural Ventilation. Smokeproof enclosures using natural ventilation shall comply with 7.2.3.3 and the following:

- (1) Where access to the stair is by means of an open exterior balcony, the door assembly to the stair shall have a 1½-hour fire protection rating and shall be self-closing or shall be automatic-closing by actuation of a smoke detector.
- (2) Openings adjacent to the exterior balcony specified in 7.2.3.7(1) shall be protected in accordance with 7.2.2.6.4.
- (3) Every vestibule shall have a net area of not less than 1.5 m² (16 ft²) of opening in an exterior wall facing an exterior court, yard, or public space not less than 6100 mm (240 in.) in width.

- (4) Every vestibule shall have a minimum dimension of not less than the required width of the corridor leading to it and a dimension of not less than 1830 mm (72 in.) in the direction of travel.

7.2.3.8 Mechanical Ventilation. Smokeproof enclosures using mechanical ventilation shall comply with 7.2.3.3 and the requirements of 7.2.3.8(A) through 7.2.3.8(D).

(A) Vestibules shall have a dimension of not less than 1120 mm (44 in.) in width and not less than 1830 mm (72 in.) in direction of travel.

(B) The vestibule shall be provided with not less than one air change per minute, and the exhaust shall be 150 percent of the supply. Supply air shall enter and exhaust air shall discharge from the vestibule through separate tightly constructed ducts used only for such purposes. Supply air shall enter the vestibule within 150 mm (6 in.) of the floor level. The top of the exhaust register shall be located not more than 150 mm (6 in.) below the top of the trap and shall be entirely within the smoke trap area. Doors, when in the open position, shall not obstruct duct openings. Controlling dampers shall be permitted in duct openings if needed to meet the design requirements.

(C) To serve as a smoke and heat trap and to provide an upward-moving air column, the vestibule ceiling shall be not less than 510 mm (20 in.) higher than the door opening into the vestibule. The height shall be permitted to be decreased where justified by engineering design and field testing.

(D) The stair shall be provided with a dampered relief opening at the top and supplied mechanically with sufficient air to discharge at least 70.8 m³/min (2500 ft³/min) through the relief opening while maintaining a positive pressure of not less than 25 N/m² (0.10 in. water column) in the stair, relative to the vestibule with all doors closed.

Exhibit 7.48 illustrates an elevation view of a smokeproof enclosure vestibule that uses mechanical ventilation.

7.2.3.9 Stair Pressurization.

7.2.3.9.1* Smokeproof enclosures using stair pressurization shall use an approved engineered system with a design pressure difference across the barrier of not less than 12.5 N/m² (0.05 in. water column) in sprinklered buildings, or 25 N/m² (0.10 in. water column) in nonsprinklered buildings, and shall be capable of maintaining these pressure differences under likely conditions of stack effect or wind. The pressure difference across doors shall not exceed that which allows the door to begin to be opened by a force of 133 N (30 lbf) in accordance with 7.2.1.4.5.

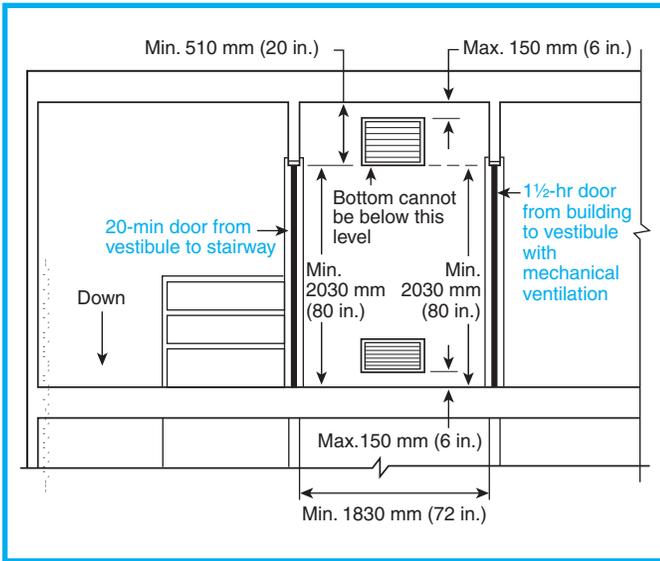

Exhibit 7.48 Mechanical ventilation form of smokeproof enclosure.

A.7.2.3.9.1 The design pressure differences required by 7.2.3.9.1 are based on specific gas temperatures and ceiling heights. The system is required to be approved because anticipated conditions might be different from those on which the design pressure differences were calculated and, thus, different design pressure differences might be needed. For additional information on necessary minimum design pressure differences, including calculational techniques, or maximum pressure differences across doors to ensure reasonable operating forces, see NFPA 92A, *Recommended Practice for Smoke-Control Systems*.

Pressurized stairs are permitted to be used as smokeproof enclosures in either nonsprinklered or sprinklered buildings. However, the design pressure difference across the barrier in a nonsprinklered building is required to be twice that required in a sprinklered building.

7.2.3.9.2 Equipment and ductwork for stair pressurization shall be located in accordance with one of the following specifications:

- (1) Exterior to the building and directly connected to the stairway by ductwork enclosed in noncombustible construction
- (2) Within the stair enclosure with intake and exhaust air vented directly to the outside or through ductwork enclosed by a 2-hour fire-resistive rating

(3) Within the building under the following conditions:

- (a) Where the equipment and ductwork are separated from the remainder of the building, including other mechanical equipment, by a 2-hour fire-resistive rating
- (b) Where the building, including the stairway enclosure, is protected throughout by an approved, supervised automatic sprinkler system installed in accordance with Section 9.7, and the equipment and ductwork are separated from the remainder of the building, including other mechanical equipment, by not less than a 1-hour fire-resistive rating

7.2.3.9.3 In all cases specified by 7.2.3.9.2(1) through 7.2.3.9.2(3), openings into the required fire resistance-rated construction shall be limited to those needed for maintenance and operation and shall be protected by self-closing fire protection-rated devices in accordance with 8.3.4.

Exhibits 7.49, 7.50, and 7.51 illustrate arrangements that comply with 7.2.3.9.2.

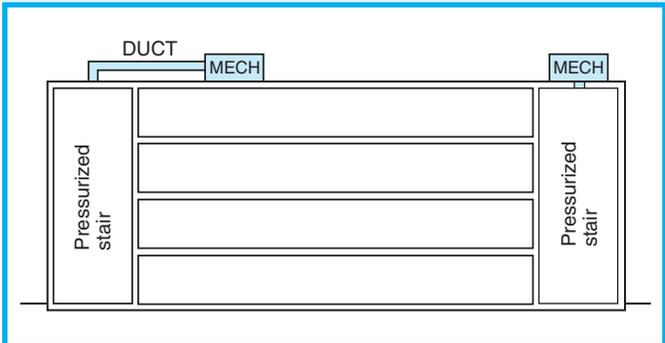

Exhibit 7.49 Mechanical equipment and ductwork complying with 7.2.3.9.2(1).

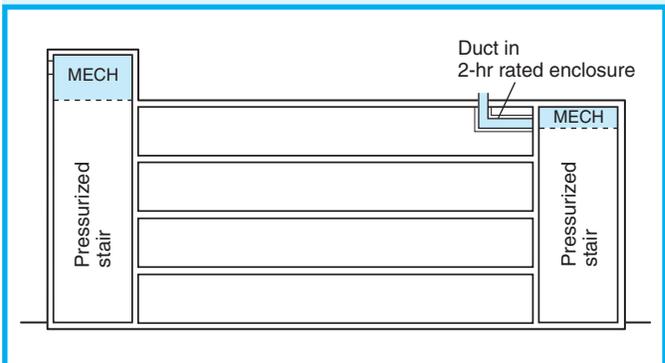

Exhibit 7.50 Mechanical equipment and ductwork complying with 7.2.3.9.2(2).

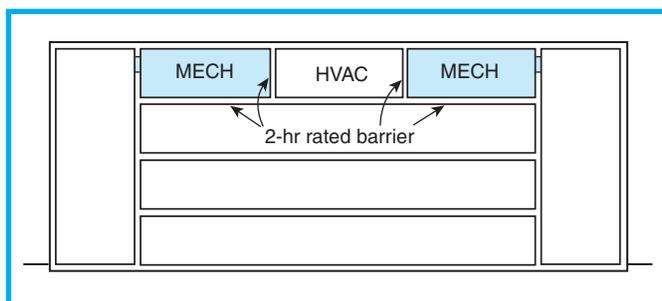

Exhibit 7.51 Mechanical equipment and ductwork complying with 7.2.3.9.2(3).

7.2.3.10 Activation of Mechanical Ventilation and Pressurized Stair Systems.

7.2.3.10.1 For both mechanical ventilation and pressurized stair enclosure systems, the activation of the systems shall be initiated by a smoke detector installed in an approved location within 3050 mm (120 in.) of the entrance to the smokeproof enclosure.

7.2.3.10.2 The required mechanical system shall operate upon the activation of the smoke detectors specified in 7.2.3.10.1 and by manual controls accessible to the fire department. The required system also shall be initiated by the following, if provided:

- (1) Waterflow signal from a complete automatic sprinkler system
- (2) General evacuation alarm signal (*see* 9.6.3.6)

7.2.3.11 Door Closers. The activation of an automatic-closing device on any door in the smokeproof enclosure shall activate all other automatic-closing devices on doors in the smokeproof enclosure.

7.2.3.12 Standby Power. Standby power for mechanical ventilation equipment shall be provided by an approved, self-contained generator that is set to operate whenever there is a loss of power in the normal house current. The generator shall be located in a room having a minimum 1-hour fire resistance-rated separation from the remainder of the building. The generator shall have a fuel supply not less than that which is adequate to operate the equipment for 2 hours.

7.2.3.13 Testing. Before the mechanical equipment is accepted by the authority having jurisdiction, it shall be tested to confirm that it is operating in compliance with the requirements of 7.2.3. All operating parts of the system shall be tested semiannually by approved personnel, and a log shall be kept of the results.

7.2.4 Horizontal Exits.

7.2.4.1 General.

7.2.4.1.1 Where horizontal exits are used in the means of egress, they shall conform to the general requirements of Section 7.1 and the special requirements of 7.2.4.

7.2.4.1.2* Horizontal exits shall be permitted to be substituted for other exits where the total egress capacity of the other exits (stairs, ramps, doors leading outside the building) is not less than half that required for the entire area of the building or connected buildings and provided that none of the other exits, is a horizontal exit, unless otherwise provided in 7.2.4.1.3.

A.7.2.4.1.2 Example. One way to provide the required egress capacity from the upper floor of a department store building 107 m × 61 m (350 ft × 200 ft), with an occupant load of 1166 per floor, would be to furnish eight 1120-mm (44-in.) stairs. [*See Figure A.7.2.4.1.2(a).*]

Assume that this building is divided into two sections by a fire barrier meeting the requirements for a horizontal exit, one 40 m × 61 m (130 ft × 200 ft) and the other 67 m × 61 m (220 ft × 200 ft), with two pairs of 1170-mm (46-in.) double egress doors, with each door providing 1120 mm (44 in.) of clear egress width [*see Figure A.7.2.4.1.2(b)*]. The smaller section, considered separately, will require the equivalent of three 1120-mm (44-in.) exit stairs, and the larger section will require five such exits. The horizontal exits will serve as one of the three exits required for the smaller section and two of the five exits required for the larger section. Therefore, only two 1120-mm (44-in.) exit stairs from the smaller section and three 1120-mm (44-in.) exit stairs from the larger section will be required if the exits can be arranged to meet the requirements for the 46-m (150-ft) travel distance permitted from any point in a nonsprinklered building. Thus, the total number of exit stairs required for the building will be five, as compared to eight if no horizontal exit had been provided.

Another option would be the use of two 1420-mm (56-in.) exit stairs from the larger section, which would reduce the total number of stairways required from the floor to four [*see Figure A.7.2.4.1.2(c)*]. However, if the building were further subdivided by a second fire wall meeting the requirements for a horizontal exit, no further reduction in stairways would be permitted in order to comply with the requirement that horizontal exits provide a maximum of one-half of egress capacity.

7.2.4.1.3 The requirement of 7.2.4.1.2 shall not apply to the following:

- (1) Health care occupancies as otherwise provided in Chapter 18 and Chapter 19

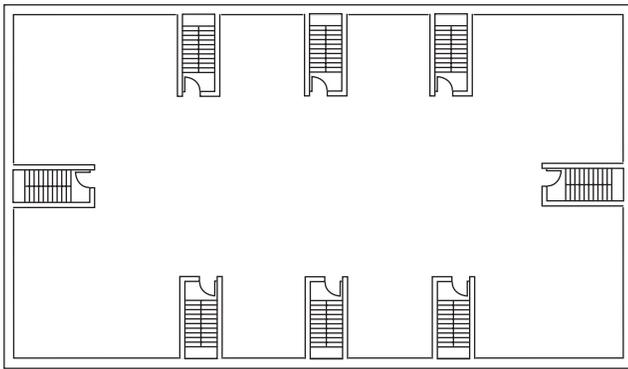

Figure A.7.2.4.1.2(a) Eight Exits, None via Horizontal Exit, Required to Provide the Necessary Egress Capacity.

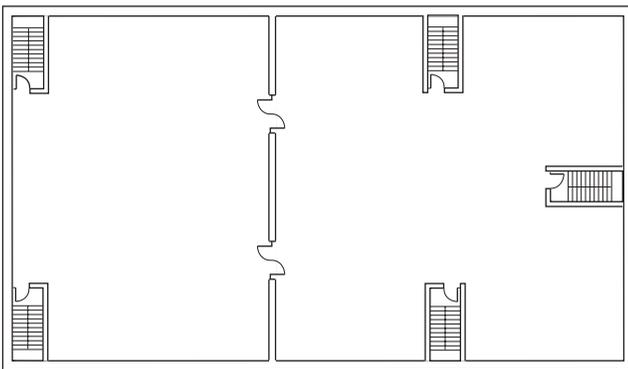

Figure A.7.2.4.1.2(b) Number of Stairs Reduced by Three Through Use of Two Horizontal Exits; Egress Capacity Not Reduced.

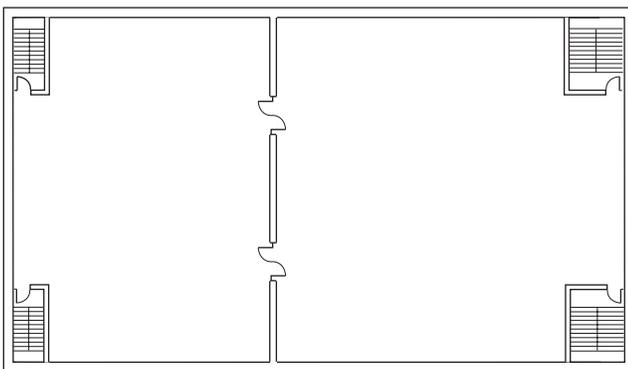

Figure A.7.2.4.1.2(c) Number of Stairs Further Reduced by Widening Stairs in Larger Compartment, But Not to Less Than One-Half the Required Number and Capacity of Exits from That Compartment.

- (2) Detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23

A horizontal exit is a combination of fire-rated walls with fire-rated doors providing passage from one building area into another building area; each area is a fire compartment independent of the other compartment. A horizontal exit, however, need not be confined to one building. It can be used as a bridge from one building to another. Just as with other types of exits, the horizontal exit has components consisting of doors and enclosure walls. Structural features, such as bridges and balconies, are often used in the passage from one area to the other. Horizontal exits typically do not include stairs or ramps, because they are usually located on the same level as the area from which escape is desired.

Horizontal exits are internal exits that might be located some distance from a door leading to the outside at grade level, so the Code permits them to provide not more than one-half the required number of exits or egress capacity of the building or buildings that they connect. However, in health care occupancies and detention and correctional occupancies, special exemptions apply, as noted in 7.2.4.1.3.

Before any space can be used as an occupant accumulation area on either side of a horizontal exit, it must satisfy certain criteria. Such a space, although separated with 2-hour fire barriers (see 7.2.4.3 for details on the fire barrier), cannot be used as a horizontal exit unless there is at least one standard type of exit, not an additional horizontal exit, leading from the space. Additionally, the compartment must be large enough to provide occupant accumulation space for the occupants of both the fire compartment containing the fire and the non-fire compartment, allowing 0.28 m² (3 ft²) of floor space per person. The required accumulation space per person is increased in health care occupancies, because occupants might be on beds and stretchers, and is also increased in detention and correctional occupancies where the residents are normally held in the non-fire compartment for a considerable time rather than being released to the outside. The nature of a horizontal exit is such that it provides psychological comfort. Being held in an area or building that is away from the fire reassures occupants and prevents disorderly movement.

Exhibit 7.52 illustrates how to apply the requirement when substituting horizontal exits for other exits. Note that the doors in the horizontal exits (circled) substitute for exit stair enclosures for the occupants on either side of the 2-hour fire resistance-rated

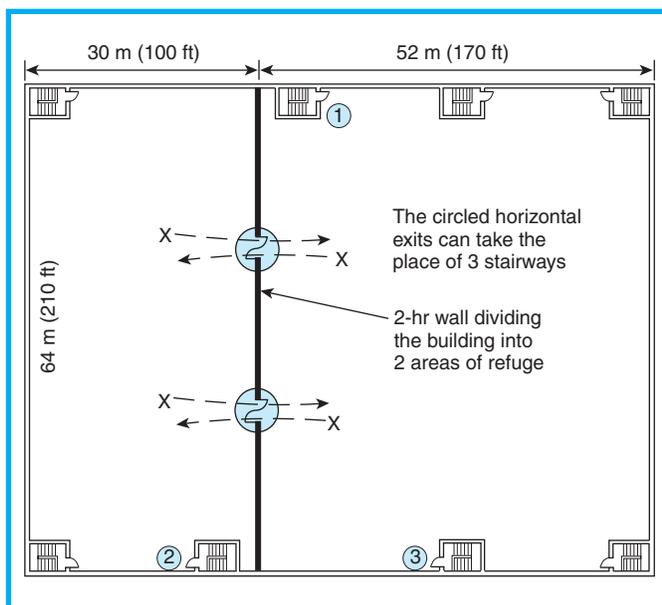

Exhibit 7.52 Example of substituting horizontal exits for other exits.

barrier that creates the horizontal exit. The doors permit the elimination of the three stair enclosures closest to the horizontal exits, stair enclosures that would otherwise be required if the entire floor area were left undivided.

7.2.4.2 Fire Compartments.

7.2.4.2.1 Every fire compartment for which credit is permitted in connection with a horizontal exit(s) also shall have at least one additional exit, but not less than 50 percent of the required number and capacity of exits, that is not a horizontal exit, unless otherwise provided in 7.2.4.2.1.2.

7.2.4.2.1.1 Any fire compartment not having an exit leading outside shall be considered as part of an adjoining compartment with an exit leading to the outside.

7.2.4.2.1.2 The requirement of 7.2.4.2.1 shall not apply to the following:

- (1) Health care occupancies as otherwise provided in Chapter 18 and Chapter 19
- (2) Detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23

7.2.4.2.2 Every horizontal exit for which credit is permitted shall be arranged so that there are continuously available paths of travel leading from each side of the exit to stairways or other means of egress leading to outside the building.

7.2.4.2.3 Wherever either side of a horizontal exit is occupied, the doors used in connection with the horizontal exit

shall be unlocked from the egress side, unless otherwise permitted for the following:

- (1) Health care occupancies as otherwise provided in Chapter 18 and Chapter 19
- (2) Detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23

7.2.4.2.4 The floor area on either side of a horizontal exit shall be sufficient to hold the occupants of both floor areas and shall provide at least 0.28 m² (3 ft²) clear floor area per person, unless otherwise permitted for the following:

- (1) Health care occupancies as otherwise provided in Chapter 18 and Chapter 19
- (2) In detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23

The design of a horizontal exit and the incorporation of a horizontal exit into a building are not complicated. For proper arrangement of the total means of egress system, it is simply a matter of designing each separated portion, or compartment, as if it were a completely separate building. The point of passage through the horizontal exit is treated as if it were an exterior exit door. In determining the required egress capacities from each separated portion or compartment, the occupant loads of multiple compartments are not to be combined.

Although each compartment must contain sufficient available floor area [at least 0.28 m² (3 ft²) per person for the total occupant load of both compartments], occupants will not remain in the safe compartment indefinitely. Egress from the safe compartment continues through its other exits, such as enclosed exit stairs or doors to the outside. The 2-hour fire resistance-rated barrier separating the safe compartment from the compartment of fire origin provides the additional time needed for all occupants to egress the building. Egress through other exits might be relatively slow, because such exits are typically sized for occupants of that safe compartment alone, not the combined loads of both compartments.

7.2.4.3 Fire Barriers.

7.2.4.3.1 Fire barriers separating building areas between which there are horizontal exits shall have a 2-hour fire resistance rating and shall provide a separation that is continuous to ground. (See also Section 8.3.)

7.2.4.3.2 Where a fire barrier provides a horizontal exit in any story of a building, such fire barrier shall not be required on other stories, provided that the following criteria are met:

- (1) The stories on which the fire barrier is omitted are separated from the story with the horizontal exit by construction having a fire resistance rating at least equal to that of the horizontal exit fire barrier.
- (2) Vertical openings between the story with the horizontal exit and the open fire area story are enclosed with construction having a fire resistance rating at least equal to that of the horizontal exit fire barrier.
- (3) All required exits, other than horizontal exits, discharge directly to the outside.

Exhibit 7.53 illustrates how the exemption detailed in 7.2.4.3.2 can be used to avoid extending the 2-hour fire resistance-rated barrier through all floors. Horizontal exits occur on floors 5 and 6 only. Fire-rated floor construction and associated supporting construction provide the needed separation between the floors with horizontal exits and those without them.

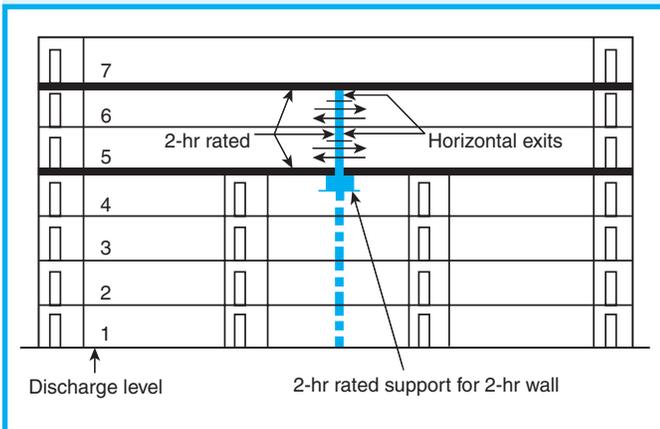

Exhibit 7.53 Building with horizontal exits on certain floors only.

7.2.4.3.3 Where fire barriers serving horizontal exits, other than existing horizontal exits, terminate at outside walls, and the outside walls are at an angle of less than 180 degrees for a distance of 3050 mm (120 in.) on each side of the horizontal exit, the outside walls shall have not less than a 1-hour fire resistance rating, with opening protectives of not less than a ¾-hour fire protection rating, for a distance of 3050 mm (120 in.) on each side of the horizontal exit.

Paragraph 7.2.4.3.3 requires additional protection where the horizontal exit wall joins the building's exterior wall if there is potential at that location for fire to spread to the adjoining fire compartment. Such potential is judged to exist where the building walls on each side of the horizontal exit expose each other

at an angle of less than 180 degrees. The intent is the same as in 7.2.2.6.3 for the protection of exterior walls associated with outside stairs.

The required 3050-mm (120-in.) extensions to each side of the 2-hour fire resistance-rated horizontal exit only need to have a 1-hour fire resistance rating. One-hour fire-resistance-rated walls are permitted ¾-hour fire protection-rated opening protectives; therefore, the rated extensions are permitted to use fire windows.

The concept of the 180-degree rule is illustrated in Exhibit 7.54. Where the building walls on each side of the horizontal exit expose each other at an angle of less than 180 degrees, additional 3050-mm (120-in.), 1-hour fire protection-rated extensions to each side of the horizontal exit are required. At the right of Exhibit 7.54, additional protection is not required where the building walls at each side of the horizontal exit expose each other at a full 180 degrees.

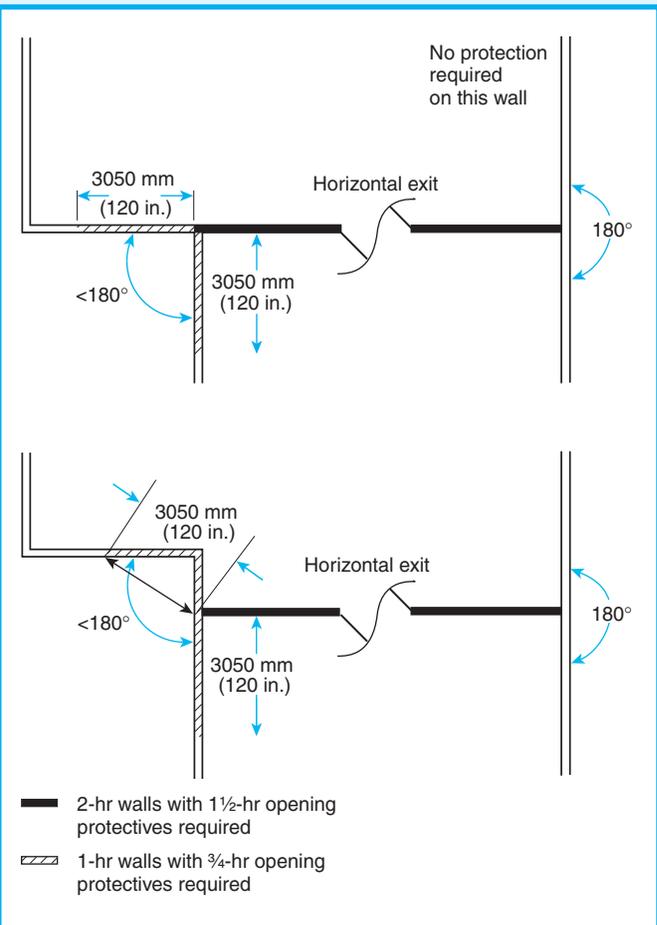

Exhibit 7.54 Protection of building exterior walls abutting a horizontal exit.

7.2.4.3.4 Fire barriers forming horizontal exits shall not be penetrated by ducts, unless one of the following criteria is met:

- (1) The ducts are existing penetrations protected by approved and listed fire dampers.
- (2) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (3) The duct penetrations are those permitted in detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23 and are protected by combination fire dampers/smoke leakage-rated dampers that meet the smoke damper actuation requirements of 8.5.4.

Paragraph 7.2.4.3.4 addresses horizontal exit barrier penetrations other than those provided for doors used for accessing the adjacent fire compartments. Because horizontal exit barriers usually subdivide floor spaces, any prohibition on penetrations by ductwork complicates the design and installation of the heating, ventilating, and air conditioning system.

Paragraph 7.2.4.3.4(1) recognizes existing ductwork penetrations only if the penetrations are protected by listed fire dampers that are also approved by the authority having jurisdiction.

Paragraph 7.2.4.3.4(2) provides for an acceptable level of safety and permits duct penetrations. Such penetrations are allowed if the building is protected throughout by sprinklers. The penetrating duct also requires an approved fire damper, because the horizontal exit is a 2-hour fire-rated barrier.

Paragraph 7.2.4.3.4(3) recognizes that local policy prohibits some detention and correctional occupancies from having automatic sprinkler protection. Nonsprinklered buildings are not permitted to use 7.2.4.3.4(2), yet horizontal exits are desirable means of egress features in this defend-in-place occupancy. Duct penetrations, therefore, are permitted if protected by combination fire/smoke leakage-rated dampers that meet the smoke damper actuation requirements of 8.5.4.

7.2.4.3.5 Any opening in the fire barriers specified in 7.2.4.3.4 shall be protected as provided in 8.3.4.

7.2.4.3.6 Doors in horizontal exits shall comply with 7.2.1.4, unless they are sliding doors in industrial or storage occupancies as otherwise provided in Chapter 40 and Chapter 42.

An exemption for industrial occupancies in Chapter 40 and an exemption for storage occupancies in

Chapter 42 permit a fire-rated sliding door in addition to a swinging door in a door opening in a horizontal exit. Such a door might be installed for property protection, insurance-related reasons, or building code compliance. See 40.2.2.5.2 and 42.2.2.5.2.

7.2.4.3.7 Unless otherwise specified in 7.2.4.3.7.1 and 7.2.4.3.7.2, swinging fire doors shall be permitted in horizontal exits, provided that the criteria of both 7.2.4.3.7(1) and 7.2.4.3.7(2), or the criteria of both 7.2.4.3.7(1) and 7.2.4.3.7(3), are met as follows:

- (1) The doors shall swing in the direction of egress travel.
- (2) In other than sleeping room areas in detention and correctional occupancies, where a horizontal exit serves areas on both sides of a fire barrier, adjacent openings with swinging doors that open in opposite directions shall be provided, with signs on each side of the fire barrier identifying the door that swings with the travel from that side.
- (3) The doors shall be of any other approved arrangement, provided that the doors always swing with any possible egress travel.

7.2.4.3.7.1 The requirements of 7.2.4.3.7 shall not apply to horizontal exit door swing as provided in Chapter 19 and Chapter 23.

7.2.4.3.7.2 The requirements of 7.2.4.3.7 shall not apply to horizontal exit doors in corridors not more than 1830 (72 in.) wide in existing buildings.

Paragraph 7.2.4.3.7.2 recognizes the impracticality and hardship of installing a pair of doors that meets the minimum width requirements of 7.2.1.2.4 in an opening across an existing corridor that is 1830 mm (72 in.) or less in width.

7.2.4.3.8* Doors in horizontal exits shall be designed and installed to minimize air leakage.

A.7.2.4.3.8 For further information, see NFPA 105, *Standard for the Installation of Smoke Door Assemblies*.

7.2.4.3.9* All fire doors in horizontal exits shall be self-closing or automatic-closing in accordance with 7.2.1.8.

A.7.2.4.3.9 Fusible link-actuated automatic-closing doors do not qualify for use in horizontal exits under these provisions, because smoke might pass through the opening before there is sufficient heat to release the hold-open device. Such doors are also objectionable because, once closed, they are difficult to open and would inhibit orderly egress.

7.2.4.3.10 Horizontal exit doors located across a corridor, other than approved existing doors, shall be automatic-closing in accordance with 7.2.1.8.2.

Because cross-corridor doors are so commonly wedged open in violation of *Code* requirements, 7.2.4.3.10 does not offer the option of using self-closing doors but mandates the use of automatic-closing doors in these horizontal exit, cross-corridor locations. Because the authority having jurisdiction can observe if the wedging open of doors has been a problem in existing installations, 7.2.4.3.10 gives the enforcer the authority to permit existing self-closing doors to continue to be used.

7.2.4.4 Bridges and Balconies.

7.2.4.4.1 Each bridge or balcony used in conjunction with horizontal exits shall have guards and handrails in conformity with the requirements of 7.2.2.4.

7.2.4.4.2 Every bridge or balcony shall be not less than the width of the door to which it leads and shall be not less than 1120 mm (44 in.) wide for new construction.

7.2.4.4.3 Where the bridge or balcony serves as a horizontal exit in one direction, the horizontal exit door shall be required to swing only in the direction of egress travel, unless the door complies with the swing requirements for the following:

- (1) Existing health care occupancies in Chapter 19
- (2) Existing detention and correctional occupancies in Chapter 23

7.2.4.4.4 Where the bridge or balcony serves as a horizontal exit in both directions, doors shall be provided in pairs that swing in opposite directions, with only the door swinging in the direction of egress travel included when determining egress capacity, unless otherwise provided in 7.2.4.4.4.1 through 7.2.4.4.4.3.

7.2.4.4.4.1 Approved existing doors on both ends of the bridge or balcony shall be permitted to swing out from the building.

7.2.4.4.4.2 The requirement of 7.2.4.4.4 shall not apply if the bridge or balcony has sufficient floor area to accommodate the occupant load of either connected building or fire area based on 0.28 m² (3 ft²) per person.

7.2.4.4.4.3 The requirement of 7.2.4.4.4 shall not apply to horizontal exit door swing as provided for the following:

- (1) Existing health care occupancies in Chapter 19
- (2) Existing detention and correctional occupancies in Chapter 23

7.2.4.4.5 In climates subject to the accumulation of snow and ice, the bridge or balcony floor shall be protected to prevent the accumulation of snow and ice.

7.2.4.4.6 In existing buildings, one step not exceeding 205 mm (8 in.) shall be permitted below the level of the inside floor.

7.2.4.4.7 In both of the connected buildings or fire areas, any part of any wall opening that is within 3050 mm (120 in.) of any bridge or balcony, as measured horizontally or below, shall be protected with fire door assemblies or fixed fire window assemblies having a ¾-hour fire protection rating, unless otherwise provided in 7.2.4.4.8.

7.2.4.4.8 The requirement of 7.2.4.4.7 shall not apply to approved existing bridges and balconies.

7.2.5 Ramps.

Ramps are permitted as a part of a means of egress and are preferred over stairs under some circumstances. To quote from a 1974 publication:

One can consider ramps and steps simply as prosthetic devices for assisting the human organism in climbing from floor to floor When one must consider the energy cost of both horizontal and vertical movement, one finds that a ramp with a gradient of less than about eight degrees is more economical than any stairway that is likely to be encountered in normal activity.⁹

A study by the National Bureau of Standards (now the National Institute of Standards and Technology — NIST) states, in part:

For certain occupancies, such as schools and institutions, they [ramps] are believed to be more satisfactory and their use in these buildings is recommended Ramps have a rate of discharge between that of stairways and level passageways.¹⁰

7.2.5.1 General. Every ramp used as a component in a means of egress shall conform to the general requirements of Section 7.1 and to the special requirements of 7.2.5.

7.2.5.2 Dimensional Criteria. The following dimensional criteria shall apply to ramps:

- (1) New ramps shall be in accordance with Table 7.2.5.2(a), unless otherwise permitted by the following:
 - (a) Table 7.2.5.2(a) shall not apply to industrial equipment access areas as otherwise provided in 40.2.5.2
 - (b) The maximum slope requirement shall not apply to ramps in assembly occupancies as otherwise provided in Chapter 12.

Table 7.2.5.2(a) New Ramps

Feature	Dimensional Criteria
Minimum width clear of all obstructions, except projections not more than 114 mm (4½ in.) at or below handrail height on each side	1120 mm (44 in.)
Maximum slope	1 in 12
Maximum cross slope	1 in 48
Maximum rise for a single ramp run	760 mm (30 in.)

- (c) The maximum slope or maximum rise for a single ramp run shall not apply to ramps providing access to vehicles, vessels, mobile structures, and aircraft.
- (2) Existing ramps shall be permitted to remain in use or be rebuilt, provided that they meet the requirements shown in Table 7.2.5.2(b), unless otherwise permitted by the following:
 - (a) The requirements of Table 7.2.5.2(b) shall not apply to industrial equipment access areas as otherwise provided in 40.2.5.2.
 - (b) The maximum slope or maximum height between landings for a single ramp run shall not apply to ramps providing access to vehicles, vessels, mobile structures, and aircraft.
 - (c) Approved existing ramps with slopes not steeper than 1 in 6 shall be permitted to remain in use.
 - (d) Existing ramps with slopes not steeper than 1 in 10 shall not be required to be provided with landings.

Table 7.2.5.2(b) Existing Ramps

Feature	Dimensional Criteria
Minimum width	760 mm (30 in.)
Maximum slope	1 in 8
Maximum height between landings	3660 mm (144 in.)

The dimensional criteria and other details applicable to ramps were extensively rewritten for the 1994 edition of the *Code*. In the 1994 and 1997 editions, the maximum allowed slope of a new ramp varied with the total vertical rise provided by the ramp. In the past two editions, the slope of new ramps is limited to a maximum of 1 in 12. Such ramps are particularly useful for persons with severe mobility impairment. See ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*. Paragraph 7.2.5.2(2) continues to recognize existing ramps

and the rebuilding of existing ramps to the former criteria.

Paragraphs 7.2.5.2(1)(c) and 7.2.5.2(2)(b) recognize that ramps providing access to vehicles, vessels, mobile structures, and aircraft must be able to accommodate the variety of conditions encountered. For example, not all ships have entrances mounted at the same height, and, due to tidal influences, the water level rises and falls with respect to a stationary pier. Because ships are regulated under special rules, have their own exiting programs, and usually provide staff assistance during the disembarkation process, the maximum ramp slope requirements of Tables 7.2.5.2(a) and 7.2.5.2(b) are exempted.

7.2.5.3 Ramp Details.

7.2.5.3.1 Construction. Ramp construction shall be as follows:

- (1) All ramps serving as required means of egress shall be of permanent fixed construction.
- (2) Each ramp in buildings required by this *Code* to be of Type I or Type II construction shall be noncombustible or limited-combustible throughout.
- (3) The ramp floor and landings shall be solid and without perforations.

7.2.5.3.2 Landings. Ramp landings shall be as follows:

- (1) Ramps shall have landings located at the top, at the bottom, and at doors opening onto the ramp.
- (2) The slope of the landing shall not be steeper than 1 in 48.
- (3) Every landing shall have a width not less than the width of the ramp.
- (4) Every landing shall be not less than 1525 mm (60 in.) long in the direction of travel, unless the landing is an approved existing landing.
- (5) Any changes in travel direction shall be made only at landings, unless the ramp is an existing ramp.
- (6) Ramps and intermediate landings shall continue with no decrease in width along the direction of egress travel.

Landings are required to be nearly horizontal to provide transition areas to and from ramps that are usable to persons with severe mobility impairments. Landings at doors allow for movement through the door without the burden of dealing with a sloping floor section. The requirement for intermediate landings on ramps is similar to that part of 7.2.2.3.2 applicable to landings on stairs.

The minimum 1525-mm (60-in.) landing depth,

measured in the direction of travel, is intended to accommodate a person in a wheelchair.

The effect of 7.2.5.3.2(5) is to prohibit curved ramps. With a curved ramp, the travel direction changes continually. The change in direction is accomplished by introducing a cross slope that might make use of the ramp by persons with severe mobility impairments overly burdensome. Thus, the *Code* requires that any changes in travel direction occur only at level landings.

7.2.5.3.3 Drop-Offs. Ramps and landings with drop-offs shall have curbs, walls, railings, or projecting surfaces that prevent people from traveling off the edge of the ramp. Curbs or barriers shall be not less than 100 mm (4 in.) in height.

7.2.5.4 Guards and Handrails.

7.2.5.4.1 Guards complying with 7.2.2.4 shall be provided for ramps, unless otherwise provided in 7.2.5.4.4.

7.2.5.4.2 Handrails complying with 7.2.2.4 shall be provided along both sides of a ramp run with a rise greater than 150 mm (6 in.), unless otherwise provided in 7.2.5.4.4.

7.2.5.4.3 The height of handrails and guards shall be measured vertically to the top of the guard or rail from the walking surface adjacent thereto.

7.2.5.4.4 The requirements of 7.2.5.4.1 and 7.2.5.4.2 shall not apply to guards and handrails provided for ramped aisles in assembly occupancies as otherwise provided in Chapter 12 and Chapter 13.

Ramps are subject to the guard and handrail requirements of 7.2.2.4. However, per 7.2.5.4.2, the handrail requirements apply only to ramps with a rise of more than 150 mm (6 in.).

7.2.5.5 Enclosure and Protection of Ramps. Ramps in a required means of egress shall be enclosed or protected as a stair in accordance with 7.2.2.5 and 7.2.2.6.

7.2.5.6 Special Provisions for Outside Ramps.

Outside ramps are permitted to serve as part of a means of egress subject to the criteria governing exit access, exits, and exit discharge.

7.2.5.6.1* Visual Protection. Outside ramps shall be arranged to avoid any impediments to their use by persons

having a fear of high places. For ramps more than three stories in height, any arrangement intended to meet this requirement shall be at least 1220 mm (48 in.) in height.

A.7.2.5.6.1 The guards required by 7.1.8 and detailed in 7.2.2.4.5 for the unenclosed sides of ramps will usually meet this requirement where the ramp is not more than three stories high. Special architectural treatment, including application of such devices as metal or masonry screens and grilles, will usually be necessary to comply with the intent of the requirements for ramps over three stories in height.

7.2.5.6.2* Water Accumulation. Outside ramps and landings shall be designed to minimize water accumulation on their surfaces.

A.7.2.5.6.2 Providing a pitch of 10 mm/m to 21 mm/m ($\frac{1}{8}$ in./ft to $\frac{1}{4}$ in./ft) will aid the shedding of water from a nominally horizontal surface.

7.2.6* Exit Passageways.

A.7.2.6 An exit passageway serves as a horizontal means of exit travel that is protected from fire in a manner similar to an enclosed interior exit stair. Where it is desired to offset exit stairs in a multistory building, an exit passageway can be used to preserve the continuity of the protected exit by connecting the bottom of one stair to the top of the stair that continues to the street floor. Probably the most important use of an exit passageway is to satisfy the requirement that at least 50 percent of the exit stairs discharge directly outside from multistory buildings (*see* 7.7.2). Thus, if it is impractical to locate the stair on an exterior wall, an exit passageway can be connected to the bottom of the stair to convey the occupants safely to an outside exit door. In buildings of extremely large area, such as shopping malls and some factories, the exit passageway can be used to advantage where the travel distance to reach an exit would otherwise be excessive.

The word *exit* used in the term *exit passageway* helps to distinguish between an exit passageway and an ordinary passageway or corridor. An exit passageway is an exit; it provides a path of travel offering the same level of protection and safety that is required of an enclosed exit stair. An exit passageway is a versatile feature, because it can be used to extend an exit, or, as is done in many cases, it can be used to bring an exit closer to where the occupants are located.

In Exhibit 7.55, an exit passageway is used to continue the exit to the outside from one of the two enclosed interior exit stairs. This arrangement might be used to help comply with the requirements of 7.7.2, which mandate that at least one-half of the egress

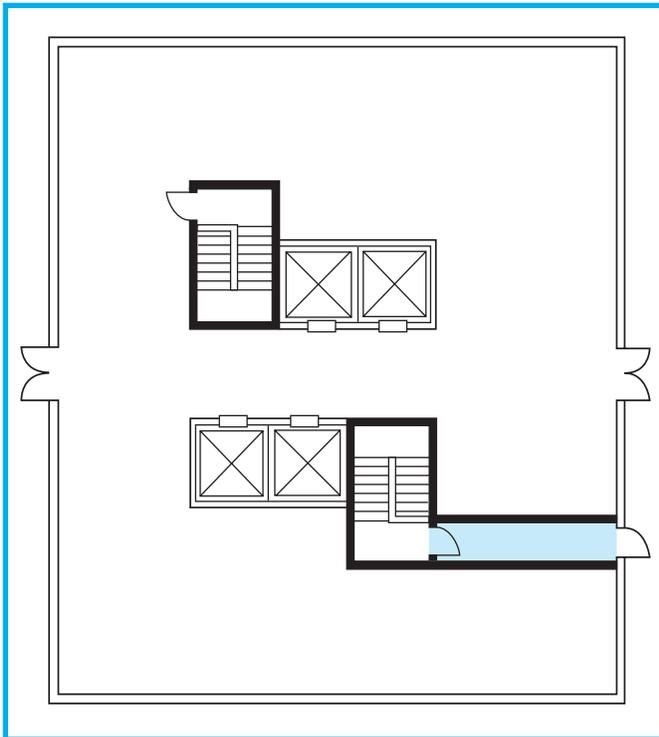

Exhibit 7.55 Exit passageway used to connect exit stair with exterior of building.

capacity and number of exits must discharge directly to the outside at the level of exit discharge.

Extending the exit stair’s required enclosure to include a portion of the corridor creates an exit passageway that brings the exit closer to the occupants, as is demonstrated by Exhibit 7.56. Travel distance measurement ends at entrance E1 to the exit passageway. The distance from X to E2 exceeds the allowed travel distance. The distance from X to E1 is within the allowed travel distance. Extension of an exit stair’s enclosure is often used where travel distance to the

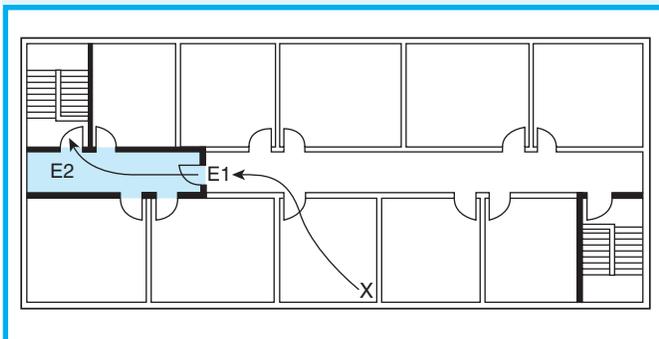

Exhibit 7.56 Exit passageway used to keep travel distance from becoming excessive.

exit enclosure would otherwise be in excess of Code allowance. Because it is an exit, an exit passageway qualifies as the point at which travel distance measurement ends.

In Exhibit 7.57, the two exit passageways marked A bring exits within allowable travel distances for the occupants in the mall (similar to the exit passageway illustrated in Exhibit 7.56). The exit passageway marked B allows occupants of multiple stores in the covered mall to enter the exit directly from the rear of each store. This arrangement is often used to limit the number of doors that open directly to the outside for security purposes.

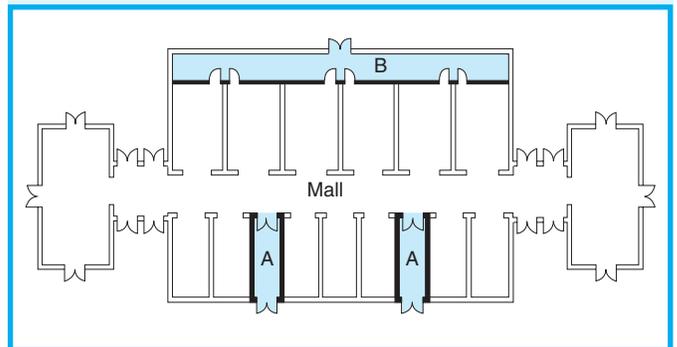

Exhibit 7.57 Exit passageways used for multiple purposes in mall building.

7.2.6.1* General. Exit passageways used as exit components shall conform to the general requirements of Section 7.1 and to the special requirements of 7.2.6.

A.7.2.6.1 Examples of building elements that might be arranged as exit passageways include hallways, corridors, passages, tunnels, underfloor passageways, or overhead passageways.

7.2.6.2 Enclosure. An exit passageway shall be separated from other parts of the building as specified in 7.1.3.2, and the following alternatives shall be permitted:

- (1) Fire windows in accordance with 8.3.3 shall be permitted to be installed in the separation in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) Existing fixed wired glass panels in steel sash shall be permitted to be continued in use in the separation in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

7.2.6.3 Stair Discharge. An exit passageway that serves as a discharge from a stair enclosure shall have not less than

the same fire resistance rating and opening protective fire protection rating as those required for the stair enclosure.

Paragraph 7.2.6.2 requires exit passageways to have walls with the hourly fire resistance ratings and doors with the fire protection ratings required of exit stair enclosures, as detailed in 7.1.3.2.1(1) or 7.1.3.2.1(2). The requirement also limits door openings into and penetrations through the exit enclosure created by the exit passageway, as detailed in 7.1.3.2.1(5) and 7.1.3.2.1(6). In Exhibit 7.58, exit passageway A on the first floor—the level of exit discharge—opens at one end to a five-story exit stair enclosure and at the other end to a door to the outside. This exit passageway also serves as a horizontal continuation of, and discharge for, the stair enclosure. In serving as a discharge for the exit stair, the exit passageway must provide the same degree of protection required of the stair enclosure. Given that the exit stair must be enclosed by 2-hour fire resistance-rated construction because it serves four or more stories, the exit passage-

way must also be enclosed by 2-hour fire resistance-rated construction. This protection is addressed in 7.2.6.3.

In Exhibit 7.58, exit passageway B, on the fourth floor, is used to provide the safety of an exit to occupants traveling to the exit stair enclosure. This exit passageway might have been built to meet the travel distance limitation. If a rated wall and door separate exit passageway B from the 2-hour exit stair enclosure, the required rating of exit passageway B is only 1 hour, because the exit passageway serves only the occupants of the fourth floor. A similar 1-hour fire resistance-rated enclosure requirement applies, for example, to a horizontal exit serving a single-story of a shopping mall building. Contrast this configuration with exit passageway A on the first floor, which potentially serves occupants of the second through fifth floors and must provide a continuation of the 2-hour separation required of the stair enclosure.

For the same reasons that the exit stair enclosure cannot have doors opening directly onto it from normally unoccupied spaces, a storage room, for example, is prohibited from opening directly onto exit passageways A and B and the exit stair enclosures. Penetrations through the enclosing walls are limited to those necessary for the functioning of life safety systems, such as lighting powered by electrical cables that enter the exit enclosure via properly sealed conduit penetrations. Ductwork for climate control is prohibited from penetrating enclosing walls. Thus, the exit passageways and the exit stair enclosures must receive their heating and cooling by systems independent of those serving the remainder of the building. Ductwork serving other parts of the floor must be routed around the outside of, not through, the enclosures.

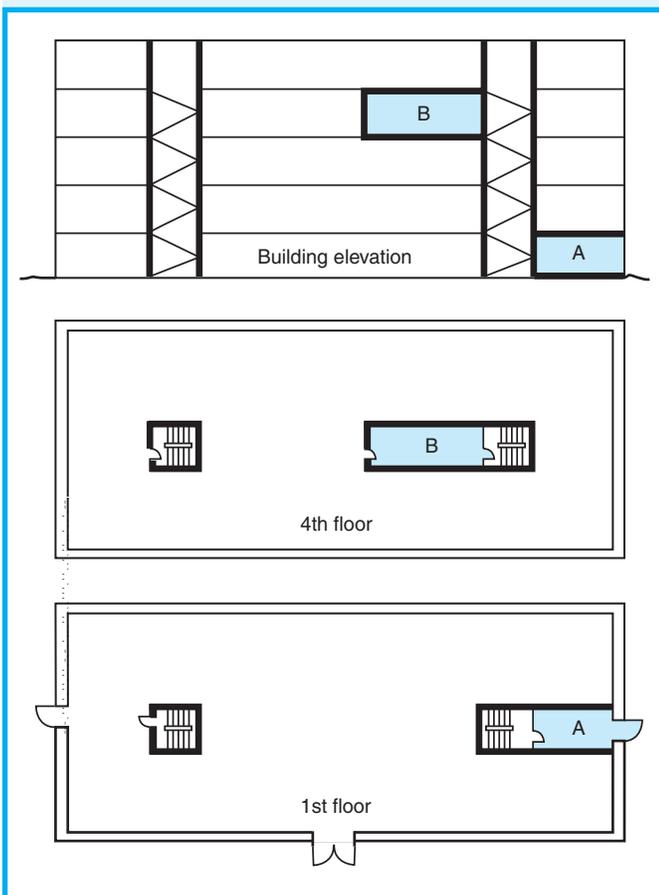

Exhibit 7.58 Exit passageways with fire resistance-rated enclosures and fire protection-rated doors.

7.2.6.4 Width. The width of an exit passageway shall be adequate to accommodate the aggregate required capacity of all exits that discharge through it, unless one of the following conditions applies:

- (1)* Where an exit passageway serves occupants of the level of exit discharge as well as other stories, the capacity shall not be required to be aggregated.

A.7.2.6.4(1) Where an exit passageway serves occupants on the level of exit discharge as well as other floors, it should not be required that the occupant loads be added, thus increasing the width of the exit passageway. The situation is the same as that in which occupants from the level of exit discharge join occupants from upper floors for a few feet of horizontal travel through a stair enclosure.

- (2) As provided in Chapter 36 and Chapter 37, an exit passageway in a mall building shall be permitted to accommodate occupant loads independently from the mall and the tenant spaces. (See 36.2.2.7.2 and 37.2.2.7.2.)

The annex text in A.7.2.6.4(1) explains the exemption to aggregate the sizing of exit passageways where accommodating occupant loads from various floors. See the annex text and commentary associated with 36.2.2.7.2 for a detailed explanation of the situation permitted in covered mall buildings by 7.2.6.4(2).

7.2.6.5 Floor. The floor shall be solid and without perforations.

7.2.7 Escalators and Moving Walks.

Escalators and moving walks shall not constitute a part of the required means of egress, unless they are previously approved existing escalators and moving walks.

Older editions of the *Code* allowed some egress capacity credit for escalators. However, because riser/tread sections of escalators and standing surfaces of moving walks are removed for maintenance, it cannot be ensured that occupants will be able to walk on these devices when emergency egress is needed. Therefore, new escalators and moving walks receive no credit within the required means of egress. Existing, previously approved escalators and moving walks are permitted to continue to be used as part of the means of egress if permitted by the appropriate occupancy chapter. Although not permitted as part of the required means of egress in new construction, escalators and moving walks, where installed, must comply with ASME A17.1, *Safety Code for Elevators and Escalators*¹¹.

Escalators are acceptable as an egress component in existing buildings only in the following occupancies:

- (1) Existing assembly occupancies (13.2.2.8)
- (2) Existing hotels (29.2.2.8)
- (3) Existing apartment buildings (31.2.2.8)
- (4) Existing mercantile occupancies (37.2.2.8)
- (5) Existing business occupancies (39.2.2.8)
- (6) Existing industrial occupancies (40.2.2.8)

When evaluating escalators in existing buildings, the following factors should be considered.

- (a) The escalator should comply with the applicable requirements for stairs in 7.2.2. It is assumed that, where escalators serve as required means of

egress, they will continue to operate in case of fire. However, if they stop due to electric current failure or other cause, they can be used as ordinary stairs.

(b) Escalators constituting a means of egress should operate only in the direction of egress. Usually escalators are provided in pairs, with one separate stairway moving up and another moving down; however, if the electric power fails and both stop, two stairs would be available for downward movement. In this situation, one might propose that both stairways be accepted as constituting a means of egress, since the power could be turned off intentionally. The problem is that, in an emergency, the power might not be turned off, and one stairway would continue to move against traffic. For this reason, only those escalators moving in the direction of egress should be allowed to be part of a means of egress.

(c) Escalators should be of the horizontal-tread type and, with the exception of step tread surfaces, handrails, and step wheels, should be of noncombustible construction throughout.

(d) A single escalator that is 810 mm (32 in.) wide should be given credit for 75 people. An escalator that is 1220 mm (48 in.) wide should be given credit for 150 people. Even though a person does not have to exert any energy or do any moving while on an operating escalator, there are many people who are frightened by escalators and many who are extremely cautious in approaching them. These are factors that could contribute to a bottleneck. Thus, it is recognized that an escalator would have to be wider than a stair to accommodate the same number of people.

(e) There should be unobstructed spaces of at least 100 mm (4 in.) outside the handrail and above the handrail for the full length of the escalator.

(f) No single escalator should travel uninterrupted for more than one story.

The guidelines of (a) through (f) in this commentary were taken from older editions of the *Code* and were required in those years when escalators were given credit in new construction and are offered here as guidance for existing escalator installations.

Even in an existing building, an escalator cannot be counted as an exit unless it is enclosed as an exit in accordance with 7.1.3.2. Such an arrangement is rare. Typically, an existing escalator might serve as exit access or exit discharge.

Most of the same principles that apply to the design and operation of escalators also apply when evaluating existing moving walkways. The major difference is that a moving walkway that moves in the

direction of egress travel can be evaluated in terms of the usual egress width and associated capacity rather than the larger dimensions specified for escalators in item (d) of this commentary.

7.2.8 Fire Escape Stairs.

Fire escape stairs and ladders have fallen into disfavor for a variety of reasons, including the following:

- (1) Unsightly appearance
- (2) Possible icing in winter weather
- (3) Expense of maintenance (that is, the metal is subject to corrosion)
- (4) Possibility of users being trapped by a fire below
- (5) Fear of height and, therefore, an objection to using fire escape stairs and ladders

On the other hand, well-maintained fire escape stairs can and have saved many lives when smoke-filled stairs have become impassable. A classic example is the June 5, 1946, fire in the 22-story LaSalle Hotel in Chicago. Hundreds of people made their escape from the building on outside fire escape stairs¹².

In the past, fire fighters have found outside fire escape stairs advantageous. However, instances can be cited where corroded fire escapes have collapsed, or where people have been fatally burned because fire broke out of windows or doors at a lower level as they were descending on a fire escape. The *Code* requires proper means of egress using interior or outside stairs and the gradual phasing out of fire escape stairs as new buildings replace old ones.

Fire escape stairs can, however, help correct serious means of egress deficiencies in existing buildings and are helpful to fire department rescue and fire-fighting efforts. If fire escape stairs are part of an existing building, or must be included on a building (perhaps due to insufficient space for an outside stair in accordance with 7.2.2), they must adhere to the provisions of the *Code* to provide an acceptable level of life safety.

7.2.8.1 General.

7.2.8.1.1 Fire escape stairs shall comply with the provisions of 7.2.8, unless they are approved, existing fire escape stairs.

Fire escape stairs as specified in 7.2.8 of the *Code* should not be confused with the outside stairs cov-

ered in 7.2.2. Neither should the fire escape stairs specified by 7.2.8.1.1 of the *Code* be confused with the inferior fire escapes that are commonly found on old buildings. Such steep, inadequate, and flimsy fire escapes, unshielded against fire in the structure to which they are attached, might give an occupant a false sense of security. Such escape stairs are not recognized by this *Code*.

Even the fire escape stairs constructed in accordance with this *Code* have limitations that might prevent their effective use during a fire. Even where window protection is provided, conditions might be such that fire, or the smoke from fire, on lower floors might render the stairs impassable before the occupants of the upper floors have had time to use them. Fire escape stairs might be blocked by snow or ice when they are most needed. People are likely to be timid about descending fire escape stairs from a considerable height, so their downward travel is much slower than for inside stairs. Slower travel is a factor even where *Code*-specified solid-tread stairs without perforations are used in place of ordinary slatted-tread construction. Fire escape stairs are not the usual means of egress. Occupants of buildings will not use them as readily in case of fire as they will an inside stair, which is the more common egress component. Because fire escape stairs are an emergency device and are not ordinarily used, their proper upkeep is often neglected.

7.2.8.1.2 Fire escape stairs shall not constitute any of the required means of egress, unless otherwise provided in 7.2.8.1.2.1 and 7.2.8.1.2.2.

7.2.8.1.2.1 Fire escape stairs shall be permitted on existing buildings as provided in Chapter 11 through Chapter 42 but shall not constitute more than 50 percent of the required means of egress.

7.2.8.1.2.2 New fire escape stairs shall be permitted to be erected on existing buildings only where the authority having jurisdiction has determined that outside stairs are impractical. (See 7.2.2.)

7.2.8.1.2.3 New fire escape stairs permitted by 7.2.8.1.2.2 shall not incorporate ladders or access windows, regardless of occupancy classification or occupant load served.

No recognition of any kind is given by the *Code* to the use of fire escape stairs in new buildings for any of the three parts of a means of egress. A token recognition of 50 percent of egress capacity is given for

their use in existing buildings, simply because the fire escape stairs have already been installed or because such stairs might be the only feasible way in which to upgrade a means of egress in an existing building.

In most cases, outside stairs complying with 7.2.2 must be used rather than fire escape stairs. However, the *Code* recognizes that, in the case of some existing buildings, there are situations in which modifying stairs to comply with 7.2.2 would be impractical. For example, the space between the building and the property line might be too narrow to accommodate a *Code*-conforming stair, or it might be necessary to have the stair located over a sidewalk, alley, or similar space that cannot be permanently blocked by stair construction.

Fire escape stairs are regarded as an expedient remedy for deficiencies in means of egress of existing buildings where it might not be feasible to provide outside stairs or properly enclosed, additional inside stairways required by the *Code*.

Because effective use of fire escape stairs might be seriously impaired by conditions such as snow and ice, authorities having jurisdiction might wish to impose additional requirements because of climate. In such a case, egress capacity credit for the fire escape stairs might be reduced.

7.2.8.1.3 Fire escape stairs of the return-platform type with superimposed runs, or of the straight-run type with a platform that continues in the same direction, shall be permitted. Either type shall be permitted to be parallel to, or at right angles to, buildings. Either type shall be permitted to be attached to buildings or erected independently of buildings and connected by walkways.

7.2.8.2 Protection of Openings. Fire escape stairs shall be exposed to the smallest possible number of window and door openings, and each opening shall be protected with approved fire door or fire window assemblies where the opening or any portion of the opening is located as follows:

- (1) Horizontally, within 4570 mm (180 in.) of any balcony, platform, or stairway constituting a component of the fire escape stair
- (2) Below, within three stories or 10.7 m (35 ft) of any balcony, platform, walkway, or stairway constituting a component of the fire escape stair, or within two stories or 6100 mm (240 in.) of a platform or walkway leading from any story to the fire escape stair
- (3) Above, within 3050 mm (120 in.) of any balcony, platform, or walkway, as measured vertically, or within 3050 mm (120 in.) of any stair tread surface, as measured vertically

- (4) Facing a court served by a fire escape stair where the least dimension of the court does not exceed one-third of the height to the uppermost platform of the fire escape stair, measured from the ground
- (5) Facing an alcove served by a fire escape stair where the width of the alcove does not exceed one-third, or the depth of the alcove does not exceed one-fourth, of the height to the uppermost platform of the fire escape stair, measured from the ground

7.2.8.2.1 The requirements of 7.2.8.2 shall not apply to openings located on the top story where stairs do not lead to the roof.

7.2.8.2.2 The requirements of 7.2.8.2 shall be permitted to be modified by the authority having jurisdiction where automatic sprinkler protection is provided, where the occupancies is limited to low hazard contents, or where other special conditions exist.

7.2.8.2.3 The requirements of 7.2.8.2 for the protection of window openings shall not apply where such window openings are necessary for access to existing fire escape stairs.

7.2.8.3 Access.

7.2.8.3.1 Access to fire escape stairs shall be in accordance with 7.2.8.4 and 7.5.1.1.1 through 7.5.1.1.3.

Exhibit 7.59 illustrates the minimum opening dimensions for windows that open onto fire escape stairs serving more than 10 occupants. The exhibit also depicts the maximum interior measurements from the floor to the windowsill. See Table 7.2.8.4.1(a) and Table 7.2.8.4.1(b).

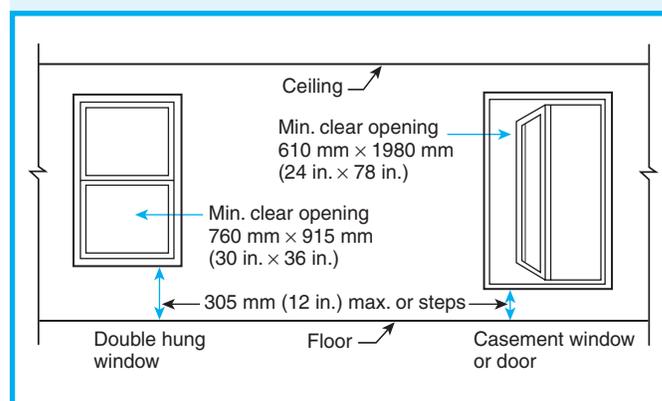

Exhibit 7.59 Window openings for access to fire escape stairs.

7.2.8.3.2 Where access is permitted by way of windows, the windows shall be arranged and maintained so as to be

easily opened. Screening or storm windows that restrict free access to the fire escape stair shall be prohibited.

7.2.8.3.3 Fire escape stairs shall extend to the roof in all cases where the roof is subject to occupancy or provides an area of safe refuge, unless otherwise provided in 7.2.8.3.4.

7.2.8.3.4 If the roof has a pitch that does not exceed 1 to 6, fire escape ladders in accordance with 7.2.9 or alternating tread devices in accordance with 7.2.11 shall be provided for access to the roof.

7.2.8.3.5 Access to a fire escape stair shall be directly to a balcony, landing, or platform; shall not exceed the floor or windowsill level; and shall not be more than 205 mm (8 in.) below the floor level or 455 mm (18 in.) below the windowsill level.

The height requirements of 7.2.8.3.5 establish the maximum distance, on the outside of the building, down to the balcony, landing, or platform of the fire escape stair, measured from the windowsill level or from the floor level.

7.2.8.4 Stair Details.

Generally, the requirements for fire escape stairs are similar to those specified for outside stairs. The major difference between the two types of stairs is the dimensions in Commentary Table 7.1, which details the differences between the generally accepted fire escape stair of existing buildings and the lighter fire

escape stair considered acceptable for “very small” existing buildings serving 10 or fewer occupants.

The existing fire escape stair with a minimum width of 560 mm (22 in.) is a type that is permitted for buildings of small or moderate size, depending on the specific features of an installation.

The existing fire escape stair with a minimum width of 455 mm (18 in.) represents the absolute minimum that is permitted. Because of access over windowsills, steep pitch, and a narrow width, travel down such stairs will be necessarily slow and possibly dangerous. Even worse are stairs with spiral stair treads or stairs that terminate at a balcony above ground level with a fixed or movable ladder extending downward from the balcony. These stairs are suitable only in situations where a very small number of occupants is involved.

7.2.8.4.1 General. Fire escape stairs shall comply with the requirements of Table 7.2.8.4.1(a). Replacement of fire escape stairs shall comply with the requirements of Table 7.2.8.4.1(b).

7.2.8.4.2 Slip Resistance. Stair treads and landings of new or replacement fire escape stairs shall have slip-resistant surfaces.

7.2.8.5 Guards, Handrails, and Visual Enclosures.

7.2.8.5.1 All fire escape stairs shall have walls or guards and handrails on both sides in accordance with 7.2.2.4.

Commentary Table 7.1 Differences Between Outside Stairs and Fire Escape Stairs

Design Factor	New Outside Stair	Existing Outside Stair		Fire Escape Stair	
		Class A	Class B	Standard	Small Buildings
Accepted as means of egress	Yes	Yes	Yes	Existing buildings	Existing buildings
Width	1120 mm (44 in.)†	1120 mm (44 in.)†	1120 mm (44 in.)†	560 mm (22 in.)	455 mm (18 in.)
Maximum rise	180 mm (7 in.)	190 mm (7½ in.)	205 mm (8 in.)	230 mm (9 in.)	305 mm (12 in.)
Minimum tread	280 mm (11 in.)	255 mm (10 in.)	230 mm (9 in.)	230 mm (9 in.)	150 mm (6 in.)
Tread construction	Solid	Solid	Solid	Solid, with perforations permitted	Metal bars
Access by windows	No	No	No	Yes	Yes
Swinging stair accepted	No	No	No	Yes	Yes
Ladder accepted	No	No	No	No	Yes

Note: The capacity of normal fire escape stairs is 45 persons if accessed by doors and 20 if accessed by windows where it is necessary to climb over a sill. On small buildings, the capacity is 10 persons; 5 if winders or a ladder from bottom landing; 1 if both winders and a ladder from bottom landing.

†915 mm (36 in.) where serving occupant load of fewer than 50.

Table 7.2.8.4.1(a) Fire Escape Stairs

Feature	Serving More than 10 Occupants	Serving 10 or Fewer Occupants
Minimum widths	560 mm (22 in.) clear between rails	455 mm (18 in.) clear between rails
Minimum horizontal dimension of any landing or platform	560 mm (22 in.) clear	455 mm (18 in.) clear
Maximum riser height	230 mm (9 in.)	305 mm (12 in.)
Minimum tread, exclusive of nosing	230 mm (9 in.)	150 mm (6 in.)
Minimum nosing or projection	25 mm (1 in.)	No requirement
Tread construction	Solid 13-mm (½-in.) diameter perforations permitted	Flat metal bars on edge or square bars secured against turning, spaced 32 mm (1¼ in.) maximum on centers
Winders	None	Permitted subject to capacity penalty
Risers	None	No requirement
Spiral	None	Permitted subject to capacity penalty
Maximum height between landings	3660 mm (144 in.)	No requirement
Headroom, minimum	2030 mm (80 in.)	2030 mm (80 in.)
Access to escape	Door or casement windows, 610 mm × 1980 mm (24 in. × 78 in.); or double-hung windows, 760 mm × 915 mm (30 in. × 36 in.) clear opening	Windows providing a clear opening of at least 510 mm (20 in.) in width, 610 mm (24 in.) in height, and 0.53 m ² (5.7 ft ²) in area
Level of access opening	Not over 305 mm (12 in.) above floor; steps if higher	Not over 305 mm (12 in.) above floor; steps if higher
Discharge to ground	Swinging stair section permitted if approved by authority having jurisdiction	Swinging stair, or ladder if approved by authority having jurisdiction
Capacity	13 mm (0.5 in.) per person, if access by door; 25 mm (1 in.) per person, if access by climbing over windowsill	10 persons; if winders or ladder from bottom balcony, 5 persons; if both, 1 person

Table 7.2.8.4.1(b) Replacement Fire Escape Stairs

Feature	Serving More than 10 Occupants	Serving 10 or Fewer Occupants
Minimum widths	560 mm (22 in.) clear between rails	560 mm (22 in.) clear between rails
Minimum horizontal dimension of any landing or platform	560 mm (22 in.)	560 mm (22 in.)
Maximum riser height	230 mm (9 in.)	230 mm (9 in.)
Minimum tread, exclusive of nosing	255 mm (10 in.)	255 mm (10 in.)
Tread construction	Solid, 13-mm (½-in.) diameter perforations permitted	Solid, 13-mm (½-in.) diameter perforations permitted
Winders	None	Permitted subject to 7.2.2.2.4
Spiral	None	Permitted subject to 7.2.2.2.3
Risers	None	None
Maximum height between landings	3660 mm (144 in.)	3660 mm (144 in.)
Headroom, minimum	2030 mm (80 in.)	2030 mm (80 in.)
Access to escape	Door or casement windows, 610 mm × 1980 mm (24 in. × 78 in.); or double-hung windows, 760 mm × 915 mm (30 in. × 36 in.) clear opening	Windows providing a clear opening of at least 510 mm (20 in.) in width, 610 mm (24 in.) in height, and 0.53 m ² (5.7 ft ²) in area
Level of access opening	Not over 305 mm (12 in.) above floor; steps if higher	Not over 305 mm (12 in.) above floor; steps if higher
Discharge to ground	Swinging stair section permitted if approved by authority having jurisdiction	Swinging stair section permitted if approved by authority having jurisdiction
Capacity	13 mm (0.5 in.) per person, if access by door; 25 mm (1 in.) per person, if access by climbing over windowsill	10 persons

7.2.8.5.2 Replacement fire escape stairs in occupancies serving more than 10 occupants shall have visual enclosures to avoid any impediments to stair use by persons having a fear of high places. For stairs more than three stories in height, any arrangement intended to meet this requirement shall be at least 1065 mm (42 in.) in height.

7.2.8.6 Materials and Strength.

7.2.8.6.1 Noncombustible materials shall be used for the construction of all components of fire escape stairs.

7.2.8.6.2 The authority having jurisdiction shall be permitted to approve any existing fire escape stair that has been shown by load test or other satisfactory evidence to have adequate strength.

7.2.8.7* Swinging Stairs.

A.7.2.8.7 Swinging stairs, although superior to fire escape ladders, are generally unsatisfactory, even for emergency use. Although such stairs are permitted by this *Code*, they should not be used where it is reasonably possible to terminate the fire escape stair at the ground.

In cases where the use of a fire escape stair would block a sidewalk or other public way or provide ready access for intruders, the following solution is offered. The discharge might be counterweighted and the unlocked swinging stair designed so that a 68-kg (150-lb) weight applied at one quarter of the length of the stair from the pivot point causes the stair to drop into the usable position. See 7.2.8.7.7.

7.2.8.7.1 A single swinging stair section shall be permitted to terminate fire escape stairs over sidewalks, alleys, or driveways where it is impractical to make the termination with fire escape stairs.

7.2.8.7.2 Swinging stair sections shall not be located over doors, over the path of travel from any other exit, or in any locations where there are likely to be obstructions.

7.2.8.7.3 The width of swinging stair sections shall be at least that of the fire escape stairs above.

7.2.8.7.4 The pitch of swinging stair sections shall not exceed the pitch of the fire escape stairs above.

7.2.8.7.5 Guards and handrails shall be provided in accordance with 7.2.2.4 and shall be similar in height and construction to those used with the fire escape stairs above. Guards and handrails shall be designed to prevent any possibility of injury to persons where stairs swing downward. The clearance between moving sections and any other portion of

the stair system where hands have the potential to be caught shall be not less than 100 mm (4 in.).

7.2.8.7.6 If the distance from the lowest platform to ground is not less than 3660 mm (144 in.), an intermediate balcony not more than 3660 mm (144 in.) from the ground and not less than 2135 mm (84 in.) in the clear underneath shall be provided, with width not less than that of the stairs and length not less than 1220 mm (48 in.).

7.2.8.7.7 Swinging stairs shall be counterbalanced about a pivot, and cables shall not be used. A weight of 68 kg (150 lb) located one step from the pivot shall not cause the stairs to swing downward, and a weight of 68 kg (150 lb) located one-quarter of the length of the swinging stairs from the pivot shall cause the stairs to swing down.

7.2.8.7.8 The pivot for swinging stairs shall be of a corrosion-resistant assembly or shall have clearances to prevent sticking due to corrosion.

7.2.8.7.9* Devices shall not be installed to lock a swinging stair section in the up position.

A.7.2.8.7.9 A latch is desirable for holding swinging stairs down after they have swung to the ground.

7.2.8.8 Intervening Spaces.

7.2.8.8.1 Where approved by the authority having jurisdiction, fire escape stairs shall be permitted to lead to an adjoining roof that is crossed before continuing downward travel. The direction of travel shall be clearly marked, and walkways with guards and handrails complying with 7.2.2.4 shall be provided.

7.2.8.8.2 Where approved by the authority having jurisdiction, fire escape stairs shall be permitted to be used in combination with inside or outside stairs complying with 7.2.2, provided that a continuous safe path of travel is maintained.

7.2.9 Fire Escape Ladders.

7.2.9.1 General. Fire escape ladders complying with 7.2.9.2 and 7.2.9.3 shall be permitted in the means of egress only where providing one of the following:

- (1) Access to unoccupied roof spaces as permitted in 7.2.8.3.4
- (2) A second means of egress from storage elevators as permitted in Chapter 42
- (3) A means of egress from towers and elevated platforms around machinery or similar spaces subject to occupancy not to exceed three persons who are all capable of using the ladder
- (4) A secondary means of egress from boiler rooms or similar spaces subject to occupancy not to exceed three persons who are all capable of using the ladder

- (5) Access to the ground from the lowest balcony or landing of a fire escape stair for small buildings as permitted in 7.2.8.4 where approved by the authority having jurisdiction

The intent of the *Code* is not to encourage the use of ladders but to provide access to an exit from any regularly occupied area. The *Code* contains provisions for fire escape ladders only because these ladders are sometimes one of the only practical means of moving from one space to another along what might be a path of escape from spaces not normally occupied. The *Code* does specify requirements for ladder construction and installation to ensure structural integrity and ease of use if ladders must be used. The provisions of 7.2.9.1 constitute the minimal recognition given fire escape ladders by this *Code*. Subsection 7.2.11 also addresses alternating tread devices for use under conditions similar to those specified for fire escape ladders.

7.2.9.2 Construction and Installation.

7.2.9.2.1 Fire escape ladders shall comply with ANSI A14.3, *Safety Code for Fixed Ladders*, unless one of the following criteria is met:

- (1) Approved existing ladders complying with the edition of this *Code* that was in effect when the ladders were installed shall be permitted.
- (2) Industrial stairs complying with the minimum requirements for fixed stairs of ANSI A1264.1, *Safety Requirements for Workplace Floor and Wall Openings, Stairs and Railing Systems*, shall be permitted where fire escape ladders are permitted in accordance with Chapter 40.

Fixed industrial stairs can have dimensional criteria that are comparable to ladders or that are nearly comparable to existing means of egress stairs in accordance with 7.2.2. Paragraph 7.2.9.2.1(2) recognizes that some industrial stairs are safer to use than ladders and allows such stairs to be used at locations where fire escape ladders are permitted in industrial occupancies.

7.2.9.2.2 Ladders shall be installed with a pitch that exceeds 75 degrees.

7.2.9.3 Access. The lowest rung of any ladder shall not be more than 305 mm (12 in.) above the level of the surface beneath it.

7.2.10 Slide Escapes.

7.2.10.1 General.

7.2.10.1.1 A slide escape shall be permitted as a component in a means of egress where permitted in Chapter 12 through Chapter 42.

Slide escapes are permitted in specified locations as a component in a means of egress and can even be considered exits. Ordinarily, an occupant enters a slide escape through a window or special opening in an exterior wall. From that point on, the slide escape functions as an exit discharge. If the slide escape is entered from within the building, it is considered an exit and must be protected by enclosure as required by 7.1.3.2.

Where provided, slide escapes should be used regularly in practice drills or for normal egress so that occupants are familiar with their use.

A slide pole of the type found in fire stations is not considered a slide escape. Slide escapes are permitted in means of egress only in high hazard industrial occupancies and existing storage occupancies. See 40.2.2.11 and 42.2.2.10.

7.2.10.1.2 Each slide escape shall be of an approved type.

7.2.10.2 Capacity.

7.2.10.2.1 Slide escapes, where permitted as a required means of egress, shall have a capacity of 60 persons.

7.2.10.2.2 Slide escapes shall not constitute more than 25 percent of the required egress capacity from any building or structure or any individual story thereof, unless otherwise provided for industrial occupancies in Chapter 40.

The 25 percent limitation on slide escapes as required means of egress emphasizes that other, more common egress components must comprise the majority of the egress capacity.

7.2.11* Alternating Tread Devices.

A.7.2.11 Special consideration should be given prior to the application of such devices where children, the elderly, or physically disabled persons use such devices. These devices present obstacles in ascent and descent that differ from those for stairs and ladders.

As used in the *Code*, an *alternating tread device* is an intermediate form of climbing implement that is be-

tween a ladder and a stair. It consists of a steep succession of treads that alternate from the left side to the right side at intervals of one riser height. A person using the device is forced to place the correct foot on each tread. This alternating tread design, now generally manufactured as a series of treads supported by a central spine, permits stairlike half-treads to be used with ladderlike slopes. The use of such devices, which might be awkward due to unfamiliarity or infrequent use, might be acceptable for some occupancies and locations where the alternative means of changing levels are ladders or ships' ladders, devices that generally have pitches of 50 degrees to 75 degrees. Such pitches are approximately twice those permitted for stairs by the *Code*.

An advantage of alternating tread devices is that one can descend with one's back to the device—unlike a ladder where one can only descend safely while facing the ladder because of the more limited surface area and depth of ladder rungs. A further benefit of the device is that objects can be carried more easily while ascending or descending, because the handrails provide support under the arms, which are left free. The *Code* limits the use of alternating tread devices to those situations where a ladder is acceptable. Exhibit 7.60 illustrates an alternating tread device.

7.2.11.1 Alternating tread devices complying with 7.2.11.2 shall be permitted in the means of egress only where providing one of the following:

- (1) Access to unoccupied roof spaces as permitted in 7.2.8.3.4
- (2) A second means of egress from storage elevators as permitted in Chapter 42
- (3) A means of egress from towers and elevated platforms around machinery or similar spaces subject to occupancy not to exceed three persons who are all capable of using the alternating tread device
- (4) A secondary means of egress from boiler rooms or similar spaces subject to occupancy not to exceed three persons who are all capable of using the alternating tread device

7.2.11.2 Alternating tread devices shall comply with the following:

- (1) Handrails shall be provided on both sides of alternating tread devices in accordance with 7.2.2.4.4.
- (2) The clear width between handrails shall be not less than 430 mm (17 in.) and not more than 610 mm (24 in.).
- (3) Headroom shall be not less than 2030 mm (80 in.).

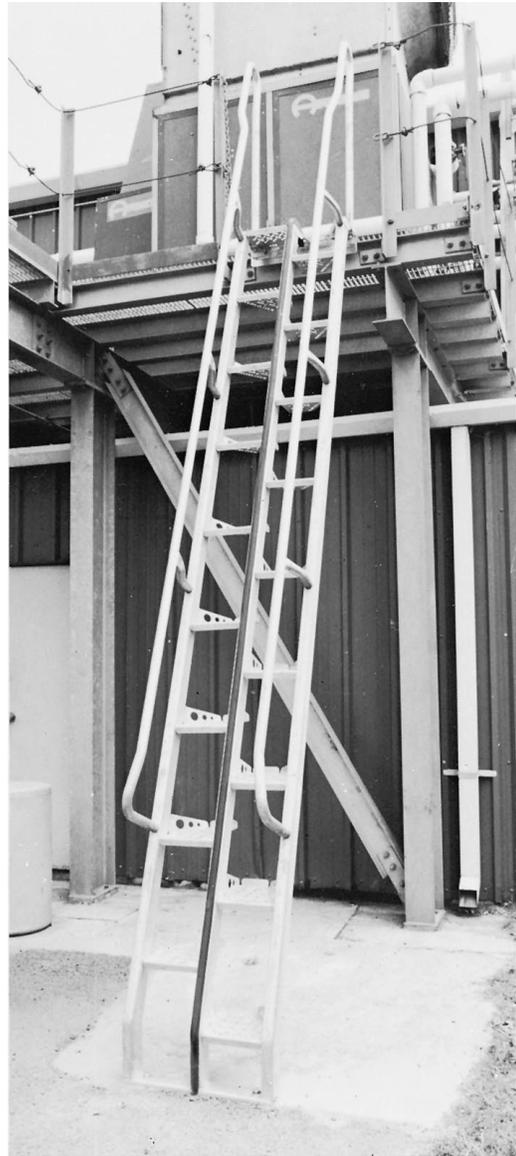

Exhibit 7.60 Alternating tread device.

- (4) The angle of the device shall be between 50 degrees and 68 degrees to horizontal.
- (5) The height of the riser shall not exceed 240 mm (9.5 in.).
- (6) Treads shall have a projected tread depth of not less than 145 mm (5.8 in.), measured in accordance with 7.2.2, with each tread providing 240 mm (9.5 in.) of depth, including tread overlap.
- (7) A distance of not less than 150 mm (6 in.) shall be provided between the stair handrail and any other object.

- (8) The initial tread of the stair shall begin at the same elevation as the platform, landing, or floor surface.
- (9) The alternating treads shall not be laterally separated by a distance of more than 51 mm (2 in.).
- (10) The occupant load served shall not exceed three.

7.2.12 Areas of Refuge.

Subsection 7.2.12 presents the detailed criteria applicable to an area of refuge. The term *area of refuge* and the related terms *accessible area of refuge* and *accessible means of egress* are defined in 3.3.17, 3.3.17.1, and 3.3.136.1, respectively.

Subsection 7.5.4 requires accessible means of egress in all new construction in areas accessible to persons with severe mobility impairment. Because an accessible means of egress must be usable by a person with severe mobility impairment, the components most commonly used in such means of egress will be ramps and areas of refuge. Areas of refuge will be extensively used from the upper stories of multistory buildings where it might not be feasible to install ramp systems.

The criteria of 7.2.12 were written to bring the Code into substantial agreement with the *Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities* (ADAAG) and ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

7.2.12.1 General.

7.2.12.1.1 Unless otherwise provided in 7.2.12.1.2, an area of refuge used as part of a required accessible means of egress in accordance with 7.5.4, or used as a part of any required means of egress, shall conform to the following:

- (1) General requirements of Section 7.1
- (2) Requirements of 7.2.12.2 and 7.2.12.3

7.2.12.1.2 The requirements of 7.2.12.1.1(2) shall not apply to areas of refuge consisting of stories of buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

The provisions of 7.2.12.1.2 and the definition of *area of refuge* in 3.3.17 are interrelated. Their combined effect is to permit three forms of area of refuge to serve as part of an accessible means of egress, as follows.

(a) On a floor of a building not protected throughout by an approved, supervised automatic

sprinkler system, the area of refuge must meet the special requirements of 7.2.12.2 and 7.2.12.3, as well as the general requirements of Section 7.1.

(b) On a floor of a building protected throughout by an approved, supervised automatic sprinkler system—and involving an occupancy that does not exempt itself from the minimum two accessible rooms provision of the definition of *area of refuge*—the area of refuge is exempt from the special requirements of 7.2.12.2 and 7.2.12.3. However, the area of refuge must meet the general requirements of Section 7.1 and consist of at least two accessible rooms or spaces separated from each other by smoke-resisting partitions. The following occupancies are not exempt from the minimum two accessible rooms provision of the definition of *area of refuge*:

- (1) Assembly
- (2) Educational
- (3) Health care
- (4) Detention and correctional
- (5) Board and care
- (6) Industrial
- (7) Storage

(c) On a floor of a building protected throughout by an approved, supervised automatic sprinkler system—and involving an occupancy that exempts itself from the minimum two accessible rooms provision of the definition of *area of refuge*—the area of refuge is exempt from the special requirements of 7.2.12.2 and 7.2.12.3 and is also exempt from having to provide the two accessible rooms or spaces separated from each other by smoke-resisting partitions. However, the area of refuge must meet the general requirements of Section 7.1. The following occupancies are exempt from the minimum two accessible rooms provision of the definition of *area of refuge*:

- (1) Hotels and dormitories (28.2.2.12.2, 29.2.2.12.2)
- (2) Apartment buildings (30.2.2.12.2, 31.2.2.12.2)
- (3) Mercantile (36.2.2.12.2, 37.2.2.12.2)
- (4) Business (38.2.2.12.2, 39.2.2.12.2)

7.2.12.2 Accessibility.

7.2.12.2.1 Required portions of an area of refuge shall be accessible from the space they serve by an accessible means of egress.

To help ensure that persons with mobility impairments can access the area of refuge, 7.2.12.2.1 requires

such accessibility via an accessible means of egress. Thus, a person attempting to reach the area of refuge must be provided with either level floor travel or ramp travel, not stairs. Similarly, the door to the area of refuge must provide sufficient clear width, typically the 810-mm (32-in.) minimum specified by 7.2.1.2.4, to permit a person in a wheelchair to move through the door opening. See the definition of *accessible means of egress* in 3.3.136.1.

7.2.12.2.2 Required portions of an area of refuge shall have access to a public way via an exit or an elevator without requiring return to the building spaces through which travel to the area of refuge occurred.

An area of refuge is intended to provide only a temporary point of safety to permit delayed egress travel from any level. Therefore, an area of refuge cannot be a room or space whose only access to the building spaces is via the room or space through which the user arrived. Such an arrangement might trap a person within the area of refuge, since no egress has been provided other than that which requires travel back through the space where the fire is located. Rather, the area of refuge must provide access to a public way via either an elevator or an exit such as an enclosed exit stair.

7.2.12.2.3* Where the exit providing egress from an area of refuge to a public way that is in accordance with 7.2.12.2.2 includes stairs, the clear width of landings and stair flights, measured between handrails and at all points below handrail height, shall be not less than 1220 mm (48 in.), unless otherwise permitted by the following:

- (1) The minimum 1220-mm (48-in.) clear width shall not be required where the area of refuge is separated from the remainder of the story by a horizontal exit meeting the requirements of 7.2.4. (See also 7.2.12.3.4.)
- (2) For stairs where egress is in the descending direction, a clear width of not less than 940 mm (37 in.), measured at and below handrail height, shall be permitted if approved alternative measures are provided that do not necessitate carrying occupied wheelchairs on the stairs.
- (3) Existing stairs and landings that provide a clear width of not less than 940 mm (37 in.), measured at and below handrail height, shall be permitted.

A.7.2.12.2.3 The clear width of not less than 1220 mm (48 in.) is needed for a three-person carry of an occupied wheelchair up or down a stair. This procedure, as well as the more difficult two-person wheelchair carry or roll, requires

training and experience. Safer, alternative stair descent measures for transporting a person who normally requires a wheelchair include evacuation chairs and self-braking stair descent devices. In addition to having such devices available where needed, and having persons trained and experienced in their use, it is important to have people trained and experienced in wheelchair transfer techniques.

In view of the logistical difficulties as well as the dangers inherent in carrying occupied wheelchairs or otherwise transporting their occupants on stairs, the preferred means of egress from an area of refuge consists of facilities normally employed for ingress and egress by people using wheelchairs. Foremost among these options are elevators meeting the fire-fighter service requirements of ASME A17.1, *Safety Code for Elevators and Escalators*.

The *Code* requires 1220 mm (48 in.) of clear width between handrails on exit stairs that provide the required access from the area of refuge to the exit discharge. The 1220-mm (48-in.) clear width requirement is wider than the minimum 1120 mm (44 in.) stair width required by Tables 7.2.2.2.1(a) and 7.2.2.2.1(b), which typically provides only 890 mm to 940 mm (35 in. to 37 in.) of clear width between handrails. [A 114-mm (4½-in.) encroachment is currently permitted at each side of the stair by Tables 7.2.2.2.1(a) and 7.2.2.2.1(b) and paragraph 7.3.2.2. In earlier editions of the *Code*, the permitted encroachment was 90 mm (3½ in.)] The extra width is required to facilitate the carrying of persons in wheelchairs as explained in A.7.2.12.2.3. The minimum 1220-mm (48-in.) stair width is a clear width dimension measured between handrails. The allowances of Tables 7.2.2.2.1(a) and 7.2.2.2.1(b) and paragraph 7.3.2.2 that permit handrails to encroach as much as 114 mm (4½ in.) on each side of a stair without considering the reduced clear width does not apply. For a stair with normal handrails to provide the required 1220-mm (48-in.) clear width, the stair needs to be approximately 1445 mm (57 in.) wide.

Paragraph 7.2.12.2.3(1) exempts areas of refuge created by horizontal exits from the extra-wide stair requirement. Horizontal exits in accordance with 7.2.4 consist of barriers with a minimum 2-hour fire resistance rating. The 2-hour rating increases the time for which the area of refuge can maintain tenable conditions. It is believed that this increase in time allows a slower evacuation on a narrower, typical stair to be effectively accomplished.

Paragraph 7.2.12.2.3(2) recognizes an 1120-mm (44-in.) stair with handrails encroaching up to 90 mm (3½ in.) as permitted by earlier editions of the *Code*

so as to provide a minimum 940-mm (37-in.) clear width. However, egress must be in the descending direction, which is easier than climbing stairs and lifting persons with disabilities. Also, egress must not involve carrying occupied wheelchairs on the stairs. Special controlled-descent boards, chairs, and other devices, which are operable by one able-bodied person, are available. Such devices can be effectively used with the 940-mm (37-in.) clear width afforded by the typical 1120-mm (44-in.) width stair.

Paragraph 7.2.12.2.3(3) recognizes that areas of refuge might be created in existing buildings with existing 1120-mm (44-in.) stairs that provide only 940-mm (37-in.) clear width because of 90-mm (3 ½-in.) handrail encroachment permitted by earlier editions of the *Code*. To require the stairs in such buildings to be widened retroactively would create a severe hardship.

7.2.12.2.4* Where an elevator provides access from an area of refuge to a public way that is in accordance with 7.2.12.2.2, the following criteria shall be met:

- (1) The elevator shall be approved for fire fighter service as provided in ASME A17.1, *Safety Code for Elevators and Escalators*.
- (2) The power supply shall be protected against interruption from fire occurring within the building but outside the area of refuge.
- (3) The elevator shall be located in a shaft system meeting the requirements for smokeproof enclosures in accordance with 7.2.3, unless otherwise provided in 7.2.12.2.4.1 and 7.2.12.2.4.2.

A.7.2.12.2.4 The use of elevators for egress, especially during an emergency such as a fire, is not an approach to be taken without considerable planning, ongoing effort, and a high degree of understanding by everyone involved with the evacuation of persons with mobility impairments. Due in part to the limited capacity of elevators, as well as to the conflicting demands for elevator use for fire-fighting activities, even elevators in accordance with 7.2.12.2.4 cannot be considered as satisfying any of the *Code's* requirements for egress capacity, number of means of egress, or travel distance to an exit.

7.2.12.2.4.1 The smokeproof enclosure specified in 7.2.12.2.4(3) shall not be required for areas of refuge that are more than 93 m² (1000 ft²) and that are created by a horizontal exit meeting the requirements of 7.2.4.

7.2.12.2.4.2 The smokeproof enclosure specified in 7.2.12.2.4(3) shall not be required for elevators complying with 7.2.13.

An elevator used to provide the required access from the area of refuge to the exit discharge must be safe to operate in a building with a fire. The *Code* requires such an elevator to have the fire fighter service features required by ASME A17.1, *Safety Code for Elevators and Escalators*. One of these features is elevator recall, whereby the elevator is taken out of service if smoke is detected in the elevator machine room of any elevator lobby it serves. Fire service personnel or other trained persons can put the elevator back into service for manual operation.

Also, the power supply for the elevator must be protected against interruption caused by fire occurring within the building but outside the area of refuge. The electrical wiring would require enclosure within protecting construction if it runs through other floors or other areas on the same floor as the area of refuge. The *Code's* intent is to ensure that, if it is safe to operate an elevator within a portion of the building, a fire in some other area will not adversely affect the power to the elevator. If the fire is in the same area as the elevator, it will not be safe to operate. Therefore, the electrical wiring in the same area as the elevator is not required to be protected.

For an elevator to pass a fire floor safely, its shaft must be kept free of smoke. The elevator must be located in a shaft system meeting the requirements of 7.2.3 for smokeproof enclosures. To achieve such compliance, the elevator lobbies on each floor need to be separated from the remainder of the floor. In effect, elevator vestibules are required. See 7.2.3 for additional details on smokeproof enclosures.

Paragraph 7.2.12.2.4.1 exempts the smokeproof enclosure for elevators in areas of refuge when those areas of refuge are more than 93 m² (1000 ft²) in area and are created by horizontal exits. Horizontal exits in accordance with 7.2.4 consist of barriers with a minimum 2-hour fire resistance rating. The 2-hour rating increases the time for which the area of refuge can maintain tenable conditions.

7.2.12.2.5 The area of refuge shall be provided with a two-way communication system for communication between the area of refuge and a central control point. The door to the stair enclosure or the elevator door and the associated portion of the area of refuge that the stair enclosure door or elevator door serves shall be identified by signage. (*See 7.2.12.3.5.*)

7.2.12.2.6* Instructions for summoning assistance, via the two-way communication system, and written identification of the area of refuge location shall be posted adjacent to the two-way communication system.

A.7.2.12.2.6 The instructions should include the following:

- (1) Directions to find other means of egress
- (2) Advice that persons able to use exit stairs do so as soon as possible, unless they are assisting others
- (3) Information on planned availability of assistance in the use of stairs or supervised operation of elevators and how to summon such assistance
- (4) Directions for use of the emergency communication system

To facilitate an adequate degree of understanding of the use of areas of refuge and of the associated assisted egress procedures, information should be provided to those using the facilities. The exact content of the information, its organization (for example, as a set of instructions), and its format (for example, either posted instructions in the area of refuge or information otherwise transmitted to facility users) should be determined on a case-by-case basis. The information should be tailored to the specific facility, its emergency plan, the intended audience, and the intended presentation format. The following provides suggested information content addressing two situations.

- (1) *Refuge with Elevator Use.* An area of refuge provided in the elevator lobby serves as a staging area for persons unable to use stairs and needing assistance for their evacuation during an emergency. The elevator(s) will be taken out of automatic service and operated by emergency service personnel. Persons unable to evacuate down the exit stairs without assistance and needing transportation by elevator should make certain the elevator lobby doors are closed while they wait in the elevator lobby for assistance. The two-way communication system should be used if there is a delay of more than several minutes in the arrival of an elevator that will provide transportation to the ground floor. Alternatively, another refuge area, and assistance with evacuation, is available in the designated exit stair.
- (2) *Refuge with Stair Use.* An area of refuge within the designated exit stair serves as a staging area for persons needing assistance for their evacuation during an emergency. Persons unable to use the stairs unassisted, or who wish to move down the stairs at a slower pace, should wait on the stair landing. The two-way communication system should be used if assistance is needed.

In a nonsprinklered building, either an elevator or a stair will be provided as access from the area of refuge to a public way, and it cannot be ensured that persons with mobility impairments will be able to use the elevator or stair without assistance. For example, an elevator might have been called out of service because smoke was detected in one of the elevator lobbies serving that elevator. Therefore, the *Code* re-

quires a two-way communication system between the area of refuge and a central control point; the communication system will be used to summon assistance. Additionally, signage and instructions are required to help complete the package of features for use by persons with disabilities.

These requirements for communication capability, signage, and instructions are not required for areas of refuge in buildings protected throughout by approved, supervised automatic sprinkler systems.

7.2.12.3 Details.

7.2.12.3.1* Each area of refuge shall be sized to accommodate one wheelchair space of 760 mm × 1220 mm (30 in. × 48 in.) for every 200 occupants, or portion thereof, based on the occupant load served by the area of refuge. Such wheelchair spaces shall maintain the width of a means of egress to not less than that required for the occupant load served and to not less than 915 mm (36 in.).

A.7.2.12.3.1 Figure A.7.2.12.3.1 illustrates the application of the minimum space requirement to an area of refuge located within an exit stair enclosure. Note that each of the two required spaces is sufficient to allow the parking of a standard wheelchair. Preferably, such spaces should be provided adjacent to each other in a location where the presence of people taking temporary shelter in an area of refuge will be immediately apparent to rescue personnel and other evacuees.

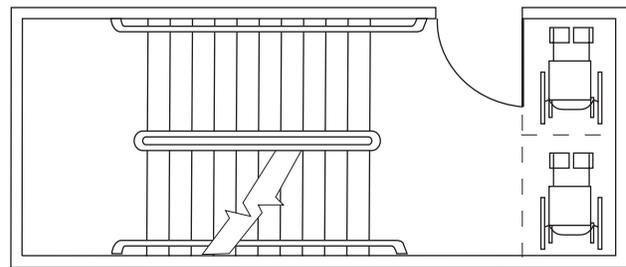

Figure A.7.2.12.3.1 Exit Stair Used as an Area of Refuge.

7.2.12.3.2* For any area of refuge that does not exceed 93 m² (1000 ft²), it shall be demonstrated by calculation or test that tenable conditions are maintained within the area of refuge for a period of 15 minutes when the exposing space on the other side of the separation creating the area of refuge is subjected to the maximum expected fire conditions.

Areas of refuge of less than 93 m² (1000 ft²) might be more easily affected than larger areas by the products

of combustion from a fire in the area on the other side of the separating barrier. Thus, tenability must be demonstrated by calculation or test. An area of refuge within an exit stair enclosure, as shown in Figure A.7.2.12.3.1, would be required to demonstrate tenability. However, an area of refuge consisting of half a 205-m² (2200-ft²) floor would not be required to do so.

A.7.2.12.3.2 The method of meeting the tenability performance criteria required of an area of refuge of less than 93 m² (1000 ft²) can involve controlling the exposing fire (for example, via automatic sprinkler protection), installing smoke-resisting doors in the smoke-resisting barriers (see *NFPA 105, Standard for the Installation of Smoke Door Assemblies*), providing smoke control to prevent or limit smoke migration through cracks or other leakage paths (see *NFPA 92A, Recommended Practice for Smoke-Control Systems*), or providing other means or a combination of these means.

Calculations, if used, need to be based on established engineering relationships and equations. Such calculational procedures are described in *NFPA 92A, Recommended Practice for Smoke-Control Systems*, and the *SFPE Handbook of Fire Protection Engineering*. Tenable conditions are those that maintain the temperature of any smoke in the area of refuge at less than 93°C (200°F) if the smoke is more than 1525 mm (60 in.) above the floor, and at less than 49°C (120°F) if the smoke descends below the 1525 mm (60 in.) level in the area of refuge. Also, if the smoke descends below the 1525 mm (60 in.) level, tenable conditions require not less than 16 percent oxygen and not more than 30,000 ppm/min exposure to carbon monoxide. The exposing conditions used in the calculations should be in accordance with the following:

- (1) The exposing space is sprinkler protected: the temperature of the exposing smoke is 93°C (200°F), the smoke layer extends to the floor, the oxygen content is 16 percent, and the carbon monoxide concentration is 2000 ppm (0.2 percent).
- (2) The exposing space is a nonsprinklered corridor finished with Class A interior wall and ceiling finish: the temperature of the exposing smoke is 316°C (600°F), the smoke layer extends to a level 610 mm (24 in.) above the floor, the oxygen content is 3 percent, and the carbon monoxide concentration is 50,000 ppm (5 percent).
- (3) The exposing space is either not a corridor or, if a corridor, the corridor is not finished with a Class A interior wall and ceiling finish: the temperature of the exposing smoke is 815°C (1500°F), the smoke layer extends to a level 610 mm (24 in.) above the floor, the

oxygen content is 3 percent, and the carbon monoxide concentration is 50,000 ppm (5 percent).

7.2.12.3.3 Access to any designated wheelchair space in an area of refuge shall not pass through more than one adjoining wheelchair space.

7.2.12.3.4* Each area of refuge shall be separated from the remainder of the story by a barrier with not less than a 1-hour fire resistance rating, unless one of the following criteria applies:

- (1) A greater rating is required in other provisions of this *Code*.
- (2) The barrier is an existing barrier with a minimum 30-minute fire resistance rating.

A.7.2.12.3.4 Requirements for fire resistance ratings in excess of 1 hour, fire protection ratings in excess of 20 minutes, and prohibitions on duct penetrations appear in other *Code* sections. For example, if the barrier creating the area of refuge is also part of an exit stair enclosure that connects more than three stories or is a horizontal exit, a fire resistance rating of the barrier of not less than 2 hours and a fire protection rating for opening protectives such as doors of not less than 1½ hours would be required for most occupancies.

For further information on door openings in smoke-resisting barriers, see *NFPA 105, Standard for the Installation of Smoke Door Assemblies*.

Generally, by providing one barrier that subdivides a floor area, two areas of refuge can be created. This subdivision method and the possibility of creating areas of refuge within compartmented elevator lobbies or on enlarged stair landings of exit stair enclosures make less onerous any requirement for a story to have more than one accessible means of egress.

7.2.12.3.4.1 New fire door assemblies serving an area of refuge shall be positive-pressure rated in accordance with 8.2.2.4.

7.2.12.3.4.2 The barriers specified in 7.2.12.3.4, and any openings in them, shall minimize air leakage and retard the passage of smoke.

7.2.12.3.4.3 Doors in the barriers specified in 7.2.12.3.4 shall have not less than a 20-minute fire protection rating, unless a greater rating is required in other provisions of this *Code*, and shall be either self-closing or automatic-closing in accordance with 7.2.1.8.

7.2.12.3.4.4 Ducts shall be permitted to penetrate the barrier specified in 7.2.12.3.4, unless prohibited in other provisions of this *Code*, and shall be provided with smoke-actuated dampers or other approved means to resist the transfer of smoke into the area of refuge.

As explained in the commentary following 7.2.12.1.2, these requirements for fire resistance-rated separating barriers and fire protection-rated separating doors are not required for areas of refuge in buildings protected throughout by approved, supervised automatic sprinkler systems.

Exhibits 7.61 through 7.65 illustrate various arrangements of areas of refuge.

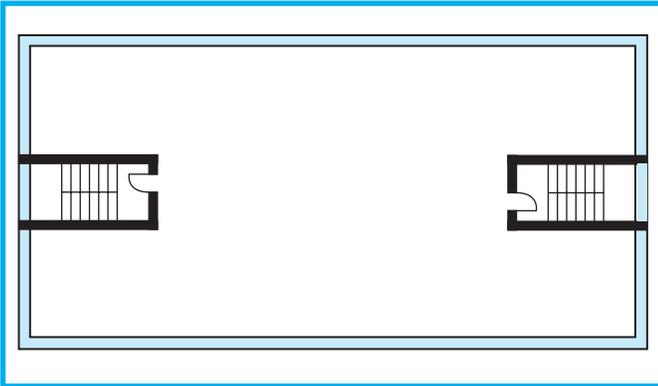

Exhibit 7.61 Area of refuge in new sprinklered business occupancy.

Exhibit 7.61 depicts an area of refuge in a new sprinklered business occupancy. Paragraph 38.2.2.12.2 exempts the floor that serves as an area of refuge from having to provide two rooms or spaces separated from each other by smoke-resistant partitions if the building is protected throughout by an approved, supervised automatic sprinkler system. The open floor area depicted therefore meets the requirements for an area of refuge.

Exhibit 7.62 depicts an area of refuge in a new

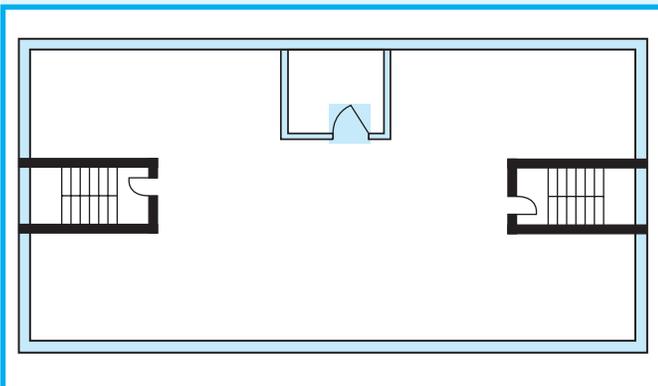

Exhibit 7.62 Area of refuge in new sprinklered industrial occupancy.

sprinklered industrial occupancy. Industrial occupancies are not exempt from the area of refuge provision for two rooms or spaces separated from each other by smoke-resistant partitions. Thus, in this building, which is protected throughout by an approved, supervised automatic sprinkler system, a second room is provided on this floor. Although the separating barriers and door are not required to be fire rated, they must be smoke resistant. With this arrangement, the floor meets the requirements for an area of refuge.

Exhibit 7.63 depicts areas of refuge in nonsprinklered new construction. The barrier dividing the floor into two areas of refuge has a 1-hour fire resistance rating; the door has a 20-minute fire protection rating. Each area is more than 93 m² (1000 ft²), and no tenability calculations are required. In the area of refuge at the left, the elevator is provided with fire fighter service features and serves as access to the public way; the stair in that compartment is permitted to have the usual 1120-mm (44-in.) width. In the area of refuge at the right, the stair serves as access to the public way and must be approximately 1455 mm (57 in.) wide to provide the required 1220-mm (48-in.) clear width between handrails. Two-way communication capability, signage, and posted instructions are required in each area of refuge.

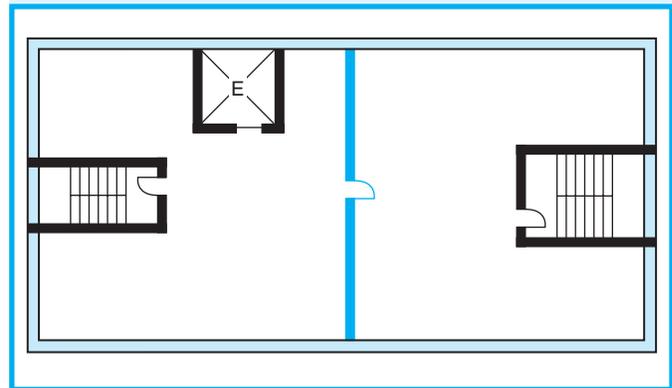

Exhibit 7.63 Areas of refuge in nonsprinklered new construction.

Exhibit 7.64 depicts areas of refuge created by a horizontal exit in new construction. The barrier dividing the floor into two areas of refuge is a horizontal exit with a 2-hour fire resistance rating; the doors have a 1½-hour fire protection rating. Each area is more than 93 m² (1000 ft²), so no tenability calculations are required. Because the separating barrier is a horizontal exit, the stairs are permitted to be typical 1120-mm (44-in.) width stairs. Two-way communica-

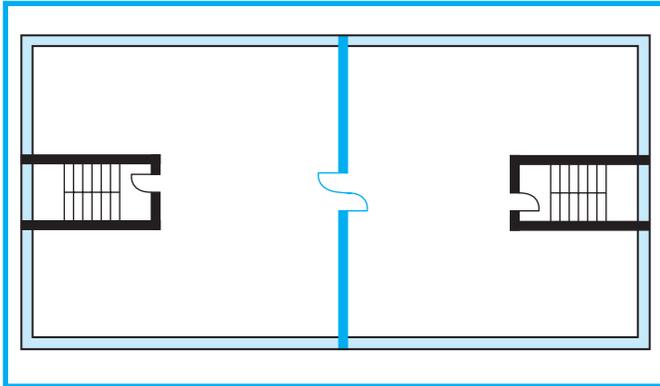

Exhibit 7.64 Areas of refuge created by horizontal exit in new construction.

tion capability, signage, and posted instructions are required in each area of refuge.

Exhibit 7.65 depicts an area of refuge that uses space within the exit stair enclosure in nonsprinklered new construction. The exit stair enclosure walls at the right of the figure provide the barrier that creates two areas of refuge on the floor. The area of refuge within that exit stair enclosure is less than 93 m² (1000 ft²), and tenability must be demonstrated. The remainder of the floor serves as the second area of refuge; it is larger than 93 m² (1000 ft²), and no tenability calculation is required. Stairs provide access from each area of refuge to a public way. The stairs must be approximately 1455 mm (57 in.) wide to provide the required 1220-mm (48-in.) clear width between handrails. Two-way communication capability, signage, and posted instructions are required in each area of refuge.

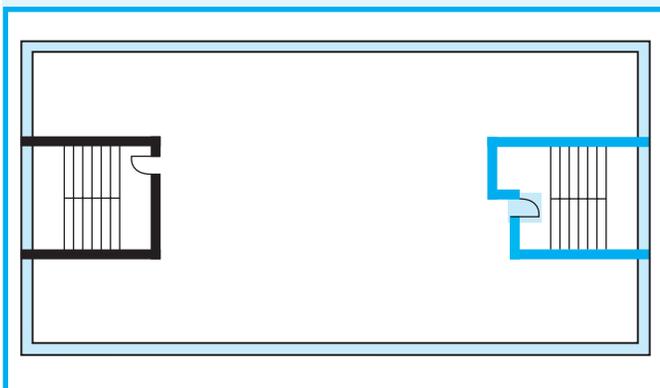

Exhibit 7.65 Area of refuge using space within exit stair enclosure in nonsprinklered new construction.

7.2.12.3.5 Each area of refuge shall be identified by a sign that reads as the follows:

AREA OF REFUGE

7.2.12.3.5.1 The sign required by 7.2.12.3.5 shall conform to the requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, for such signage and shall display the international symbol of accessibility. Signs also shall be located as follows:

- (1) At each door providing access to the area of refuge
- (2) At all exits not providing an accessible means of egress, as defined in 3.3.136.1
- (3) Where necessary to indicate clearly the direction to an area of refuge

7.2.12.3.5.2 Signs required by 7.2.12.3.5 shall be illuminated as required for exit signs where exit sign illumination is required.

7.2.12.3.6 Tactile signage complying with ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, shall be located at each door to an area of refuge.

7.2.13 Elevators.

Prior to the 1997 edition, the *Code* treated elevators as a means of moving persons with mobility impairment from an area of refuge to the exit discharge (see 7.2.12). The earlier editions also addressed the situation of taking an elevator out of service and making it available to fire fighters to prevent its misuse by building occupants during a fire (see Section 9.4). However, elevators were not recognized as a component of typical means of egress. The concept of elevators as a component of the means of egress, which is addressed in 7.2.13, was new to the 1997 edition of the *Code*.

7.2.13.1* General. An elevator complying with the requirements of Section 9.4 and 7.2.13 shall be permitted to be used as a second means of egress from towers, as defined in 3.3.224, provided that the following criteria are met:

- (1) The tower and any attached structure shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) The tower shall be subject to occupancy not to exceed 90 persons.
- (3) Primary egress discharges shall be directly to the outside.
- (4) No high hazard content areas shall exist in the tower or attached structure.
- (5) One hundred percent of the egress capacity shall be provided independent of the elevators.
- (6) An evacuation plan that specifically includes the elevator shall be implemented and staff personnel shall be trained in operations and procedures for elevator emergency use in normal operating mode prior to fire fighter recall.
- (7) The tower shall not be used by the general public.

A.7.2.13.1 It is the intent of 7.2.13.1 that elevators serving as a means of egress serve only independent towers or the tower portion of any integral structure. For elevators that are used as a component in the means of egress, the elevator lobbies, elevator shaft, and machine room need to be protected from the effects of fire.

Subsections 7.2.1 through 7.2.12 are formatted to describe one of 12 potential components of means of egress, such as doors (7.2.1), stairs (7.2.2), ramps (7.2.5), or slide escapes (7.2.10). The occupancy chapters specify whether each of these components is permitted to be used within the required means of egress. The recognition of these components by the occupancy chapters ranges from “permitted by all” for doors to “very limited use” for slide escapes in high-hazard industrial and existing storage occupancies. However, in each case, it is the occupancy chapter that determines the applicability of any of the 12 egress components. Subsection 7.2.13 is formatted differently. It limits the use of elevators within means of egress to serving only as a secondary, not primary, means of egress from towers.

The recognition of elevators for emergency egress is limited to towers not used by the general public. The occupants will generally be employees, who are familiar with the structure because of repeated occupancy. Although members of the public have likely been taught not to use elevators during fire or similar emergency, the tower’s employees can be trained to use elevators effectively for egress.

Note that 7.2.13.1(1) requires the tower to be sprinklered to keep conditions tenable while the elevator is being used. Paragraph 7.2.13.1(2) limits occupancy in the tower to a maximum of 90 persons. Paragraph 7.2.13.1(5) requires that 100 percent of the egress capacity be provided without considering the capacity provided by the elevator. Thus, the elevator helps to satisfy the requirement for a redundant, second egress route, but the primary route (typically a stair) must be sized to accommodate the entire occupant load.

The restrictions imposed on the use of elevator evacuation systems resulted from the consensus process by which the *Code* is revised. One faction favored recognition of elevator evacuation systems for any occupancy. The other faction did not want elevators to be recognized at all. As tangible experience is gained in the design and use of elevator evacuation systems, additional recognition of the emergency egress use of elevators will be included in future editions of the *Code*.

At the time this commentary was being updated for this edition of the *Code*, ASME was planning for a Spring 2004 symposium, co-sponsored by NFPA, on the use of elevators in fire emergencies for egress and for fire service use. An anticipated product of the symposium is a package of recommended changes to the model fire and life codes.

7.2.13.2 Elevator Evacuation System Capacity.

7.2.13.2.1 The elevator car shall have a capacity of not less than eight persons.

7.2.13.2.2 The elevator lobby shall have a capacity of not less than 50 percent of the occupant load of the area served by the lobby. The capacity shall be calculated based on 0.28 m² (3 ft²) per person and shall also include one wheelchair space of 760 mm × 1220 mm (30 in. × 48 in.) for every 50 persons, or portion thereof, of the total occupant load served by that lobby.

7.2.13.3 Elevator Lobby. Every floor served by the elevator shall have an elevator lobby. Barriers forming the elevator lobby shall have a fire resistance rating of not less than 1 hour and shall be arranged as a smoke barrier in accordance with Section 8.5.

7.2.13.4 Elevator Lobby Doors. Elevator lobby doors shall have a fire protection rating of at least 1 hour. The transmitted temperature end point shall not exceed 250°C (450°F) above ambient at the end of 30 minutes of the fire exposure specified in the test method referenced in 8.3.3.2. Elevator lobby doors shall be self-closing or automatic-closing in accordance with 7.2.1.8.

7.2.13.5 Door Activation. The elevator lobby doors shall close in response to a signal from a smoke detector located directly outside the elevator lobby adjacent to or on each door opening. Elevator lobby doors shall be permitted to close in response to a signal from the building fire alarm system. Where one elevator lobby door closes by means of a smoke detector or a signal from the building fire alarm system, all elevator lobby doors serving that elevator evacuation system shall close.

7.2.13.6* Water Protection. Building elements shall be used to restrict water exposure of elevator equipment.

A.7.2.13.6 One or more of the following approaches can be used to restrict exposure of elevator equipment to water:

- (1) A combination of sealed elevator lobby doors, sloped floors, floor drains, and sealed elevator shaft walls is used.
- (2) The elevator is mounted on the building exterior that normally operates in the elements, and seals are used on the elevator lobby doors.

- (3) The elevator shaft is separated from the building at each floor by an exterior elevator lobby designed to prevent water entry into the elevator shaft.

Information gained from ongoing research concerning waterflow and elevators could lead to the development of water-resistant or water-protected elevator equipment specifically for fire applications. Such equipment should be used only with the building elements (for example, sealed elevator lobby doors, sloped floors, floor drains) for which it is developed. Further information is available from the NIST publication, *Feasibility of Fire Evacuation by Elevators at FAA Control Towers*.

7.2.13.7* Power and Control Wiring. Elevator equipment, elevator communications, elevator machine room cooling, and elevator controller cooling shall be supplied by both normal and standby power. Wiring for power and control shall be located and properly protected to ensure at least 1 hour of operation in the event of a fire.

A.7.2.13.7 Cooling equipment dedicated to the elevator machine room can be used to minimize requirements for standby power.

7.2.13.8* Communications. Two-way communication systems shall be provided between elevator lobbies and a central control point and between elevator cars and a central control point. Communications wiring shall be protected to ensure at least 1 hour of operation in the event of fire.

A.7.2.13.8 Communication between elevator lobbies and a central control point can be by telephone or intercom. Auditory alarms should be designed so that they do not interfere with people talking on communications systems.

7.2.13.9* Elevator Operation. Elevators shall be provided with fire fighter service in accordance with ASME A17.1, *Safety Code for Elevators and Escalators*.

A.7.2.13.9 Smoke detection in the elevator lobby will result in a Phase I recall of the elevators. The elevators will then be automatically taken out of normal service and will be available to be operated by emergency service personnel.

7.2.13.10 Maintenance. Where an elevator lobby is served by only one elevator car, the elevator evacuation system shall have a program of scheduled maintenance during times of building shutdown or low building activity. Repairs shall be performed within 24 hours of breakdown.

7.2.13.11 Earthquake Protection. Elevators shall have the capability of orderly shutdowns during earthquakes at locations where such shutdowns are an option of ASME A17.1, *Safety Code for Elevators and Escalators*.

7.2.13.12 Signage. Signage shall comply with 7.10.8.2.

Section 7.3 Capacity of Means of Egress

7.3.1 Occupant Load.

7.3.1.1 Sufficient Capacity for Occupant Load. The total capacity of the means of egress for any story, balcony, tier, or other occupied space shall be sufficient for the occupant load thereof.

It is a basic concept of the *Code* that the means of egress system be sized to accommodate all people occupying a building.

The geometry of a building, its occupancy and related occupant load, and the travel distance to exits dictate, in large measure, the location of exits, the number of exits, and the capacity of exits and access thereto. As a consequence, the exits themselves influence the plan and layout of the entire system of means of egress. The number of people that the means of egress system can accommodate is determined not solely by the capacity of the exits but also by the number of persons each component within the means of egress can accommodate. Very wide corridors that lead to very wide exit-stair enclosure doors that then lead to much narrower stairs provide a system comparable to average-width corridors that lead to average-width exit-stair enclosure doors that then lead to average-width stairs. A means of egress system is only as good as its most constricting component.

The number of people or occupant load for which the means of egress system must provide egress capacity is calculated or determined. The occupant load is to reflect the maximum number of people anticipated to occupy the building rooms or spaces at any given time and under all probable situations. The occupant load must not be based only on normal occupancy.

Occupant load distribution in buildings might vary, with greater concentrations of people in some areas. However, good egress system design should ensure that egress capacity distribution among the exits is basically balanced. Multiple means of egress are required to provide alternate routes in case one of the means of egress becomes obstructed by the fire and becomes unavailable. Although the exit with the greatest share of the total required egress capacity might be the exit closest to the majority of the occupants, it might also be the exit that is lost in a fire. Consequently, a disproportionate amount of the total egress capacity might be lost.

7.3.1.2* Occupant Load Factor. The occupant load in any building or portion thereof shall be not less than the number

of persons determined by dividing the floor area assigned to that use by the occupant load factor for that use as specified in Table 7.3.1.2, Figure 7.3.1.2(a), and Figure 7.3.1.2(b). Where both gross and net area figures are given for the same occupancy, calculations shall be made by applying the gross

Mall buildings ⁴	Per factors applicable to use of space ⁵	Per factors applicable to use of space ⁵

Note: NA = not applicable. The occupant load is the maximum probable number of occupants present at any time.

¹All factors are expressed in gross area unless marked “net.”

²For the purpose of determining occupant load in mercantile occupancies where, due to differences in grade of streets on different sides, two or more floors directly accessible from streets (not including alleys or similar back streets) exist, each such floor is permitted to be considered a street floor. The occupant load factor is one person for each 3.7 m² (40 ft²) of gross floor area of sales space.

³For the purpose of determining occupant load in mercantile occupancies with no street floor, as defined in 3.3.216, but with access directly from the street by stairs or escalators, the floor at the point of entrance to the mercantile occupancy is considered the street floor.

⁴For any food court or other assembly use areas located in the mall that are not included as a portion of the gross leasable area of the mall building, the occupant load is calculated based on the occupant load factor for that use as specified in Table 7.3.1.2. The remaining mall area is not required to be assigned an occupant load.

⁵The portions of the mall that are considered a pedestrian way and not used as gross leasable area are not required to be assessed an occupant load based on Table 7.3.1.2. However, means of egress from a mall pedestrian way are required to be provided for an occupant load determined by dividing the gross leasable area of the mall building (not including anchor stores) by the appropriate lowest whole number occupant load factor from Figure 7.3.1.2(a) or Figure 7.3.1.2(b).

Each individual tenant space is required to have means of egress to the outside or to the mall based on occupant loads calculated by using the appropriate occupant load factor from Table 7.3.1.2.

Each individual anchor store is required to have means of egress independent of the mall.

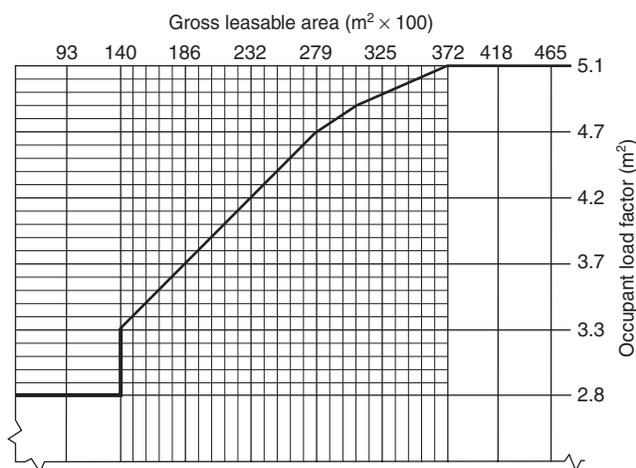

Figure 7.3.1.2(a) Mall Building Occupant Load Factors.

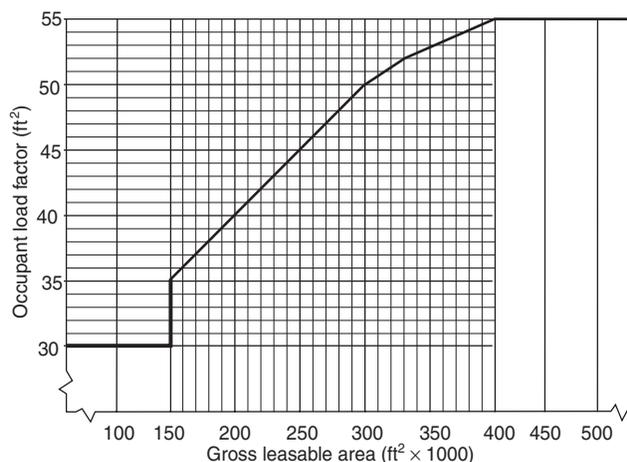

Figure 7.3.1.2(b) Mall Building Occupant Load Factors.

area figure to the gross area of the portion of the building devoted to the use for which the gross area figure is specified and by applying the net area figure to the net area of the portion of the building devoted to the use for which the net area figure is specified.

A.7.3.1.2 The normal occupant load is not necessarily a suitable criterion, because the greatest hazard can occur when an unusually large crowd is present, which is a condition often difficult for authorities having jurisdiction to control by regulatory measures. The principle of this Code is to provide means of egress for the maximum probable number of occupants rather than to attempt to limit occupants to a number commensurate with available means of egress. However, limits of occupancy are specified in certain special cases for other reasons.

Suggested occupant load factors for components of large airport terminal buildings are given in Table A.7.3.1.2. However, the authority having jurisdiction might elect to use different occupant load factors, provided that egress requirements are satisfied.

Table A.7.3.1.2 Airport Terminal Occupant Load Factors

Airport Terminal Area	m ² (gross)	ft ² (gross)
Concourse	9.3	100
Waiting areas	1.4	15
Baggage claim	1.9	20
Baggage handling	27.9	300

Mall Buildings. The figure used in determining the occupancy load for mall shopping centers of varying sizes was arrived at empirically by surveying over 270 mall shopping centers, by studying mercantile occupancy parking requirements, and by observing the number of occupants per vehicle during peak seasons.

These studies show that, with an increase in shopping center size, there is a decrease in the number of occupants per square foot of gross leasable area.

This phenomenon is explained when one considers that above a certain shopping center gross leasable area [approximately 56,000 m² (600,000 ft²)], there exists a multiplicity of the same types of stores. The purpose of duplicate types of stores is to increase the choices available to a customer for any given type of merchandise. Therefore, when shopping center size increases, the occupant load increases as well, but at a declining rate. In using Table 7.3.1.2, the occupant load factor is applied only to the gross leasable area that uses the mall as a means of egress.

Occupant load is determined by the nature of the use of a building or space and the amount of space available for that use. Since different generic uses will be characterized by different occupant densities, Table 7.3.1.2 has established occupant load factors for each use. The first column of the table is deliberately headed *use* rather than *occupancy* because the use of an area might differ from its occupancy classification. For example, a meeting room for fewer than 50 people in an office building is not an assembly occupancy; it is a business occupancy, but its occupant load is based on an assembly use. The same concept applies to a classroom in a university, which, although classified as a business occupancy, would have its occupant load based on educational use (for traditional classroom style) or assembly use (for lecture style).

The occupant load factor, as a density factor, as-

sumes the presence of at least one person for each specified unit of area. Note that some values are for net area, while others are based on gross area. The gross area figure applies to the building as a whole (the area within the confining perimeter walls of the building); the net area figure applies to actual occupied spaces, such as classroom spaces, and does not include the corridors, the area occupied by walls, or other unoccupied areas.

Cases of mixed use might exist where, for example, an assembly use space having an occupant load based on net floor area might be located in a building that is primarily a business occupancy, a classification for which the occupant load is based on gross area. In such instances, the net area calculations should be performed for those specific areas that use occupant load factors based on net area; the remaining floor area can then be used to calculate the occupant load for the uses employing gross floor area. This is illustrated in Exhibit 7.66.

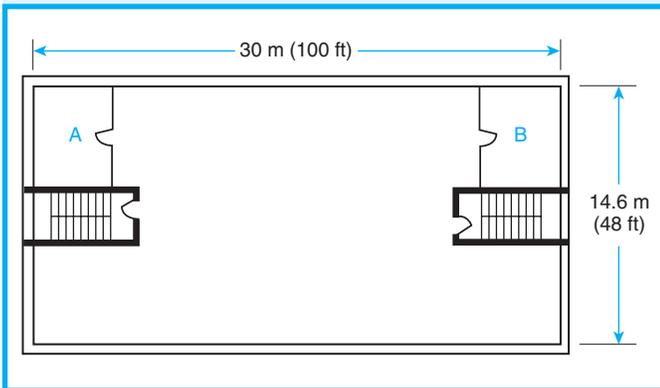

Exhibit 7.66 Floor area for occupant load considerations.

In Exhibit 7.66, the majority of the 446-m² (4800-ft²) gross floor area is used for business purposes and is occupied by desks, chairs, file cabinets, office machines, and associated office personnel. Rooms A and B are conference rooms with tables and chairs used on a regular basis primarily by company personnel from other floors in the building. These rooms can be expected to be occupied simultaneously with the remainder of the floor. Each conference room provides 30 m² (320 ft²) of net usable area. Because neither conference room can accommodate 50 or more persons, an assembly occupancy is not created. Rather, the floor is a business occupancy with some assembly use.

Because occupant load is calculated based on use of the space (not occupancy classification), the occu-

pant load of the floor shown in Exhibit 7.66 is calculated using occupant load factors for both an assembly use, which is based on net area, and a business use, which is based on gross area. The occupant load of the assembly use spaces (conference rooms A and B) is calculated first. Using Table 7.3.1.2, a net area factor of 1.4 m² (15 ft²) per person for assembly, *less concentrated use*, is chosen. The two conference rooms must be assumed to have a combined occupant load of at least 43 persons, according to the following calculation:

$$\frac{60 \text{ m}^2}{1.4 \text{ m}^2 \text{ per person}} = 43 \text{ persons}$$

$$\left[\frac{640 \text{ ft}^2}{15 \text{ ft}^2 \text{ per person}} = 43 \text{ persons} \right]$$

Next, the occupant load of the remainder of the floor must be calculated. The use is business, so a gross area factor of 9.3 m² (100 ft²) per person is assumed per Table 7.3.1.2. Because the net area usable as conference rooms has already been assigned an occupant load, that area can be subtracted from the gross floor area, and the remaining business use area is then assigned an occupant load as follows:

$$\left(446 \text{ m}^2 \text{ gross area} \right) - \left(60 \text{ m}^2 \text{ net assembly use area} \right) = 386 \text{ m}^2$$

$$\left[\left(4800 \text{ ft}^2 \text{ gross area} \right) - \left(640 \text{ ft}^2 \text{ net assembly use area} \right) = 4160 \text{ ft}^2 \right]$$

$$\frac{386 \text{ m}^2 \text{ gross business use area}}{9.3 \text{ m}^2 \text{ per person}} = 42 \text{ persons}$$

$$\left[\frac{4160 \text{ ft}^2 \text{ gross business use area}}{100 \text{ ft}^2 \text{ per person}} = 42 \text{ persons} \right]$$

Adding together the assembly use occupant load (43) and the business use occupant load (42) results in an occupant load of 85 persons for the floor.

Egress capacity must be provided for at least the number of persons determined by dividing each area of the space by the appropriate occupant load factor. This calculation must be performed regardless of whether the building operator claims that the occupant load will never reach the occupant load determined by calculation. However, if the building operator plans to have more occupants present than the number determined by calculation using occupant load factors, the means of egress system must be sized to accommodate that larger number. In re-

turn for providing the larger egress system, the building operator is permitted to claim the larger number of persons as the occupant load. This concept is further explained in the commentary following 7.3.1.3.1.

7.3.1.3 Occupant Load Increases.

7.3.1.3.1 The occupant load in any building or portion thereof shall be permitted to be increased from the occupant load established for the given use in accordance with 7.3.1.2 where all other requirements of this Code are also met, based on such increased occupant load.

The Code’s intent for other than assembly occupancies is not to restrict the occupant load of a building based on the floor area of the building. Nor is the Code specifying the minimum area needed by each occupant for efficient use of the space. An occupant load is established for use in sizing the means of egress system and in determining thresholds at which additional provisions, such as mandatory sprinklers, become applicable. If Code provisions can be met for a larger number of persons than the calculation determines, the larger number of occupants is permitted to be present, provided that the authority having jurisdiction is satisfied that all corridors, aisles, stairs, and other means of egress components can accommodate the larger occupant load.

For example, an office area of 1860 m² (20,000 ft²) would be assigned an occupant load of 200 persons if the typical 9.3-m² (100-ft²) occupant load factor were used. However, the occupant load would be permitted to be increased if all Code provisions dependent on numbers of persons were met for the increased load.

Assembly occupancies have special but similar provisions for increasing occupant load. Densities greater than one person for each 0.46 m² (5 ft²) are prohibited, because movement speeds are reduced to a crawl where the density exceeds one person for each 0.28-m² (3-ft²) density. This density is approaching the jam point at which movement stops, as addressed in the commentary following 12/13.1.7.4.

7.3.1.3.2 The authority having jurisdiction shall be permitted to require an approved aisle, seating, or fixed equipment diagram to substantiate any increase in occupant load and shall be permitted to require that such a diagram be posted in an approved location.

7.3.1.4 Exits Serving More than One Story. Where an exit serves more than one story, only the occupant load of

each story considered individually shall be used in computing the required capacity of the exit at that story, provided that the required egress capacity of the exit is not decreased in the direction of egress travel.

Paragraph 7.3.1.4 provides that, once a maximum required egress capacity is determined, such required capacity must be maintained—in the direction of egress travel—for the remainder of the egress system.

Required stair width is determined by the required egress capacity of each floor the stair serves. It is not necessary to accumulate occupant loads from floor to floor to determine stair width. Each story or floor level is considered separately when calculating the occupant load to be served by the means of egress from that floor. The size or width of the stair need only accommodate the portion of the floor’s occupant load assigned to that stair. However, in a multistory building, the floor requiring the greatest egress capacity dictates the minimum width of egress components, such as stairs, from that floor in the direction of egress travel. It is not permissible to reduce such stair width on the floors below, that is, stairs included in the direction of egress travel. Exits serving floors above the floor of greatest egress capacity are permitted to use components with widths that are less than or equal to those of that floor.

Exhibit 7.67 illustrates the intent of 7.3.1.4. It is not necessary to accumulate required egress capacity from floor to floor; no decrease in egress capacity is permitted in the direction of egress travel.

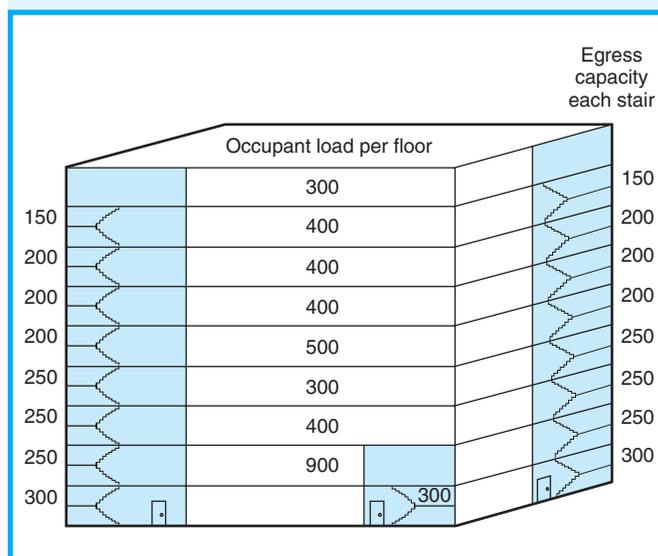

Exhibit 7.67 Capacity of exit stairs serving multiple floors.

7.3.1.5 Capacity from a Point of Convergence. Where means of egress from a story above and a story below converge at an intermediate story, the capacity of the means of egress from the point of convergence shall be not less than the sum of the capacity of the two means of egress.

Exhibit 7.68 illustrates the intent of 7.3.1.5. Convergence from floors above and below requires the accumulation of required egress capacity. Note that occupants of the second floor will move down the stairs and converge with occupants of the basement, who will have moved up the stairs. The occupants of the first floor (X) experience level travel through the stair enclosure; they are not considered to have merged from above or below and do not have their egress capacity added to that of the second floor and basement.

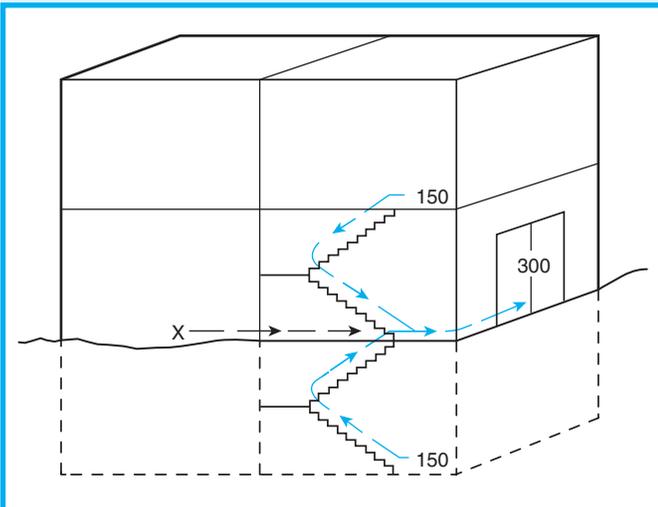

Exhibit 7.68 Capacity of exit stairs where occupants from floors above and below converge.

7.3.1.6 Egress Capacity from Balconies and Mezzanines. Where any required egress capacity from a balcony or mezzanine passes through the room below, that required capacity shall be added to the required egress capacity of the room below.

Mezzanines and balconies are considered as part of the room in which they are located. Occupants of mezzanines and balconies experience the effects of a fire in the room to which such spaces are open as readily as do the occupants of those spaces. Thus, mezzanines and balconies must have their occupant load added to that of the room or space in which they are located if their egress passes through that room or space.

An example is depicted in Exhibit 7.69. There is no direct access to the enclosed exit stair from the mezzanine; therefore, egress from the mezzanine is through the main floor. Thus, the street floor egress capacity must accommodate the occupant load of the street floor and that of the mezzanine. If the main floor has an occupant load of 200 persons and the mezzanine has an occupant load of 50 persons, the egress capacity for the room must accommodate at least 250 persons.

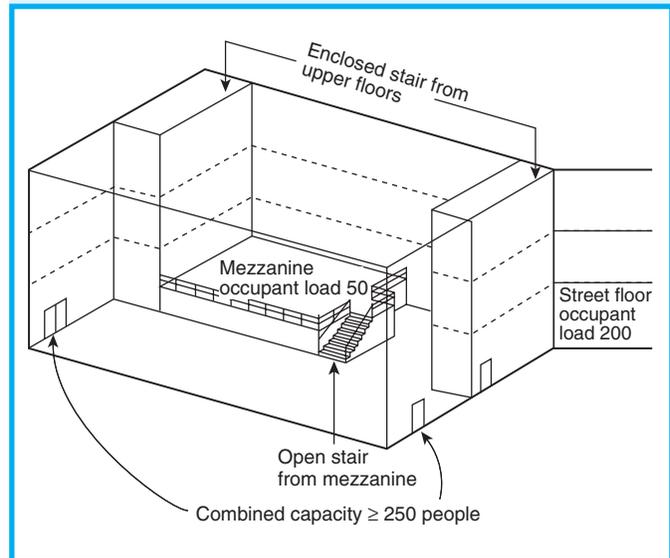

Exhibit 7.69 Capacity of main floor with mezzanine egress through that floor.

7.3.2 Measurement of Means of Egress.

7.3.2.1 The width of means of egress shall be measured in the clear at the narrowest point of the exit component under consideration, unless otherwise provided in 7.3.2.2.

7.3.2.2 Projections within the means of egress of not more than 114 mm (4½ in.) on each side shall be permitted at a height of 965 mm (38 in.) and below.

Paragraph 7.3.2.2 permits maximum 114-mm (4½-in.) projections at each side of an egress component, provided that such projections occur at a height of no more than 965 mm (38 in.), which is the maximum mounting height for handrails. Note that such encroachments are not limited to items such as handrails that are required by the Code. The encroachment might be the result of wainscoting applied to the lower portion of a wall, or it might be caused by the metal stringers to which metal pan stair treads and

risers are welded. Figure A.7.2.1.2.1(b) depicts the allowable encroachment at each side of a door. The same encroachment is permitted along stairs, corridors, passageways, and other components of the means of egress.

Projections at or below 965 mm (38 in.) (that is, handrail height) and not exceeding 114 mm (4½ in.) do not adversely restrict the effective width of stairs or corridors, because the human body is normally widest at shoulder level. Also, the body sway associated with walking, particularly on stairs, is greater at shoulder height than it is at waist height. Other projections, however, might constitute obstructions and cause impediments to the free flow of pedestrian travel. The *Code*, therefore, bases the measurements of widths of means of egress used for egress capacity calculation purposes on the clear, net, usable, unobstructed width. Only those projections specified are permitted to encroach on the required widths. Note that the minimum clear width of 1220-mm- (48-in.-) wide stairs serving areas of refuge as required by 7.2.12.2.3 does not allow for handrail and other encroachments located below handrail height. This prohibition is based on providing sufficient clear width to carry a person in a wheelchair on the stair. Also see 7.2.1.2.1.

7.3.3 Egress Capacity.

7.3.3.1 Egress capacity for approved components of means of egress shall be based on the capacity factors shown in Table 7.3.3.1.

Table 7.3.3.1 Capacity Factors

Area	Stairways (width per person)		Level Components and Ramps (width per person)	
	mm	in.	mm	in.
Board and care	10	0.4	5	0.2
Health care, sprinklered	7.6	0.3	5	0.2
Health care, nonsprinklered	15	0.6	13	0.5
High hazard contents	18	0.7	10	0.4
All others	7.6	0.3	5	0.2

A significant change in egress capacity calculations was introduced in the 1988 edition of the *Code*. The unit of exit width formerly used as a measure of

egress capacity was replaced by a system of smaller increments of egress width and capacity. For egress widths that were close to, and no smaller than, the previously used units [560 mm (22 in.)] and half units [305 mm (12 in.)], there is little difference in the egress capacities calculated by the two methods. For other widths, such as for doors and nonstandard stairs, the new method of using smaller increments (approximating a linear formula) provides increased egress capacity. This concept is demonstrated in the following examples.

Example 1

The common combination of an 865-mm (34-in.) clear width door that provides access to a stair 1120 mm (44 in.) wide with a 865-mm (34-in.) clear width discharge door has a capacity based on the capacity of its least efficient element. The individual capacities of the elements are calculated by dividing the widths by the appropriate capacity factor from Table 7.3.3.1. The doors have a capacity of 865 mm (34 in.) divided by 5 mm (0.2 in.) per person, or 170 persons. The stair has a capacity of 1120 mm (44 in.) divided by 7.6 mm (0.3 in.) per person, or 147 persons. The capacity of the exit is 147, the smaller of the two capacities. Under the use of the pre-1988 unit of exit width method, the capacities were 150 for the 1½-unit doors [those 865 mm (34 in.) or more in width] and 150 for the 2-unit stair.

Example 2

If the entry doorway provides 810 mm (32 in.) in clear width, the stair is 1370 mm (54 in.) wide, and the discharge doorway provides 915 mm (36 in.) in clear width, the individual capacities are, respectively, as follows:

- (1) 810 mm (32 in.) divided by 5 mm (0.2 in.) per person, or 160 persons, for the entry door
- (2) 1370 mm (54 in.) divided by 7.6 mm (0.3 in.) per person, or 180 persons, for the stair
- (3) 915 mm (36 in.) divided by 5 mm (0.2 in.) per person, or 180 persons, for the discharge door

Therefore, the capacity of the overall combination is the smallest of the three capacities—160 persons, as provided by the entry door. Under the previous unit of exit width method, the capacities would have been, respectively, as follows:

- (1) 1 unit for the entry door multiplied by 100 persons per unit, or 100 persons
- (2) 2 units for the stair multiplied by 75 persons per unit, or 150 persons

- (3) 1.5 units for the discharge door multiplied by 100 persons per unit, or 150 persons

Therefore, the capacity for the combination as previously calculated using the unit of exit width would have been only 100 persons, based on the entry door.

The width per person figures specified in Table 7.3.3.1 are based on previously used values credited for full units. The chief difference is that small increments are now considered to add to the capacity. Although Canadian research studies of egress movement in tall office buildings and in larger assembly occupancy buildings have demonstrated the validity of the small increment approach, there was evidence for this approach even in some significant early studies of egress and exit design. Two early, influential reports are of interest. One dates from 1935 in the United States¹³, the other was published in 1952 in Great Britain¹⁴. Both reports are provided in a discussion of the issue of exit unit size that was published in 1984 in *Fire Technology*¹⁵. The reports clearly show that the small increment approach was an unsettled issue even in those reports that were thought to support only the unit width method. More recent evidence has related egress facility width and crowd flow capacity. Clear documentation shows that crowds do not move in regular files or lanes, especially on stairs where side-to-side body sway almost prevents people from walking shoulder to shoulder. The combination of the recent evidence and documentation has led to the change to the more linear, small increment method.

The capacity figures found in Table 7.3.3.1 are simply derived from previously used combinations of egress component width and capacity, such as 75 persons per 22-in. unit of exit width for stairs (22 divided by 75 is 0.293, which, when rounded to the closest single digit, is 0.3). Similarly, for level and ramped components, the derivation is simply 22 divided by 100, which is rounded to 0.2.

The differences in the width figures specified in Table 7.3.3.1 arise from the following factors. Stairs entail a totally different type of movement, by both individuals and crowds, than do level and ramped components. There are differences in biomechanics as well as in the difficulty of seeing (or otherwise detecting) the next stepping surface in order to avoid misstepping and suffering a fall and resulting injury. The approximate ratio of 3 to 2, relating the required widths for vertical travel on stairs and level travel on floors, is based on previous ratios and on empirical observations.

The greater range of width requirements for different occupancies reflects the following two factors:

- (1) The need for a much more rapid egress time in the case of high-hazard occupancies
- (2) The slower movement and greater need for assistance from others during evacuations in health care and related institutional and semi-institutional occupancies

In summary, given the designer's knowledge of the occupancy, the occupant load of the floor level, and the type of egress component, the required minimum width for each component can be determined by simple multiplication (that is, multiply the occupant load by the appropriate width-per-person factor found in Table 7.3.3.1 to obtain the minimum width of the component under consideration). If the width of the component under consideration is known, divide that width by the appropriate width-per-person factor to obtain the number of persons the component can accommodate over the entire evacuation. These calculated minimum widths are then considered along with other *Code* requirements, including minimum widths based on other factors, to design a system in which performance will be closely matched from one part of the system to another.

7.3.3.2 The required capacity of a corridor shall be the occupant load that utilizes the corridor for exit access divided by the required number of exits to which the corridor connects, but the corridor capacity shall be not less than the required capacity of the exit to which the corridor leads.

For example, in Exhibit 7.70, a corridor system serves a floor with a 660-person occupant load and three means of egress. The corridor must be wide enough to accommodate the portion of the floor's occupant

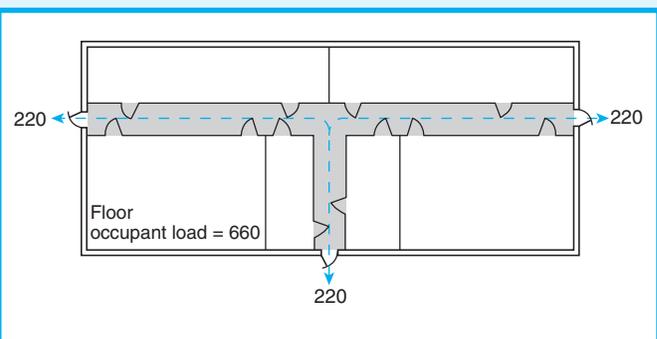

Exhibit 7.70 Corridor capacity.

load that it serves. Typical design practice is to divide the floor occupant load by the number of means of egress provided. In this three-exit example, no portion of the corridor needs capacity for more than one-third of the floor's occupant load, which by calculation ($660 \div 3$) is 220 persons. The required corridor width would be determined to be 1120 mm (44 in.) wide [220 persons \times 5 mm (0.2 in.) per person]. Some occupancies, such as health care occupancies, require wider minimum corridor widths than the 1120-mm (44-in.) width calculated.

The *Code* states that the corridor required capacity cannot be less than the required capacity of the exit to which it leads. In other words, the corridor cannot create a bottleneck that is too narrow and impedes the flow of occupants to the exit door.

7.3.4 Minimum Width.

7.3.4.1 The width of any means of egress, unless otherwise provided in 7.3.4.1.1 through 7.3.4.1.3, shall be as follows:

- (1) Not less than that required for a given egress component in this chapter or Chapter 12 through Chapter 42
- (2) Not less than 915 mm (36 in.)

7.3.4.1.1* The width of exit access that is formed by furniture and movable partitions, that serves not more than six people, and that has a length not exceeding 15 m (50 ft) shall meet both of the following criteria:

- (1) The width shall be not less than 455 mm (18 in.) at and below a height of 965 mm (38 in.), and not less than 710 mm (28 in.) above a height of 965 mm (38 in.).
- (2) A width of not less than 915 mm (36 in.) for new exit access, and not less than 710 mm (28 in.) for existing exit access, shall be capable of being provided without moving permanent walls.

A.7.3.4.1.1 The criteria of 7.3.4.1.1 provide for minimum widths for small spaces such as individual offices. The intent is that these reductions in required width apply to spaces formed by furniture and movable walls so that accommodations can easily be made for mobility-impaired individuals. One side of a path could be a fixed wall, provided that the other side is movable. This does not exempt the door widths or widths of fixed-wall corridors, regardless of the number of people or length.

Figure A.7.3.4.1.1(a) and Figure A.7.3.4.1.1(b) present selected anthropometric data for adults. The male and female figures depicted in the figure are average, 50th percentile, in size. Some dimensions apply to very large, 97.5 percentile, adults (noted as 97.5 P).

Paragraph 7.3.4.1.1 and the associated annex material explain the intent behind permitting spaces, such as individual offices or work stations, an exemption from the 915-mm (36-in.) minimum width requirement of 7.3.4.1(2) for new construction. If any one path (for example, a "mini-aisle") requires a maximum of 6 people to travel no more than 15 m (50 ft) to reach a minimum 915-mm- (36-in.-) wide egress path (for example, a major aisle), the path is permitted to be as narrow as 710 mm (28 in.). The width of the path is permitted to be reduced further to 455 mm (18 in.) near the floor but not at points more than 965 mm (38 in.) above the floor, as might be characteristic of a small bookcase.

Other paths within the same room are permitted the same reduction in required width, provided that each individually meets the 6-person and 15-m (50-ft) criteria for travel to a minimum 915-mm-(36-in.-) wide egress path. This is illustrated in Exhibit 7.71. The minimum 710-mm

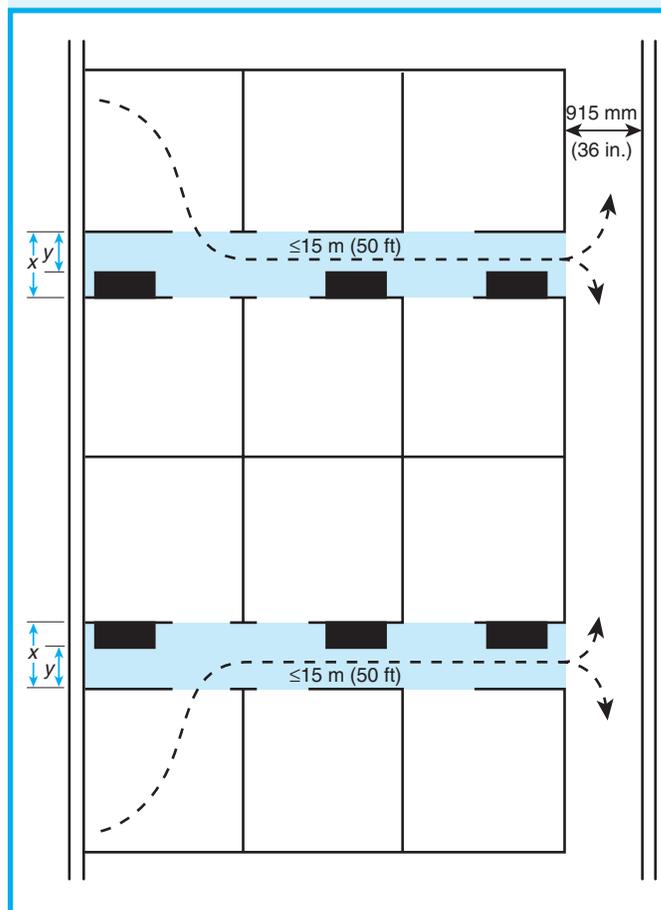

Exhibit 7.71 Minimum exit access width created by movable furniture and partitions.

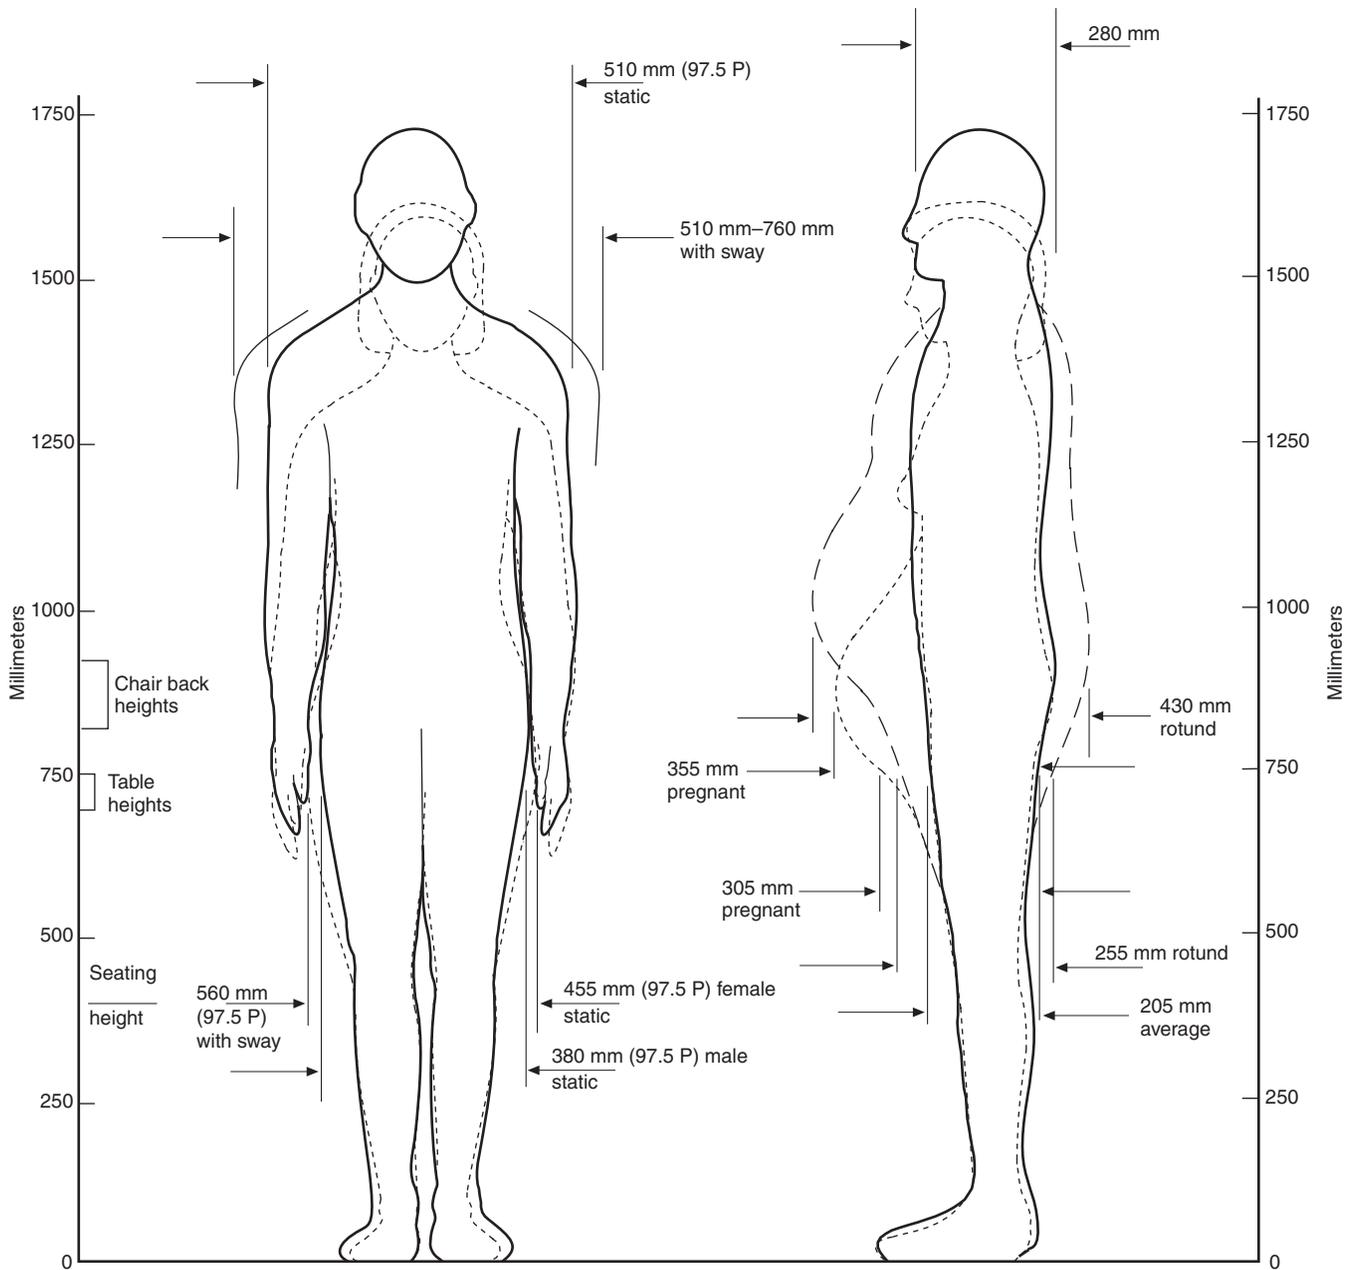

Figure A.7.3.4.1(a) Anthropometric Data (in mm) for Adults; Male and Female Figures of Average, 50th Percentile, Size, Some Dimensions Apply to Very Large, 97.5 Percentile (97.5 P), Adults.

(28-in.) width (shown as dimension *x*) allowed by 7.3.4.1.1(1) is a relaxation of the 915-mm (36-in.) minimum required by 7.3.4.1(2). This width can be further reduced to 455 mm (18 in.) (shown as dimension *y*) at floor level up to a height of 965 mm (38 in.) above the floor. Both width reduction options are condi-

tional on a maximum of 6 people traveling no more than 15 m (50 ft) along a resultant miniaisle to reach a minimum 915-mm (36-in.) wide exit access component such as an aisle.

Use of 7.2.4.1.1 is not limited to business occupancies. The same provisions could be applied to factory

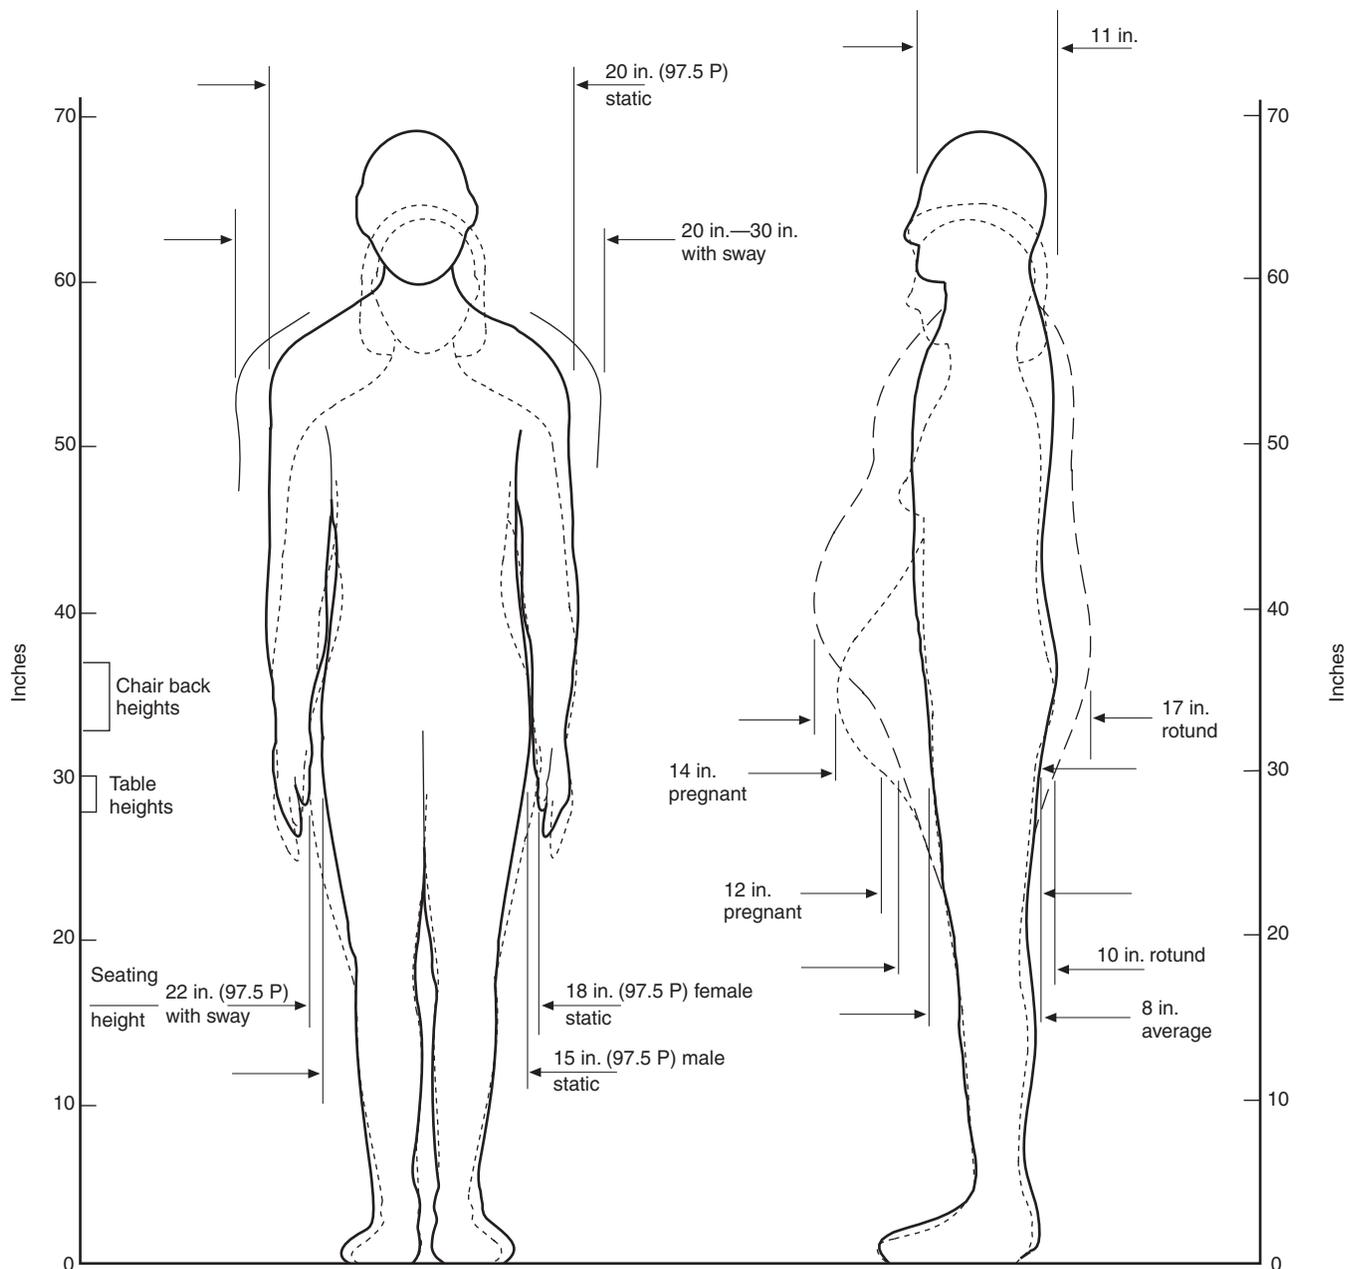

Figure A.7.3.4.1(b) Anthropometric Data (in in.) for Adults; Male and Female Figures of Average, 50th Percentile, Size, Some Dimensions Apply to Very Large, 97.5 Percentile (97.5 P), Adults.

work stations in an industrial occupancy or to library study carrels in an assembly occupancy.

7.3.4.1.2 In existing buildings, the width of exit access shall be permitted to be not less than 710 mm (28 in.).

7.3.4.1.3 The requirement of 7.3.4.1 shall not apply to the following:

- (1) Doors as otherwise provided for in 7.2.1.2
- (2) Aisles and aisle accessways in assembly occupancies as otherwise provided in Chapter 12 and Chapter 13
- (3) Industrial equipment access as otherwise provided in 40.2.5.2

The minimum width required in any egress path is dependent on the occupancy and is thus specified in Chapters 12 through 42 for individual occupancies. The widths are based on experience and on observations of the manner in which people move along paths used for egress purposes. The minimum width permitted for any new egress component other than a door is 915 mm (36 in.), but most occupancies require additional width. Educational occupancies require a corridor width of not less than 1830 mm (72 in.). Health care occupancies require a corridor width of not less than 2440 mm (96 in.), which reflects the need to move bedridden patients and multiple lines of people along the path to an exit. Hotels, apartment buildings, and business occupancies generally require 1120-mm (44-in.) minimum width corridors. Some occupancies rely wholly on the provisions of 7.3.4.1.

7.3.4.2 Where a single exit access leads to an exit, its capacity in terms of width shall be not less than the required capacity of the exit to which it leads.

7.3.4.3 Where more than one exit access leads to an exit, each shall have a width adequate for the number of persons it accommodates.

The intent of 7.3.4.2 and 7.3.4.3 are to balance the flow of persons from the exit access to the exit to avoid a bottleneck and to ensure that the occupants being served by the exit can, in fact, reach it.

Section 7.4 Number of Means of Egress

7.4.1 General.

7.4.1.1 The number of means of egress from any balcony, mezzanine, story, or portion thereof shall be not less than two, except under one of the following conditions:

- (1) Where a single means of egress is permitted in Chapter 11 through Chapter 42.
- (2) Where a single means of egress is permitted for a mezzanine or balcony and the common path of travel limitations of Chapter 12 through Chapter 42 are met

Most of the occupancy chapters provide redundancy with respect to the number of means of egress by requiring at least two means of egress. Some occupancies identify specific arrangements under which only a single means of egress is needed. Where large

numbers of occupants are to be present, more than two means of egress must be provided as required by 7.4.1.2.

Mezzanines are required to have the same number of means of egress as any story of the building, unless an occupant can reach either the single exit or the bottom of a single open stair within the allowable common path of travel permitted for the applicable occupancy.

Exhibit 7.72 illustrates the mezzanine provisions of 7.4.1.1 and 7.4.1.1(2), which are not intended to override the provisions for openness of mezzanines imposed by 8.6.9.3. In Exhibit 7.72, the top figure (a) illustrates the requirement for a minimum of two means of egress, per 7.4.1.1. One means of egress is an open stair to the floor below, and the other is an enclosed exit stair. Both could be open stairs to the floor below unless the openness requirements of 8.6.9.3 are not met. If the mezzanine were enclosed, such that more than 10 persons were in the enclosed area, 8.6.9.3 would require a second means of egress [similar to the enclosed exit stair in exhibit (a)] that provides direct access from the enclosed area to an

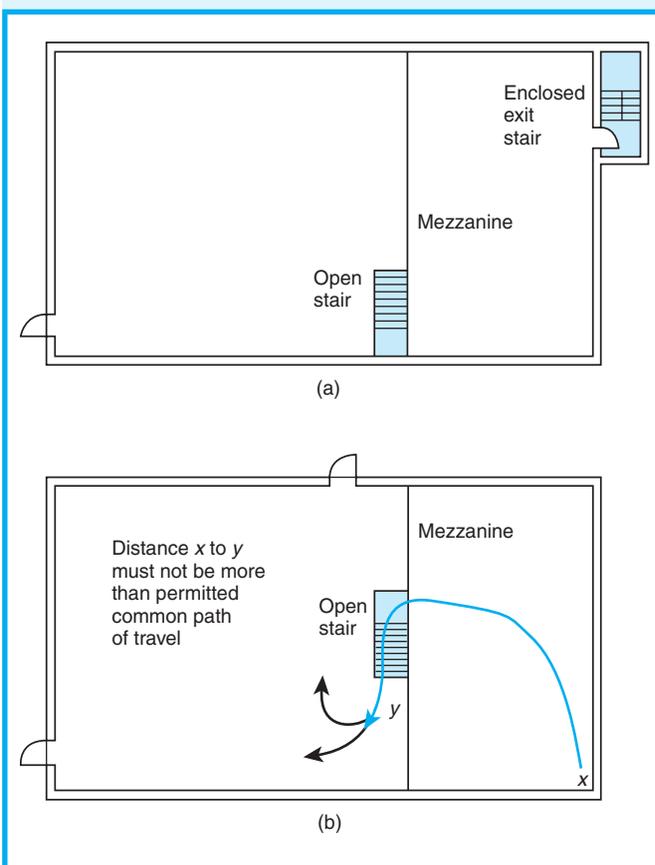

Exhibit 7.72 Egress from mezzanines.

exit at the mezzanine level. In the bottom exhibit (b), a single means of egress is permitted, in accordance with 7.4.1.1(2), because the common path of travel is within the limits specified for the occupancy involved.

See also Section 7.5 with respect to remoteness of exits and common paths of travel; 7.6.4 with respect to measuring travel distance in the plane of the tread nosings on open stairs; and 8.6.9 on mezzanines.

7.4.1.2 The number of means of egress from any story or portion thereof, other than for existing buildings as permitted in Chapter 12 through Chapter 42, shall be as follows:

- (1) Occupant load more than 500 but not more than 1000—not less than 3
- (2) Occupant load more than 1000—not less than 4

Chapter 7 requires a minimum number of means of egress unless otherwise specified by the occupancy chapters. Several occupancies establish not only the minimum number of means of egress but also the minimum number of actual exits that must be provided on each floor. For example, for new educational occupancies, 14.2.4 requires access to two exits and further requires that both of the exits be provided on the floor. In contrast, for industrial occupancies, 40.2.4.1.1 requires access to two exits and further requires that at least one of the exits is to be located on the floor. Access to the other exit can involve traveling to another floor via an egress component such as an open stair.

In most occupancies, meeting the requirements for egress capacities and travel distances means the required minimum number of means of egress will automatically be met. However, in occupancies characterized by high occupant loads, such as assembly and mercantile occupancies, compliance with requirements for more than two exits might require specific attention.

7.4.1.3 Accessible means of egress in accordance with 7.5.4 that do not utilize elevators shall be permitted to serve as any or all of the required minimum number of means of egress.

Because an accessible means of egress can effectively serve the needs of persons with mobility impairments, the same accessible means of egress should effectively serve the needs of persons without disabilities. Therefore, the Code permits accessible means of egress to fulfill any requirements for means of

egress. However, this permission does not apply to elevators because of the small number of occupants accommodated during each run of the elevator and concerns that the elevator might be automatically called out of service upon the detection of smoke in an elevator lobby on any floor served by the elevator.

7.4.1.4 The occupant load of each story considered individually shall be required to be used in computing the number of means of egress at each story, provided that the required number of means of egress is not decreased in the direction of egress travel.

Similar to the procedures for determining required egress capacity (see 7.3.1.4), the number of required means of egress is based on a floor-by-floor consideration, rather than the accumulation of the occupant loads of all floors. For example, see Exhibit 7.73, where the fourth floor of the building has an occupant load of 600 persons and would require three means of egress. The third floor of the same building has an occupant load of 400 persons and would require two means of egress; regardless of the fact that the two floors together have an occupant load in excess of 1000 persons, four means of egress are not required. However, the number of means of egress cannot decrease as an occupant proceeds along the egress path. The three exits required from the fourth floor in this example cannot be merged into two exits on the third floor, even though the third floor requires only two

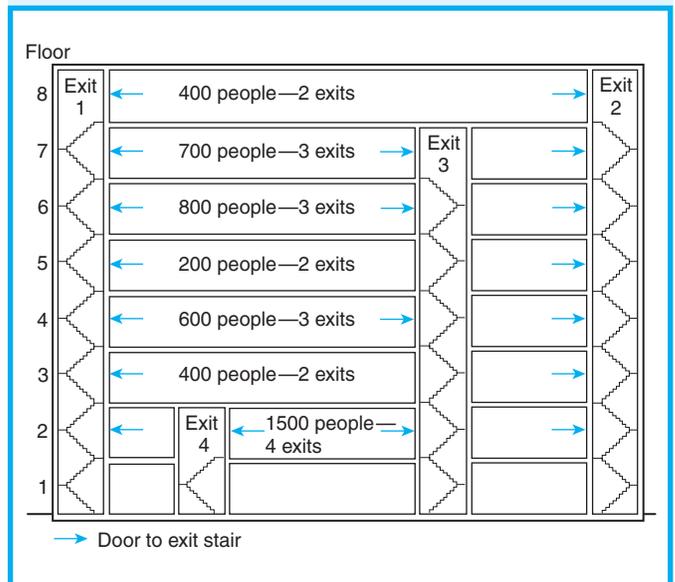

Exhibit 7.73 Minimum number of required means of egress.

exits. On any floor requiring only two exits, one of the three exits could be left inaccessible (blind) on that floor as shown at exit 3 in Exhibit 7.73 on the third and fifth floors. The second floor, with an occupant load of 1500 persons, requires a fourth means of egress.

7.4.1.5 Doors other than the hoistway door; the elevator car door; and doors that are readily openable from the car side without a key, a tool, special knowledge, or special effort shall be prohibited at the point of access to an elevator car.

Paragraph 7.4.1.5 prohibits the installation of a door at the entrance to an elevator unless that door is readily operable by those in the elevator. This prohibition prevents entrapment between the elevator and the door. The primary concern is the potential for an occupant to enter this small space and become trapped during a fire.

7.4.1.6 Elevator lobbies shall have access to at least one exit. Such exit access shall not require the use of a key, a tool, special knowledge, or special effort.

The purpose of 7.4.1.6 is to ensure that an occupant who has gained access to an elevator lobby can get out of the lobby without the use of a tool or key. It is not uncommon, especially in office buildings where a tenant occupies an entire floor, for the elevator lobby to be locked after normal business hours to prevent entry into the tenant space. This problem is illustrated in Exhibit 7.74. Because the doors between the elevator lobby and the tenant spaces can be locked, access to an exit is not assured to a person who arrives at the floor via elevator. At least one exit must be accessible from the elevator lobby. The situation can be corrected by repositioning one of the exit stair enclosures so that it is in the elevator lobby.

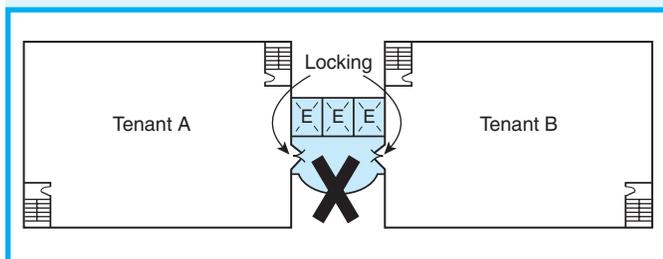

Exhibit 7.74 Exit access from an elevator lobby.

Section 7.5 Arrangement of Means of Egress

7.5.1 General.

7.5.1.1 Exits shall be located and exit access shall be arranged so that exits are readily accessible at all times.

7.5.1.1.1* Where exits are not immediately accessible from an open floor area, continuous passageways, aisles, or corridors leading directly to every exit shall be maintained and shall be arranged to provide access for each occupant to not less than two exits by separate ways of travel, unless otherwise provided in 7.5.1.1.3 and 7.5.1.1.4.

A.7.5.1.1.1 See A.7.5.1.5.

7.5.1.1.2 Exit access corridors shall provide access to not less than two approved exits, unless otherwise provided in 7.5.1.1.3 and 7.5.1.1.4.

7.5.1.1.3 The requirements of 7.5.1.1.1 and 7.5.1.1.2 shall not apply where a single exit is permitted in Chapter 12 through Chapter 42.

7.5.1.1.4 Where common paths of travel are permitted for an occupancy in Chapter 12 through Chapter 42, such common paths of travel shall be permitted but shall not exceed the limit specified.

Paragraphs 7.5.1.1.1 and 7.5.1.1.2 reinforce the desirability of always being able to move in different directions from any location so as to permit different paths of travel to different exits. However, typical floor layouts and furnishing arrangements often create spaces where travel in a single direction is necessary for a limited distance before it becomes possible to travel in different directions.

Paragraph 7.5.1.1.3 recognizes that a single exit creates a condition under which travel is possible in only one direction. The conditions under which an occupancy chapter permits a single exit usually produce a situation that is as safe as, or safer than, a building that is provided with two exits but includes substantial common path of travel before access to both exits is possible.

Paragraph 7.5.1.1.4 recognizes common paths of travel within the limits set by the individual occupancy chapters. For additional information on common paths of travel, see A.7.5.1.5.

7.5.1.2 Corridors shall provide exit access without passing through any intervening rooms other than corridors, lobbies, and other spaces permitted to be open to the corridor, unless otherwise provided in 7.5.1.2.1 and 7.5.1.2.2.

7.5.1.2.1 Approved existing corridors that require passage through a room to access an exit shall be permitted to continue to be used, provided that the following criteria are met:

- (1) The path of travel is marked in accordance with Section 7.10.
- (2) Doors to such rooms comply with 7.2.1.
- (3) Such arrangement is not prohibited by the applicable occupancy chapter.

The requirement of 7.5.1.2 that corridors provide access to at least two exits without passing through intervening rooms (other than corridors) was new to the 1997 edition of the *Code*, though a similar requirement had been in effect for health care occupancies for many years.

The exit access arrangement illustrated in Exhibit 7.75 is deficient. Occupants reaching the corridor have access only to exit B without leaving the protection afforded by the corridor. Paragraph 7.5.1.2 requires access to both exit A and exit B without leaving the corridor and traveling within another use area. One possible solution to this problem would be to extend the corridor walls to the far left of the floor so as to connect directly with exit stair enclosure A.

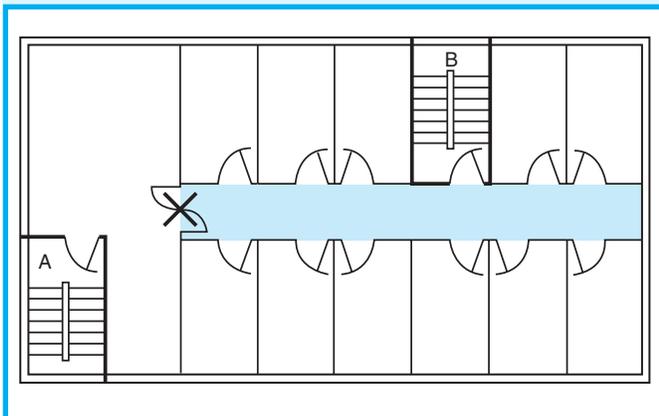

Exhibit 7.75 Deficient corridor exit access.

Paragraph 7.5.1.2.1 recognizes the continued use of existing corridors that force occupants to travel through a room to access an exit. If the exemption were not permitted, existing arrangements that were in compliance with earlier editions of the *Code* might suddenly be considered noncompliant.

7.5.1.2.2 Corridors that are not required to be fire resistance rated shall be permitted to discharge into open floor plan areas.

7.5.1.3 Remoteness shall be provided in accordance with 7.5.1.3.1 through 7.5.1.3.7.

7.5.1.3.1 Where more than one exit is required from a building or portion thereof, such exits shall be remotely located from each other and shall be arranged and constructed to minimize the possibility that more than one has the potential to be blocked by any one fire or other emergency condition.

It is a precept of life safety in buildings, repeated many times in the *Code*, that if multiple exits are required, they should be not only separate but also remote from one another. While the objective of this requirement is clear (if one exit is blocked by smoke or fire, the other needs to be maintained available), the term *remote* cannot always be sharply defined.

Where exits are located at each end of a long corridor or at each end or side of a building, they qualify as remotely located exits. However, core-type buildings with elevators, service shafts, and stairs in one central or side core introduce some challenging problems with respect to exit remoteness. Exhibit 7.76 shows two core-type buildings that illustrate this problem.

Exhibit 7.76 (top view) shows the plan of the Rault Center Building in New Orleans where five women were trapped by fire on the 15th floor. Travel to both exit stairs was blocked by fire, and the women eventually jumped to the roof of an adjacent eight-story building. Four of the five died¹⁶.

Exhibit 7.76 (bottom view) shows the plan of the twentieth floor of a New York City office building. An incendiary device was set off somewhere near the lobby reception area. One of 15 people on the floor at the time made it to the stair exit, but the other 14 were trapped and rescued by fire fighters. One of the 14 died¹⁷.

With more attention given to life safety during the design stage, a much better solution might have been devised for these buildings. In the upper plan view of Exhibit 7.77, the exit stairs are not as remote from each other as practicable. They are both located on the same end of the core, a detriment when tenants, current and future, lay out their own partition arrangements to suit their needs. By removing the elevator lobby from the core, as shown in the lower plan of Exhibit 7.77, and adding a corridor around three sides of the core, the designer can ensure that tenants will have access to two remote exits. This solution also assists in providing two ways out of each tenant space. The exhibits illustrate how, with thought, imagination, and little, if any, added expense, a poor design can be greatly improved.

Also see the commentary following 7.5.1.3.7.

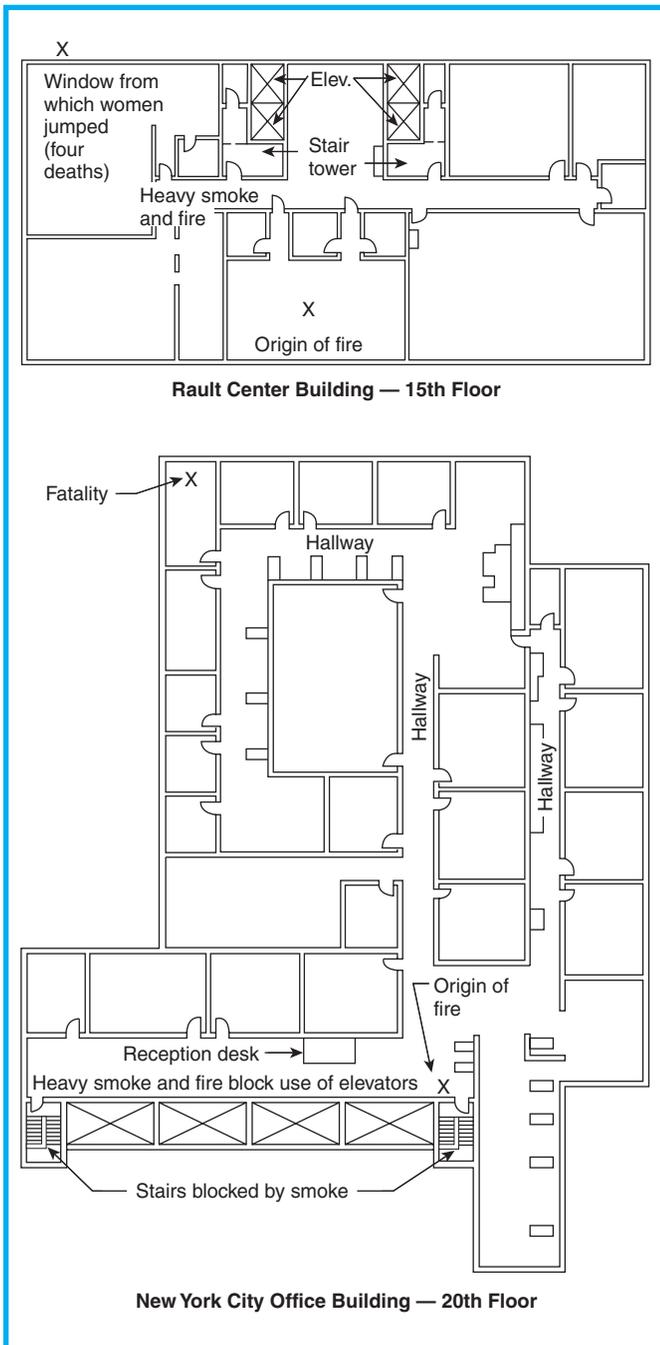

Exhibit 7.76 Plan views of upper floors of two core-type high-rise buildings where fires occurred.

7.5.1.3.2* Where two exits or exit access doors are required, they shall be located at a distance from one another not less than one-half the length of the maximum overall diagonal dimension of the building or area to be served, measured in a straight line between the nearest edge of the exit doors or exit access doors, unless otherwise provided in 7.5.1.3.3 through 7.5.1.3.5.

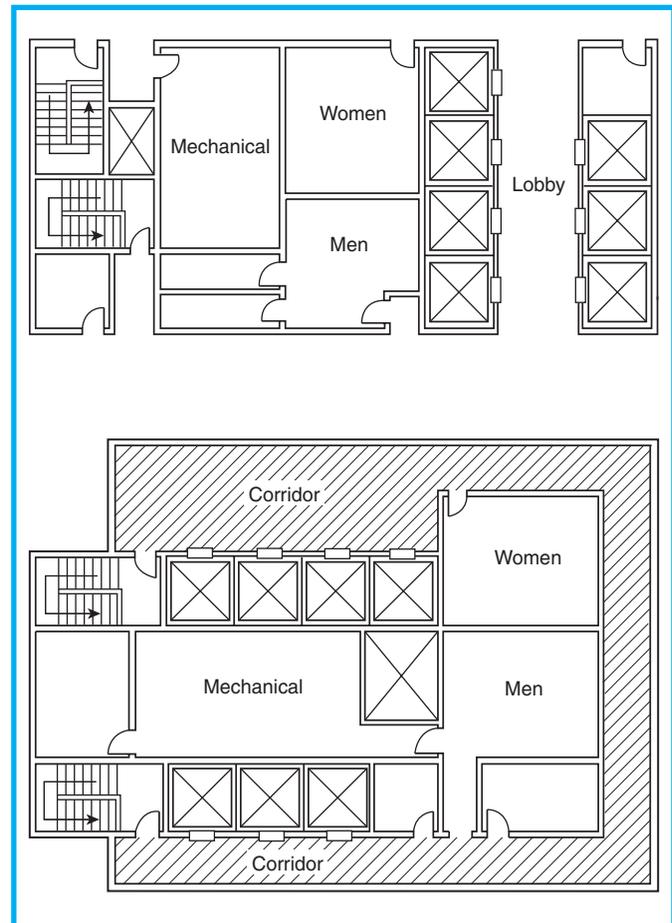

Exhibit 7.77 Access to exits in core-type multitenant buildings.

A.7.5.1.3.2 Figure A.7.5.1.3.2(a) through Figure A.7.5.1.3.2(e) illustrate the method of measurement intended by 7.5.1.3.2.

7.5.1.3.3 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, the minimum separation distance between two exits or exit access doors measured in accordance with 7.5.1.3.2 shall be not less than one-third the length of the maximum overall diagonal dimension of the building or area to be served.

7.5.1.3.4 Where exit enclosures are provided as the required exits specified in 7.5.1.3.2 and are interconnected by not less than a 1-hour fire resistance-rated corridor, exit separation shall be permitted to be measured along the line of travel within the corridor.

7.5.1.3.5 In existing buildings, where more than one exit or exit access door is required, such exits or exit access doors shall be permitted to be remotely located in accordance with 7.5.1.3.1.

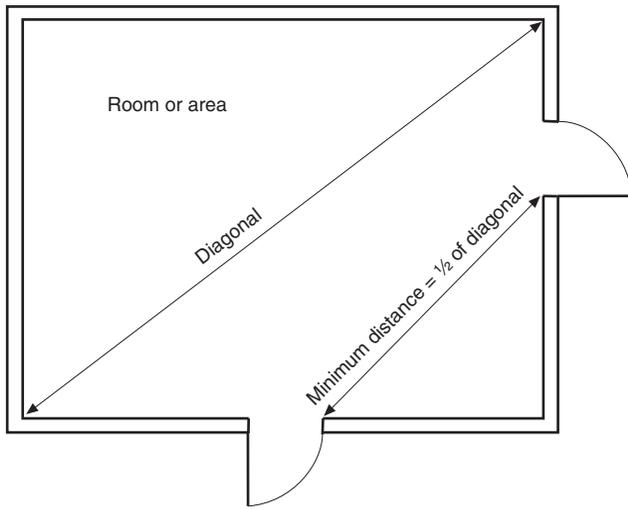

Figure A.7.5.1.3.2(a) Diagonal Rule for Exit Remoteness.

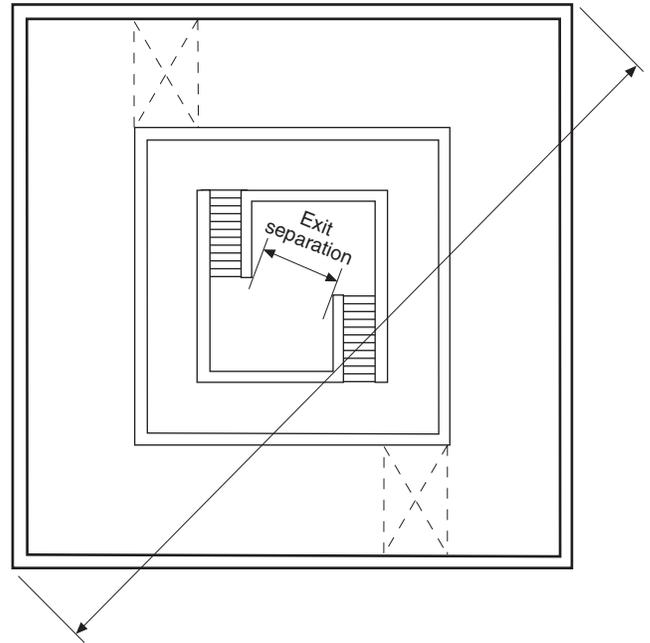

Figure A.7.5.1.3.2(c) Exit Separation and Diagonal Measurement of Area Served.

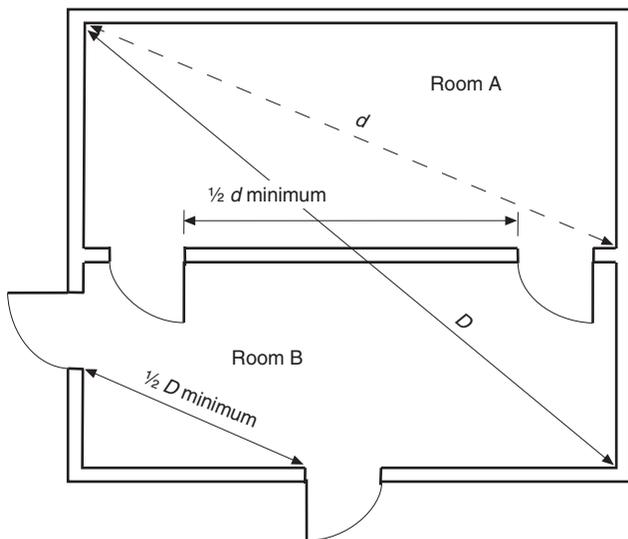

Figure A.7.5.1.3.2(b) Diagonal Rule for Exit and Exit Access Remoteness.

7.5.1.3.6 Where more than two exits or exit access doors are required, at least two of the required exits or exit access doors shall be arranged to comply with the minimum separation distance requirement.

7.5.1.3.7 The balance of the exits or exit access doors specified in 7.5.1.3.6 shall be located so that, if one becomes blocked, the others shall be available.

Since 1988, the Code has contained a remoteness formula referred to as the *one-half diagonal rule*. This

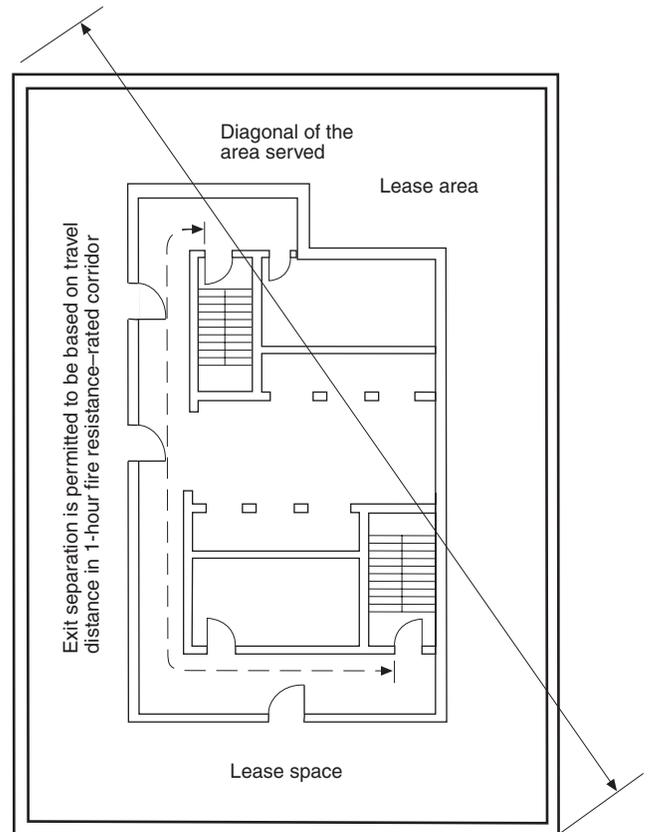

FIGURE A.7.5.1.3.2(d) Exit Separation Measured Along Corridor Path.

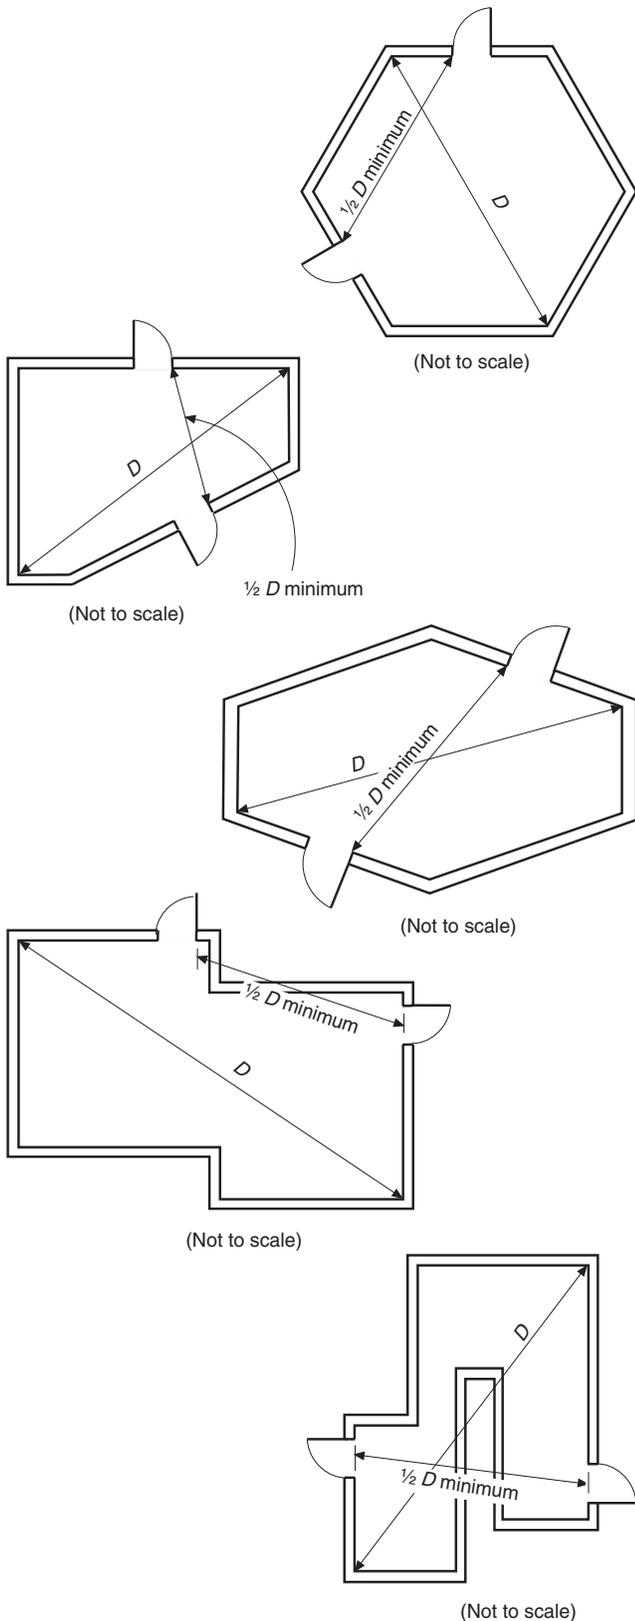

Figure A.7.5.1.3.2(e) Diagonal Measurement for Unusually Shaped Areas.

basic rule is stated in 7.5.1.3.2. Figures A.7.5.1.3.2(a) through A.7.5.1.3.2(e) detail the application of the rule. The *Code* uses the one-half diagonal rule to quantify remoteness and to make certain that exits are sufficiently remote to ensure, with reasonable certainty, that multiple exits will not be obstructed by the same fire. The exit separation is permitted by 7.5.1.3.3 to be reduced to one-third of the maximum overall diagonal measurement in fully sprinklered buildings, because the sprinkler system is expected to control the fire so that the use of multiple exits will not be lost.

Although existing buildings are exempt from the diagonal rule, 7.5.1.3.5 requires that they meet the remoteness requirement via the performance requirement of 7.5.1.3.1.

Exhibit 7.78 illustrates the provision of 7.5.1.3.4, which permits the distance between exit enclosures to be measured along a minimum 1-hour fire resistance-rated corridor with appropriate fire protection-rated doors. Although the exit enclosures are physically closer to each other than the dimension measured along the corridor, the exits will behave, under fire conditions, as if they were a corridor length apart.

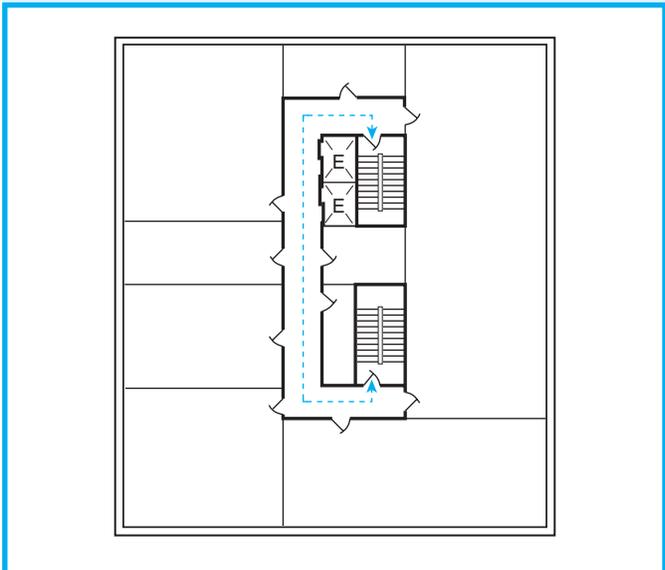

Exhibit 7.78 Exit remoteness measured along 1-hour-rated corridor.

7.5.1.4 Interlocking or scissor stairs shall comply with the 7.5.1.4.1 and 7.5.1.4.2.

7.5.1.4.1 New interlocking or scissor stairs shall be permitted to be considered only as a single exit.

7.5.1.4.2* Existing interlocking or scissor stairs shall be permitted to be considered separate exits if they meet the following criteria:

- (1) They are enclosed in accordance with 7.1.3.2.
- (2) They are separated from each other by 2-hour fire resistance-rated noncombustible construction.
- (3) No protected or unprotected penetrations or communicating openings exist between the stair enclosures.

A.7.5.1.4.2 It is difficult in actual practice to construct scissor stairs so that products of combustion that have entered one stairway do not penetrate into the other. Use as separate required exits is discouraged. The term *limited-combustible* is intentionally not included in 7.5.1.4.2. The user's attention is directed to the definitions of *limited-combustible* and *non-combustible* in 3.3.135.2 and 3.3.135.3, respectively.

New scissor stairs are restricted by 7.5.1.4.1 to serving only as a single exit. For existing installations, scissor stairs are regulated by 7.5.1.4.2 to ensure that they will perform similarly to two more widely separated exit stairs under fire conditions. Some design professionals believe scissor stairs are hazardous and should not be permitted; others believe just the opposite. Generally, the principal objection is that scissor stairs cannot be reliably built to create an absolute barrier to the passage of smoke and toxic gases between the stairs. Even if such a barrier is created, there is still concern that settling of the building or exposure to fire conditions might result in the cracking of the separating wall, which could permit smoke and gases to pass from one exit stair into the other. On the other hand, those who do not believe that scissor stairs present such problems point to their advantages in reducing construction costs and saving space.

Paragraph 7.5.1.4.2(2) requires existing scissor stairs to have separating construction that is noncombustible and 2-hour fire resistance-rated. Some form of masonry or poured concrete wall is normally used to meet the definition of *noncombustible* (see 3.3.135.3). Although scissor stairs can be located with their entrances remote from one another and their discharges also remotely placed, the remoteness requirements are applicable to scissor stairs only if they are to be considered as separate exits. Where not sufficiently separated or not remote from each other—or in new construction—scissor stairs cannot be used as separate exits but can be considered as a single exit, with their combined egress width providing increased capacity over that of a single stair. These points are illustrated in Exhibit 7.79 and Exhibit 7.80.

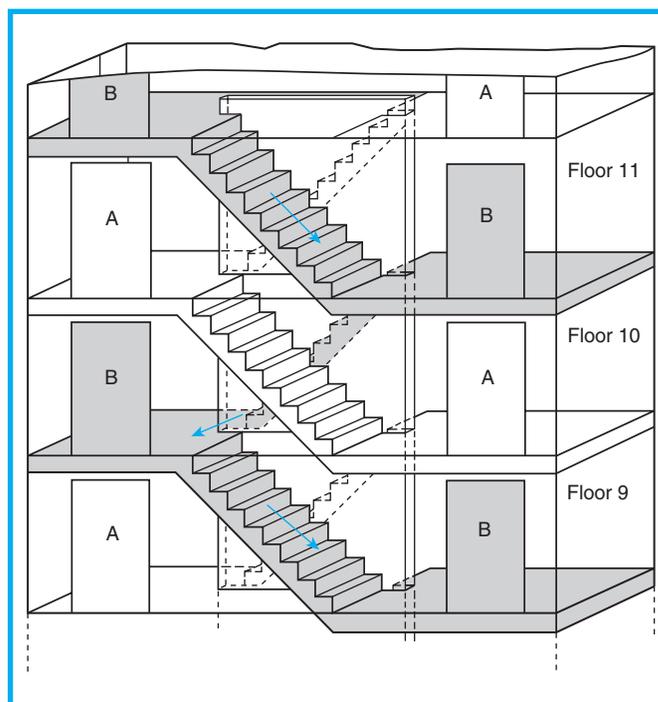

Exhibit 7.79 Scissor stairs.

In Exhibit 7.79, the two existing entwined stairways sharing the same enclosing walls are called scissor stairs. To be considered separate exits, the existing stairs must be completely separated from each other. In effect, each stair's enclosure must consist of a fire resistance-rated tube entwined around the other stair in a form similar to a helix. This arrangement results in space and cost savings by permitting the stairs to share the common enclosing walls that separate them from the remainder of the building. With this arrangement, two independent escape paths are created, similar to those provided by two independent stair enclosures positioned at a distance from each other. The continuity of all walls provides a complete separation at all points. The arrows designate the direction of egress travel in stair B.

Exhibit 7.80 illustrates some of the advantages of scissor stairs versus conventional exit stairs. The two stairs, positioned at the center of the figure and highlighted by placement within the oval, are entwined to create a set of scissor stairs. They provide the same degree of remoteness as the separate and independent stairs shown by the dashed lines at the sides of the figure and encircled. Travel distance to either the scissor stairs or the independent stairs is equal, even if the independent exit stairs were located at the opposite corners (X).

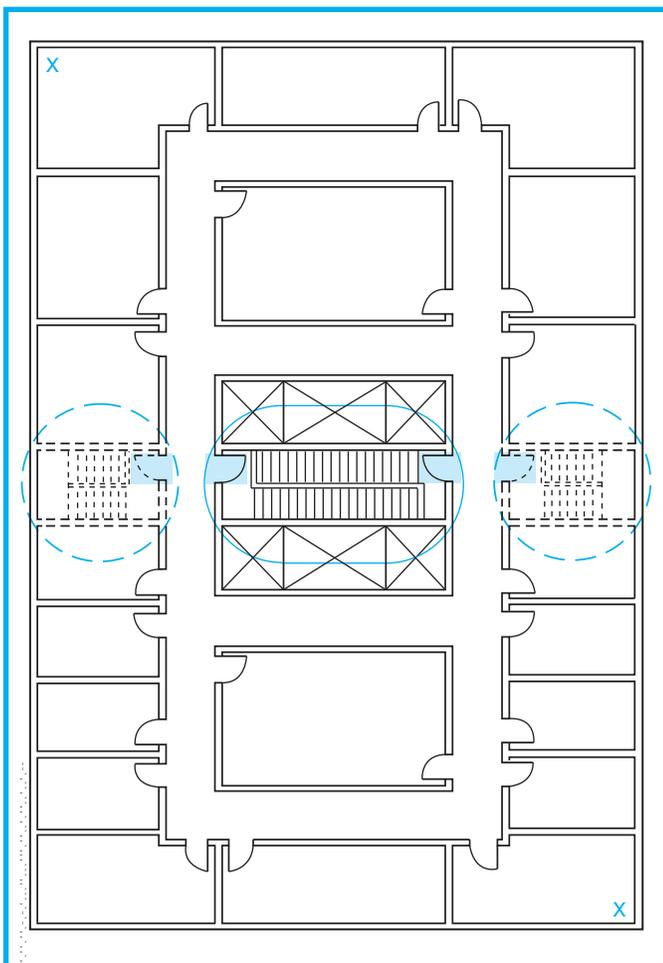

Exhibit 7.80 Scissors stairs contrasted with conventional exit stairs.

7.5.1.5* Exit access shall be arranged so that there are no dead ends in corridors, unless permitted by, and limited to the lengths specified in, Chapter 12 through Chapter 42.

A dead end exists in a corridor where the corridor continues past an exit and creates a pocket into which an occupant might travel. The occupant then recognizes there is no exit at that end of the pocket and is forced into retracing the original path to reach the exit. Although relatively short dead-end corridors are permitted for most occupancies by the chapter applicable to that occupancy, it is a better practice to avoid them; dead ends increase the danger of people becoming trapped during a fire. Note that compliance with the limits on dead-end corridors does not necessarily mean that the requirements for remoteness of exits are met. Requirements for remoteness are

especially difficult to meet in small buildings or buildings with short public hallways.

Exhibit 7.81 illustrates examples of two common types of dead-end corridors. In moving toward exits, occupants from building spaces other than the rooms served by the dead-end portion of the corridor could mistakenly travel into the dead end. Similarly, any occupant of the floor might mistakenly travel into the dead end created by the elevator lobby. Neither of the dead-end pockets leads to an exit.

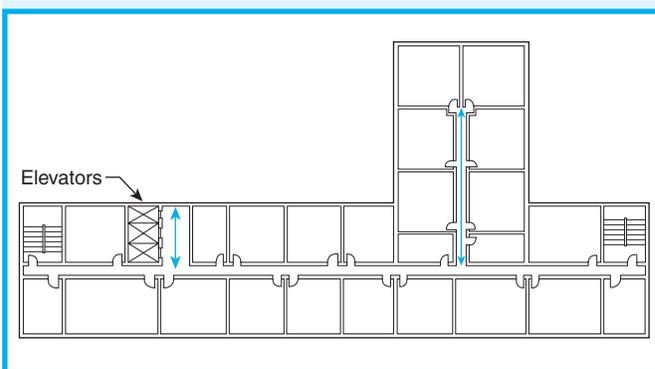

Exhibit 7.81 Examples of common types of dead-end corridors.

For persons occupying the two rooms located at the very end of the dead-end corridor section, the travel from those rooms through this portion of the corridor system involves the concept of common path of travel, not dead-end corridors. Because the concepts of dead-end corridors and common path of travel are often confused, dead ends have been blamed for fire deaths more correctly attributable to common path of travel problems. For example, the report on a 1977 Rhode Island dormitory fire in which 10 people died reads:

Dead-end corridors approximately 61 feet long existed at each end of the dormitory. These dead-ends were allowed by the Rhode Island building code in effect at the time when the building renovations were made in 1972. . . . A factor contributing to four of the . . . deaths and several of the injuries was the long, dead-end corridor. Residents who left their rooms in this dead end were . . . [kept from reaching] their only exit¹⁸.

For the occupants of the other five rooms with doors opening into the dead-end corridor section in Exhibit 7.81, the concepts of both dead-end corridors and common path of travel are applicable. Although

occupants must travel in one direction to reach an exit, they also might mistakenly turn the wrong way when leaving their rooms and travel into the remainder of the dead-end pocket, only to have to retrace their steps to reach an exit.

A.7.5.1.5 The terms *dead end* and *common path of travel* are commonly used interchangeably. Although the concepts of each are similar in practice, they are two different concepts.

A common path of travel exists where a space is arranged so that occupants within that space are able to travel in only one direction to reach any of the exits or to reach the point at which the occupants have the choice of two paths of travel to remote exits. Part (a) of Figure A.7.5.1.5 is an example of a common path of travel.

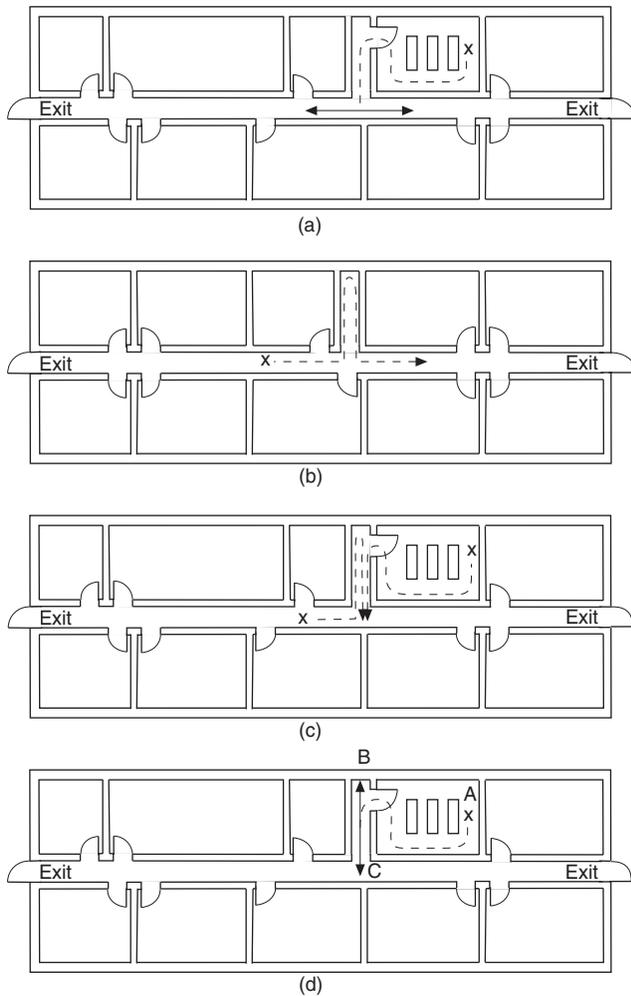

Figure A.7.5.1.5 Common Paths of Travel and Dead-End Corridors.

While a dead end is similar to a common path of travel, a dead end can exist where there is no path of travel from an occupied space but can also exist where an occupant enters a corridor thinking there is an exit at the end and, finding none, is forced to retrace his or her path to reach a choice of exits. Part (b) of Figure A.7.5.1.5 is an example of such a dead-end arrangement.

Combining the two concepts, part (c) of Figure A.7.5.1.5 is an example of a combined dead-end/common path of travel problem.

Common paths of travel and dead-end travel are measured using the same principles used to measure travel distance as described in Section 7.6 of the *Code*. Starting in the room shown in part (d) of Figure A.7.5.1.5, measurement is made from the most remote point in the room, A, along the natural path of travel, and through the doorway along the centerline of the corridor to point C, located at the centerline of the corridor, which then provides the choice of two different paths to remote exits; this is common path of travel. The space between point B and point C is a dead end. (See 3.3.34 for the definition of common path of travel.)

Common paths of travel are explained in A.7.5.1.5. The portion of the exit access travel to which an occupant is steered in one direction only without the option of traveling in another independent direction toward an exit is common path of travel (see definition in 3.3.34). Exhibit 7.82 shows examples of common paths of travel (illustrated by the dashed lines). In each case illustrated, an occupant is steered in only one direction before reaching a point at which travel in independent directions becomes possible. Common path of travel might exist only within rooms and occupied spaces, or it might exist within the combination of room space and corridors.

Exhibit 7.83 depicts the Rault Center Building shown in the top view of Exhibit 7.76 under the dis-

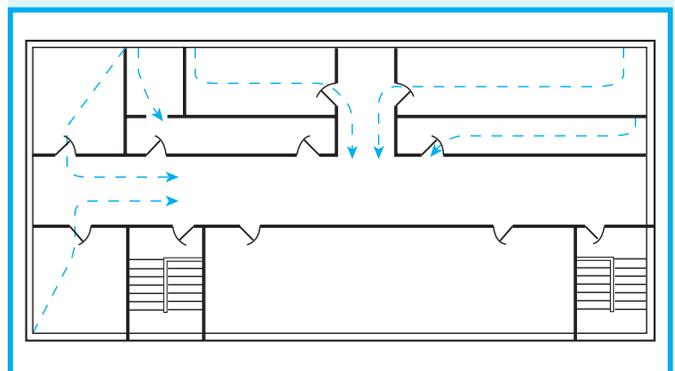

Exhibit 7.82 Common paths of travel.

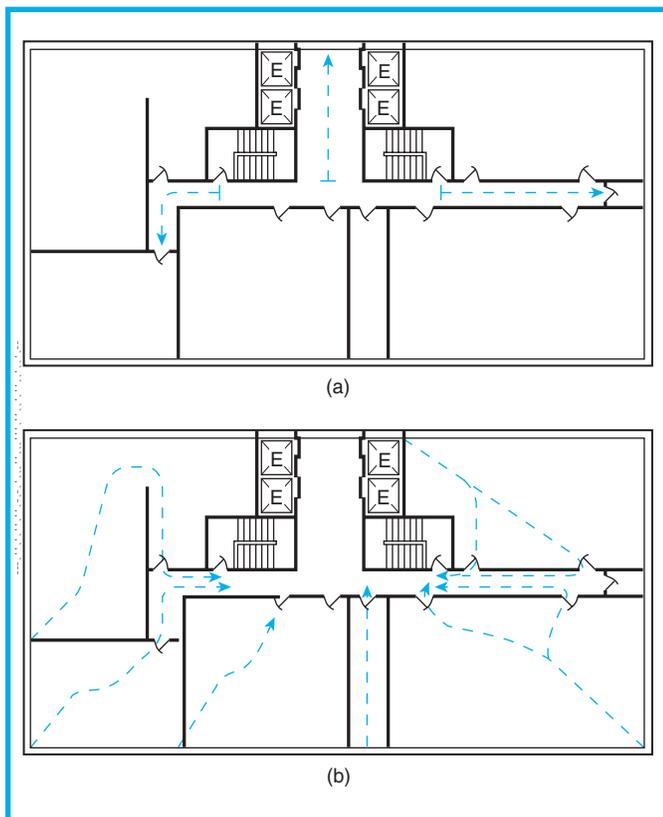

Exhibit 7.83 Dead-end corridors and common paths of travel.

cussion of exit remoteness. In the top view (a), the dashed lines indicate the extent of the three dead-end pockets in the corridor. In the bottom view (b), the dashed lines illustrate the numerous common paths of travel.

7.5.1.6 Exit access from rooms or spaces shall be permitted to be through adjoining or intervening rooms or areas, provided that such rooms or areas are accessory to the area served. Foyers, lobbies, and reception rooms constructed as required for corridors shall not be construed as intervening rooms. Exit access shall be arranged so that it is not necessary to pass through any area identified under Protection from Hazards in Chapter 11 through Chapter 42.

Paragraph 7.5.1.6 permits exit access travel through adjoining spaces if such spaces are accessory to the area served and such travel is not through any area identified under protection from hazards in an occupancy chapter (generally subsection ____3.2). Exhibit 7.84 illustrates exit access travel through intervening

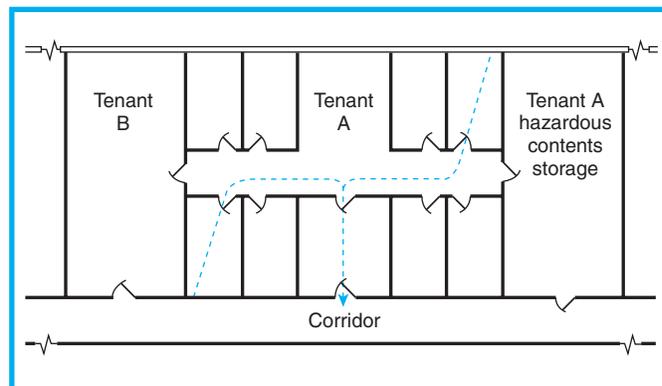

Exhibit 7.84 Exit access through adjoining rooms.

spaces that are under the control of the tenant and are not hazardous. Even though the hazardous contents storage room is under the control of the occupants of tenant space A, the hazard makes passage through the room unsafe. Passage from tenant space A into tenant space B is not permitted, because there is no assurance that the door into tenant space B will be left unlocked, unblocked, and usable to occupants of tenant space A.

7.5.2 Impediments to Egress.

See also 7.1.9 and 7.2.1.5.

7.5.2.1 Access to an exit shall not be through kitchens, storerooms other than as provided in Chapter 36 and Chapter 37, restrooms, workrooms, closets, bedrooms or similar spaces, or other rooms or spaces subject to locking, unless passage through such rooms or spaces is permitted for the occupancy by Chapter 18, Chapter 19, Chapter 22, and Chapter 23.

Paragraph 7.5.2.1, in combination with 7.5.1.6, prevents exit access from passing through certain rooms due to either increased relative hazard or potential blockage or locking.

7.5.2.2* Exit access and exit doors shall be designed and arranged to be clearly recognizable.

A.7.5.2.2 Doors that lead through wall paneling and that harmonize in appearance with the rest of the wall to avoid detracting from some desired aesthetic or decorative effect are not acceptable, because casual occupants might not be aware of such means of egress even though it is visible.

7.5.2.2.1 Hangings or draperies shall not be placed over exit doors or located so that they conceal or obscure any exit, unless otherwise provided in 7.5.2.2.2.

7.5.2.2.2 Curtains shall be permitted across means of egress openings in tent walls if the following criteria are met:

- (1) They are distinctly marked in contrast to the tent wall so as to be recognizable as means of egress.
- (2) They are installed across an opening that is at least 1830 mm (72 in.) in width.
- (3) They are hung from slide rings or equivalent hardware so as to be readily moved to the side to create an unobstructed opening in the tent wall that is of the minimum width required for door openings.

7.5.2.2.3 Mirrors shall not be placed on exit doors.

7.5.2.2.4 Mirrors shall not be placed in or adjacent to any exit in such a manner as to confuse the direction of exit.

See the commentary following A.7.1.10.1 for more information on maintaining means of egress free of obstructions or impediments.

7.5.3 Exterior Ways of Exit Access.

The provisions of 7.5.3 apply to exit access in the typical “motel” arrangement where exit access is provided via an open-air exit access balcony to an open stair. This arrangement is also common in apartment buildings and office buildings in warm climates. An understanding of these provisions is important, because many of the exemptions from the mandatory sprinkler requirements for the various residential occupancies conditionally apply where exterior exit access is provided.

7.5.3.1 Exit access shall be permitted to be by means of any exterior balcony, porch, gallery, or roof that conforms to the requirements of this chapter.

7.5.3.2 The long side of the balcony, porch, gallery, or similar space shall be at least 50 percent open and shall be arranged to restrict the accumulation of smoke.

Exterior ways of exit access need significant openings to the exterior so as not to become smoke-logged and unusable. Paragraph 7.5.3.2 establishes that at least 50 percent of the long side of the balcony, porch, gallery, or similar space is required to be open.

7.5.3.3 Exterior exit access balconies shall be separated from the interior of the building by walls and opening protectives as required for corridors, unless the exterior exit access balcony is served by at least two remote stairs that can be accessed without any occupant traveling past an unprotected opening to reach one of the stairs, or where dead ends on the exterior exit access do not exceed 6100 mm (240 in.).

Paragraph 7.5.3.3 requires the exterior exit access to be protected by separating construction from the interior of the building via the same rules that are applicable to corridors. However, this requirement does not apply to exit access served by at least two remote stairs, as detailed. Such an arrangement is used more often than the rated construction required by 7.5.3.3. To use this arrangement, access must be possible to both of the required remote stairs, one of which must be reachable without traveling past an unprotected opening.

Exhibit 7.85 illustrates three arrangements permitted by 7.5.3.3. In illustrations (a) and (b), it is possible for occupants of all rooms to reach one of the stairs without having to travel past any opening from which fire might issue; thus, fire-rated walls and doors are not required. In illustration (c), the occupants of rooms at the ends of the building must travel

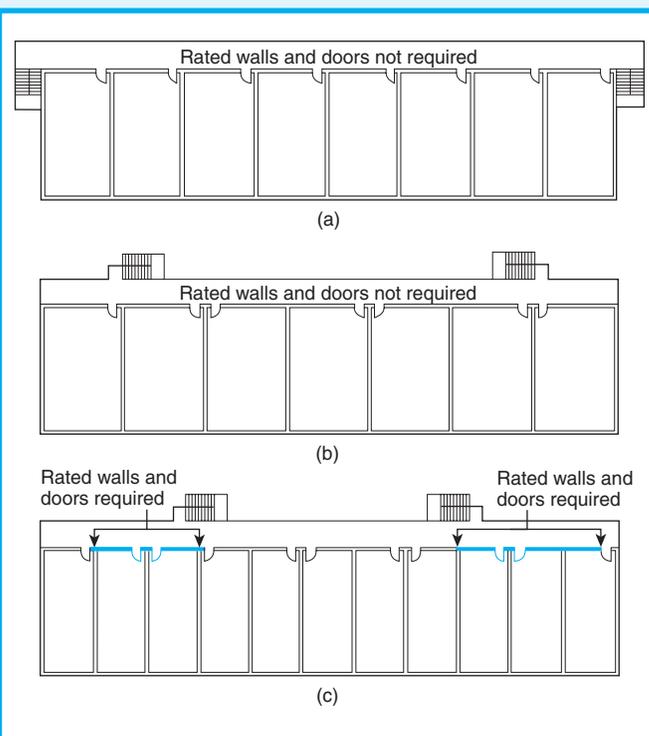

Exhibit 7.85 Exterior ways of exit access.

past other rooms to reach a stair; thus, fire resistance-rated walls and fire protection-rated opening protectives, such as windows and doors, are required in the areas indicated.

Paragraph 7.5.3.3 offers another alternative to rated wall construction and rated opening protectives along an exterior exit access path. Provided that the dead end does not exceed 6100 mm (240 in.), the occupant using the exterior exit access will not be exposed to an excessive number of unprotected openings.

7.5.3.4 Exterior exit access shall be arranged so that there are no dead ends in excess of those permitted for dead-end corridors in Chapter 11 through Chapter 42.

Because 7.5.3.3 permits unrated construction along a maximum 6100-mm (240 in.) dead-end exterior exit access path, it seems logical to recognize longer dead ends, as permitted by some of the occupancy chapters, where the exterior exit access path is protected by rated walls and rated opening protectives.

7.5.4 Accessible Means of Egress.

7.5.4.1* Areas accessible to people with severe mobility impairment, other than in existing buildings, shall have not less than two accessible means of egress, unless otherwise provided in 7.5.4.1.2 through 7.5.4.1.4.

A.7.5.4.1 An accessible means of egress should comply with the accessible route requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

7.5.4.1.1 Access within the allowable travel distance shall be provided to not less than one accessible area of refuge or one accessible exit providing an accessible route to an exit discharge.

7.5.4.1.2 A single accessible means of egress shall be permitted from buildings or areas of buildings permitted to have a single exit.

7.5.4.1.3 Accessible means of egress shall not be required in health care occupancies protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

Paragraph 7.5.4.1 requires that accessible means of egress be provided for all areas accessible to persons

with severe mobility impairment. *Accessible means of egress* is defined in 3.3.136.1 as a means of egress that provides an accessible route to an area of refuge, a horizontal exit, or a public way. *Severe mobility impairment* is defined in 3.3.195 as the ability to move to stairs but without the ability to use the stairs.

For a single-story building with typical exit doors to the exterior at grade level, the requirement for accessible means of egress is normally met without having to provide any additional features. For a multistory building involving vertical travel to grade level, the requirement for accessible means of egress from the upper floors might be met by providing ramps. Because ramp systems use considerable space, the requirement for accessible means of egress from the upper floors will most often be met by providing areas of refuge meeting the requirements of 7.2.12.

Exhibit 7.86 illustrates arrangements providing accessible means of egress. In illustrations (a) and (b), accessible means of egress are provided via ground level doors or ramps from the second story. In illustration (c), areas of refuge with rated barrier and extra-width stairs in accordance with 7.2.12 provide accessible means of egress. In illustration (d), the floor of a fully sprinklered building with a second accessible room on the floor creates an area of refuge via the definition in 3.3.17, thus providing an accessible means of egress.

The *Code* does not require areas of refuge; it requires accessible means of egress. The easiest way to meet the requirements for accessible means of egress in multistory buildings is by providing areas of refuge. See 7.2.12.

Paragraph 7.5.4.1 clarifies that the requirement for accessible means of egress is not retrospectively required in existing buildings, unless specifically required by the applicable occupancy chapter.

7.5.4.1.4 Exit access travel along the accessible means of egress shall be permitted to be common for the distances permitted as common paths of travel.

7.5.4.2 Where two accessible means of egress are required, the exits serving such means of egress shall be located at a distance from one another not less than one-half the length of the maximum overall diagonal dimension of the building or area to be served, measured in a straight line between the nearest edge of the exit doors or exit access doors, unless otherwise provided in 7.5.4.2.1 through 7.5.4.2.3.

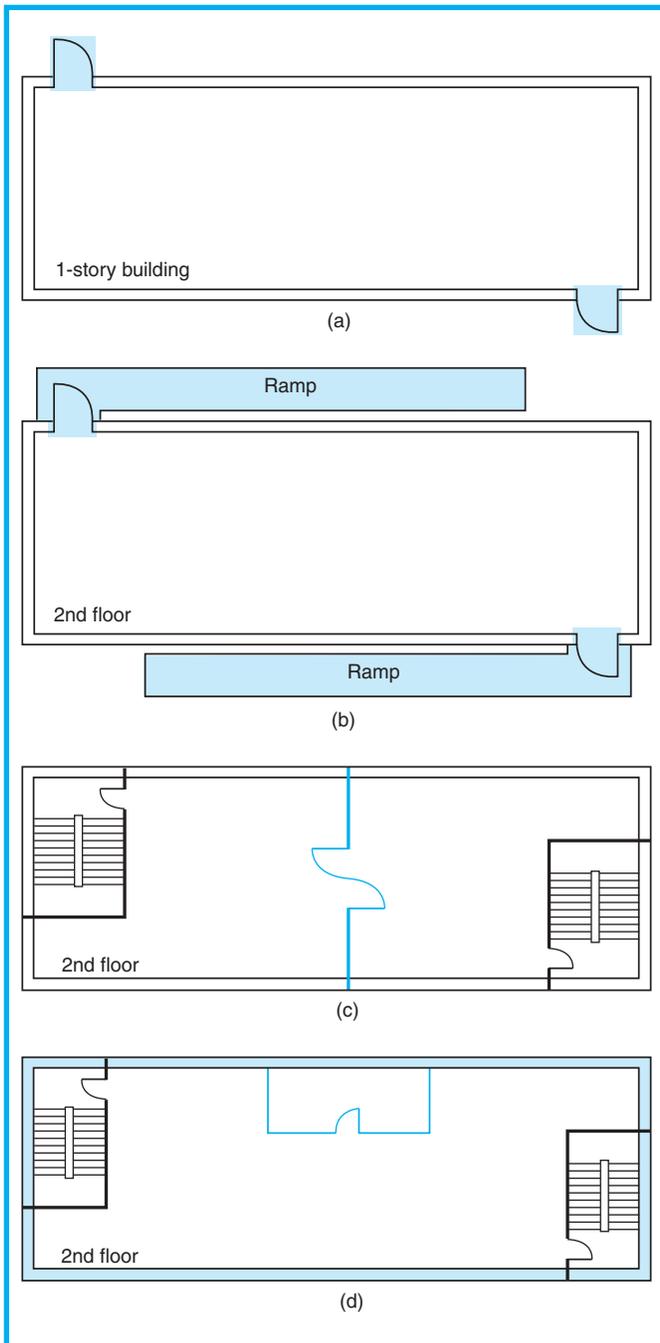

Exhibit 7.86 Accessible means of egress.

Paragraph 7.5.4.2 establishes criteria for judging the remoteness of exits serving accessible means of egress paths. It is analogous to 7.5.1.3.2, which establishes remoteness for means of egress using the half-diagonal rule. See A.7.5.1.3.2.

7.5.4.2.1 Where exit enclosures are provided as the required exits specified in 7.5.4.2 and are interconnected by not less than a 1-hour fire resistance-rated corridor, exit separation shall be permitted to be measured along the line of travel within the corridor.

7.5.4.2.2 The requirement of 7.5.4.2 shall not apply to buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

7.5.4.2.3 The requirement of 7.5.4.2 shall not apply where the physical arrangement of means of egress prevents the possibility that access to both accessible means of egress will be blocked by any one fire or other emergency condition as approved by the authority having jurisdiction.

7.5.4.3 Each required accessible means of egress shall be continuous from each accessible occupied area to a public way or area of refuge in accordance with 7.2.12.2.2.

7.5.4.4 Where an exit stair is used in an accessible means of egress, it shall comply with 7.2.12.2.3 and shall either incorporate an area of refuge within an enlarged story-level landing or shall be accessed from an area of refuge.

7.5.4.5 To be considered part of an accessible means of egress, an elevator shall be in accordance with 7.2.12.2.4.

7.5.4.6 To be considered part of an accessible means of egress, a smoke barrier in accordance with Section 8.5 with not less than a 1-hour fire resistance rating, or a horizontal exit in accordance with 7.2.4, shall discharge to an area of refuge in accordance with 7.2.12.

7.5.4.7 Accessible stories that are four or more stories above or below a story of exit discharge shall have not less than one elevator complying with 7.5.4.5.

Where it might be necessary to carry persons and their wheelchairs on stairs for four or more stories to the ground level, the *Code* requires at least one elevator complying with 7.5.4.5.

7.6* Measurement of Travel Distance to Exits

A.7.6 Table A.7.6 is a compilation of the requirements of the individual occupancy chapters (Chapters 12 through 42) for permissible length of common path of travel, dead-end corridors, and travel distance to not less than one of the required exits.

Table A.7.6 Common Path, Dead-End, and Travel Distance Limits (by occupancy)

NA: Not applicable.

NR: No requirement.

^a6.1 m (20 ft) for common path serving >50 persons; 23 m (75 ft) for common path serving ≤50 persons.

^b6.1-m (20-ft) Dead-end corridors permitted; 6.1-m (20-ft) dead-end aisles permitted.

^cSee Chapter 12 and Chapter 13 for special considerations for smoke-protected assembly seating in arenas and stadia.

^dThis dimension is for the total travel distance, assuming incremental portions have fully utilized their permitted maximums. For travel distance within the room, and from the room exit access door to the exit, see the appropriate occupancy chapter.

^eSee business occupancies, Chapter 38 and Chapter 39.

^fSee Chapter 23 for special considerations for existing common paths.

^gThis dimension is from the room/corridor or suite/corridor exit access door to the exit; thus, it applies to corridor common path.

^hSee appropriate occupancy chapter for special travel distance considerations for exterior ways of exit access.

ⁱSee appropriate occupancy chapter for requirement for second exit access based on room area.

^jSee 36.4.4 and 37.4.4 for special travel distance considerations in covered malls considered pedestrian ways.

^kSee Chapter 38 and Chapter 39 for special common path considerations for single tenant spaces.

^lSee Chapter 40 for industrial occupancy special travel distance considerations.

^mSee Chapter 40 and Chapter 42 for special requirements if high hazard.

ⁿSee Chapter 40 and Chapter 42 for special requirements on spacing of doors in aircraft hangars.

A dead end exists where an occupant enters a corridor thinking there is an exit at the end and, finding none, is forced to retrace the path traveled to reach a choice of egress travel paths. Although relatively short dead ends are permitted by this *Code*, it is better practice to eliminate them wherever possible, as they increase the danger of persons being trapped in case of fire. Compliance with the dead-end limits does not necessarily mean that the requirements for remoteness of exits have been met. Such lack of compliance is particularly true in small buildings or buildings with short public hallways. Adequate remoteness can be obtained in such cases by further reducing the length of dead ends. (See also A.7.5.1.5.)

The *Code* specifies the maximum distance that occupants are permitted to travel from their position in a building to the nearest exit. There is no formula by which this distance can be established.

Maximum allowed travel distances are based on factors that include the following:

- (1) Number, age, and physical condition of building occupants and the rate at which they can be expected to move
- (2) Type and number of obstructions (for example, display cases, seating, heavy machinery) around which occupants must travel
- (3) Number of people in any room or space and the distance from the farthest point in that room to the door
- (4) Amount and nature of combustibles expected in a particular occupancy
- (5) Rapidity with which fire might spread (a function of type of construction, materials used, degree of compartmentation, and presence or absence of automatic fire detection and extinguishing systems)

Allowable travel distances will vary with the type and size of occupancy and the degree of hazard present. As shown in Table A.7.6, maximum travel distances can vary from 23 m (75 ft) in nonsprinklered high-hazard storage occupancies to 122 m (400 ft) in sprinklered mall buildings or sprinklered special-purpose industrial occupancies meeting additional criteria. For most occupancies, the allowable travel distance is permitted to be increased if the building is protected throughout by automatic sprinkler systems.

Where the occupant has been provided with at least two paths of travel to an exit, it becomes important that the time needed to travel the shorter of the two paths not be so great as to place the occupant

in further danger. There are no formulae or exact criteria for determining maximum permitted travel distances. Many factors have been considered and weighed in establishing these distances; they are the result of observing people who are in motion, consensus judgment, and many years of studying the results of fires in which the pre-fire conditions of a building were known.

Excessive travel distances can be a factor in large losses of life in fires because they increase the time required to reach the safety of an exit, whether the exit is a door directly to the outside or into a properly enclosed exit stair on an upper floor of a building. There is evidence that excessive travel distances played a role in a number of the fatalities on the casino floor at the MGM Grand Hotel fire in Las Vegas in 1980¹⁹. Of the 85 fatalities, 18 victims were located on the casino level, and some apparently were overrun by the flame front.

7.6.1* The travel distance to an exit shall be measured on the floor or other walking surface as follows:

- (1) Along the centerline of the natural path of travel, starting from the most remote point subject to occupancy
- (2) Curving around any corners or obstructions with a 305-mm (12-in.) clearance therefrom
- (3) Terminating at one of the following:
 - (a) Center of the doorway
 - (b) Other point at which the exit begins
 - (c) Smoke barrier in an existing detention and correctional occupancy as provided in Chapter 23.

A.7.6.1 The natural exit access (path of travel) is influenced by the contents and occupancy of the building. Furniture, fixtures, machinery, or storage can serve to increase the length of travel. It is good practice in building design to recognize the influence of contents and occupancy by spacing exits for a completely open floor area at closer intervals than is required, thus reducing the hazard of excessive travel distances due to the introduction of furniture, fixtures, machinery, or storage and minimizing the possibility of violating the travel distance requirements of this *Code*.

Exhibit 7.87 illustrates the path along which travel distance to an exit is measured. In illustration (a), the stair is not appropriately enclosed to qualify as an exit; second floor travel distance measurement continues to the first floor at the exit door to the outside. In illustration (b), the stair is properly enclosed and constitutes an exit; travel distance measurement ends

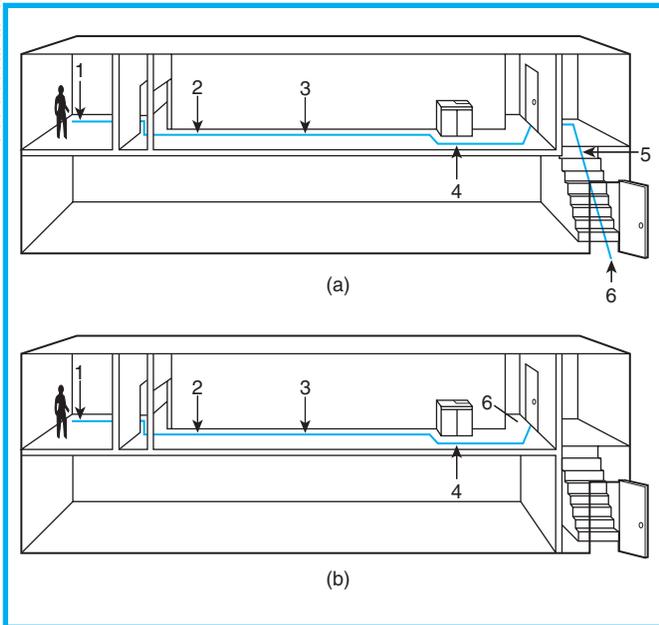

Exhibit 7.77 Measuring travel distance to an exit.

on the second floor at the entrance door to the stair enclosure. The travel paths marked as 1 through 6 show that travel distance is measured as follows:

- (1) Starting at the most remote point subject to occupancy
- (2) On the floor or other walking surface
- (3) Along the centerline of the natural path of travel
- (4) Around corners and obstructions with a clearance of 305 mm (12 in.)
- (5) Over open exit access ramps and open exit access stairs in the plane of tread nosings
- (6) Ending where the exit begins

Travel distance is that length of travel to an exterior exit door [as shown in Exhibit 7.87, illustration (a)], an enclosed exit stair [as shown in Exhibit 7.87, illustration (b)], an exit passageway, or a horizontal exit. It includes all travel within the occupied space until an occupant reaches that level of protection afforded by an exit. Therefore, where stairs form part of an exit access rather than an exit, the travel over such stairs is included in the travel distance measurement [as shown in Exhibit 7.87, illustration (a)].

The measurement of travel distance along stairs, as detailed in 7.6.4, is to be made in the plane of the tread nosings, not along each riser and tread. This measurement is illustrated in Exhibit 7.88.

In reviewing plans for compliance with the travel distance limitations established for any occupancy, it is important to know the natural path of travel and

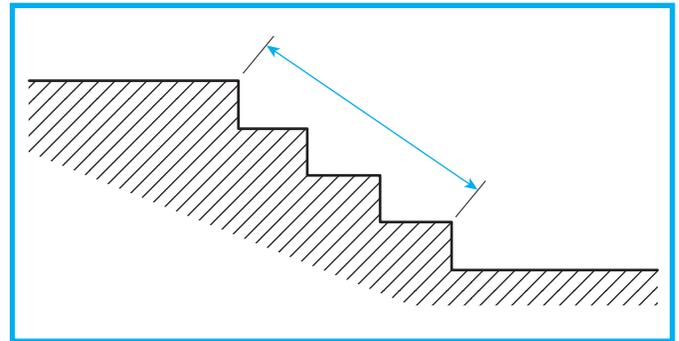

Exhibit 7.88 Measuring travel distance on stairs.

the obstacles that are present. In Exhibit 7.89, illustrations (a) and (b) depict the same building. In illustration (a), points X and Y are located at the same physical distance from the exit door. Without further information related to the layout of furniture and partitions, it isn't clear whether the occupant will be able to travel in a straight line, as shown from point

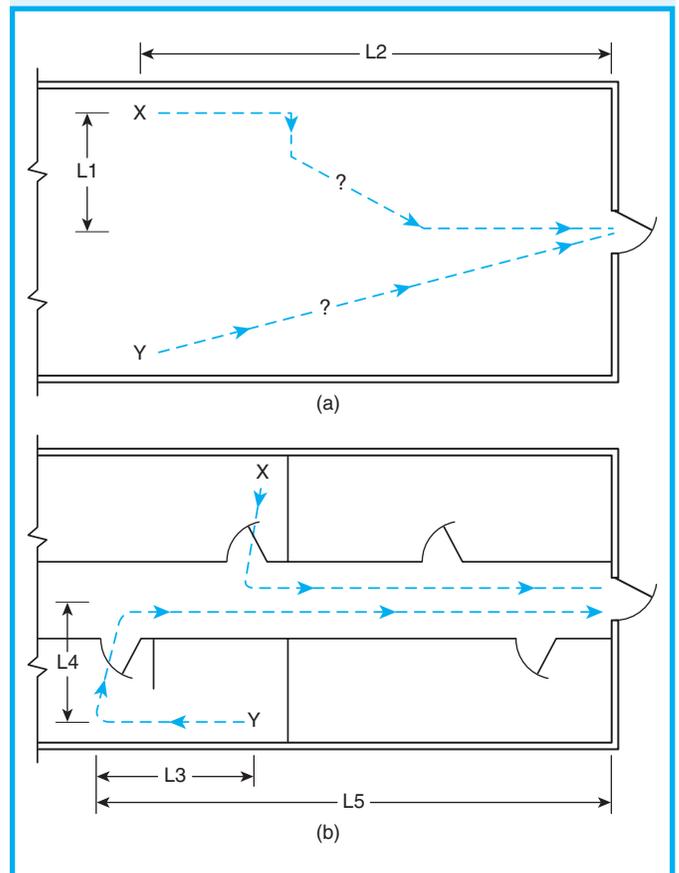

Exhibit 7.89 Measuring travel distance along the natural path of travel.

Y to the exit door, or will need to follow a longer travel path that zigzags around obstacles, as shown from point X to the exit door. A prudent designer, with lack of knowledge about the actual placement of furniture and partitions, will not assume that travel distance is a straight-line measurement. Rather, the prudent designer would estimate the travel distance to be at least the distance calculated by adding travel path segments L1 and L2.

In Exhibit 7.89, illustration (b), the placement of partitions appears on the plan. An occupant is unable to travel in a straight “bee line” path to the exit door from either point X or point Y; the partitions preclude this. Further, the occupant at point Y must first move in a direction opposite from that of the building’s exit door to reach the room door before turning and traveling in a direction toward the exit door. In this case, the travel distance is calculated by adding together travel path segments L3, L4, and L5.

7.6.2* Where open stairways or ramps are permitted as a path of travel to required exits, the distance shall include the travel on the stairway or ramp and the travel from the end of the stairway or ramp to an outside door or other exit in addition to the distance traveled to reach the stairway or ramp.

A.7.6.2 Examples of locations where open stairways might exist include between mezzanines or balconies and the floor below.

7.6.3 Where any part of an exterior exit is within 3050 mm (120 in.) of horizontal distance of any unprotected building opening, as permitted by 7.2.2.6.3 for outside stairs, the travel distance to the exit shall include the length of travel to ground level.

The intent of 7.6.3 is to clarify that if the exterior stair is exposed to unprotected building openings, it is not considered an exit but is considered exit access; the travel distance, therefore, includes the measurement along the stair.

7.6.4 Where measurement includes stairs, the measurement shall be taken in the plane of the tread nosing.

7.6.5 The travel distance in any occupied space to not less than one exit, measured in accordance with 7.6.1 through 7.6.4, shall not exceed the limits specified in this *Code*. (See 7.6.6.)

The maximum permitted travel distance is that length of travel path that must not be exceeded to reach the nearest exit. Although more than one exit might be required, the distance to exits other than that which is nearest is not regulated.

7.6.6 Travel distance limitations shall be as provided in Chapter 11 through Chapter 42 and, for high hazard areas, shall be in accordance with Section 7.11.

Although Section 7.6 establishes the method for measuring travel distance, it does not set the maximum travel distance permitted for a specific occupancy. Travel distance limitations are contained in subsection ____2.6 of Chapters 12 through 42. The travel distance limitations for all occupancies are summarized in Table A.7.6.

In the 1988 edition of the *Code*, the maximum permitted travel distances were increased in most occupancies to maintain the status quo, because an exemption was deleted that permitted the travel within small rooms or spaces to be excluded from the overall measurement of travel distance. This former provision exempted rooms that contained six or fewer people, and that had a travel distance within them of less than 15 m (50 ft), from being included in the overall travel distance measurement.

Section 7.7 Discharge from Exits

7.7.1* Exit Termination.

Exits shall terminate directly, at a public way or at an exterior exit discharge, unless otherwise provided in 7.7.1.2 through 7.7.1.4.

A.7.7.1 An exit from the upper stories in which the direction of egress travel is generally downward should not be arranged so that it is necessary to change to travel in an upward direction at any point before discharging to the outside. A similar prohibition of reversal of the vertical component of travel should be applied to exits from stories below the floor of exit discharge. However, an exception is permitted in the case of stairs used in connection with overhead or underfloor exit passageways that serve the street floor only.

It is important that ample roadways be available from buildings in which there are large numbers of occupants so that exits will not be blocked by persons already outside. Two or more avenues of departure should be available for all but very small places. Location of a larger theater—for

example, on a narrow dead-end street—might be prohibited by the authority having jurisdiction under this rule, unless some alternate way of travel to another street is available.

Exterior walking surfaces within the exit discharge are not required to be paved and often are provided by grass or similar surfaces. Where discharging exits into yards, across lawns, or onto similar surfaces, in addition to providing the required width to allow all occupants safe access to a public way, such access also is required to meet the following:

- (1) The provisions of 7.1.7 with respect to changes in elevation
- (2) The provisions of 7.2.2 for stairs, as applicable
- (3) The provisions of 7.2.5 for ramps, as applicable
- (4) The provisions of 7.1.10 with respect to maintaining the means of egress free of obstructions that would prevent its use, such as snow and the need for its removal in some climates

7.7.1.1 Yards, courts, open spaces, or other portions of the exit discharge shall be of required width and size to provide all occupants with a safe access to a public way.

7.7.1.2 The requirement of 7.7.1 shall not apply to interior exit discharge as otherwise provided in 7.7.2.

7.7.1.3 The requirement of 7.7.1 shall not apply to rooftop exit discharge as otherwise provided in 7.7.6.

7.7.1.4 Means of egress shall be permitted to terminate in an exterior area of refuge for detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23.

The principle addressed in 7.7.1 is that, once a building occupant reaches an exit (the protected portion of the means of egress), the level of protection afforded by that exit cannot be reduced or eliminated. Therefore, except as noted, all exits must be continuous to a public way or other safe place, or to an exit discharge that must, in turn, be continuous to the public way.

It is not sufficient to permit the egress system to terminate at the outside of a building, because there might not be enough space to provide safe movement away from the building. Also, the terminus of the egress system cannot be located at the outside in a closed court from which travel back through the building might be necessary to get away from the building. In such a case, an exit passageway at least as wide as the exit itself and constructed as specified for exits is required to provide travel from the courtyard to the safe place.

7.7.2 Discharge through Areas on Level of Exit Discharge.

Not more than 50 percent of the required number of exits, and not more than 50 percent of the required egress capacity, shall be permitted to discharge through areas on the level of exit discharge, unless otherwise permitted in 7.7.2.1 and 7.7.2.2, provided that the criteria of 7.7.2.3 through 7.7.2.7 are met.

7.7.2.1 One hundred percent of the exits shall be permitted to discharge through areas on the level of exit discharge in detention and correctional occupancies as otherwise provided in Chapter 22 and Chapter 23.

7.7.2.2 In existing buildings, the 50 percent limit on egress capacity shall not apply if the 50 percent limit on the required number of exits is met.

7.7.2.3 The discharge specified in 7.7.2 shall lead to a free and unobstructed way to the exterior of the building, and such way shall be readily visible and identifiable from the point of discharge from the exit.

7.7.2.4 The level of discharge shall be protected throughout by an approved, automatic sprinkler system in accordance with Section 9.7, or the portion of the level of discharge used for discharge shall be protected by an approved, automatic sprinkler system in accordance with Section 9.7 and shall be separated from the nonsprinklered portion of the floor by a fire resistance rating meeting the requirements for the enclosure of exits. (See 7.1.3.2.1.)

7.7.2.5 The requirement of 7.7.2.4 shall not apply where the discharge area is a vestibule or foyer that meets all of the following criteria:

- (1) The depth from the exterior of the building shall be not more than 3050 mm (120 in.), and the length shall be not more than 9140 mm (360 in.).
- (2) The foyer shall be separated from the remainder of the level of discharge by construction providing protection not less than the equivalent of wired glass in steel frames.
- (3) The foyer shall serve only as means of egress and shall include an exit directly to the outside.

7.7.2.6 The entire area on the level of discharge shall be separated from areas below by construction having a fire resistance rating not less than that required for the exit enclosure, unless otherwise provided in 7.7.2.7.

7.7.2.7 Levels below the level of discharge in an atrium shall be permitted to be open to the level of discharge where such level of discharge is protected in accordance with 8.6.7.

The intent of 7.7.2 is to provide an exit stair enclosure that discharges through the level of exit discharge with approximately the same level of protection offered to exits that discharge directly to the outside. Among the questions most often asked regarding the *Code* are those that concern the requirements of 7.7.2.4. The intent of 7.7.2.4 is to require that the entire level of exit discharge and any area connected to the level of discharge with access to the discharge area be protected by automatic sprinklers. As an alternative, if sprinkler protection is installed only in the portion of the level of exit discharge the door to the outside, the sprinklered area must be used for travel from the exit stair enclosure door to separated from the rest of the level of discharge by construction as required for exits (see 7.1.3.2.1). An exemption to the sprinkler requirement is offered by 7.7.2.5 and involves providing a 3050 mm × 9140 mm (120 in. × 360 in.) maximum wired-glass foyer, which can be used only for egress and, thus, has no occupancy of its own.

Use of the 50 percent rule for discharge through the level of exit discharge is not dependent on occupancy permission; thus, it can be used in all occupancies. However, detention and correctional occupancies (see 22/23.2.7.3 and 22/23.2.7.4) permit 100 percent of the exits and 100 percent of the egress capacity to discharge through the level of exit discharge. Hotels and mercantile occupancies establish additional requirements limiting the distance occupants are permitted to travel within their exit discharge through the ground level to the door to the outside (see 28.2.7.3, 29.2.7.3, 36.2.7.2, and 37.2.7.2).

Exhibit 7.90 illustrates exit discharge arrangements meeting the requirements of subsection 7.7.2. The stairs provide four required exits from the upper floors. Exit stair A discharges directly outside. Exit stair B is also considered to discharge directly outside, because its attached exit passageway affords protected passage to the door to the outside. The other two exit stairs, C and D, are permitted to discharge across the first floor, because they do not constitute more than 50 percent of the number of exits from an upper floor or more than 50 percent of the egress capacity of any upper floor. Exit stair C discharges into an area on the discharge level that is sprinklered and separated from the remainder of the floor and the basement, which are not sprinklered. The hourly fire resistance rating of the floor slab and the separating fire barrier are the same as required for the enclosure of exit stair C. Exit stair D discharges into a wired-glass foyer in the nonsprinklered portion of the floor in accordance with 7.7.2.5.

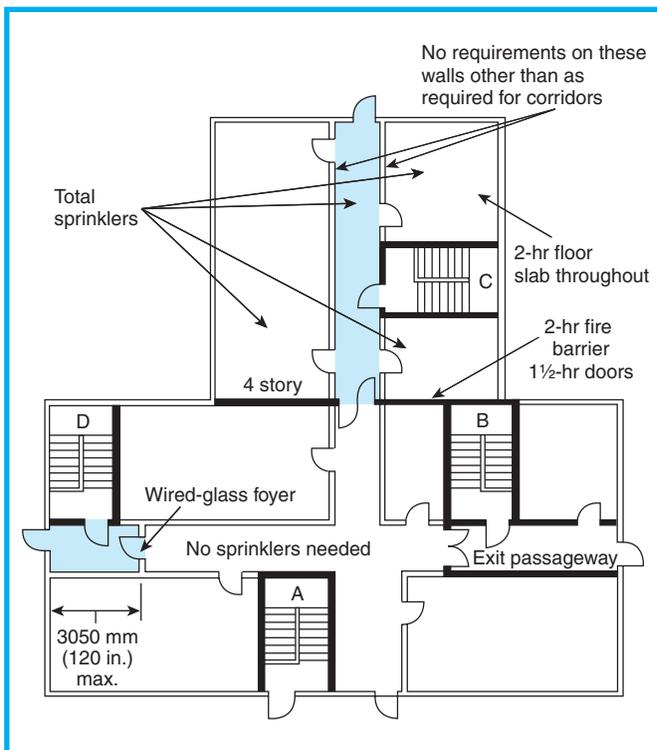

Exhibit 7.90 Exit discharge.

7.7.3 Arrangement and Marking of Exit Discharge.

The exit discharge shall be arranged and marked to make clear the direction of egress to a public way. Stairs shall be arranged so as to make clear the direction of egress to a public way. Stairs that continue more than one-half story beyond the level of exit discharge shall be interrupted at the level of exit discharge by partitions, doors, or other effective means.

Exhibit 7.91 illustrates a stair design intended to minimize the possibility that occupants traveling on stairs will inadvertently continue past the exit discharge level, stop at the basement level where the stair ends but where there is no discharge, and then retrace their steps to the level of exit discharge. The barrier needed to cue the occupant that the level of discharge has been reached can be a partition, railings, a gate, or another physical barrier that effectively interrupts the flow of travel, forcing a person to perform a deliberate act to get past the barrier.

7.7.4 Components of Exit Discharge.

Doors, stairs, ramps, corridors, exit passageways, bridges, balconies, escalators, moving walks, and other components

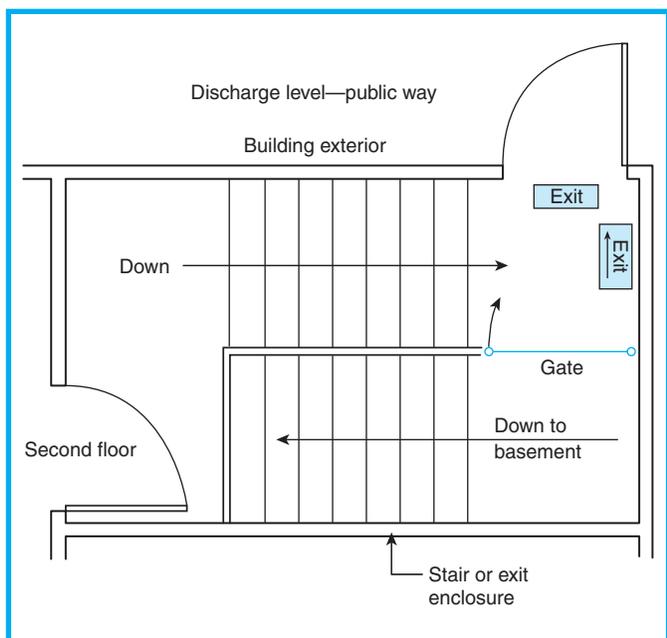

Exhibit 7.91 Interruption of exit stair at level of exit discharge.

of an exit discharge shall comply with the detailed requirements of this chapter for such components.

7.7.5 Signs.

See 7.2.2.5.4.

7.7.6 Discharge to Roofs.

Where approved by the authority having jurisdiction, exits shall be permitted to discharge to roofs or other sections of the building or an adjoining building where the following criteria are met:

- (1) The roof/ceiling assembly construction has a fire resistance rating not less than that required for the exit enclosure.
- (2) A continuous and safe means of egress from the roof is available.

An exit discharge to a roof is not acceptable, unless there is another continuous and safe means of egress from the roof and the roof construction affords protection against fire that is at least equivalent to that of the stair enclosure. Helicopter rescue from roofs is not dependable enough to be given credit as an exit; many factors in such a rescue are too unpredictable for this to be a consideration.

Outside stairs leading to the roofs of other sections of the building or onto the roofs of adjoining

buildings are acceptable as part of the means of egress, but only with the approval of the AHJ. The conditions and settings of such paths of travel are likely to be so varied that it is virtually impossible to cover them by written provisions. Ideally AHJ judges each situation individually.

Section 7.8 Illumination of Means of Egress

When fire occurs in a building, the degree of visibility in corridors, stairs, and passageways might mean the difference between orderly evacuation and chaos and, possibly, the difference between life and death. A brief glance at the history of fires reveals several noteworthy fires in which the failure of normal or emergency lighting was a major factor in the casualties incurred. A list of some of these fires follows:

Iroquois Theater, Chicago, 1903	602 deaths ²⁰
Cocoanut Grove Night Club, Boston, 1942	492 deaths ²¹
Baltimore Oyster Roast, Baltimore, 1956	11 deaths ²²
Apartment house, Boston, 1971	8 deaths ²³
Summerland amusement complex, Isle of Man, 1973	50 deaths ²⁴
Psychiatric hospital, Mississippi, 1978	15 deaths ²⁵

The report on the 1971 Massachusetts apartment fire where eight people died stated: "Among the conditions contributing to the . . . loss of life were . . . the lack of emergency lighting and the lack of illuminated exit signs."

The report on the 1973 fire in the amusement complex on the Isle of Man in Great Britain, where 50 people died, stated, "The problems with the evacuation are . . . (5) an insufficient number of exit signs and directional signs . . . (7) The emergency lighting did not come on when the main power was shut off by a staff member in an act of misguided zeal."

The report on the 1978 mental hospital fire in Mississippi, where 15 people died, stated:

Heat and flame . . . impinged directly on the emergency lighting conduit, causing . . . a short circuit to occur. The short tripped the circuit breaker . . . leaving the north end of the building without emergency lighting. However, in this fire, the emergency lighting circuits on the

first floor were not used. The dual-function lighting circuits were switched in the “off” position in both wards. The attendant entering Ward 1 to evacuate the residents did not turn the lights on. In Ward 2, the switch could not be reached by the attendants, and the circuit shorted out soon after the discovery of the fire. The darkness contributed to the difficulty in evacuating both wards²⁶.

A lack of illuminated exit signs in several key places was also noted in the report.

7.8.1 General.

7.8.1.1* Illumination of means of egress shall be provided in accordance with Section 7.8 for every building and structure where required in Chapter 11 through Chapter 42. For the purposes of this requirement, exit access shall include only designated stairs, aisles, corridors, ramps, escalators, and passageways leading to an exit. For the purposes of this requirement, exit discharge shall include only designated stairs, aisles, corridors, ramps, escalators, walkways, and exit passageways leading to a public way.

A.7.8.1.1 Illumination provided outside the building should be to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated.

Illumination of means of egress is not required unless specifically called for in the appropriate occupancy chapter. However, all occupancy chapters do require illumination, but there are a few exemptions. For example, in new assembly occupancies, 12.2.8 exempts private-party tents not larger than 112 m² (1200 ft²) from the illumination requirement. Subsection ____2.8 (for example, 36.2.8 for new mercantile occupancies) of each occupancy chapter provides illumination requirements.

7.8.1.2 Illumination of means of egress shall be continuous during the time that the conditions of occupancy require that the means of egress be available for use, unless otherwise provided in 7.8.1.2.2.

7.8.1.2.1 Artificial lighting shall be employed at such locations and for such periods of time as are necessary to maintain the illumination to the minimum criteria values herein specified.

7.8.1.2.2 Automatic, motion sensor–type lighting switches shall be permitted within the means of egress, provided that

the switch controllers are equipped for fail-safe operation, the illumination timers are set for a minimum 15-minute duration, and the motion sensor is activated by any occupant movement in the area served by the lighting units.

7.8.1.3* The floors and other walking surfaces within an exit and within the portions of the exit access and exit discharge designated in 7.8.1.1 shall be illuminated as follows:

- (1) During conditions of stair use, the minimum illumination for new stairs shall be at least 108 lux (10 ft-candle), measured at the walking surfaces.
- (2) The minimum illumination for floors and walking surfaces, other than new stairs, shall be to values of at least 10.8 lux (1 ft-candle), measured at the floor.
- (3) In assembly occupancies, the illumination of the floors of exit access shall be at least 2.2 lux (0.2 ft-candle) during periods of performances or projections involving directed light.
- (4)* The minimum illumination requirements shall not apply where operations or processes require low lighting levels.

A.7.8.1.3 A desirable form of means of egress lighting is by lights recessed in walls about 305 mm (12 in.) above the floor. Such lights are not likely to be obscured by smoke.

A.7.8.1.3(4) Some processes, such as manufacturing or handling of photosensitive materials, cannot be performed in areas provided with the minimum specified lighting levels. The use of spaces with lighting levels below 10.8 lux (1 ft-candle) might necessitate additional safety measures, such as written emergency plans, training of new employees in emergency evacuation procedures, and periodic fire drills.

The *Code* requires that there be at least 10.8 lux (1 ft-candle) of illumination at floor level in all three elements of a means of egress, that is, the exit access, the exit, and the exit discharge. For the purposes of Section 7.8, the *Code* limits exit access to designated stairs, aisles, corridors, ramps, escalators, and passageways leading to an exit. Such components should include those portions of the exit access serving occupied spaces. It is not necessary to keep the lights on in all rooms if the rooms are not occupied. For the purposes of Section 7.8, the *Code* limits exit discharge to designated stairs, aisles, corridors, ramps, escalators, walkways, and passageways leading to a public way. *Designated* is meant to indicate designation by the authority having jurisdiction.

Paragraph 7.8.1.3(1), requiring at least 108 lux (10 ft-candle) for new stairs during conditions of stair use, is new to this edition of the *Code*.

While motion pictures, slides, and the like are being shown in theaters, auditoriums, and other assembly occupancies, 7.8.1.3(3) permits the level of illumination to be reduced to 2.2 lux (0.2 ft-candle).

7.8.1.4* Required illumination shall be arranged so that the failure of any single lighting unit does not result in an illumination level of less than 2.2 lux (0.2 ft-candle) in any designated area.

A.7.8.1.4 An example of the failure of any single lighting unit is the burning out of an electric bulb.

All lights, circuits, or auxiliary power must be arranged to ensure continuity of egress lighting. This arrangement can be accomplished by means such as use of duplicate light bulbs in fixtures, overlapping light patterns, or overlapping dual circuits.

7.8.1.5 The equipment or units installed to meet the requirements of Section 7.10 also shall be permitted to serve the function of illumination of means of egress, provided that all requirements of Section 7.8 for such illumination are met.

7.8.2 Sources of Illumination.

7.8.2.1* Illumination of means of egress shall be from a source considered reliable by the authority having jurisdiction.

A.7.8.2.1 An example of a power source with reasonably ensured reliability is a public utility electric service.

7.8.2.2 Battery-operated electric lights and other types of portable lamps or lanterns shall not be used for primary illumination of means of egress. Battery-operated electric lights shall be permitted to be used as an emergency source to the extent permitted under Section 7.9.

Section 7.9 Emergency Lighting

Emergency lighting is not required unless specifically called for in the appropriate occupancy chapter. Most occupancy chapters require emergency lighting in medium-to-large buildings. Subsection ____2.9 of each occupancy chapter (for example, 12.2.9 or 36.2.9 for new assembly and new mercantile occupancies, respectively) provides emergency lighting requirements.

7.9.1 General.

7.9.1.1* Emergency lighting facilities for means of egress shall be provided in accordance with Section 7.9 for the following:

- (1) Buildings or structures where required in Chapter 11 through Chapter 42
- (2) Underground and limited access structures as addressed in Section 11.7
- (3) High-rise buildings as required by other sections of this Code
- (4) Doors equipped with delayed-egress locks
- (5) Stair shaft and vestibule of smokeproof enclosures, for which the following also apply:
 - (a) The stair shaft and vestibule shall be permitted to include a standby generator that is installed for the smokeproof enclosure mechanical ventilation equipment.
 - (b) The standby generator shall be permitted to be used for the stair shaft and vestibule emergency lighting power supply.

A.7.9.1.1 Emergency lighting provided outside the building should be to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated.

7.9.1.2 For the purposes of 7.9.1.1, exit access shall include only designated stairs, aisles, corridors, ramps, escalators, and passageways leading to an exit. For the purposes of 7.9.1.1, exit discharge shall include only designated stairs, ramps, aisles, walkways, and escalators leading to a public way.

7.9.1.3 Where maintenance of illumination depends on changing from one energy source to another, a delay of not more than 10 seconds shall be permitted.

An on-site generator driven by a prime mover must be automatically started and capable of picking up the emergency lighting load within 10 seconds. Where the generator set is not able to supply power within this time frame, an auxiliary power source must be provided.

Some turbine-driven emergency generators take longer than 10 seconds to reach operating speed. A backup battery pack, such as an uninterruptible power supply (UPS), capable of delivering emergency power for a few minutes must be used in conjunction with any on-site generator that cannot meet the 10-second requirement.

NFPA 70, *National Electrical Code*^{®27}, allows use of

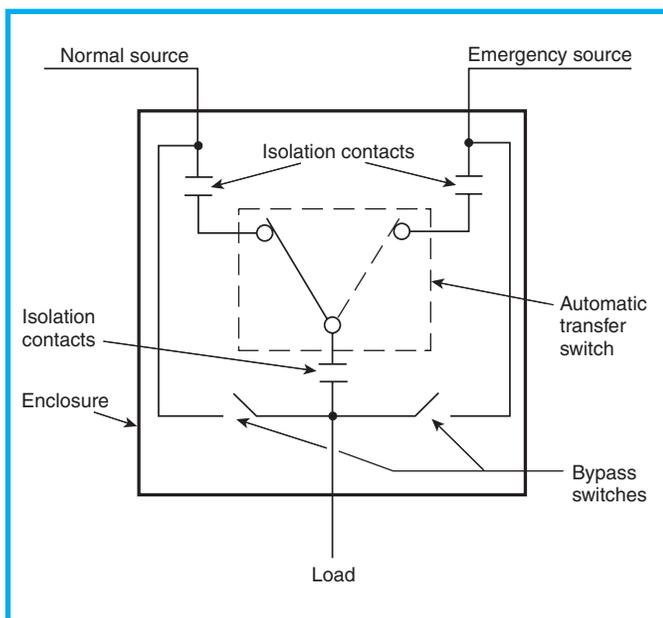

Exhibit 7.92 Schematic of bypass-isolation transfer switch.

an emergency generator for load shedding and peak load shaving, provided that these loads can be disconnected when normal power to the emergency lighting system is lost.

Although not required by NFPA 70, the use of bypass-isolation transfer switches should be considered. These devices allow maintenance and repair of the transfer switch mechanism without interruption of power to the emergency loads. Bypass switches are interlocked to prevent simultaneous interconnection of the two power sources, and isolation of the transfer switch is usually accomplished by operation of a drawout handle. This type of construction should be used where continuity of electrical service to the emergency system is essential. See Exhibit 7.92.

7.9.2 Performance of System.

7.9.2.1* Emergency illumination shall be provided for not less than 1½ hours in the event of failure of normal lighting. Emergency lighting facilities shall be arranged to provide initial illumination that is not less than an average of 10.8 lux (1 ft-candle) and, at any point, not less than 1.1 lux (0.1 ft-candle), measured along the path of egress at floor level. Illumination levels shall be permitted to decline to not less than an average of 6.5 lux (0.6 ft-candle) and, at any point, not less than 6.5 lux (0.06 ft-candle) at the end of the 1½ hours. A maximum-to-minimum illumination uniformity ratio of 40 to 1 shall not be exceeded.

A.7.9.2.1 The illumination uniformity ratio is determined by the following formula:

$$\frac{\text{Maximum illumination at any point}}{\text{Minimum illumination at any point}}$$

The Code requires a 10.8-lux (1-ft-candle) average and establishes a 1.1-lux (0.1-ft-candle) minimum, with a uniformity ratio maximum of 40 to 1 to prevent excessively bright and dark spots.

7.9.2.2* The emergency lighting system shall be arranged to provide the required illumination automatically in the event of any interruption of normal lighting due to any of the following:

- (1) Failure of a public utility or other outside electrical power supply
- (2) Opening of a circuit breaker or fuse
- (3) Manual act(s), including accidental opening of a switch controlling normal lighting facilities

A.7.9.2.2 Where approved by the authority having jurisdiction, this requirement is permitted to be met by means such as the following.

- (1) Two separate electric lighting systems with independent wiring, each adequate alone to provide the specified lighting. One such system is permitted to be supplied from an outside source such as a public utility service and the other from an electric generator on the premises driven by an independent source of power. Both sources of illumination should be in regular simultaneous operation whenever the building is occupied during periods of darkness.
- (2) An electric circuit or circuits used only for means of egress illumination, with two independent electric sources arranged so that, on the failure of one, the other will automatically and immediately operate. One such source is permitted to be a connection from a public utility or similar outside power source and the other an approved storage battery with suitable provision to keep it automatically charged. Such a battery should be provided with automatic controls that, after operation of the battery due to failure of the primary power source or to turn-off the primary electric source for the lights, the battery will be shut off after its specified period of operation and will be automatically recharged and ready for further service when the primary current source is turned on again.
- (3) Electric battery-operated emergency lighting systems complying with the provisions of 7.9.2.2 and operating on a separate circuit and at a voltage different from that

of the primary light can be used where permitted. (See NFPA 70, *National Electrical Code*®.)

These requirements are not intended to prohibit the connection of a feeder serving exit lighting and similar emergency functions ahead of the service disconnecting means, but such provision does not constitute an acceptable alternate source of power. Such a connection furnishes only supplementary protection for emergency electrical functions, particularly where intended to allow the fire department to open the main disconnect without hampering exit activities. Provision should be made to alert the fire department that certain power and lighting is fed by an emergency generator and will continue operation after the service disconnect is opened.

Where emergency lighting is provided by automatic transfer between normal power service and an emergency generator, it is the intent to prohibit the installation, for any reason, of a single switch that can interrupt both energy sources.

Six methods of providing emergency power are recognized in NFPA 70, *National Electrical Code*; however, some of these sources do not meet the requirements for emergency lighting under the *Life Safety Code*.

Storage batteries are an acceptable emergency source and are permitted to be used to supply continuous, required emergency lighting. For this arrangement, two separate lighting systems with independent wiring are employed. One system is permitted to be supplied from a public utility, and the other from storage batteries. Each supply source must have sufficient capacity, and emergency lighting must be designed so that adequate light is available for a specified time if one system fails.

Instead of installing two separate wiring systems, a single emergency system connected to an automatic transfer switch is often used. The two sources of power, normal and emergency, are connected to the transfer switch, which automatically switches the emergency lighting load from the normal source to the emergency source upon loss of normal power. When normal power is restored, the emergency load is transferred back to the normal source.

Batteries that are used for the emergency source must be suitable for the application. Automotive-type batteries are not acceptable.

Where an on-site generator is the emergency power source, it is generally controlled by a transfer switch. Upon loss of normal emergency power, a signal is sent to start the generator. When the generator is running at rated speed and its output voltage is correct, the emergency load is connected to this

source by operation of the automatic transfer switch. This transfer must take place in 10 seconds or less. See Exhibit 7.93.

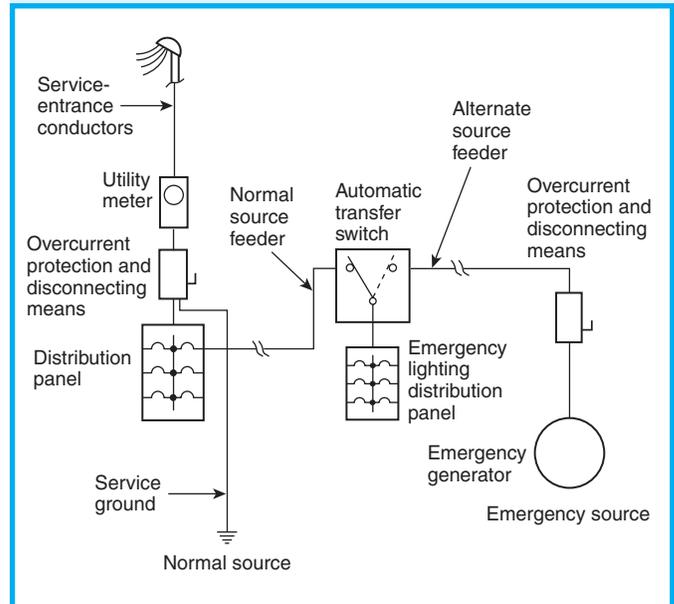

Exhibit 7.93 Arrangement of normal and alternate sources where emergency power is supplied from on-site generator.

Exhibit 7.94 shows two methods of obtaining an emergency power supply by connection ahead of the service disconnecting means. Although not prohibited by NFPA 70, this method does not comply with the requirements for emergency lighting of the *Life Safety Code* and might not be acceptable to the authority having jurisdiction. Before considering this method to supply emergency power for other than emergency lighting, the reliability of the utility system in the area must be evaluated, and the risk to building occupants must be carefully considered. This arrangement only provides protection from electrical failures in the occupancy, such as blown fuses, tripped circuit breakers, or a localized fire at such locations as the electrical service or distribution panels. In such instances, the availability of the emergency source is dependent on the reliability of the public utility.

The advantage of connecting the emergency lighting circuit to the main power line on the live side of the main disconnect is service continuity if the main switch is thrown by employees or fire fighters as a precautionary measure. The *Code* does not prohibit this practice; however, it should be noted that this method does not meet the requirements for emergency lighting.

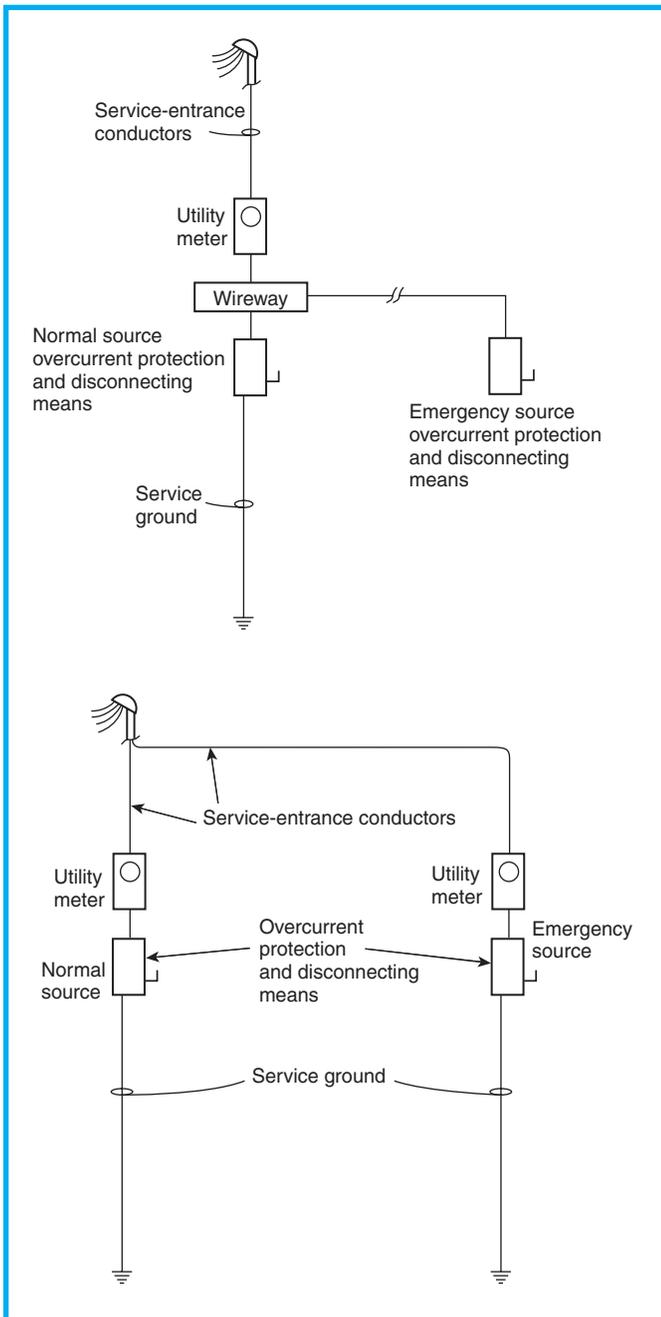

Exhibit 7.94 Two methods (not Life Safety Code-compliant) of obtaining an emergency source by connection ahead of service disconnecting means.

Two separate services, one for normal power and the other for emergency power, are also recognized by NFPA 70, subject to approval by the authority having jurisdiction but, again, not accepted by the *Life Safety Code* for emergency lighting. Usually, this method provides a higher degree of reliability than the connection ahead of the service disconnecting

means but does not satisfy the requirements of 7.9.2.2. However, underground loop systems in downtown areas of large cities are quite reliable. Many public utilities have not experienced an outage on their loop systems for many years, but there is no protection from any electrical failures that might occur outside of the occupancy. One way to reduce the possibility of simultaneous loss of both power sources is to use different voltages for the normal and emergency systems, taking power for each system from separate manholes or employing other schemes that provide both electrical and physical separation between the normal and emergency sources. See Exhibit 7.95.

Individual battery-operated lights can also be used for emergency lighting. Specific rules in NFPA 70 govern the installation of these products, referred to in NFPA 70 as *unit equipment*.

To qualify for emergency lighting, each unit equipment must have a rechargeable battery, a battery-charging means, provisions for one or more lamps, and a relay to energize the lamps automati-

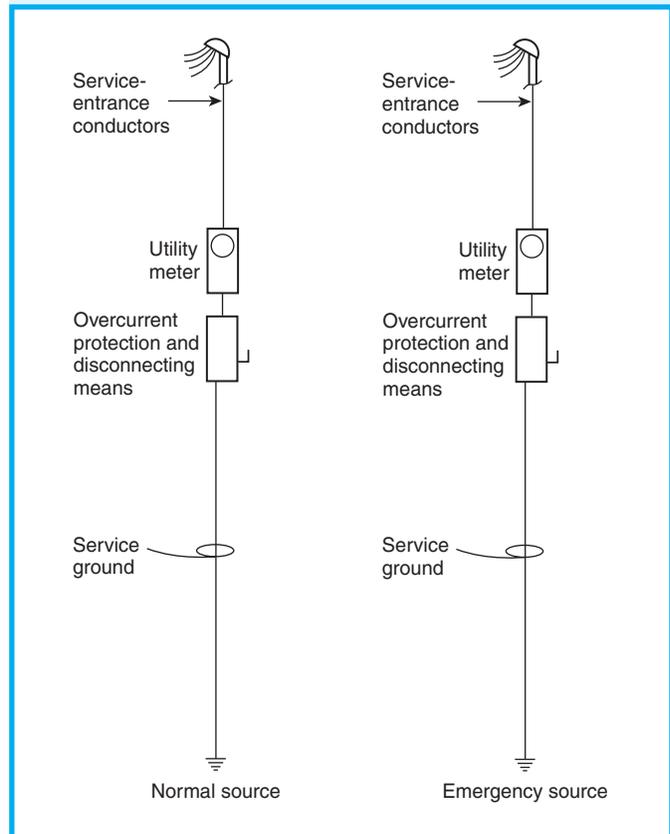

Exhibit 7.95 Two separate services to the same building permitted by NFPA 70, National Electrical Code, but not recognized by Life Safety Code for emergency lighting.

cally upon failure of the normal supply. Unit equipment must be connected to the same branch circuit that supplies normal lighting to the area in which the unit equipment is located. Connection to this branch circuit must be ahead of, or on the line side of, any switches controlling the normal lighting. An exception in NFPA 70 allows connection of unit equipment directly to a branch circuit from a panelboard that also supplies a minimum of three normal lighting circuits to the area in which the unit equipment is installed. The overcurrent device protecting this unit equipment circuit must be provided with a lock-on feature that will prevent accidental disconnection.

7.9.2.3 Emergency generators providing power to emergency lighting systems shall be installed, tested, and maintained in accordance with NFPA 110, *Standard for Emergency and Standby Power Systems*. Stored electrical energy systems, where required in this *Code*, shall be installed and tested in accordance with NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems*.

7.9.2.4* Battery-operated emergency lights shall use only reliable types of rechargeable batteries provided with suitable facilities for maintaining them in properly charged condition. Batteries used in such lights or units shall be approved for their intended use and shall comply with NFPA 70, *National Electrical Code*®.

A.7.9.2.4 Automobile-type lead storage batteries are not suitable by reason of their relatively short life when not subject to frequent discharge and recharge as occurs in automobile operation.

For proper selection and maintenance of appropriate batteries, see NFPA 70, *National Electrical Code*®.

7.9.2.5 The emergency lighting system shall be either continuously in operation or shall be capable of repeated automatic operation without manual intervention.

7.9.3 Periodic Testing of Emergency Lighting Equipment.

7.9.3.1 Required emergency lighting systems shall be tested in accordance with one of the three options offered by 7.9.3.1.1, 7.9.3.1.2, or 7.9.3.1.3.

7.9.3.1.1 Testing of required emergency lighting systems shall be permitted to be conducted as follows:

- (1) Functional testing shall be conducted at 30-day intervals for not less than 30 seconds.
- (2) Functional testing shall be conducted annually for not less than 1½ hours if the emergency lighting system is battery powered.

- (3) The emergency lighting equipment shall be fully operational for the duration of the tests required by 7.9.3.1.1(1) and 7.9.3.1.1(2).
- (4) Written records of visual inspections and tests shall be kept by the owner for inspection by the authority having jurisdiction.

7.9.3.1.2 Testing of required emergency lighting systems shall be permitted to be conducted as follows:

- (1) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall be provided.
- (2) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall automatically perform not less than once every 30 days a test for not less than 30 seconds and a diagnostic routine.
- (3) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall indicate failures by a status indicator.
- (4) A visual inspection shall be performed at intervals not exceeding 30 days.
- (5) Functional testing shall be conducted annually for not less than 1½ hours.
- (6) Self-testing/self-diagnostic battery-operated emergency lighting equipment shall be fully operational for the duration of the 1½ hour test.
- (7) Written records of visual inspections and tests shall be kept by the owner for inspection by the authority having jurisdiction.

7.9.3.1.3 Testing of required emergency lighting systems shall be permitted to be conducted as follows:

- (1) Computer-based, self-testing/self-diagnostic battery-operated emergency lighting equipment shall be provided.
- (2) The emergency lighting equipment shall automatically perform not less than once every 30 days a test for not less than 30 seconds and a diagnostic routine.
- (3) The emergency lighting equipment shall automatically perform annually a test for not less than 1½ hours.
- (4) The emergency lighting equipment shall be fully operational for the duration of the tests required by 7.9.3.1.3(2) and 7.9.3.1.3(3).
- (5) The computer-based system shall be capable of providing a report of the history of tests and failures at all times.

Section 7.10 Marking of Means of Egress

In the fatal Westchase Hilton Hotel fire, which occurred in Houston, Texas, in March of 1982, “several people were confused by the exit markings or the

similarity of exit doors and adjacent storage room doors. The directional exit signs within the exit foyers at the ends of the hotel corridors indicated that the exit path from this point would be perpendicular to the exit access corridor. Some of the occupants moved toward the locked storage room doors and away from the exits.²⁸⁷ See also commentary on Sections 7.8 and 7.9.

7.10.1 General.

7.10.1.1 Where Required. Means of egress shall be marked in accordance with Section 7.10 where required in Chapter 11 through Chapter 42.

Marking of means of egress is not required unless specifically called for by the applicable occupancy chapter. Subsection 12.2.10 of each occupancy chapter (for example, 12.2.10 for new assembly occupancies) details where exit signs and directional exit signs are required.

7.10.1.2* Exits. Exits, other than main exterior exit doors that obviously and clearly are identifiable as exits, shall be marked by an approved sign that is readily visible from any direction of exit access.

A.7.10.1.2 Where a main entrance serves also as an exit, it will usually be sufficiently obvious to occupants so that no exit sign is needed.

The character of the occupancy has a practical effect on the need for signs. In any assembly occupancy, hotel, department store, or other building subject to transient occupancy, the need for signs will be greater than in a building subject to permanent or semipermanent occupancy by the same people, such as an apartment house where the residents are presumed to be familiar with exit facilities by reason of regular use thereof. Even in a permanent residence-type building, however, there is need for signs to identify exit facilities such as outside stairs that are not subject to regular use during the normal occupancy of the building.

There are many types of situations where the actual need for signs is debatable. In cases of doubt, however, it is desirable to be on the safe side by providing signs, particularly because posting signs does not ordinarily involve any material expense or inconvenience.

The requirement for the locations of exit signs visible from any direction of exit access is illustrated in Figure A.7.10.1.2.

7.10.1.3 Exit Stair Door Tactile Signage. Tactile signage shall be provided to meet the following criteria, unless otherwise provided in 7.10.1.4:

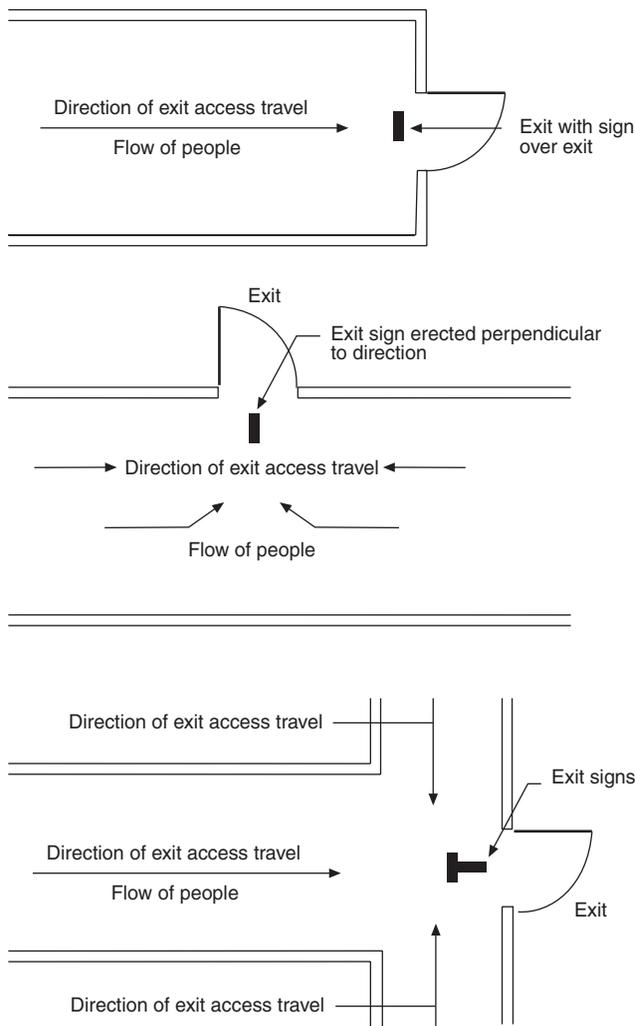

Figure A.7.10.1.2 Location of Exit Signs.

- (1) Tactile signage shall be located at each exit door requiring an exit sign.
- (2) Tactile signage shall read as follows:
EXIT
- (3) Tactile signage shall comply with ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*.

7.10.1.4 Existing Exemption. The requirements of 7.10.1.3 shall not apply to existing buildings, provided that the occupancy classification does not change.

The standardized location of required tactile signage permits persons with vision impairment to locate the sign easily. For the same reasons that the requirements of 7.5.4 on accessible means of egress are not

required for existing buildings, tactile signage is not required in existing buildings unless the occupancy classification changes. (Recall that under 4.6.12, the requirements applicable to new construction must be followed if the occupancy classification of an existing building changes.)

7.10.1.5 Exit Access.

7.10.1.5.1 Access to exits shall be marked by approved, readily visible signs in all cases where the exit or way to reach the exit is not readily apparent to the occupants.

7.10.1.5.2* New sign placement shall be such that no point in an exit access corridor is in excess of the rated viewing distance or 30 m (100 ft), whichever is less, from the nearest sign.

A.7.10.1.5.2 For externally illuminated signs in accordance with 7.10.6 and internally illuminated signs listed without a viewing distance, the rated viewing distance should be considered to be 30 m (100 ft). However, placing signs to meet the 30 m (100 ft) viewing distance in other than exit access corridors might create operating difficulties or encourage placement of a sign above the line of sight. To resolve the viewing distance versus placement issue, consideration should be given to increasing the level of illumination and the size of the exit legend to the viewing distance proportionally if signs are placed at greater distances.

The placement distance requirement in 7.10.1.5.2 applies only to new exit sign installations in corridors. Internally illuminated signs are required by 7.10.7.1 to be listed in accordance with UL 924, *Standard for Safety Emergency Lighting and Power Equipment*²⁹. The testing procedures of UL 924 determine a distance rating for the listed sign. Externally illuminated signs are not required to be listed and do not have a distance rating associated with them; however, they are subject to the maximum 30 m (100 ft) placement distance requirement.

The allowance by 7.10.1.5.2 to position internally illuminated signs based on their listed distance rating is another step toward promoting performance-based design in lieu of the traditional prescription-based approach [that is, use of the maximum 30-m (100-ft) distance]. Listed exit signs will be marked with a distance rating only if the rating is something other than the 30 m (100 ft) default value.

7.10.1.6* **Floor Proximity Exit Signs.** Where floor proximity exit signs are required in Chapter 11 through Chapter 42, such signs shall be located near the floor level in addition

to those signs required for doors or corridors. The signs shall be illuminated in accordance with 7.10.5. Externally illuminated signs shall be sized in accordance with 7.10.6.1. The bottom of the sign shall be not less than 150 mm (6 in.) but not more than 455 mm (18 in.) above the floor. For exit doors, the sign shall be mounted on the door or adjacent to the door, with the nearest edge of the sign within 100 mm (4 in.) of the door frame.

A.7.10.1.6 See A.7.10.3.

Because locations near the ceiling might be the first to become obstructed by smoke, the provision of 7.10.1.6 makes it possible for the occupancy chapters to specify floor proximity signs to supplement the regular exit signs that are usually placed above the exit doors or near the ceiling in corridors. They are not intended to replace standard exit signs but are designed as an extra asset to a building occupant seeking egress in a smoke-filled environment. Because the signs are positioned near the floor, they will be among the last signs to become obscured by the descending smoke layer.

The provisions of 7.10.1.6 can be used as guidance on the placement and installation of floor proximity signs, even though they might not be required.

The only occupancies currently mandating floor proximity exit signs are assembly occupancies, where they are required in special amusement buildings in accordance with the provisions of 12.4.7.7.2 and 13.4.7.7.2.

7.10.1.7* **Floor Proximity Egress Path Marking.** Where floor proximity egress path marking is required in Chapter 11 through Chapter 42, a listed and approved floor proximity egress path marking system that is internally illuminated shall be installed within 455 mm (18 in.) of the floor. The system shall provide a visible delineation of the path of travel along the designated exit access and shall be essentially continuous, except as interrupted by doorways, hallways, corridors, or other such architectural features. The system shall operate continuously or at any time the building fire alarm system is activated. The activation, duration, and continuity of operation of the system shall be accordance with 7.9.2.

A.7.10.1.7 See 3.3.114.2 for definition of *internally illuminated*.

Paragraph 7.10.1.7 provides a standard for floor proximity egress path marking for mandatory use by the occupancy chapters or for voluntary use by any party.

This type of marking has been mandatory on aircraft for several years. It is not mandatory for any occupancy under the *Code*. However, it could be used as part of the directional exit marking system required for special amusement buildings by the provisions of 12.4.7.7.3 and 13.4.7.7.3.

7.10.1.8* Visibility. Every sign required in Section 7.10 shall be located and of such size, distinctive color, and design that it is readily visible and shall provide contrast with decorations, interior finish, or other signs. No decorations, furnishings, or equipment that impairs visibility of a sign shall be permitted. No brightly illuminated sign (for other than exit purposes), display, or object in or near the line of vision of the required exit sign that could detract attention from the exit sign shall be permitted.

In some locations, an otherwise adequate exit sign or directional exit sign might be rendered inconspicuous by a high-intensity illuminated advertising sign in the immediate vicinity. For this reason, such signs are not allowed in the line of vision of any required sign addressed by Section 7.10.

The location of exit signs and directional exit signs is not specified. Usually they are placed above exit doors and near the ceiling. There are those who argue, with reason, that smoke builds up more rapidly at higher levels, and signs positioned near the floor would be visible for a much longer time during a fire. However, when several people are moving toward an exit, those in the rear might not be able to see signs located near the floor because of the obstruction created by others. Also, in the absence of careful housekeeping, such signs might be damaged or blocked. Thus, the *Code* simply states that exit signs and directional exit signs are to be located to be readily visible and to provide contrast with their surroundings. See also 7.10.1.6 and its related commentary.

A.7.10.1.8 In stores, for example, an otherwise adequate exit sign could be rendered inconspicuous by a high-intensity illuminated advertising sign located in the immediate vicinity.

Red is the traditional color for exit signs and is required by law in many places. However, at an early stage in the development of the *Code*, a provision made green the color for exit signs, following the concept of traffic lights in which green indicates safety and red is the signal to stop. During the period when green signs were specified by the *Code*, many such signs were installed, but the traditional red signs

also remained. In 1949, the Fire Marshals Association of North America voted to request that red be restored as the required exit sign color, because it was found that the provision for green involved difficulties in law enactment that were out of proportion to the importance of safety. Accordingly, the 10th edition of the *Code* specified red where not otherwise required by law. The present text avoids any specific requirement for color on the assumption that either red or green will be used in most cases and that there are some situations in which a color other than red or green could actually provide better visibility.

As indicated in A.7.10.1.8, the issue of sign color has been the subject of considerable debate. The *Building Exits Code* required, from its first edition in 1927 through 1947, that exit signs use white letters on a green field, unless such color was contrary to local law. The annex text in A.7.10.1.8 describes the development of events since 1949. Currently, color is not specified.

7.10.1.9 Mounting Location. The bottom of new egress markings shall be located at a vertical distance of not more than 2030 mm (80 in.) above the top edge of the egress opening intended for designation by that marking. Egress markings shall be located at a horizontal distance of not more than the required width of the egress opening, as measured from the edge of the egress opening intended for designation by that marking to the nearest edge of the marking.

7.10.2* Directional Signs.

A sign complying with 7.10.3 with a directional indicator showing the direction of travel shall be placed in every location where the direction of travel to reach the nearest exit is not apparent.

A.7.10.2 A sign complying with 7.10.2 and indicating the direction of the nearest approved exit should be placed at the point of entrance to any escalator or moving walk. (See A.7.10.3.)

Subsection 7.10.2 mandates that a directional sign is to be placed where the direction of travel to reach the nearest exit is not apparent. The directional sign uses an exit sign to which one or two directional indicators are added. For externally illuminated signs, which are not required to be laboratory listed, the detailed criteria for the directional indicator appear in 7.10.6.2. Internally illuminated signs, which are required be tested and listed in accordance with

UL 924, *Standard for Safety Emergency Lighting and Power Equipment*, have their directional indicators evaluated by the performance criteria of the UL 924 test procedure; they are exempt from the specification-based criteria of 7.10.6.2.

The requirement of 7.10.2 is somewhat performance-based in that it adds another directional exit sign wherever the direction of travel to reach the *nearest* exit is not apparent. The enforcement of this provision will typically be somewhat subjective, because a judgment call must be made as to whether the direction of travel to reach the nearest exit is apparent. A strict reading and application of the requirement, especially with respect to the word *nearest*, could conceivably lead to the installation of many more signs than are practically needed.

See Exhibit 7.96, which depicts a warehouse with storage racks and aisles. The racks are of sufficient height and construction to prevent an occupant from seeing either of the exit doors from the building. The designer is charged with specifying exit sign and directional sign placement that meets the provisions of Section 7.10. An occupant standing at point X within an aisle has a choice of many possible paths for travel to the two exit doors; there are no dead-end aisles in

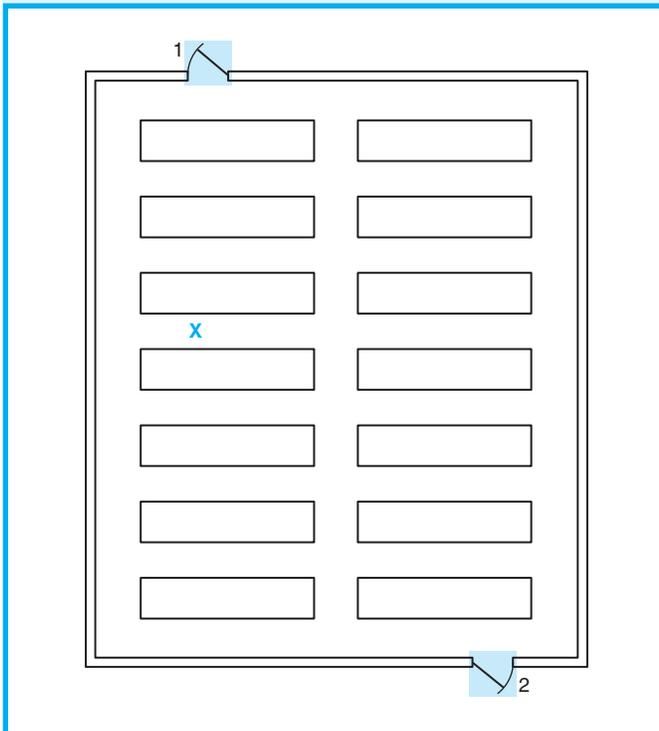

Exhibit 7.96 Warehouse exit sign and directional sign placement to be determined.

which to become trapped. The criterion test for exit sign placement is 7.10.2, which requires that a directional sign be placed in every location where the direction of travel to reach the *nearest* exit is not apparent. Exit door 1 is the nearest exit, but neither exit door 1 nor exit door 2 can be seen from within the aisle or from within any of the three cross-aisles. A strict interpretation of 7.10.2, coupled with the requirement of 7.10.1.2 that the exit doors themselves be provided with exit signs, could lead to the installation of 20 signs as shown in Exhibit 7.97. A reasonable person would argue that it is neither unreasonable nor unsafe to reduce the number of signs so as to require the occupant to travel to either of the two nearest cross-aisles in order to see a directional sign that leads to an exit. A check for reasonableness could lead to the placement of eight signs as shown in Exhibit 7.98.

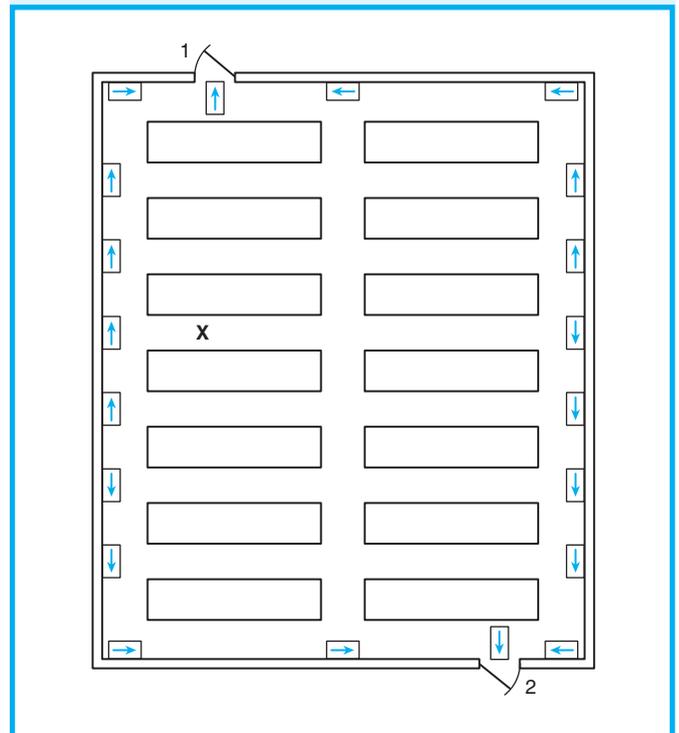

Exhibit 7.97 Excessive placement of directional signs.

7.10.3* Sign Legend.

A.7.10.3 Where graphics are used, the symbols provided in NFPA 170, *Standard for Fire Safety Symbols*, should be used. Such signs need to provide equal visibility and illumination and are to comply with the other requirements of Section 7.10.

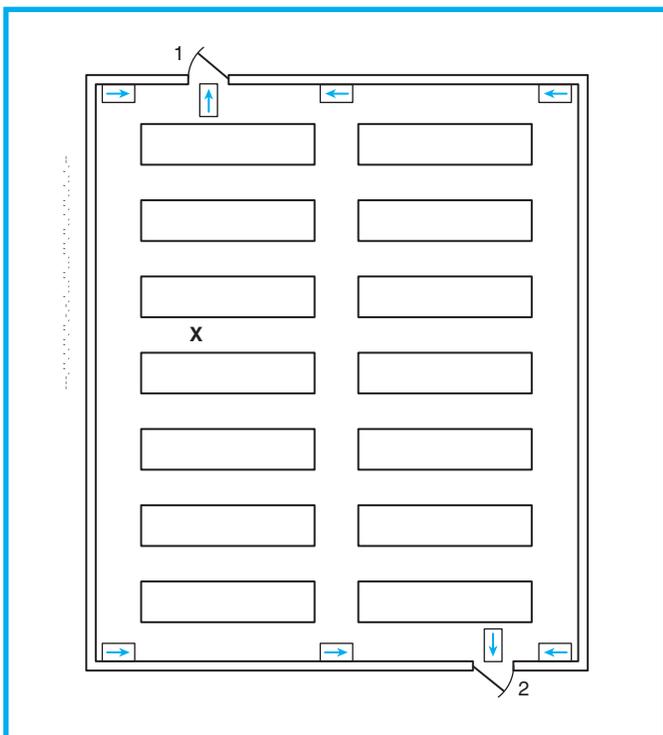

Exhibit 7.98 Reasonable placement of directional signs.

7.10.3.1 Signs required by 7.10.1 and 7.10.2 shall read as follows in plainly legible letters, or other appropriate wording shall be used:

EXIT

7.10.3.2* Where approved by the authority having jurisdiction, pictograms shall be permitted.

A.7.10.3.2 Pictograms may be used in lieu of, or in addition to, signs with text.

Paragraph 7.10.3.1 permits other wording in lieu of the word EXIT where the alternative wording is appropriate. In countries where Spanish is the predominant language, one might find the word SALIDA. In Canada, where signage appears in both French and English, exit signs have been increased in size to accommodate the words EXIT and SORTIE.

Although 7.10.3.1 refers to wording “in plainly legible letters,” it is evident from the language of 7.10.3.2 that it is not the intent to prohibit graphics in lieu of words. Graphics have the advantage of being nonspecific to a written language.

NFPA 170, *Standard for Fire Safety Symbols*³⁰, provides a symbol for an emergency exit that should be

considered the equivalent of the *Life Safety Code’s* exit sign. NFPA 170 also provides two symbols that—when used together—designate an emergency exit route. This diptych uses the emergency exit symbol and an arrow symbol and should be considered the equivalent of the *Code’s* directional exit sign. See Exhibits 7.99 and 7.100.

Exhibit 7.99 NFPA 170 symbol for emergency exit.

Exhibit 7.100 NFPA 170 symbols for emergency exit route.

7.10.4* Power Source.

Where emergency lighting facilities are required by the applicable provisions of Chapter 11 through Chapter 42 for individual occupancies, the signs, other than approved self-luminous signs, shall be illuminated by the emergency lighting facilities. The level of illumination of the signs shall be in accordance with 7.10.6.3 or 7.10.7 for the required emergency lighting duration as specified in 7.9.2.1. However, the level of illumination shall be permitted to decline to 60 percent at the end of the emergency lighting duration.

A.7.10.4 It is not the intent of this paragraph to require emergency lighting but only to have the sign illuminated by emergency lighting if emergency lighting is required and provided.

It is not the intent to require that the entire stroke width and entire stroke height of all letters comprising the word EXIT be visible per the requirements of 7.10.6.3 under normal or emergency lighting operation, provided that the sign

is visible and legible at a 30-m (100-ft) distance under all room illumination conditions.

The text of A.7.10.4 explains that it is not the intent of 7.10.4 to require an emergency power source for the illumination of exit signs. Rather, it is the intent that the required exit signs be provided with emergency power if the occupancy is required to have emergency lighting. For example, there are business occupancies that are small enough to be exempt from the emergency lighting requirement of 38.2.9.1 and 39.2.9.1. Yet, business occupancies are required to have exit signs in accordance with Section 7.10. Such exit signs are required to be illuminated per 7.10.5.1. In the small business occupancy that is exempt from emergency lighting, if a power failure occurs, the exit signs are permitted to go dark. The business occupancy example can be contrasted with an assembly occupancy. Assembly occupancies are required to have emergency lighting and exit signs. The exit signs must be illuminated in accordance with 7.10.5.1 when the building's normal power is available; the illumination must also be maintained in accordance with 7.10.4 upon failure of the normal power service.

7.10.5 Illumination of Signs.

7.10.5.1* General. Every sign required by 7.10.1.2 or 7.10.1.5, other than where operations or processes require low lighting levels, shall be suitably illuminated by a reliable light source. Externally and internally illuminated signs shall be legible in both the normal and emergency lighting mode.

A.7.10.5.1 See A.7.8.1.3(4).

Internally illuminated signs are particularly useful in occupancies where reduction of normal illumination is permitted, such as in movie theaters. However, the intent of 7.10.5.1 is to treat externally illuminated and internally illuminated signs equally, with no preference shown to one or the other. Subsequent subsections then treat each type of sign via a specialized package of requirements, such as 7.10.6 for externally illuminated signs and 7.10.7 for internally illuminated signs. This format is provided because externally illuminated signs are not required to be tested and listed by a laboratory. Due to the lack of testing, it is necessary for the *Code* to specify detailed criteria such as the letter height and stroke width addressed in 7.10.6.1.1 and illumination levels as addressed in 7.10.6.3. Because internally illuminated signs must be laboratory tested and listed, the *Code* can rely on the listing to ensure that necessary criteria are met.

7.10.5.2* Continuous Illumination.

A.7.10.5.2 It is the intent to prohibit a freely accessible light switch to control the illumination of either an internally or externally illuminated exit sign.

7.10.5.2.1 Every sign required to be illuminated by 7.10.6.3 and 7.10.7 shall be continuously illuminated as required under the provisions of Section 7.8 unless otherwise provided in 7.10.5.2.2.

7.10.5.2.2* Illumination for signs shall be permitted to flash on and off upon activation of the fire alarm system.

A.7.10.5.2.2 The flashing repetition rate should be approximately one cycle per second, and the duration of the off-time should not exceed $\frac{1}{4}$ second per cycle. During on-time, the illumination levels need to be provided in accordance with 7.10.6.3. Flashing signs, when activated with the fire alarm system, might be of assistance.

7.10.6 Externally Illuminated Signs.

7.10.6.1* Size of Signs.

A.7.10.6.1 Experience has shown that the word EXIT or other appropriate wording is plainly legible at 30 m (100 ft) if the letters are as large as specified in 7.10.6.1.

7.10.6.1.1 Externally illuminated signs required by 7.10.1 and 7.10.2, other than approved existing signs, unless otherwise provided in 7.10.6.1.2, shall read EXIT, or other appropriate wording shall be used, in plainly legible letters sized as follows:

- (1) For new signs, the letters shall be not less than 150 mm (6 in.) high, with the principal strokes of letters not less than 19 mm ($\frac{3}{4}$ in.) wide.
- (2) For existing signs, the required wording shall be permitted to be in plainly legible letters not less than 100 mm (4 in.) high.
- (3) The word EXIT shall be in letters of a width not less than 51 mm (2 in.), except the letter I, and the minimum spacing between letters shall be not less than 9.5 mm ($\frac{3}{8}$ in.).
- (4) Sign legend elements larger than the minimum established in 7.10.6.1.1(1) through 7.10.6.1.1(3) shall use letter widths, strokes, and spacing in proportion to their height.

7.10.6.1.2 The requirements of 7.10.6.1.1 shall not apply to marking required by 7.10.1.3 and 7.10.1.6.

Traditionally, the letters in an exit sign have been required to be 150 mm (6 in.) in height with the principal strokes not less than 19 mm ($\frac{3}{4}$ in.) wide. In an effort to increase visibility, the *Code* requires that the

letters, other than *I*, be at least 51 mm (2 in.) wide and have a minimum spacing between letters of 9.5 mm (3/8 in.). These dimensional criteria have been maintained, but they apply only to externally illuminated signs. Internally illuminated signs are exempt from these criteria because they must be tested and listed in accordance with UL 924, *Standard for Safety Emergency Lighting and Power Equipment*. The UL 924 test procedures include assessing the readability of a sign's letters.

7.10.6.2* Size and Location of Directional Indicator.

A.7.10.6.2 Figure A.7.10.6.2 shows examples of acceptable locations of directional indicators with regard to left and right orientation. Directional indicators are permitted to be placed under the horizontal stroke of the letter T, provided that spacing of not less than 9.5 mm (3/8 in.) is maintained from the horizontal and vertical strokes of the letter T.

Figure A.7.10.6.2 Directional Indicators.

7.10.6.2.1 Directional indicators, unless otherwise provided in 7.10.6.2.2, shall comply with the following:

- (1) The directional indicator shall be located outside of the EXIT legend, not less than 9.5 mm (3/8 in.) from any letter.
- (2) The directional indicator shall be of a chevron type, as shown in Figure 7.10.6.2.1.
- (3) The directional indicator shall be identifiable as a directional indicator at a distance of 12 m (40 ft).
- (4) A directional indicator larger than the minimum established for compliance with 7.10.6.2.1(3) shall be proportionately increased in height, width and stroke.
- (5) The directional indicator shall be located at the end of the sign for the direction indicated.

Figure 7.10.6.2.1 Chevron-Type Indicator.

7.10.6.2.2 The requirements of 7.10.6.2.1 shall not apply to approved existing signs.

To improve the effectiveness of directional indicators on directional exit signs, the requirements have been changed over the past several years. The directional indicator cannot be positioned between the letters in the word EXIT. The directional indicator, which formerly was an arrow, must be a chevron. Research showed that a chevron indicator was more effective than an arrow. Performance criteria are specified to ensure that the chevron is of adequate size, contrast, and illumination. A specific size is not required, because size depends on factors such as color, contrast, and illumination. However, the directional indicator must be identifiable as a directional indicator at a minimum distance of 12.2 m (40 ft), which is another performance-based requirement.

7.10.6.3* Level of Illumination. Externally illuminated signs shall be illuminated by not less than 54 lux (5 ft-candles) at the illuminated surface and shall have a contrast ratio of not less than 0.5.

A.7.10.6.3 Colors providing a good contrast are red or green letters on matte white background. Glossy background and glossy letter colors should be avoided.

The average luminance of the letters and background is measured in footlamberts or candela per square meter. The contrast ratio is computed from these measurements by the following formula:

$$\text{Contrast} = \frac{L_g - L_e}{L_g}$$

Where L_g is the greater luminance and L_e is the lesser luminance, either the variable L_g or L_e is permitted to represent the letters, and the remaining variable will represent the background. The average luminance of the letters and background can be computed by measuring the luminance at the positions indicated in Figure A.7.10.6.3 by numbered spots.

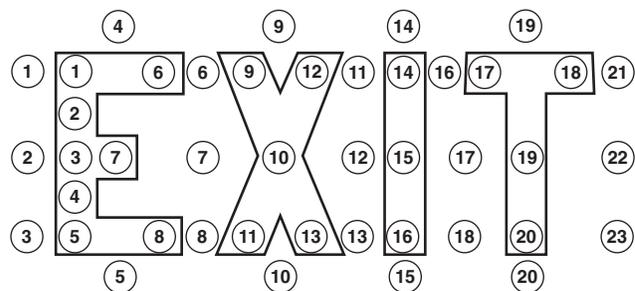

Figure A.7.10.6.3 Measurement of Exit Sign Luminance.

7.10.7 Internally Illuminated Signs.

7.10.7.1 Listing. Internally illuminated signs shall be listed in accordance with UL 924, *Standard for Safety Emergency Lighting and Power Equipment*, unless they meet one of the following criteria:

- (1) They are approved existing signs.
- (2) They are existing signs having the required wording in legible letters not less than 100 mm (4 in.) high.
- (3) They are signs that are in accordance with 7.10.1.3 and 7.10.1.6.

Internally illuminated signs must be laboratory tested and listed in accordance with UL 924, *Standard for Safety Emergency Lighting and Power Equipment*. Reliance is placed on the laboratory having conducted a comprehensive examination. By relying on the laboratory listing, the *Code* does not need to address the detailed criteria that it requires of externally illuminated signs, which are not required to be listed.

7.10.7.2* Photoluminescent Signs. The face of a photoluminescent sign shall be continually illuminated while the building is occupied. The illumination levels on the face of the photoluminescent sign shall be in accordance with its listing. The charging illumination shall be a reliable light source as determined by the authority having jurisdiction. The charging light source shall be of a type specified in the product markings.

A.7.10.7.2 Photoluminescent signs need a specific minimum level of light on the face of the sign to ensure that the sign is charged for emergency operation and legibility in both the normal and emergency modes. Additionally, the type of light source (for example, incandescent, fluorescent, halogen, metal halide) is important. Each light source produces different types of visible and invisible light (for example, UV) that might affect the ability of some photoluminescent signs to charge and might also affect the amount of light output available during emergency mode. This type of sign would not be suitable where the illumination levels are permitted to decline. The charging light source should not be connected to automatic timers, because the continuous illumination of the sign is needed; otherwise, the sign illumination would not be available because it would be discharged.

A photoluminescent sign absorbs light from an activation light source in order to emit light (that is, luminesce). The sign continues to emit light for a time after the activation light source has been removed.

The requirements of 7.10.7.2 for photoluminescent signs were new to the 2000 edition of the *Code*. Note that these requirements are contained as a subset of the internally illuminated sign requirements of 7.10.7. A photoluminescent sign is an internally illuminated sign. Photoluminescent exit signs are permitted, provided that they are listed in accordance with UL 924, *Standard for Safety Emergency Lighting and Power Equipment* and meet the criteria of 7.10.7.2. The criteria of 7.10.7.2 are meant to highlight some of the special considerations needed to use photoluminescent exit signs effectively for life safety.

7.10.8 Special Signs.

7.10.8.1 Sign Illumination.

7.10.8.1.1 Where required by other provisions of this *Code*, special signs shall be illuminated.

7.10.8.1.2 Where emergency lighting facilities are required by the applicable provisions of Chapter 12 through Chapter 42, the required illumination of special signs shall additionally be provided under emergency lighting conditions.

7.10.8.2 Characters. Special signs, where required by other provisions of this *Code*, shall comply with the visual character requirements of ICC/ANSI A117.1 *American National Standard for Accessible and Usable Buildings and Facilities*.

7.10.8.3* No Exit.

A.7.10.8.3 The likelihood of occupants mistaking passageways or stairways that lead to dead-end spaces for exit doors and becoming trapped governs the need for exit signs. Thus, such areas should be marked with a sign that reads as follows:

NO EXIT

Supplementary identification indicating the character of the area, such as TO BASEMENT, STOREROOM, LINEN CLOSET, or the like, is permitted to be provided.

7.10.8.3.1 Any door, passage, or stairway that is neither an exit nor a way of exit access and that is located or arranged so that it is likely to be mistaken for an exit shall be identified by a sign that reads as follows:

NO
EXIT

7.10.8.3.2 The NO EXIT sign shall have the word NO in letters 51 mm (2 in.) high, with a stroke width of 9.5 mm ($\frac{3}{8}$ in.), and the word EXIT in letters 25 mm (1 in.) high, with the word EXIT below the word NO, unless such sign is an approved existing sign.

7.10.8.4 Elevator Signs. Elevators that are a part of a means of egress (*see* 7.2.13.1) shall have signs with a minimum letter height of 16 mm (5/8 in.) posted in every elevator lobby as follows:

- (1)* Signs that indicate that the elevator can be used for egress, including any restrictions on use

A.7.10.8.4(1) These signs are to be used in place of signs that indicate that elevators are not to be used during fires. Examples of these signs include the following:

In The Event of Fire, This Elevator Will Be Used
by the Fire Department for Evacuation of People.

PROTECTED ELEVATOR—
USABLE IN EMERGENCIES

- (2)* Signs that indicate the operational status of elevators

A.7.10.8.4(2) The wording of these signs should reflect human behavior in fires and the control specifics of the elevator system. Subparagraph 7.10.8.4 addresses signs, but provisions for notification of the vision impaired need to be considered. For information about human behavior with respect to elevator evacuation see Groner and Levin, “Human Factors Considerations in the Potential for Using Elevators in Building Emergency Evacuation Plans”; Levin and Groner, “Human Behavior Aspects of Staging Areas for Fire Safety in GSA Buildings”; and Levin and Groner, “Human Factors Considerations for the Potential Use of Elevators for Fire Evacuation of FAA Air Traffic Control Towers.” Some examples of messages on signs that could be displayed are shown in Table A.7.10.8.4(2).

Table A.7.10.8.4(2) Elevator Status Messages

Elevator Status	Message
Normal use	Elevator in Service
Elevators recalled and waiting for fire service	Please Wait for Fire Department or Use Stairs
Elevator out of service	Elevator Out of Service

The requirements in 7.10.8.4 for elevator signs apply only where the elevator is part of the means of egress. The only current application is for elevators used as the second means of egress from a tower. See 7.2.13.1.

7.10.9 Testing and Maintenance.

7.10.9.1 Inspection. Exit signs shall be visually inspected for operation of the illumination sources at intervals not to exceed 30 days, or shall be periodically monitored in accordance with 7.9.3.1.3.

7.10.9.2 Testing. Exit signs connected to or provided with a battery-operated emergency illumination source, where required in 7.10.4, shall be tested and maintained in accordance with 7.9.3.

Section 7.11 Special Provisions for Occupancies with High Hazard Contents

See Section 6.2.

The wording associated with the classification of *high hazard contents* from 6.2.2.4 states that “high hazard contents shall be classified as those that are likely to burn with extreme rapidity or from which explosions are likely.”

7.11.1* Where the contents are classified as high hazard, exits shall be provided and arranged to allow all occupants to escape from the building or structure or from the hazardous area thereof to the outside or to a place of safety with a travel distance of not more than 23 m (75 ft), measured as required in 7.6.1, unless otherwise provided in 7.11.2.

A.7.11.1 Twenty-three meters (75 ft) can be traversed in approximately 10 seconds to 15 seconds, even when allowing for a momentary delay to decide which way to go, during which it can be assumed that the average individual can hold his or her breath.

Subsection 7.11.1 does not limit occupants to a 23-m (75-ft) travel distance, but requires escape from the hazardous area itself with no more than 23 m (75 ft) of travel. The place of safety outside the hazardous area is permitted to be within the building’s exit access; additional travel might be necessary to reach an exit.

7.11.2 The requirement of 7.11.1 shall not apply to storage occupancies as otherwise provided in Chapter 42.

7.11.3 Egress capacity for high hazard contents areas shall be based on 18 mm/person (0.7 in./person) for stairs or 10 mm/person (0.4 in./person) for level components and ramps in accordance with 7.3.3.1.

7.11.4 Not less than two means of egress shall be provided from each building or hazardous area thereof, unless all of the following criteria are met:

- (1) Rooms or spaces do not exceed 18.6 m² (200 ft²).
- (2) Rooms or spaces have an occupant load not exceeding three persons.
- (3) Rooms or spaces have a travel distance to the room door not exceeding 7620 mm (300 in.).

Subsection 7.11.4 recognizes that it is not always necessary or feasible to provide two ways out of very small high hazard contents spaces. Provided that all three conditional features—limited room area, occupant load, and travel distance—can be met, a single means of egress is permitted.

7.11.5 Means of egress, for rooms or spaces other than those that meet the criteria of 7.11.4(1) through 7.11.4(3), shall be arranged so that there are no dead ends in corridors.

7.11.6 Doors serving high hazard contents areas with occupant loads in excess of five shall be permitted to be provided with a latch or lock only if the latch or lock is panic hardware or fire exit hardware complying with 7.2.1.7.

It is not the intent of the *Code* to apply the provisions of Section 7.11 to the hazardous areas addressed by subsection 7.11.3.2 of each occupancy chapter. Those hazardous areas are generally rooms or spaces with contents that make them somewhat more hazardous than the rooms or spaces normally associated with a given occupancy. For example, soiled linen storage rooms in a health care occupancy create contents that are more hazardous than those within a patient room, but they don't create a hazard that warrants protection by Section 7.11. The decision as to when an area is sufficiently hazardous to warrant protection by the requirements of Section 7.11 is left to the authority having jurisdiction.

Section 7.12 Mechanical Equipment Rooms, Boiler Rooms, and Furnace Rooms

Section 7.12 applies to mechanical equipment rooms, boiler rooms, and furnace rooms in all buildings, regardless of occupancy. The number of exits and common path of travel limitations in these spaces are addressed independent of the occupancy in which they are located. The presence of these rooms does not result in a facility being designated a mixed occupancy.

7.12.1 Mechanical equipment rooms, boiler rooms, furnace rooms, and similar spaces shall be arranged to limit common path of travel to a distance not exceeding 15 m (50 ft), unless otherwise permitted by the following:

- (1) A common path of travel not exceeding 30 m (100 ft) shall be permitted in the following locations:
 - (a) In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7
 - (b) In mechanical equipment rooms with no fuel-fired equipment
 - (c) In existing buildings
- (2) In an existing building, a common path of travel not exceeding 46 m (150 ft) shall be permitted if all of the following criteria are met:
 - (a) The building is protected throughout by an approved, supervised automatic sprinkler system installed in accordance with Section 9.7
 - (b) No fuel-fired equipment is within the space.
 - (c) The egress path is readily identifiable.
- (3) The requirement of 7.12.1 shall not apply to rooms or spaces in existing health care occupancies complying with the arrangement of means of egress provisions of 19.2.5 and the travel distance limits of 19.2.6.

7.12.2 Stories used exclusively for mechanical equipment, furnaces, or boilers shall be permitted to have a single means of egress where the travel distance to an exit on that story is not in excess of the common path of travel limitations of 7.12.1.

Paragraph 7.12.2 is especially useful in equipment penthouses and for basement furnace and boiler rooms. As long as the common path of travel specified by 7.12.1 is not exceeded, a story used exclusively for mechanical equipment, boilers, or furnaces is permitted to be served by a single exit.

CHAPTER 8

Features of Fire Protection

Chapter 8 establishes basic requirements for features of fire protection, which include the following:

- (1) Construction
- (2) Compartmentation through use of fire barriers
- (3) Protection of vertical openings
- (4) Protection of concealed spaces
- (5) Subdivision of building space through use of smoke barriers and smoke partitions
- (6) Protection from hazards

This chapter specifies a menu of protection options that are mandated to varying degrees by specific occupancy chapters. Some of the provisions apply as requirements to all occupancies.

While the title suggests that the chapter encompasses any and all subject matter dealing with fire protection and fire safety, Chapter 8 focuses on a number of building features that contribute to minimizing the impact of a fire on the building occupants. The bulk of this protection scheme is associated with a series of methods and techniques that are used to control the construction and compartmentation features of a building.

Managing the spread of a fire from the room of origin, or between floors in a building, is an important consideration. Section 8.2 addresses methods used to separate and compartmentalize egress components such as stairs and corridors. Some means of egress components such as exit stairs are designed to be safe havens once an occupant reaches them. This chapter provides the level of detail needed to keep heat, fire, and smoke out of such areas.

The *Code* mandates that openings through or into separated areas be protected with appropriately rated doors, windows, or other devices that will pre-

vent or minimize the movement of the products of combustion into or through these areas.

Recognizing that there are acceptable, safe methods for permitting building spaces to be open to each other, Chapter 8 addresses openings between floors, such as an atrium opening that communicates among the multiple floors of a building.

Section 8.1 General

8.1.1 Application.

The features of fire protection set forth in this chapter shall apply to both new construction and existing buildings.

Lack of compartmentation and rapid fire development have been significant factors in numerous multiple-fatality fires, especially in residential occupancies. Smoke spread throughout a floor not subdivided by smoke barriers has been identified as a factor contributing to loss of life in fires reported in health care occupancies. Unprotected vertical openings have repeatedly provided the route for fire spread in various occupancies. The ongoing role played by these factors in fires demonstrates the need to apply Chapter 8 requirements to both new construction and existing buildings.

8.1.2 Automatic Sprinkler Systems.

Where another provision of this chapter requires an automatic sprinkler system, the automatic sprinkler system shall be installed in accordance with the subparts of 9.7.1.1 as permitted by the applicable occupancy chapter.

Section 8.2 Construction and Compartmentation

The general requirements in Section 8.2 limit smoke and fire penetration and protect exit access corridors, exits, and other areas of the building from fire in adjoining areas and on other floors. Construction and compartmentation requirements vary by occupancy and are specified in Chapters 12 through 42 of the *Code*.

To preserve the integrity of the compartment, or safe area, all openings for doors, ducts, and building services (for example, electric power, telephone, water supply, and waste lines) must also be effectively closed or fitted with automatic closures. Equally important, and sometimes overlooked, are concealed spaces, particularly those above suspended ceilings, that frequently have been the means of spreading fire into otherwise protected areas¹. In some instances, these interstitial spaces might be 2440 mm (96 in.) or more in height; in others, they might serve as supply- or return-air plenum chambers for air conditioning systems. Proper protection of concealed spaces can include firestopping, draftstopping, automatic extinguishment, area limitations, and other limitations on the combustibility of contents, interior linings, and construction materials. For specific concealed space protection details, see 8.6.10.

In Section 8.2, and throughout the *Code*, a distinction is made between smoke partitions, smoke barriers, and fire barriers. The function of a smoke partition and a smoke barrier is to restrict the passage of smoke, including fire gases. The fire barrier needs to be reasonably airtight under increased air pressure on the fire side from heated air expansion and must prevent the passage of heat and flame for a designated time. The fire barrier also must be capable of withstanding direct impingement by the fire as determined by large-scale tests conducted in accordance with the following:

- (1) NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*²
- (2) NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*³

8.2.1 Construction.

8.2.1.1 Buildings or structures occupied or used in accordance with the individual occupancy chapters, Chapter 12 through Chapter 42, shall meet the minimum construction requirements of those chapters.

8.2.1.2* NFPA 220, *Standard on Types of Building Construction*, shall be used to determine the requirements for the construction classification.

A.8.2.1.2 Table A.8.2.1.2 is Table 3.1 from NFPA 220, *Standard on Types of Building Construction*, and is reproduced in this annex for the convenience of users of this *Code*.

The *Code* is not a building code. However, in certain occupancies, minimum construction requirements are established to help maintain structural integrity for the time needed for evacuation. In the case of health care occupancies, an even longer time is needed to ensure the safety of nonambulatory occupants; a safe fire and smoke compartment needs to be established within the building but away from the zone of fire origin.

Minimum construction requirements are not mandated by 8.2.1; however, the detailed classification criteria of NFPA 220, *Standard on Types of Building Construction*, are referenced⁴. Therefore, construction types specified in other sections of the *Code* (particularly in Chapters 12 through 42—the occupancy chapters) can use a shorthand notation, such as Type I(332), without additional, expansive detail. The user then refers to NFPA 220 for the necessary details.

8.2.1.3 Where the building or facility includes additions or connected structures of different construction types, the rating and classification of the structure shall be based on one of the following:

- (1) Separate buildings, if a 2-hour or greater vertically aligned fire barrier wall in accordance with NFPA 221, *Standard for Fire Walls and Fire Barrier Walls*, exists between the portions of the building
- (2) Separate buildings, if provided with previously approved separations
- (3) The least fire-resistive type of construction of the connected portions, if separation as specified in 8.2.1.3(1) or 8.2.1.3(2) is not provided

Some buildings are composed of sections and wings of differing construction types. For example, the portion of the building first constructed might be of Type III(200) (sometimes referred to as “ordinary”) construction; an addition of Type II(111) (noncombustible-protected) construction; and the most current section of the building of Type V(000) (combustible-unprotected) construction (see Exhibit 8.1). Prior to the 2000 edition of the *Code*, it was left to the user

Table A.8.2.1.2 Fire Resistance Ratings (in hours) for Type I through Type V Construction

	Type I		Type III			Type III		Type IV	Type V

Exterior Nonbearing Walls³	0 ¹									

Those members that shall be permitted to be of approved combustible material.

¹See A.3.1 (table) [in NFPA 220].

²“H” indicates heavy timber members; see text for requirements.

³Exterior nonbearing walls meeting the conditions of acceptance of NFPA 285, *Standard Method of Test for the Evaluation of Flammability Characteristics of Exterior Non-Load-Bearing Wall Assemblies Containing Combustible Components Using the Intermediate Scale, Multistory Test Apparatus*, shall be permitted to be used.

[220:Table 3.1]

and the authority having jurisdiction to determine the construction type classification assigned to a building with multiple construction types. The minimum fire resistance rating required of a vertically aligned fire barrier to create the equivalent of separate buildings, each of one construction type, is now specified by 8.2.1.3.

In Exhibit 8.1, illustration (a), the minimum 2-hour fire resistance-rated, vertically aligned fire barrier (that is, a wall, not a floor) is provided be-

tween the three portions of the building with differing construction types. For purposes of applying the minimum construction requirements, each section is permitted to be treated as a separate building; one building is of Type III(200) construction, a second building is of Type II(111) construction, and a third is of Type V(000) construction. In Exhibit 8.1, illustration (b), the non-rated partitions separating the portions of the building do not provide a minimum 2-hour fire resistance rating, so the building is classified as

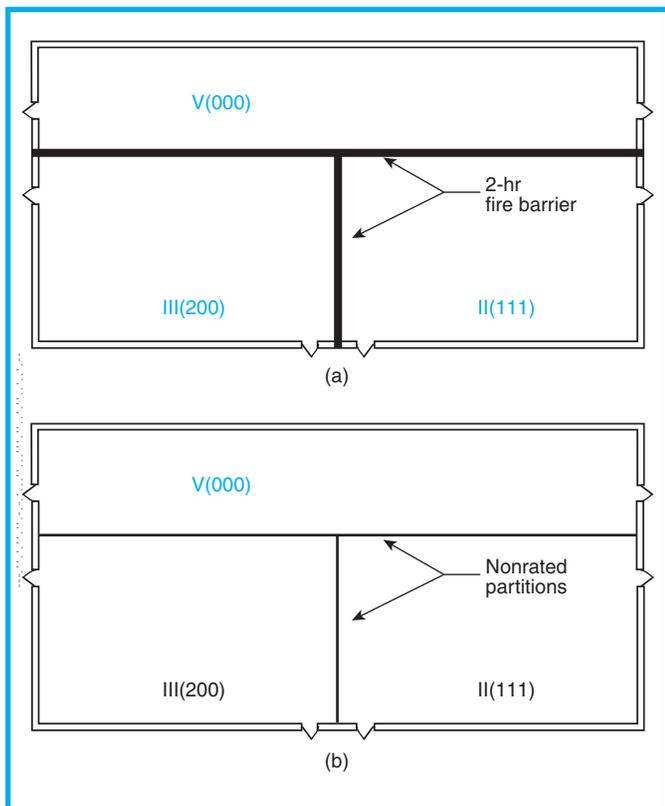

Exhibit 8.1 Building composed of sections with varying construction types.

one building having the least fire resistance offered by any of the three construction types. Thus, the building construction is classified as Type V(000).

Table A.8.2.1.2 provides the Code user with a reprint of the key table from NFPA 220. (A nearly identical table appears in *NFPA 5000™, Building Construction and Safety Code™*; see Table 7.2.2 of that code.⁵) The table summarizes the text of NFPA 220. Note that the shorthand notation, such as *Type I(332)*, provides the minimum hourly fire resistance ratings required to meet the definition of that construction type for only three components of the building—exterior

bearing walls, structural frame/columns/girders, and floor construction. To meet the definition fully, other building components, such as roof construction and interior bearing walls, need to have certain, minimum fire resistance ratings. Thus, the shorthand notation alone does not provide all the needed information. NFPA 220 should be consulted as necessary.

The minimum construction requirements of other sections of the Code might establish criteria, in addition to those of NFPA 220, for use in judging compliance with the definition of a specific building construction type. Chapter 18, which is applicable to new health care occupancies, recognizes that an overall life safety package is necessary for a population that is incapable of self-preservation and thus difficult to protect. Therefore, 18.1.6.6 requires that, for a building to be classified as either Type I or Type II construction, it must meet the requirements of NFPA 220 and have noncombustible or limited-combustible interior nonbearing walls. NFPA 220 does not address interior nonbearing walls.

Commentary Table 8.1 matches the various NFPA 220 and NFPA 5000 construction types with their approximate equivalent construction types, as contained in the following model building codes used throughout the United States:

- (1) *Uniform Building Code (UBC)*⁶
- (2) *BOCA National Building Code (BNBC)*⁷
- (3) *Standard Building Code (SBC)*⁸
- (4) *International Building Code (IBC)*⁹

For example, a building that NFPA 220 or NFPA 5000 classifies as Type II(111), the UBC classifies as Type II 1-hour, the BNBC classifies as Type 2B, the SBC classifies as Type IV 1-hour, and the IBC classifies as Type II-A. When using the *Life Safety Code* in conjunction with one of these building codes, the authority having jurisdiction might wish to use Commentary Table 8.1 to consider (per Section 1.4) the corresponding construction classification. Note the building con-

Commentary Table 8.1 Cross-Reference of Building Construction Types

*I(442) per NFPA 5000, *Building Construction and Safety Code*.

struction types specified by *NFPA 5000* and *NFPA 220* are essentially the same, with one exception: *NFPA 5000* does not recognize Type I(443) construction; rather, it recognizes Type I(442) as the most highly fire-resistive construction type.

8.2.2 General.

8.2.2.1 Where required by other chapters of this *Code*, every building shall be divided into compartments to limit the spread of fire and restrict the movement of smoke.

8.2.2.2 Fire compartments shall be formed with fire barriers that comply with Section 8.3.

8.2.2.3* Fire compartments shall be formed by fire barriers complying with one of the following:

- (1) The fire barriers are continuous from outside wall to outside wall or from one fire barrier to another, or a combination thereof, including continuity through all concealed spaces, such as those found above a ceiling, including interstitial spaces.
- (2) The fire barriers are continuous from outside wall to outside wall or from one fire barrier to another, or from the floor to the bottom of the interstitial space, provided that the construction assembly forming the bottom of the interstitial space has a fire resistance rating not less than that of the fire barrier.

A.8.2.2.3 To ensure that a fire barrier is continuous, it is necessary to seal completely all openings where the fire barrier abuts other fire barriers, the exterior walls, the floor below, and the floor or ceiling above. In 8.2.2.3(2), the fire resistance rating of the bottom of the interstitial space is provided by that membrane alone. Ceilings of rated floor/ceiling and roof/ceiling assemblies do not necessarily provide the required fire resistance.

In Exhibit 8.2, the bold, solid lines designate a variety of fire barriers that meet the requirement of horizontal continuity to prevent a fire from spreading around the end of the barrier into the adjoining fire compartment.

Fire barrier A divides the building into two distinct fire compartments by running continuously from an outside wall to an outside wall. This barrier could, but does not, have door openings that would be protected by fire protection-rated door assemblies meeting the requirements of 8.3.4. Fire barrier B further subdivides the building into a third fire compartment and achieves its required continuity by running from an outside wall to a fire barrier (barrier A). The

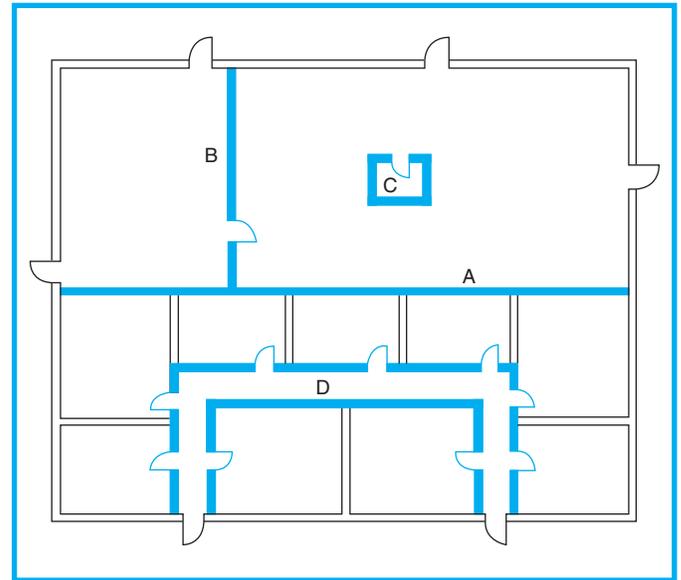

Exhibit 8.2 Typical fire barriers.

door opening is allowed if protected by an appropriately rated fire door assembly.

The fire barriers surrounding room C meet the continuity requirement by running from one fire barrier to another fire barrier, to another; they envelop the room. This arrangement is commonly used to isolate a room and, thus, meet the protection requirements associated with protecting a hazardous area such as a hazardous contents storage room.

Fire barriers are often used to meet the protection and isolation requirements associated with corridors. Corridor D is protected by fire barriers that run from an outside wall to a fire barrier, to another fire barrier, to an outside wall. They isolate the corridor from other spaces on the floor and meet the horizontal continuity requirements.

In addition to horizontal continuity, fire barriers are required to be vertically continuous through all interstitial spaces.

In some cases, above-ceiling and between-floors interstitial spaces contain a considerable fuel load and are readily accessible by people. The possibility that an interstitial space will be used for storage should not be overlooked. These factors must be considered to determine whether an interstitial space is, in fact, another floor. See Exhibit 7.6, which illustrates an exit enclosure and egress provision of Chapter 7 but also shows interstitial spaces that constitute the equivalent of separate floors.

Normally, ceilings are tested as part of a floor/ceiling or roof/ceiling assembly rather than alone. The test does not indicate the performance of the

ceiling but the performance of the total assembly. For example, the ceiling of a 1-hour floor/ceiling assembly might experience failure in a fire in less than 20 minutes, but the overall assembly might pass the 1-hour test. Often a designer or contractor will refer to a 1-hour or 2-hour ceiling and request permission to terminate a fire barrier at the ceiling, but, in reality, the ceiling is part of a 1-hour or 2-hour floor/ceiling or roof/ceiling assembly. Because the ceiling itself does not provide the appropriately rated fire barrier against which the wall assembly can be terminated, the fire barrier must run through and above the ceiling; it must extend from slab to slab.

Tests reported by the Gypsum Association in the *Fire Resistance Design Manual* indicate that two layers of 16-mm ($\frac{5}{8}$ -in.), fire-rated, Type X gypsum wall-board, applied at right angles to the underside of nominal 50 mm \times 250 mm (nominal 2 in. \times 10 in.) wood joists and spaced 610 mm (24 in.) on centers, with the face layer of the gypsum board offset by 610 mm (24 in.) from the base layer joints, will provide 1-hour fire resistance protection for the wood framing¹⁰. Using this information, the authority having jurisdiction could judge that such a ceiling meets the intent of 8.2.2.3(2), and could allow a 1-hour fire resistance-rated wall assembly to terminate tightly against the underside of the ceiling.

Illustration (a) of Exhibit 8.3 shows a 1-hour fire resistance-rated wall assembly continuing up through the ceiling and void space of a 1-hour fire resistance-rated floor/ceiling assembly so as to terminate tightly against the underside of the floor slab to achieve the required vertical continuity. In Exhibit 8.3, illustration (b), 8.2.2.3(2) is used to allow for the 1-hour rated wall assembly to terminate at a ceiling that provides the required 1-hour fire resistance rating by itself.

Some occupancies do allow the fire barrier to terminate at the underside (that is, ceiling) of a fire resistance-rated floor/ceiling assembly. However, caution must be exercised, because ceilings of these assemblies are often improperly installed or, once installed, may have their integrity violated during routine building maintenance.

8.2.2.4 Where required elsewhere in this *Code* to comply with 8.2.2.4, door assemblies also shall comply with the following:

- (1) They shall be tested in accordance with UL 1784, *Standard for Air Leakage Tests for Door Assemblies*.
- (2) The maximum air leakage rate of the door assembly shall be $0.9 \text{ m}^3/\text{min}/\text{m}^2$ ($3.0 \text{ ft}^3/\text{min}/\text{ft}^2$) of door opening

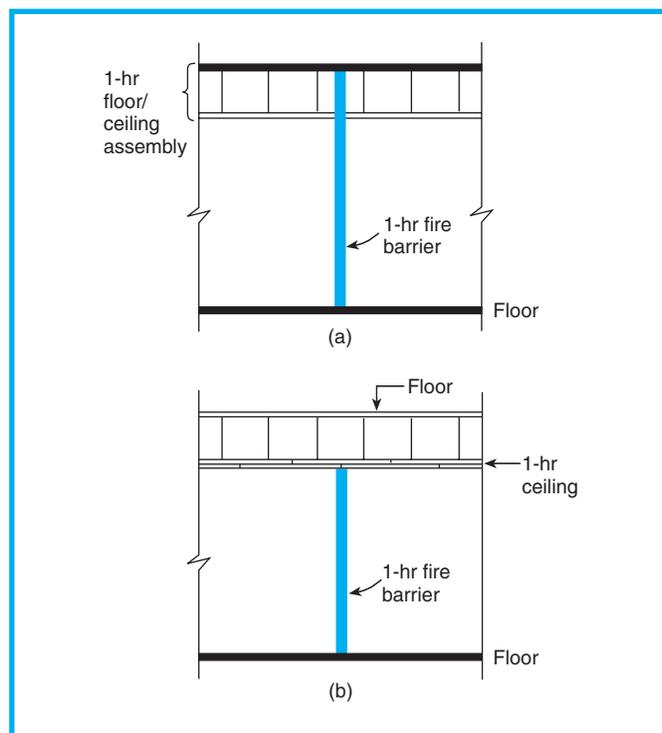

Exhibit 8.3 Fire barrier vertical continuity.

at $25 \text{ N}/\text{m}^2$ (0.10 in. water column) for both the ambient and elevated temperature tests.

Minimum criteria for air leakage rates of door assemblies are specified by 8.2.2.4 to provide a smoketight assembly. However, the criteria in 8.2.2.4 are mandatory only when referenced by another section of the *Code*—such as in Chapters 12 through 42. Currently, only new fire doors serving areas of refuge are required to meet the 8.2.2.4 air-leakage rate criteria (see 7.2.12.3.4.1).

8.2.3 Fire Resistive-Rated Construction.

8.2.3.1* The fire resistance of structural elements and building assemblies shall be determined in accordance with test procedures set forth in NFPA 251, or other approved test methods, or analytical methods approved by the authority having jurisdiction. Materials used to construct fire resistance-rated elements and assemblies shall be limited to those permitted in this *Code*.

A.8.2.3.1 NFPA 251, ANSI/UL 263, and ASTM E119 are considered nationally recognized methods of determining fire resistance and have been found to yield equivalent test methods.

8.2.3.2 Fire resistance-rated floor and roof assemblies shall be classified as restrained or unrestrained in accordance with NFPA 251 or other approved test methods. The construction shall be considered restrained only where a registered design professional has furnished the authority having jurisdiction with satisfactory documentation verifying that the construction is restrained. The classification of fire resistance-rated floor and roof construction shall be identified on the plans as restrained or unrestrained.

The fire resistance of a fire barrier is determined by the test method described in NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*. The test is also commonly known by its ASTM designation, ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*¹¹. The Underwriters Laboratories designation is UL 263, *Fire Tests of Building Construction and Materials*¹². The NFPA 251/ASTM E 119/UL 263 test standard provides for the rating of the construction of the particular assembly and the actual testing of the assembly in the test furnace. The test is conducted under very rigid conditions, so that test results on the same assembly are reproducible and tests of different assemblies are comparable. During the test, the assembly being tested is loaded the same way it would be expected to be loaded when installed in a building. Temperatures in the furnace are generated in strict accordance with the standard time-temperature curve and reach levels of 538°C (1000°F), 704°C (1300°F), 843°C (1550°F), 927°C (1700°F), 1010°C (1850°F), and 1093°C (2000°F) at intervals 5, 10, 30, 60, 120, and 240 minutes into the test. Temperatures both in the furnace and on the unexposed side of the assembly being tested are monitored, and results are recorded at specified intervals and locations. During the course of the test, cotton waste is placed against the unexposed surface and observed for flaming.

The following are acceptance criteria for a successfully completed fire test on an assembly for a specified time period:

- (1) Cotton waste on unexposed side does not ignite.
- (2) Temperature rise on the unexposed side does not exceed 180°C (325°F) at any point or an average of 139°C (250°F).
- (3) Assembly continues to support design loads.

The criteria in (1) through (3) apply to floor, roof, wall, and partition assemblies. In addition, wall and partition assemblies that are to be rated at 1 hour or more are subjected to the hose stream test. A duplicate specimen of the assembly to be rated is tested

in the furnace for one-half the time specified as the fire resistance rating in the fire endurance test. This specimen is then removed from the furnace and immediately subjected to the hose stream test. If there is any projection of water beyond the unexposed surface, the assembly is considered to have failed.

NFPA 251 testing is commonly performed by testing laboratories, which normally issue a report of the test and then list the assembly. Listings of tested fire resistance-rated assemblies are found in publications of laboratories that conduct fire testing, such as the following:

- (1) *Underwriters Laboratories Fire Resistance Directory*¹³
- (2) *Factory Mutual Specification Tested Products Guide*¹⁴
- (3) *Omega Point Laboratories Directory of Listed Building Products, Materials & Assemblies*¹⁵

It is important that the assembly constructed is the same as that listed. For example, if a floor/ceiling assembly calls for clips on the ceiling tiles, the clips must be installed and maintained. Another example is the special treatment often required for lights or air ducts in suspended ceilings. A common problem in walls is the installation of an untested material between the wallboard and the studs or the installation of recessed wall fixtures, which requires the removal of wallboard.

8.2.3.3 Structural elements that support fire barriers shall be permitted to have only the fire resistance rating required for the construction classification of the building, provided that both of the following criteria are met:

- (1) Such structural elements support nonbearing wall or partition assemblies have a required fire resistance rating of 1 hour or less.
- (2) Such structural elements do not serve as exit enclosures or protection for vertical openings.

If 8.2.3.3 were not included in the *Code*, a two-story building, for example, used for an occupancy that (1) allows Type II(000) construction to be occupied and (2) requires the presence of 1-hour fire resistance-rated corridor walls would be required to upgrade all construction supporting the nonbearing second floor corridor walls (that is, the columns, beams, and girders supporting the second floor) to a 1-hour fire resistance rating. Because the purpose of 1-hour rated corridor walls is not to provide structural integrity but to provide barriers that create fire compartments on the floor on which they are installed, 8.2.3.3 allows the unprotected, noncombustible Type II(000) build-

ing to be occupied in accordance with subsection 18.1.6 of the applicable occupancy chapter.

Exhibit 8.4 further illustrates the use of 8.2.3.3. The floor shown in illustration (a) is the second of a two-story building that, given its occupancy, is allowed to be in a building of Type II(000) construction as defined by NFPA 220, *Standard on Types of Building Construction* (see A.8.2.1.2 and its associated commentary). In addition, the occupancy in question requires (1) corridor walls with a 1-hour fire resistance rating and (2) enclosure of hazardous area rooms, interior exit stairs, and vertical openings, such as elevator and ventilating (HVAC) shafts, by 1-hour fire resistance-rated barriers. As shown in illustration (b) of Exhibit 8.4, 8.2.3.3 allows for the building construction that supports the second floor corridor walls and the walls enclosing the hazardous storage room to remain unprotected, but such construction is to be noncombustible as specified by building construction Type II(000). However, the second floor 1-hour rated fire barriers enclosing the exit stairs, and the elevator shaft and the HVAC shaft, must be supported by 1-hour fire resistance-rated construction. In illustration

(b), only those fire barriers depicted by bold, solid lines are required to be supported by 1-hour rated construction from below.

8.2.3.4 The requirement of 8.2.3.3 shall not apply to health care occupancy structural elements supporting floor assemblies in accordance with the provisions of 18.1.6 and 19.1.6.

8.2.4 Analytical Methods.

8.2.4.1 Analytical methods utilized to determine the fire resistance of building assemblies shall comply with 8.2.4.2 or 8.2.4.3.

Analytical methods are alternate methods of determining the fire resistance ratings of construction assemblies in lieu of the large-scale test in accordance with NFPA 251 as specified in 8.2.3.1. For example, a designer who wants to provide a 2-hour fire resistance rating for a W14 × 233 steel column by boxing the column with gypsum wallboard cannot find such an assembly in the *Underwriters Laboratories Fire Resistance Directory*. Design No. X520 and design No. X521 come very close to providing the needed information but deal with W14 × 228 steel columns; they show that, with one layer of 13-mm- (½-in.-) thick gypsum wallboard, the assembly will provide a 2-hour fire resistance rating. The *UL Directory* further explains that most structural steel producers began rolling a new series of structural shapes in accordance with ASTM A 6, *Standard Specification for General Requirements for Rolled Steel Plates, Shapes, Sheet Piling, and Bars for Structural Use*¹⁶, in 1978 and that some of the column sizes specified for individual designs might have been discontinued. The designer chooses not to make a judgment call as to whether the W14 × 233 column will provide the same rating as the discontinued W14 × 228 shape by comparing flange and web thickness. Instead, the designer chooses to calculate the fire resistance rating of a W14 × 233 steel column with a single layer of 13-mm (½-in.) gypsum wallboard built around the column in a box profile using criteria from the *AISI Designing Fire Protection for Steel Columns*¹⁷.

Based on results from accumulated fire test data, the AISI manual presents the following formula for calculating the fire endurance of steel columns protected by gypsum wallboard:

$$R = 130 \left[\frac{h(W'/D)}{2} \right]^{0.75}$$

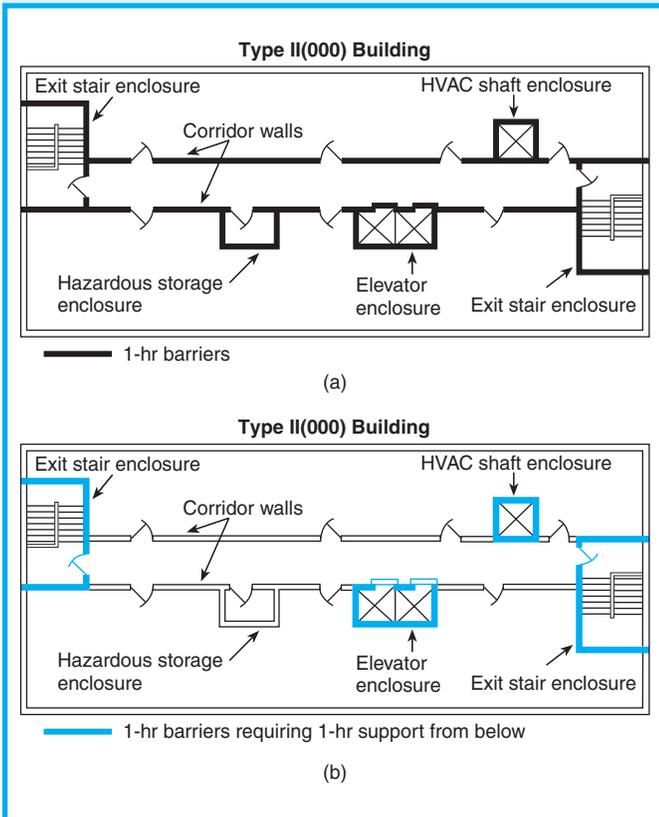

Exhibit 8.4 Fire barriers and rated structural supports.

where:

R = fire resistance (minutes)

h = thickness of gypsum wallboard (in.)

W' = weight of steel column and gypsum wallboard protection (lb/ft)

D = heated perimeter of steel column (in.) [for box profile, inside perimeter of gypsum wallboard material, calculated as $D = 2(a + b)$ per Exhibit 8.5]

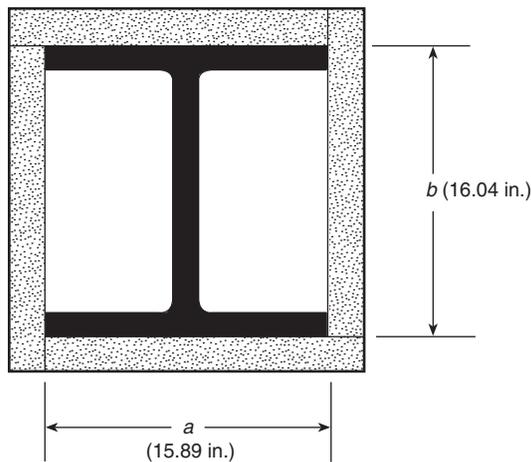

Exhibit 8.5 Box profile of gypsum wallboard around steel column for which fire resistance rating of assembly can be calculated.

The total weight (W') of both the column and its gypsum wallboard protection is calculated using the following formula:

$$W' = W + \frac{50(h)(D)}{144}$$

where W = weight of steel column (lb/ft).

Performing the calculations yields the following:

$$\begin{aligned} D &= 2(a + b) \\ &= 2(15.89 + 16.04) \\ &= 63.86 \text{ in.} \end{aligned}$$

$$\begin{aligned} W' &= W + \frac{50(h)(D)}{144} \\ &= 233 + \frac{50(0.5)(63.86)}{144} \\ &= 244.09 \text{ lb/ft} \end{aligned}$$

$$\frac{W'}{D} = \frac{244.09}{63.86} = 3.82$$

$$\begin{aligned} R &= 130 \left[\frac{h(W'/D)}{2} \right]^{0.75} \\ &= 130 \left[\frac{(0.50)(3.82)}{2} \right]^{0.75} \\ &= 125.6 \text{ minutes (approximately 2 hours)} \end{aligned}$$

Based on the calculation for fire endurance, the designer specifies, with a degree of comfort, that the 2-hour fire resistance rating for the assembly consisting of the W14 × 233 steel column and gypsum wallboard box profile enclosure be achieved using a single layer of 13-mm (½-in.) gypsum wallboard.

8.2.4.2* Where calculations are used to establish the fire resistance rating of structural elements or assemblies, they shall be permitted to be performed in accordance with ASCE/SFPE 29, *Standard Calculation Methods for Structural Fire Protection*. Where calculations are used to establish the fire resistance rating of concrete or masonry elements or assemblies, the provisions of ACI 216.1/TMS 0216.1, *Standard Method for Determining Fire Resistance of Concrete and Masonry Assemblies*, shall be permitted to be used.

A.8.2.4.2 The intent of this provision is to allow the provisions of either ASCE/SFPE 29 or ACI 216.1/TMS0216.1 for the calculation for fire resistance of concrete or masonry elements or assemblies.

8.2.4.3 Except for the method specified in 8.2.4.2, analytical methods used to calculate the fire resistance of building assemblies or structural elements shall be approved. Where an approved analytical method is utilized to establish the fire resistance rating of a structural element or building assembly, the calculations shall be based upon the fire exposure and acceptance criteria specified in NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*.

Section 8.3 Fire Barriers

8.3.1 General.

Fire barriers used to provide enclosure, subdivision, or protection under this *Code* shall be classified in accordance with one of the following fire resistance ratings:

- (1) 2-hour fire resistance rating
- (2) 1-hour fire resistance rating
- (3)* ½-hour fire resistance rating

Fire resistance testing of building construction per NFPA 251/ASTM E 119/UL 263 allows for assemblies to be assigned fire resistance ratings up through the category of *8 hours and over*. Ratings of more than 2 hours are used primarily in protecting property. The *Code* requires no more than a 2-hour fire resistance rating for building construction, even in the health care and detention and correctional occupancy chapters. These chapters promote a defend-in-place strategy, because such a strategy emphasizes life safety over property protection. Thus, in subsections 8.3.1.6 in the health care and detention and correctional occupancy chapters, construction Types I(443), I(332), and II(222) are grouped to be treated as equivalent. A design professional can specify that material assemblies with 3-hour or 4-hour fire resistance ratings are to be used. However, no reduction in requirements, other than those allowed for construction with a 2-hour fire resistance rating, is permitted.

A.8.3.1(3) Walls in good condition with lath and plaster, or gypsum board of not less than 13 mm (½ in.) on each side, can be considered as providing at least a ½-hour fire resistance rating. Additional information on archaic material assemblies can be found in Appendix D of NFPA 914, *Code for Fire Protection of Historic Structures*.

Prior to 1997, the *Code* included ¾-hour and ⅓-hour fire resistance rating classifications in addition to the current ½-hour classification. The range of fractional-hour ratings mistakenly implied a degree of accuracy and precision. The range has been revised so that the only fire resistance rating of less than 1 hour is the ½-hour classification. Because some occupancies, such as existing health care occupancies, previously permitted a fire resistance rating of ⅓-hour but now require a rating of ½-hour, A.8.3.1(3) provides guidance on evaluating existing fire barriers. The change from the ⅓-hour to the ½-hour classification was not intended to create a condition of noncompliance where existing fire barriers had previously complied with *Code* requirements. A previously approved ⅓-hour fire resistance-rated barrier should be considered as complying with the requirement for a ½-hour fire barrier.

8.3.2 Walls.

8.3.2.1 The fire-resistive materials, assemblies, and systems used shall be limited to those permitted in this *Code* and this chapter.

8.3.2.2 The construction materials and details for fire-resistive assemblies and systems for walls described shall comply with all other provisions of this *Code*, except as modified herein.

8.3.2.3 Interior walls and partitions of nonsymmetrical construction shall be evaluated from both directions and assigned a fire resistance rating based on the shorter duration obtained in accordance with NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*. When the wall is tested with the least fire-resistive side exposed to the furnace, the wall shall not be required to be subjected to tests from the opposite side.

8.3.3 Fire Doors and Windows.

8.3.3.1 Wall openings required to have a fire protection rating by Table 8.3.4.2 shall be protected by approved, listed, labeled fire door assemblies and fire window assemblies and their accompanying hardware, including all frames, closing devices, anchorage, and sills in accordance with the requirements of NFPA 80, *Standard for Fire Doors and Fire Windows*, except as otherwise specified in this *Code*.

8.3.3.2* Fire protection ratings for products required to comply with 8.3.3 shall be as determined and reported by a nationally recognized testing agency in accordance with NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, or NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*.

(A) Fire protection-rated glazing shall be evaluated under positive pressure in accordance with NFPA 257.

(B) All products required to comply with 8.3.3.2 shall bear an approved label.

A.8.3.3.2 Some door assemblies have been tested to meet the conditions of acceptance of NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*. Where such assemblies are used, the provisions of 8.3.2 should be applied instead of those of 8.3.3.2.

8.3.3.3 Unless otherwise specified, fire doors shall be self-closing or automatic-closing in accordance with 7.2.1.8.

Fire protection-rated door assemblies are tested in accordance with NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, also commonly known as ASTM E 152, *Standard Methods of Fire Tests of Door Assemblies*¹⁸. Such assemblies must be installed in accordance with the requirements of NFPA 80, *Standard for Fire Doors and Fire Windows*¹⁹. Where the *Code* uses the term *door*, it includes not only the door leaf or slab but also the doorway, frame, and necessary hardware, including hinges. Where describing a fire door, the ap-

plicable standards similarly define a fire protection-rated assembly as including all these components as well as a listed door closer and positive latching.

If they are to be effective, fire doors must not only be closed but also be held closed. Building fires are capable of generating pressures sufficient to force fire doors open if they are not held closed with positive latching, thereby rendering the doors incapable of protecting the opening in which they are installed.

The acceptance criteria for fire protection-rated assemblies, such as fire doors, differ from those for fire resistance-rated construction, such as a wall or floor/ceiling assembly. The limitation of temperature rise through the fire door is not normally a measure of acceptance, although it is for a fire resistance-rated assembly such as a wall. In addition, during the course of the fire test, fire doors will expand on the exposed side and, as a result, will warp—sometimes expanding through the door opening at the top of the door. This expansion and warping result in some flaming through the top of the door openings. The test standard recognizes this phenomenon, and a certain amount of such flaming is permitted under the acceptance criteria. This does not adversely affect safety, given that fire protection-rated assemblies are intended to protect relatively small openings in larger fire resistance-rated barriers. Also, to maintain the door as usable, combustible materials are not to be piled in front of the door opening.

8.3.3.4 Floor fire door assemblies shall be tested in accordance with NFPA 288, *Standard Methods of Fire Tests of Floor Fire Door Assemblies Installed Horizontally in Fire Resistance-Rated Floor Systems*, and shall achieve a fire resistance rating not less than the assembly being penetrated. Floor fire doors assemblies shall be listed and labeled.

8.3.3.5 Fire protection-rated glazing shall be permitted in fire barriers having a required fire resistance rating of 1 hour or less and shall be of an approved type with the appropriate fire protection rating for the location in which the barriers are installed.

8.3.3.6* Glazing in fire window assemblies, other than in existing fire window installations of wired glass and other fire-rated glazing material, shall be of a design that has been tested to meet the conditions of acceptance of NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*. Fire protection-rated glazing in fire door assemblies, other than in existing fire-rated door assemblies, shall be of a design that has been tested to meet the conditions of

acceptance of NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*.

A.8.3.3.6 Some window assemblies have been tested to meet the conditions of acceptance of NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*. Where such assemblies are used, the provisions of 8.3.2 should be applied instead of those of 8.3.3.6.

8.3.3.7 Wired glass of 6 mm (¼ in.) in thickness and labeled for fire protection purposes shall be permitted to be used in approved opening protectives provided the maximum size specified by the listing is not exceeded. Other glazing materials that have been tested and labeled to indicate the type of opening to be protected for fire protection purposes shall be permitted to be used in approved opening protectives in accordance with their listing, with the maximum sizes tested.

8.3.3.8 Nonsymmetrical fire protection-rated glazing systems shall be tested with each face exposed to the furnace, and the assigned fire protection rating shall be that of the shortest duration obtained from the two tests conducted in compliance with NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*.

8.3.3.9 The total combined area of glazing in fire-rated window assemblies and fire-rated door assemblies used in fire barriers shall not exceed 25 percent of the area of the fire barrier that is common with any room, unless the installation meets one of the following criteria:

- (1) The installation is an existing fire window installation of wired glass and other fire-rated glazing material in approved metal frames.
- (2) The installation is an existing fire window installations of wired glass and other fire-rated glazing materials in approved frames.
- (3) The fire protection-rated glazing material is installed in approved existing frames.

The provisions of 8.3.3.5 through 8.3.3.9 provide guidelines for fire window assemblies that parallel those covered by 8.3.3.1 through 8.3.3.4 for fire door assemblies. New glazing for use in fire barriers and fire doors is regulated by performance-oriented criteria, which refer to fire-rated glazing, in lieu of the more traditional but prescriptive requirements previously applicable to wired glass. The requirements limit the installation of fire windows used in fire barriers to not more than 25 percent of the area of the fire barrier that is common with any room; however, 8.3.3.9 continues to recognize the current practice of using greater percentages of wired glass for existing fire windows and vision panels in fire doors subject to the stated limitations.

8.3.4 Opening Protectives.

8.3.4.1 Every opening in a fire barrier shall be protected to limit the spread of fire and restrict the movement of smoke from one side of the fire barrier to the other.

8.3.4.2* The fire protection rating for opening protectives in fire barriers, fire-rated smoke barriers, and fire-rated smoke partitions shall be in accordance with Table 8.3.4.2.

A.8.3.4.2 Longer ratings might be required where opening protectives are provided for property protection as well as life safety. NFPA 80, *Standard for Fire Doors and Fire Windows*, should be consulted for standard practice in the selection and installation of fire door assemblies and fire window assemblies.

Table 8.3.4.2, Note 1. A vision panel in a fire door is not a fire window, and thus, it is not the intent of the “NP” notations in the “Fire Windows” column of Table 8.3.4.2 to prohibit vision panels in fire doors.

8.3.4.3 Existing fire door assemblies having a ¾-hour fire protection rating shall be permitted to continue to be used in vertical openings and in exit enclosures in lieu of the 1-hour rating required by Table 8.3.4.2.

8.3.4.4 Where a 20-minute fire protection-rated door is required in existing buildings, an existing 44-mm (1¾-in.) solid-bonded wood-core door, an existing steel-clad (tin-clad) wood door, or an existing solid-core steel door with

positive latch and closer shall be permitted, unless otherwise specified by Chapter 11 through Chapter 42.

Fire barriers have fire *resistance* ratings as addressed in 8.3.1; opening protectives, such as fire doors, have fire *protection* ratings, as discussed in 8.3.4.4. For a better understanding of the difference in test methods used for rating fire barriers and fire doors, compare the commentaries following 8.2.3.2 and 8.3.3.3.

In general, 1-hour fire barriers for the protection of vertical openings (for example, the shafts enclosing maximum three-story exit stairs) require doors with a 1-hour fire protection rating. One-hour fire barriers for other than vertical opening protection, such as those used to isolate a hazardous contents room, require doors with a ¾-hour fire protection rating.

The provisions of 8.3.3.1 allow Chapter 7 and the occupancy chapters to alter this general rule. However, for the most part, such alteration is usually done only with regard to the requirement that corridor walls be of a 1-hour fire resistance rating. Table 8.3.4.2 allows for a 1-hour or ½-hour fire resistance-rated corridor wall or 1-hour fire resistance-rated smoke barrier to have a door with a 20-minute fire protection rating.

Health care and ambulatory health care occupancies, for example, allow the omission of the self-closing devices on patient room doors installed in corridor walls. In this case, the special requirements recognize the functional needs for open doors in these facilities, and a true fire protection-rated patient room door assembly is not required.

As demonstrated above, the fire protection ratings of the opening protectives are sometimes allowed to be of a lower rating than the fire resistance rating of the fire barrier openings to be protected. For example, a 2-hour fire resistance-rated fire barrier is allowed to have its openings protected by 1½-hour fire protection-rated door assemblies. The perceived mismatch of ratings actually accomplishes a reasonable, practical match—as explained in the following paragraphs.

The test procedures on which the ratings are based, that is, NFPA 251/ASTM E 119/UL 263 for fire barriers, and NFPA 252/ASTM E 152 (see commentary following 8.3.3.3) for fire doors, are different.

Although combustibles placed against a fire resistance-rated wall expose the wall to a considerable fire challenge, a fire protection-rated door assembly will not usually have similar combustibles placed against it because the opening must be clear to use the door. Such a scenario suggests that if a door—for example, a second door to a storage room that is no

Table 8.3.4.2 Minimum Fire Protection Ratings for Opening Protectives in Fire Resistance-Rated Assemblies

Component	Walls and Partitions (hr)	Fire Door Assemblies (hr)	Fire Window Assemblies (hr)
Elevator hoistways	2	1½	NP
	1	1	NP
Vertical shafts (including stairways, exits, and refuse chutes)	2	1½	NP
	1	1	NP
	½	⅓	NP
Fire barriers	2	1½	NP
	1	¾	¾
Horizontal exits	2	1½	NP
Exit access corridors ¹	1	⅓	¾
	½	⅓	⅓
Smoke barriers ¹	1	⅓	¾
Smoke partitions ^{1,2}	½	⅓	⅓

Note: NP = not permitted.

¹ Fire doors are not required to have a hose stream test per NFPA 252.

² For residential board and care, see 32.2.3.1.1 and 33.2.3.1.1.

longer needed—is not to be used and combustible storage is to be placed at the door opening, the door should be removed and the opening filled with material to restore the wall to its required fire resistance rating.

8.3.5 Penetrations.

The provisions of 8.3.5 shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations in fire walls, fire barrier walls, and fire resistance-rated horizontal assemblies. The provisions of 8.3.5 shall not apply to approved existing materials and methods of construction used to protect existing through-penetrations and existing membrane penetrations in fire walls, fire barrier walls, or fire resistance-rated horizontal assemblies, unless otherwise required by Chapter 12 through Chapter 42.

8.3.5.1 Firestop Systems and Devices Required. Penetrations for cables, cable trays, conduits, pipes, tubes, combustion vents and exhaust vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a wall, floor, or floor/ceiling assembly constructed as a fire barrier shall be protected by a firestop system or device. The firestop system or device shall be tested in accordance with ASTM E-814 or ANSI/UL 1479 at a minimum positive pressure differential of 2.5 N/m² (0.01 in. water column) between the exposed and the unexposed surface of the test assembly.

One source of information on tested materials, devices, and systems for protecting through-penetrations of fire resistance-rated barriers is “Through-Penetration Firestop Systems” (Volume II) of the *Fire Resistance Directory*, published by Underwriters Laboratories²⁰. Such devices and systems are designed to resist the spread of fire through openings in fire resistance-rated floor or wall barriers that accommodate penetrating items, such as electrical cables, cable trays, conduits, and pipes. Such devices and systems are classified by Underwriters Laboratories with respect to installation in a wall only, installation in a floor only, or installation in a wall or floor. The basic standard used by UL to investigate products in this category is UL 1479, *Fire Tests of Through-Penetration Firestops*²¹, which is similar to ASTM E 814, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*²². A sampling of the currently classified devices includes the use of the following:

- (1) Ceramic fibers
- (2) Foamed silicones

- (3) Mineral wool batts
- (4) Intumescent sheets
- (5) Sealing blankets and plugs
- (6) Fittings and couplings
- (7) Various caulks, putties, and mastics
- (8) Spring-loaded guillotine blades

Over the life of a building, it is important to maintain the integrity of barriers to protect against fire penetration. Renovations or any changes to building utilities will tend to violate the compartmentation provided when a building is first occupied.

Exhibit 8.6 illustrates some of the typical fire barrier penetrations, which are addressed by 8.3.5.

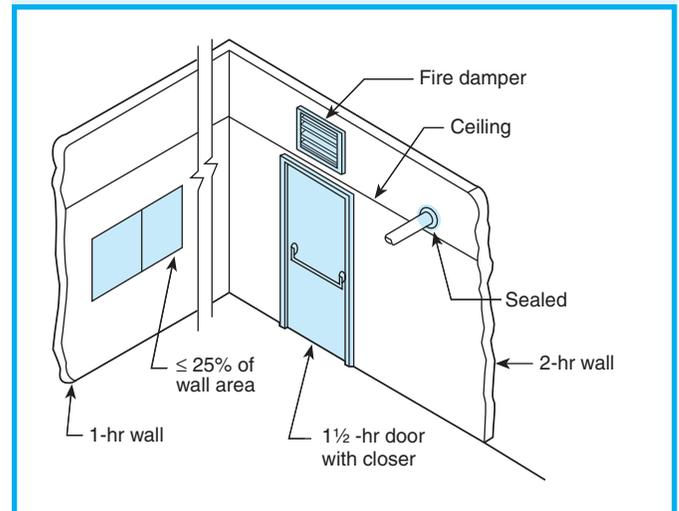

Exhibit 8.6 Typical penetrations of a fire barrier.

8.3.5.1.1 The requirements of 8.3.5.1 shall not apply where otherwise permitted by any one of the following:

- (1) Where penetrations are tested and installed as part of an assembly tested and rated in accordance with NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*
- (2) Where penetrations through floors are enclosed in a shaft enclosure designed as a fire barrier
- (3) Where concrete, grout, or mortar has been used to fill the annular spaces around cast-iron, copper, or steel piping that penetrates one or more concrete or masonry fire resistance-rated assemblies and both of the following criteria are also met:
 - (a) The nominal diameter of each penetrating item shall not exceed 150 mm (6 in.), and the opening size shall not exceed 0.09 m² (1 ft²).

- (b) The thickness of the concrete, grout, or mortar shall be the full thickness of the assembly
- (4) Where firestopping materials are used with the penetrating items in 8.3.5.1.1(1) through 8.3.5.1.1(3) and both of the following criteria are also met:
 - (a) The penetration shall be limited to only one floor.
 - (b) The firestopping material shall be capable of preventing the passage of flame and hot gases sufficient to ignite cotton waste when subjected to the time-temperature fire conditions of NFPA 251 under a minimum positive pressure differential of 2.5 N/m² (0.01 in. water column) at the location of the penetration for the time period equivalent to the required fire resistance rating of the assembly penetrated.

8.3.5.1.2 The maximum nominal diameter of the following penetrating items shall be not greater than 100 mm (4 in.), and the aggregate area of all penetrating items shall not exceed 64,520 mm² (100 in.²) in any 9.3 m² (100 ft²) of floor or wall area:

- (1) Steel, ferrous, or copper cables
- (2) Cable or wire with steel jackets
- (3) Cast-iron, steel, or copper pipes
- (4) Steel conduit or tubing

8.3.5.1.3 Firestop systems and devices shall have an F rating of at least 1 hour, but not less than the required fire-resistive rating of the fire barrier penetrated.

8.3.5.1.4 Penetrations in fire-rated horizontal assemblies shall be required to have a T rating of at least 1 hour, but not less than the rating of the horizontal assembly, and shall not be required for the following:

- (1) Floor penetrations contained within the cavity of a wall assembly
- (2) Penetrations through floors or floor assemblies where the penetration is not in direct contact with combustible material

8.3.5.2 Sleeves. Where the penetrating item uses a sleeve to penetrate the wall or floor, the sleeve shall be securely set in the wall or floor, and the space between the item and the sleeve shall be filled with a material that complies with 8.3.5.1.

8.3.5.3 Insulation and Coverings. Insulation and coverings for penetrating items shall not pass through the wall or floor unless the insulation or covering has been tested as part of the firestop system or device.

8.3.5.4 Transmission of Vibrations. Where designs take transmission of vibrations into consideration, any vibration isolation shall meet one of the following conditions:

- (1) It shall be provided on either side of the wall or floor.
- (2) It shall be designed for the specific purpose.

8.3.5.5 Transitions.

8.3.5.5.1 Where piping penetrates a fire resistance-rated wall or floor assembly, combustible piping shall not connect to noncombustible piping within 915 mm (36 in.) of the firestop system or device without demonstration that the transition will not reduce the fire resistance rating, except in the case of previously approved installations.

8.3.5.5.2 Unshielded couplings shall not be used to connect noncombustible piping to combustible piping unless it can be demonstrated that the transition complies with the fire-resistive requirements of 8.3.5.5.

8.3.5.6 Membrane Penetrations.

The term *membrane penetration* refers to openings for penetrations made through one side only of a fire resistance-rated assembly, as defined in *NFPA 5000, Building Construction and Safety Code*. The provisions of 8.3.5.6 address such penetrations, which, if not properly protected, would compromise the fire resistive integrity of the barrier. The term *through-penetration*, on the other hand, refers to openings for penetrations that pass through both sides of a fire resistance-rated assembly.

8.3.5.6.1 Membrane penetrations for cables, cable trays, conduits, pipes, tubes, combustion vents and exhaust vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a membrane of a wall, floor, or floor/ceiling assembly constructed as a fire barrier shall be protected by a firestop system or device and shall comply with 8.3.5.1 through 8.3.5.5.2.

8.3.5.6.2 The firestop system or device shall be tested in accordance with ASTM E-814 or ANSI/UL 1479 at a minimum positive pressure differential of 2.5 N/m² (0.01 in. water column) between the exposed and the unexposed surface of the test assembly, unless one of the following is met:

- (1) Membrane penetrations of ceilings that are not an integral part of a fire resistance-rated floor/ceiling or roof/ceiling assembly shall be permitted.
- (2) Membrane penetrations of steel, ferrous, or copper conduits, pipes, tubes, or combustion vents or exhaust vents shall be permitted where the annular space is protected with an approved material, and the aggregate area of the openings does not exceed 0.06 m² (0.7 ft²) in any 9.3 m² (100 ft²) of ceiling area.

- (3) Electrical outlet boxes and fittings shall be permitted, provided that such devices are listed for use in fire resistance-rated assemblies and are installed in accordance with their listing.
- (4) The annular space created by the membrane penetration of a fire sprinkler shall be permitted, provided that the space is covered by a metal escutcheon plate.

8.3.5.6.3 Where walls or partitions are required to have a fire resistance rating of not less than 1 hour, recessed fixtures shall be installed in the wall or partition in such a manner that the required fire resistance is not reduced, unless one of the following is met:

- (1) Any steel electrical box not exceeding 0.01 m² (0.1 ft²) shall be permitted where the aggregate area of the openings provided for the boxes does not exceed 0.06 m² (0.7 ft²) in any 9.3 m² (100 ft²) of wall area, and, where outlet boxes are installed on opposite sides of the wall, the boxes shall be separated by one of the following:
 - (a) Horizontal distance of not less than 610 mm (24 in.)
 - (b) Horizontal distance of not less than the depth of the wall cavity, where the wall cavity is filled with cellulose loose-fill, rock wool, or slag wool insulation
 - (c)* Solid fireblocking

A.8.3.5.6.3(1)(c) Criteria associated with fireblocking can be found in 8.14.2 of *NFPA 5000™, Building Construction and Safety Code™*.

- (d) Other listed materials and methods
- (2) Membrane penetrations for any listed electrical outlet box made of any material shall be permitted, provided that such boxes have been tested for use in fire resistance-rated assemblies and are installed in accordance with the instructions included in the listing.
- (3) The annular space created by the membrane penetration of a fire sprinkler shall be permitted, provided that the space is covered by a metal escutcheon plate.

8.3.5.7 Openings for Air-Handling Ductwork. Openings in fire barriers for air-handling ductwork or air movement shall be protected in accordance with 9.2.1.

In referencing 9.2.1 for the protection of openings in fire barriers for air-handling ductwork or air movement, the *Code* mandates that the requirements of NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*²³, and not the usual *Life Safety Code* requirements for opening protectives (contained in 8.3.4), apply to heating, ventilating, and

air conditioning (HVAC) system penetrations of fire barriers. NFPA 90A requires that approved fire dampers be provided in all air transfer openings in barriers that are required to have a fire resistance rating. It also requires that approved fire dampers be provided where ducts or air-transfer grilles penetrate barriers that are required to have a fire resistance rating of 2 hours or more. Thus, although any air transfer opening would have to be provided with a fire damper in a required fire barrier of any rating, penetrations by ducts or air grilles would not have to be provided with fire dampers if the required rating of the fire barrier were less than 2 hours. These requirements are depicted in Exhibit 8.7.

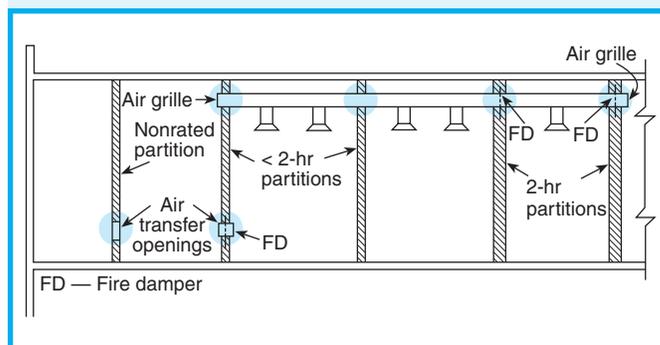

Exhibit 8.7 Fire damper requirements of NFPA 90A for HVAC penetrations of fire barriers.

Section 8.4 Smoke Partitions

The concept of the *smoke partition* was developed for the 2000 edition of the *Code*. It is intended to serve as another menu-like item that can be referenced by other parts of the *Code*, especially the occupancy chapters, instead of repeating detailed, slightly varying criteria in many chapters. In future editions of the *Code*, more occupancy chapters will reference Section 8.4 on smoke partitions where exemptions from the typical 1-hour fire resistance-rated corridor wall requirement are provided for sprinklered buildings. For an example of a mandate for the use of the smoke partition provisions of Section 8.4 in large residential board and care occupancies, see 32.3.3.6.3 and 33.3.3.6.3.2.

The smoke partition provisions offer options not available prior to the 2000 edition under the provisions for fire barriers and smoke barriers. For example, a smoke partition is not required to have a fire

resistance rating, but a fire barrier must have a rating. Also, a smoke partition is not required to have a smoke leakage-rated damper where ductwork penetrates the partition, but a duct penetration of a smoke barrier typically is.

8.4.1* General.

Where required elsewhere in this *Code*, smoke partitions shall be provided to limit the transfer of smoke.

A.8.4.1 Although a smoke partition is intended to limit the free movement of smoke, it is not intended to provide an area that would be free of smoke.

Chapter 8 does not require the installation of smoke partitions but provides detailed criteria for smoke partitions where required by other sections of the *Code*. A smoke partition is a continuous membrane designed to form a barrier to limit the transfer of smoke.

8.4.2 Continuity.

The following shall apply to smoke partitions:

- (1) They shall extend from the floor to the underside of the floor or roof deck above, through any concealed spaces, such as those above suspended ceilings, and through interstitial structural and mechanical spaces.
- (2)* They shall be permitted to extend from the floor to the underside of a monolithic or suspended ceiling system where the following conditions are met:
 - (a) The ceiling system forms a continuous membrane.
 - (b) A smoke-tight joint is provided between the top of the smoke partition and the bottom of the suspended ceiling.
 - (c) The space above the ceiling is not used as a plenum.

A.8.4.2(2) An architectural, exposed, suspended-grid acoustical tile ceiling with penetrations for sprinklers, ducted HVAC supply and return air diffusers, speakers, and recessed light fixtures is capable of limiting the transfer of smoke.

- (3) Smoke partitions enclosing hazardous areas shall be permitted to terminate at the underside of a monolithic or suspended ceiling system where the following conditions are met:
 - (a) The ceiling system forms a continuous membrane.
 - (b) A smoke-tight joint is provided between the top of the smoke partition and the bottom of the suspended ceiling.
 - (c) Where the space above the ceiling is used as a plenum, return grilles from the hazardous area into the plenums are not permitted.

A smoke partition should be thought of as a barrier that reasonably limits, but doesn't necessarily prevent, smoke transfer. As such, there are suspended ceiling systems and monolithic surfaced ceilings that provide resistance to smoke transfer that is approximately equal to that of the traditional, nonrated corridor wall or partition. Smoke partitions are permitted to terminate tightly against the underside of such ceilings in accordance with 8.4.2(2). The concept is further described in A.8.4.2(2). The list of acceptable penetrating items (for example, speakers, recessed light fixtures, and ducted HVAC air diffusers) makes it clear that a smoke partition doesn't prevent all smoke transfer; rather, it limits the transfer of smoke to an acceptable level to provide for occupant life safety.

8.4.3 Opening Protectives.

8.4.3.1 Doors in smoke partitions shall comply with 8.4.3.2 through 8.4.3.5.

8.4.3.2 Doors shall comply with the provisions of 7.2.1.

8.4.3.3 Doors shall not include louvers.

8.4.3.4* Door clearances shall be in accordance with NFPA 80, *Standard for Fire Doors and Fire Windows*.

A.8.4.3.4 Gasketing of doors should not be necessary, as the clearances in NFPA 80, *Standard for Fire Doors and Fire Windows*, effectively achieve resistance to the passage of smoke if the door is relatively tight-fitting.

NFPA 80, *Standard for Fire Doors and Fire Windows*, permits clearances of 3.2 mm (1/8 in.) between the door frame and the top and sides of the door. For swinging doors with builder's hardware, NFPA 80 permits the following clearances:

- (1) 9.5 mm (3/8 in.) between the bottom of the door and a raised noncombustible sill
- (2) 19.1 mm (3/4 in.) between the bottom of the door and the floor where no sill exists
- (3) 15.9 mm (5/8 in.) between the bottom of the door and rigid floor tile
- (4) 12.7 mm (1/2 in.) between the bottom of the door and floor coverings such as carpet

With the allowed clearances, some smoke will pass to the opposite side of a closed door. It is important to remember that the intent of the smoke partition is not to prevent all smoke transfer but, rather, to limit the transfer of smoke to an acceptable level.

8.4.3.5 Doors shall be self-closing or automatic-closing in accordance with 7.2.1.8.

The five sets of provisions applicable to doors in smoke partitions are individually addressed in 8.4.3.1 through 8.4.3.5 to permit each to be singled out in the references made by other sections of the Code that require smoke partitions. For example, 33.3.3.6.3.2 exempts existing large residential board and care occupancies in sprinklered buildings from the self-closing requirement of 8.4.3.5 but retains the other door provisions.

8.4.4 Penetrations.

The provisions of 8.4.4 shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations of smoke partitions.

8.4.4.1 Penetrations for cables, cable trays, conduits, pipes, tubes, vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a smoke partition shall be protected by a system or material that is capable of limiting the transfer of smoke.

8.4.4.2 Where designs take transmission of vibrations into consideration, any vibration isolation shall meet one of the following conditions:

- (1) It shall be provided on either side of the smoke partition.
- (2) It shall be designed for the specific purpose.

8.4.5 Joints.

8.4.5.1 The provisions of 8.4.5 shall govern the materials and methods of construction used to protect joints in between and at the perimeter of smoke partitions or, where smoke partitions meet other smoke partitions, the floor or roof deck above, or the outside walls. The provisions of 8.4.5 shall not apply to approved existing materials and methods of construction used to protect existing joints in smoke partitions, unless otherwise required by Chapter 12 through Chapter 42.

8.4.5.2 Joints made within or at the perimeter of smoke partitions shall be protected with a joint system that is capable of limiting the transfer of smoke.

8.4.6 Air-Transfer Openings.

8.4.6.1 General. The provisions of 8.4.6 shall govern the materials and methods of construction used to protect air-transfer openings in smoke partitions.

8.4.6.2* Smoke Dampers. Air-transfer openings in smoke partitions shall be provided with approved smoke dampers designed and tested in accordance with the requirements of UL 555S, *Standard for Smoke Dampers*, to limit the transfer of smoke.

A.8.4.6.2 An air transfer opening as defined in NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, is an opening designed to allow the movement of environmental air between two contiguous spaces.

8.4.6.3 Smoke Damper Ratings. Smoke damper leakage ratings shall be not less than Class II. Elevated temperature ratings shall be not less than 140°C (250°F).

8.4.6.4 Smoke Detectors. Dampers in air-transfer openings shall close upon detection of smoke by approved smoke detectors installed in accordance with *NFPA 72®*, *National Fire Alarm Code®*.

If ductwork runs to a smoke partition, pierces the partition, and continues its run on the other side of the partition, no transfer opening exists. Given that no transfer opening is present, there is no requirement for a smoke leakage-rated damper. If such ducted HVAC systems without dampers are to spread smoke, such smoke spread will occur due to the buoyant forces of the hot fire gases, because the provisions of NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, require the automatic shutdown of most of the fans that would otherwise push and pull smoke through the ductwork.

Section 8.5 Smoke Barriers

8.5.1* General.

Where required by Chapter 12 through Chapter 42, smoke barriers shall be provided to subdivide building spaces for the purpose of restricting the movement of smoke.

A.8.5.1 Wherever smoke barriers and doors therein require a degree of fire resistance as specified by requirements in the various occupancy chapters (Chapter 12 through Chapter 42), the construction should be a fire barrier that has been specified to limit the spread of fire and restrict the movement of smoke.

Although a smoke barrier is intended to restrict the movement of smoke, it may not result in tenability throughout the adjacent smoke compartment. The adjacent smoke compartment should be safer than the area on the fire side, thus allowing building occupants to move to that area. Eventually, evacuation from the adjacent smoke compartment may be required.

It is imprecise to refer to a “1-hour smoke barrier.” It is more accurate to refer to a “smoke barrier that additionally has a 1-hour fire resistance rating.” A barrier with only a fire resistance rating does not necessarily make an effective smoke barrier. For example, a fire barrier, if rated at less than 2 hours, would not be required to have either a fire damper or smoke damper where ductwork penetrates the barrier. A smoke barrier, in accordance with Section 8.5, would have ducted penetrations protected by smoke dampers per 8.5.4.2. For additional information on fire barrier testing, rating, and installation, see the commentary following 8.2.3.2 and 8.3.5.7.

8.5.2* Continuity.

A.8.5.2 To ensure that a smoke barrier is continuous, it is necessary to seal completely all openings where the smoke barrier abuts other smoke barriers, fire barriers, exterior walls, the floor below, and the floor or ceiling above. It is not the intent to prohibit a smoke barrier from stopping at a fire barrier if the fire barrier meets the requirements of a smoke barrier (that is, the fire barrier is a combination smoke barrier/fire barrier).

8.5.2.1 Smoke barriers required by this *Code* shall be continuous from an outside wall to an outside wall, from a floor to a floor, or from a smoke barrier to a smoke barrier, or a combination thereof.

8.5.2.2 Smoke barriers shall be continuous through all concealed spaces, such as those found above a ceiling, including interstitial spaces.

8.5.2.3 A smoke barrier required for an occupied space below an interstitial space shall not be required to extend through the interstitial space, provided that the construction assembly forming the bottom of the interstitial space provides resistance to the passage of smoke equal to that provided by the smoke barrier.

In occupancies where evacuation is a last resort or is expected to be otherwise delayed, smoke barriers and doors will require a degree of fire resistance as specified by the requirements found in the *Code's* occupancy chapters (Chapters 12 through 42).

Other openings in smoke and fire barriers must be protected as well. HVAC ducts provide a ready path for smoke and fire to travel from one area to another unless carefully protected. Penetrations in walls and ceiling construction for utility lines and other building services must be firestopped to prevent fire spread. The hidden spaces above sus-

pended ceilings and attic spaces are out of sight and easily overlooked.

The provision of 8.5.2.3 must be used with care. Several chapters require the smoke barrier to be fire resistance rated and, therefore, the smoke barrier would be permitted to terminate at the ceiling only if the ceiling were of the same rating (see commentary on 8.2.2.3). Also, even if no fire resistance rating were required, it is difficult to ensure that a ceiling is smoketight unless it is of monolithic construction without air-handling penetrations. This kind of construction is often found in apartment buildings, hotels, and dormitories; consequently, the provision of 8.5.2.3 can be useful.

8.5.3 Fire Barrier Used as Smoke Barrier.

A fire barrier shall be permitted to be used as a smoke barrier, provided that it meets the requirements of 8.5.3 through 8.5.6.

8.5.3.1* Doors in smoke barriers shall close the opening leaving only the minimum clearance necessary for proper operation and shall be without undercuts, louvers, or grilles.

A.8.5.3.1 The clearance for proper operation of smoke doors is defined as 3 mm ($\frac{1}{8}$ in.). For additional information on the installation of smoke-control door assemblies, see NFPA 105, *Standard for the Installation of Smoke Door Assemblies*.

NFPA 105, *Standard for the Installation of Smoke Door Assemblies*²⁴, acknowledges that no nationally recognized test for the measurement of smoke leakage exists. However, NFPA 105 notes that UL 1784, *Standard for Air Leakage Tests of Door Assemblies*²⁵, can be used to measure ambient and warm air leakage rates of door assemblies.

UL 1784, which is also referenced in 8.2.2.4, should determine satisfactory performance if recognized design features are also taken into account, such as close-fitting assemblies, limited deflections, and the use of gasketing and sealing materials. The document then provides performance criteria for determining maximum air leakage rates expressed in air volume per time per area of door opening.

8.5.3.2 Where required by Chapter 12 through Chapter 42, doors in smoke barriers shall comply with the requirements of 8.2.2.4.

8.5.3.3 Latching hardware shall not be required on doors in smoke barriers where permitted by Chapter 12 through Chapter 42.

8.5.3.4* Doors in smoke barriers shall be self-closing or automatic-closing in accordance with 7.2.1.8 and shall comply with the provisions of 7.2.1.

A.8.5.3.4 Where, because of operational necessity, it is desired to have smoke barrier doors that are usually open, such doors should be provided with hold-open devices that are activated to close the doors by means of the operation of smoke detectors and other alarm functions.

Doors in smoke barriers are not required to have a fire protection rating unless the occupancy chapter requires the smoke barrier itself to have a fire resistance rating. Therefore, any door that resists the passage of smoke, even a hollow-core wood door or glass door, is acceptable, provided it is tight-fitting. Stops at the head and sides of the door help resist the passage of smoke. Where a pair of doors is used, it is recommended (and required for cross-corridor door assemblies in new health care occupancies) that they open in opposite directions from each other so that rabbets, bevels, or astragals can be provided at the meeting edges without the use of coordinators. See also 18.3.7.10.

Doors in smoke barriers, although not the equivalent of fire doors and not completely smoketight, are effective in restricting the spread of smoke and reducing drafts, which might otherwise spread fire rapidly. Where the smoke barrier is required by an occupancy chapter to have a fire resistance rating, a 20-minute fire protection-rated door assembly in a smoke partition should be accepted as a reasonable barrier. It has been shown through tests that the commonly used 44-mm- (1¾-in.-) thick solid-wood core door assembly can be expected to fail in fire tests in 22 minutes to 24 minutes, but it has performed well in actual fires when closed²⁶.

Doors in a fire separation, horizontal exit, or smoke barrier should be closed at all times to impede the spread of smoke and fire gases. Functionally, however, keeping the doors closed decreases efficiency. In a health care occupancy, for example, closed doors limit patient observation by the professional staff. To accommodate such situations, it is practical to presume that the door will be kept open, even with the use of wood chocks or other makeshift devices. Where operational necessity dictates that smoke barrier doors normally are to be kept open, such doors should be provided with hold-open devices that are triggered to close the doors by the operation of smoke detectors (see Exhibit 8.8). See 7.2.1.8 for details on hold-open devices with automatic release mecha-

Exhibit 8.8 Hold-open mechanism on automatic-closing door.

nisms. For additional information on the use of smoke detectors for releasing service, see the commentary to 9.6.3.2.3.

8.5.3.5 Fire window assemblies shall comply with 8.3.3.

8.5.4 Ducts and Air-Transfer Openings.

8.5.4.1 General. The provisions of 8.5.4 shall govern the materials and methods of construction used to protect ducts and air-transfer openings in smoke barriers.

8.5.4.2 Smoke Dampers. Where a smoke barrier is penetrated by a duct or air-transfer opening, a smoke damper designed and tested in accordance with the requirements of UL 555S shall be installed. Where a smoke barrier is also constructed as a fire barrier, a combination fire/smoke damper designed and tested in accordance with the requirements of UL 555, *Standard for Fire Dampers*, and UL 555S shall be installed.

8.5.4.3 Smoke Damper Exemptions. Smoke dampers shall not be required under any of the following conditions:

- (1) Where specifically exempted by provisions in Chapter 12 through Chapter 42

- (2) Where ducts or air-transfer openings are part of an engineered smoke control system
- (3) Where the air in ducts continues to move and the air-handling system installed is arranged to prevent recirculation of exhaust or return air under fire emergency conditions

Paragraph 8.5.4.3(2) addresses the omission of dampers in ducts that must remain open so that an engineered smoke control system can operate. The provision of 8.5.4.3(3) applies only in very limited cases. It can be used only on small ventilation systems, because NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, requires that systems over 7080 L/sec (15,000 ft³/min) that are not part of a smoke control system shut down upon detection of smoke.

Even without the restriction of NFPA 90A, it is difficult to ensure that the air-handling system will be in continuous operation. Because of increased awareness of energy conservation, many systems are cycled or shut down during parts of the day. The cycling or shutdown feature might be added later without recognizing its potential detriment to building life safety. However, the provisions of 8.5.4.3(3) can be useful for ductwork for small ventilation systems, such as those for bathrooms or small suites.

- (4) Where the air inlet or outlet openings in ducts are limited to a single smoke compartment

Paragraph 8.5.4.3(4) addresses situations where an “express” duct has no openings other than in a single smoke compartment. This provision can reasonably be extended to situations illustrated in Exhibit 8.9.

- (5) Where ducts penetrate floors that serve as smoke barriers

The provision of 8.5.4.3(5) (which recognizes that 8.6.1 requires every floor that separates stories in a building to be constructed as a smoke barrier to provide a basic degree of compartmentation) differentiates between (1) a true smoke barrier in accordance with Section 8.5, which is provided via vertical barriers, and (2) a smoke-resisting horizontal barrier consisting of a floor not subject to the requirements of Section 8.5.

The occupancy chapters (for example, Chapters 18 and 19 for health care occupancies) that mandate the installation of smoke barriers that comply with the requirements of Section 8.5 do so to divide a floor into two or more smoke compartments. They impose

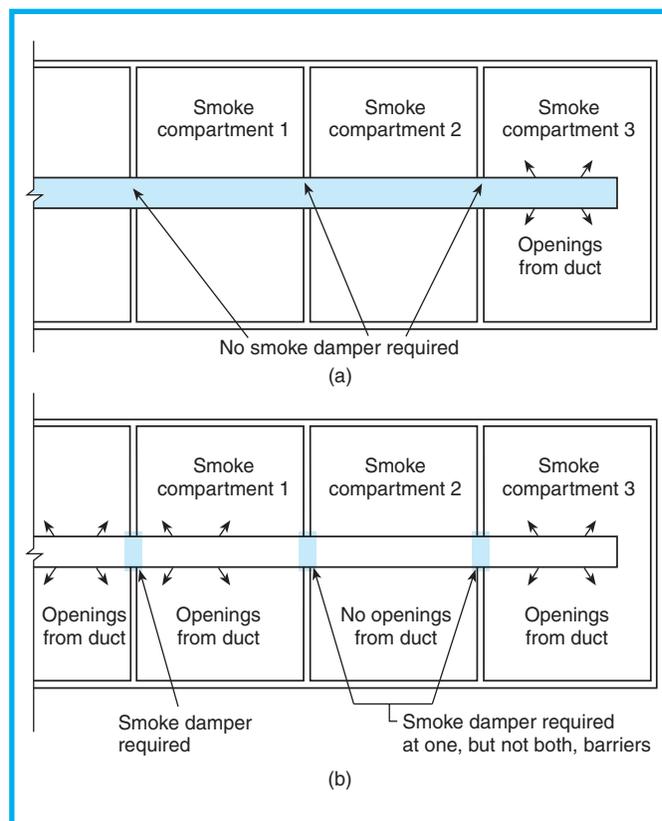

Exhibit 8.9 Position of smoke dampers in air-handling ductwork.

no further subdivision using smoke barriers, because that would separate one floor from another and create different smoke compartments stacked upon each other. Rather, the occupancy chapters rely on the vertical opening protection requirements of Section 8.6 to keep fire from spreading from floor to floor. In combination with 8.6.1, the vertical opening protection rules do an adequate job but do not elevate the floor construction to the stringent smoke barrier standards required of vertically positioned barriers that comply with Section 8.5. Ducts penetrating floors are thus exempt from the smoke damper requirements of 8.5.4.2.

Per the requirements of NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, only a single floor can be penetrated by ductwork not enclosed within a rated shaft system, and such an installation requires a fire damper at the plane of the floor where the penetration is located. Ducts penetrating more than one floor must be enclosed within an appropriately fire-rated shaft. Thus, where a smoke damper is exempted by 8.5.4.3(5), the resulting openings can potentially act as a minor route for smoke migration from one floor to another

before the actuation of a fire damper. The floor, as a whole, serves as an adequate smoke barrier in accordance with the requirements of 8.6.1.

8.5.4.4 Installation.

8.5.4.4.1 Air-conditioning, heating, ventilating ductwork, and related equipment, including smoke dampers and combination fire and smoke dampers, shall be installed in accordance with NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

8.5.4.4.2 The equipment specified in 8.5.4.4.1 shall be installed in accordance with the requirements of 8.5.4.4, the manufacturer's installation instructions, and the equipment listing.

8.5.4.5 Access and Identification. Access to the dampers shall be provided for inspection, testing, and maintenance. The access openings shall not reduce the fire resistance rating of the fire barrier assembly.

8.5.4.6 Smoke Damper Ratings. Smoke damper leakage ratings shall be not less than Class II. Elevated temperature ratings shall be not less than 140°C (250°F).

8.5.4.7 Smoke Detectors.

8.5.4.7.1 Required smoke dampers in ducts penetrating smoke barriers shall close upon detection of smoke by approved smoke detectors in accordance with *NFPA 72®*, *National Fire Alarm Code®*, unless one of the following conditions exists:

- (1) The ducts penetrate smoke barriers above the smoke barrier doors and the door release detector actuates the damper.
- (2) Approved smoke detector installations are located within the ducts in existing installations.

8.5.4.7.2 Where a duct is provided on one side of the smoke barrier, the smoke detectors on the duct side shall be in accordance with 8.5.4.7.1.

8.5.4.7.3 Required smoke dampers in air-transfer openings shall close upon detection of smoke by approved smoke detectors in accordance with *NFPA 72®*, *National Fire Alarm Code®*.

NFPA 72®, *National Fire Alarm Code®*²⁷, provides information on the installation of smoke detectors that close smoke dampers. The damper is permitted to be closed by the same detector that closes the door in a smoke barrier if the dampered duct penetrates the wall above the door. Existing installations of in-

duct detectors, which might not be in total compliance with *NFPA 72*, continue to be recognized.

8.5.5 Penetrations.

8.5.5.1 The provisions of 8.5.5 shall govern the materials and methods of construction used to protect through-penetrations and membrane penetrations of smoke barriers.

8.5.5.2 Penetrations for cables, cable trays, conduits, pipes, tubes, vents, wires, and similar items to accommodate electrical, mechanical, plumbing, and communications systems that pass through a wall, floor, or floor/ceiling assembly constructed as a smoke barrier, or through the ceiling membrane of the roof/ceiling of a smoke barrier assembly, shall be protected by a system or material capable of restricting the transfer of smoke.

8.5.5.3 Where a smoke barrier is also constructed as a fire barrier, the penetrations shall be protected in accordance with the requirements of 8.3.5 to limit the spread of fire for a time period equal to the fire resistance rating of the assembly and 8.5.5 to restrict the transfer of smoke, unless the requirements of 8.5.5.4 are met.

8.5.5.4 Where sprinklers penetrate a single membrane of a fire resistance-rated assembly in buildings equipped throughout with an approved automatic fire sprinkler system, noncombustible escutcheon plates shall be permitted, provided that the space around each sprinkler penetration does not exceed 13 mm (½ in.), measured between the edge of the membrane and the sprinkler.

8.5.5.5 Where the penetrating item uses a sleeve to penetrate the smoke barrier, the sleeve shall be securely set in the smoke barrier, and the space between the item and the sleeve shall be filled with a material capable of restricting the transfer of smoke.

8.5.5.6 Where designs take transmission of vibrations into consideration, any vibration isolation shall meet one of the following conditions:

- (1) It shall be provided on either side of the fire barrier.
- (2) It shall be designed for the specific purpose.

8.5.6 Joints.

8.5.6.1 The provisions of 8.5.6 shall govern the materials and methods of construction used to protect joints in between and at the perimeter of smoke barriers or, where smoke barriers meet other smoke barriers, the floor or roof deck above, or the outside walls. The provisions of 8.5.6 shall not apply to approved existing materials and methods of construction used to protect existing joints in smoke barriers, unless otherwise required by Chapter 12 through Chapter 42.

8.5.6.2 Joints made within or at the perimeter of smoke barriers shall be protected with a joint system that is capable of limiting the transfer of smoke.

8.5.6.3 Joints made within or between smoke barriers shall be protected with a smoke-tight joint system that is capable of limiting the transfer of smoke.

8.5.6.4 Smoke barriers that are also constructed as fire barriers shall be protected with a joint system that is designed and tested to resist the spread of fire for a time period equal to the required fire resistance rating of the assembly and restrict the transfer of smoke.

8.5.6.5 Testing of the joint system in a smoke barrier that also serves as fire barrier shall be representative of the actual installation suitable for the required engineering demand without compromising the fire resistance rating of the assembly or the structural integrity of the assembly.

As in the case of fire barriers, it is important to maintain the integrity of smoke barriers over the life of a building. Exhibit 8.10 illustrates some of the key items regarding smoke barrier penetrations discussed in 8.5.3 through 8.5.6.

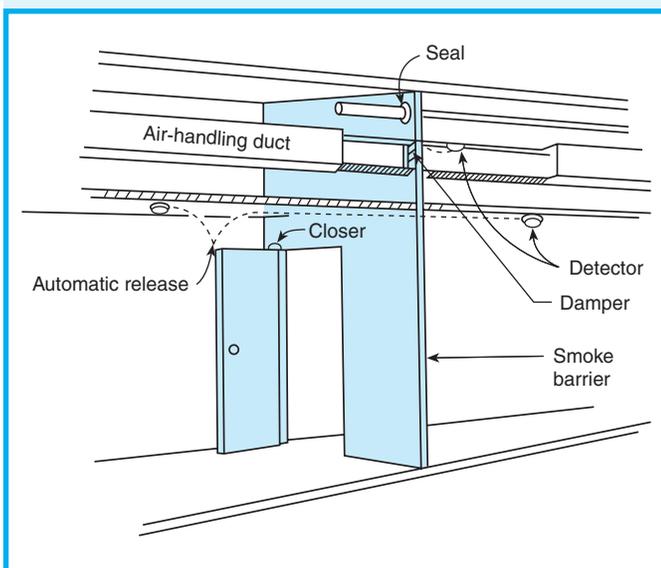

Exhibit 8.10 Typical penetrations of a smoke barrier.

Section 8.6 Vertical Openings

Unprotected or improperly protected vertical openings have consistently been major contributing factors in multiple-death fires. This is particularly well

illustrated by the two deadliest hotel fires in recent decades in the U.S. and its possessions²⁸.

In 1986, 97 people died in a fire at the Dupont Plaza Hotel in San Juan, Puerto Rico. The unprotected vertical opening between the ballroom level, where the fire originated, and the casino level, where nearly all the deaths occurred, would not be allowed by the *Code*, given the lack of other fire protection design features of that area²⁹.

In the 1980 MGM Grand Hotel fire in Las Vegas, Nevada, where 85 people died, smoke spread occurred via unprotected vertical openings (concealed spaces, elevator shafts) and insufficiently protected exit stair enclosures³⁰. Many factors contributed to the vertical smoke spread, including the following:

- (1) Unprotected seismic joint shafts and elevator hoistways
- (2) Insufficiently fire resistance-rated construction used in interior stair enclosures
- (3) Exposure of exit stair and exit passageway spaces to casino level plenum air
- (4) Heating, ventilating, and air conditioning systems with fire dampers that did not operate

Most of the hotel and motel fires of recent decades that have resulted in 10 or more fatalities have involved unprotected vertical openings, typically unenclosed interior stairs.

8.6.1 Floor Smoke Barriers.

Every floor that separates stories in a building shall meet one of the following criteria:

- (1) It shall be constructed as a smoke barrier to form a basic degree of compartmentation. (*See 3.3.23.2.*)
- (2) It shall have openings as permitted by 8.6.6, 8.6.7, 8.6.8, or Chapter 11 through Chapter 42.

Although 8.6.1(1) requires that every floor be constructed as a smoke barrier, the intent of the requirement is tempered to emphasize that a basic degree of compartmentation be provided. The definition of *smoke barrier* in 3.3.23.2 provides the user with the information that such barriers might have protected openings. Thus, it is not the *Code's* intent that every floor must restrict the passage of smoke to the same degree as that of a required smoke barrier in accordance with Section 8.5. Even required smoke barriers, which must comply with Section 8.5, are afforded the use of 8.5.4.3(5), which allows smoke dampers to be omitted where ducts penetrate floors that serve as smoke barriers. See the commentary following 8.5.4.3(5).

8.6.2* Continuity.

Openings through floors shall be enclosed with fire barrier walls, shall be continuous from floor to floor, or floor to roof, and shall be protected as appropriate for the fire resistance rating of the barrier.

A.8.6.2 Openings might include items such as stairways, hoistways for elevators, dumbwaiters, and inclined and vertical conveyors; shaftways used for light, ventilation, or building services; or expansion joints and seismic joints used to allow structural movements.

8.6.3 Continuity Exemptions.

The requirements of 8.6.2 shall not apply where otherwise permitted by the following:

- (1) Where pneumatic tube conveyors are protected in accordance with 8.3.5.1
- (2) Where specified by 8.6.6, 8.6.7, 8.6.8.1, 8.6.8.2, or Chapter 11 through Chapter 42
- (3) Where escalators and moving walks are protected in accordance with 8.6.8.5 or 8.6.8.6
- (4) Where expansion or seismic joints designed to prevent the penetration of fire and shown to have a fire resistance rating of not less than that required for the floor when tested in accordance with ANSI/UL 2079, *Test of Fire Resistance of Building Joint Systems*
- (5) Where existing mail chutes meet one of the following criteria:
 - (a) The cross-sectional area does not exceed 0.01 m² (0.1 ft²).
 - (b) The building is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

It is important to note that 8.6.1 and 8.6.2 apply to all occupancies, unless a specific occupancy chapter provides an alternative option. Protection of vertical openings is normally covered in subsection ___3.1 of each occupancy chapter (for example, 12.3.1 for new assembly occupancies or 18.3.1 for new health care occupancies).

Protection of vertical openings is extremely important in reducing fire casualties. In report after report of fires involving fatalities, unprotected vertical openings were a major factor contributing to loss of life.

Vertical fire spread is also a major factor contributing to the extensive property damage characteristic of large-loss building fires; thus a correlation frequently exists between loss of life from fire and monetary loss from fire. Vertical fire spread relates directly to the lack of protection for vertical openings, because

the principal structural weakness responsible for the vertical spread of fire is the absence of the fire cutoffs at openings between floors.

Exhibit 8.11 illustrates some typical floor openings in buildings. If the exit stairs at each end of the building are not properly enclosed per the requirements of 7.1.3.2, they do not qualify as exits. If the exit stairs do not comply with the requirements of Section 8.6 and subsection ___3.1 of the appropriate occupancy chapter, they create unprotected vertical openings. The other floor openings illustrated in Exhibit 8.11 are not affected by the requirements applicable to exits, but do, if not properly enclosed, create unprotected vertical openings.

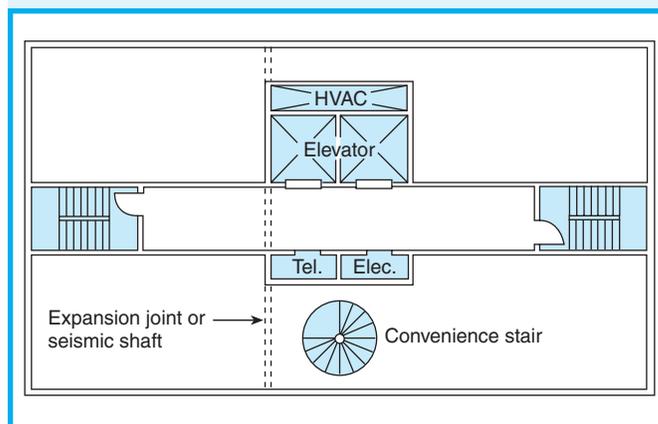

Exhibit 8.11 Typical floor openings that, if not properly enclosed, might spread the effects of a fire from floor to floor.

Based on lessons learned from the Las Vegas MGM Grand Hotel fire, the 1988 edition of the *Code* expanded the list of floor openings to include expansion joints and seismic joints that allow structural movement. In lieu of full enclosure from floor to floor, 8.6.3(4) specifically recognizes the use of fire protection-rated expansion or seismic joints, with a minimum rating of not less than the required fire resistance rating of the floor. Without appropriately rated joints, the enclosure requirements might be satisfied by an arrangement of walls and doors as shown in Exhibit 8.12. The enclosure of the seismic joint running horizontally across the building and vertically through all floors is accomplished by back-to-back fire resistance-rated barriers and cross-corridor fire protection-rated door assemblies.

8.6.4 Shafts.

Shafts that do not extend to the bottom or the top of the building or structure shall comply with either 8.6.4.1 or 8.6.4.2.

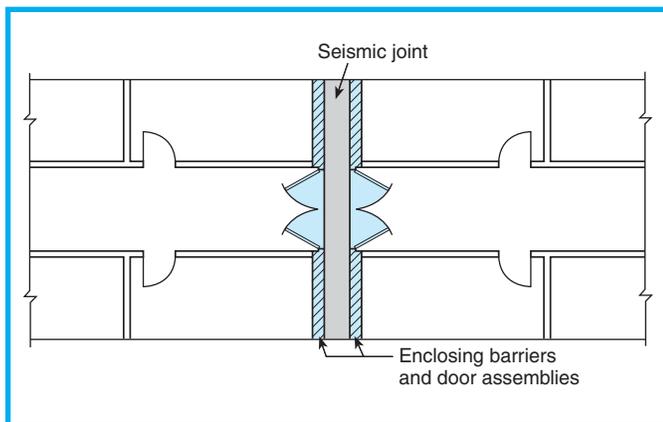

Exhibit 8.12 Enclosure of seismic joint.

8.6.4.1 Shafts shall be enclosed at the lowest or highest level of the shaft, respectively, with construction in accordance with 8.6.5.

8.6.4.2 Shafts shall be permitted to terminate in a room or space having a use related to the purpose of the shaft, provided that the room or space is separated from the remainder of the building by construction having a fire resistance rating and opening protectives in accordance with 8.6.5 and 8.3.4.

8.6.4.3 Shafts that do not extend to the bottom or top of the building or structure shall be permitted to be protected by approved fire dampers installed in accordance with their listing at the lowest or highest floor level, as applicable, within the shaft enclosure.

Some shafts commonly found in buildings do not extend through the entire height of the building. For example, in a high-rise building, a percentage of the overall number of elevator shafts will service only the lower-rise portion of the building. Such shafts might run from the street level through the 20th floor of a 40-story building. In a typical hotel that devotes the first couple of stories to assembly occupancy uses and locates guest rooms above in the hotel occupancy tower, the shafts associated with guest room bathroom exhaust might begin at the third floor and continue to the roof. In such cases, although the shaft walls are constructed of fire resistance-rated assemblies, an unprotected shaft ceiling/top or unprotected shaft floor/bottom would allow fire and other products of combustion to travel vertically to some other part of the building. Because of this concern, 8.6.4.1 requires that those shaft ceilings or floors be protected by construction as required for the shaft walls.

Exhibit 8.13 illustrates various shaft arrange-

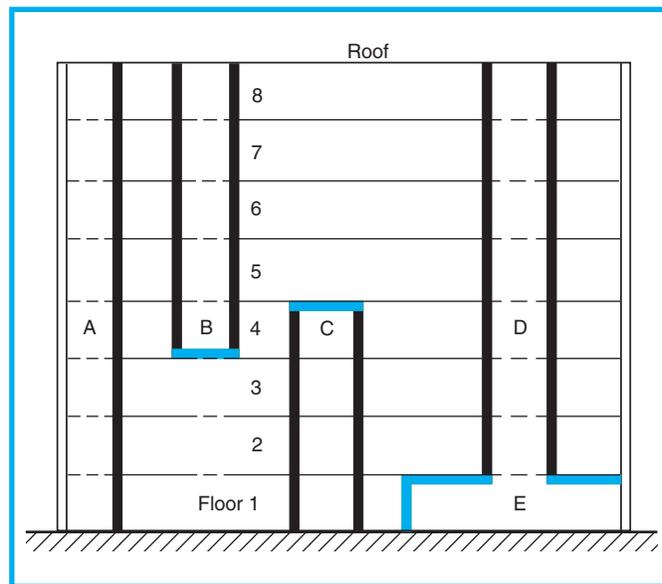

Exhibit 8.13 Shaft enclosures.

ments. Shafts that do not run the full height of a building must be capped by floors or ceilings of fire resistance-rated construction at least equal to the required rating of the shaft-enclosing walls. Shaft A runs vertically for the full height of the building and requires only vertical fire barriers to separate the shaft from the remainder of the building interior. Because neither shaft B nor shaft C extends the full height of the building, horizontal fire barriers (a floor for shaft B and a ceiling for shaft C) must be provided to complete the shaft envelope. Shaft D, which is used for heating, ventilating, and air conditioning (HVAC), extends vertically from the second floor to the roof; 8.6.4.2 makes it unnecessary to install a rated floor barrier between shaft D and the mechanical equipment room, E. In this case, the ceiling and walls of the mechanical equipment room, used for purposes related to the use of the HVAC shaft, must be constructed of material of at least the same hourly rating as required for shaft D. The room enclosure thus becomes an extension of the shaft. Access to room E from within the building would be gained through appropriately rated fire door assemblies.

8.6.5* Required Fire Resistance Rating.

The fire resistance rating for the enclosure of floor openings shall be not less than as follows (*see 7.1.3.2.1 for enclosure of exits*):

- (1) Enclosures connecting four stories or more in new construction—2-hour fire barriers
- (2) Other enclosures in new construction—1-hour fire barriers

- (3) Existing enclosures in existing buildings— $\frac{1}{2}$ -hour fire barriers
- (4) Enclosures for lodging and rooming houses—as specified in Chapter 26
- (5) Enclosures for new hotels—as specified in Chapter 28
- (6) Enclosures for new apartment buildings—as specified in Chapter 30

A.8.6.5 The application of the 2-hour rule in buildings not divided into stories is permitted to be based on the number of levels of platforms or walkways served by the stairs.

Where addressing vertical openings, the *Code* does not use the height of buildings or a designated number of floors above ground as the basis for its rated enclosure requirements. Rather, such requirements are based on the total number of floors connected by the vertical opening. For example, if there is a vertical opening between the second, third, and fourth stories of an eight-story building, the opening connects fewer than four floors and the enclosure must be of 1-hour, rather than 2-hour, fire resistance-rated construction.

Where a vertical opening in new construction connects four stories or more, the enclosure protection afforded must have at least a 2-hour fire resistance rating. This requirement applies whether the stories are above the exit discharge level, below the exit discharge level, or any combination thereof. Where three or fewer stories are connected by a vertical opening in new construction, the enclosure rating must be at least 1 hour. Existing vertical openings, regardless of the number of stories they connect, require protection by $\frac{1}{2}$ -hour fire resistance-rated enclosures.

See Exhibit 8.14 for illustrations of the vertical opening protection requirements for new construction. Although Exhibit 8.14 depicts vertical openings that resemble exit stair enclosures, the same requirements apply to any type of vertical opening, including exit access stairs and elevator, electrical, HVAC, and seismic shafts.

Experience shows that, under some circumstances, each of the 1-hour and 2-hour rating levels provides a comfortable period of time for the occupants of a building to evacuate. On the other hand, there are times when the integrity of the construction will be taxed to its limit (for example, during a fire that has gone undetected for a long period). This type of fire can generate heavy smoke and toxic gases that complicate evacuation by blocking the exit access.

An interior exit stair (see definition of *exit* in 3.3.62) must be enclosed to be separated from other

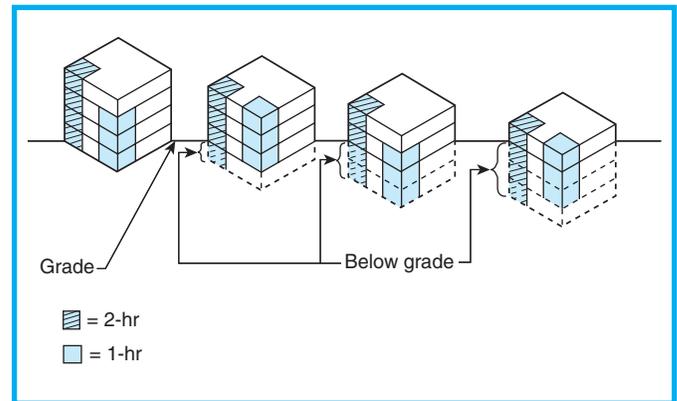

Exhibit 8.14 Vertical opening protection requirements.

building spaces and to provide a protected way of travel to the exit discharge. If not properly enclosed, the exit not only fails to meet the definition of an exit but also creates an unprotected vertical opening. Thus, an exit stair must meet the requirements for enclosure of an exit (see 7.1.3.2), as well as those for protection of vertical openings in accordance with 8.6.5, as modified by the applicable occupancy chapter. Because the requirements for exit enclosures are more stringent than the requirements for protection of vertical openings, once the more stringent requirements have been met, the other requirements are usually met automatically.

The provisions of 8.6.5(4), (5), and (6) reference the lodging or rooming, hotel, and apartment occupancy chapters, which allow modifications to the requirements of 8.6.5 under certain conditions. Some of the provisions permit 1-hour rated enclosures, regardless of the number of stories connected, if the building is protected throughout by automatic sprinklers and it is not a high-rise building. Although these occupancy chapters use such modifications to temper the basic Chapter 8 requirements with respect to the enclosure of vertical openings, it is possible for a specific occupancy chapter to be more stringent. For example, see 19.3.1.1, which requires 1-hour enclosures in existing health care occupancies rather than the $\frac{1}{2}$ -hour enclosures that would otherwise be permitted by 8.6.5(3).

8.6.6 Communicating Space.

Unless prohibited by Chapter 12 through Chapter 42, unenclosed floor openings forming a communicating space between floor levels shall be permitted, provided that the following conditions are met:

- (1) The communicating space does not connect more than three contiguous stories.

- (2) The lowest or next-to-lowest story within the communicating space is a street floor.
- (3) The entire floor area of the communicating space is open and unobstructed, such that a fire in any part of the space will be readily obvious to the occupants of the space prior to the time it becomes an occupant hazard.
- (4) The communicating space is separated from the remainder of the building by fire barriers with not less than a 1-hour fire resistance rating, unless one of the following is met:
 - (a) In buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7, a smoke barrier in accordance with Section 8.5 shall be permitted to serve as the separation required by 8.6.6(4).
 - (b) The requirement of 8.6.6(4) shall not apply to fully sprinklered residential housing units of detention and correctional occupancies in accordance with 22.3.1(2) and 23.3.1.1(2)
- (5) The communicating space has ordinary hazard contents protected throughout by an approved automatic sprinkler system in accordance with Section 9.7 or has only low hazard contents. (See 6.2.2.)
- (6) Egress capacity is sufficient to allow all the occupants of all levels within the communicating space to simultaneously egress the communicating space by considering it as single floor area in determining the required egress capacity.
- (7)* Each occupant within the communicating space has access to not less than one exit without having to traverse another story within the communicating space.

A.8.6.6(7) Given that a mezzanine meeting the maximum one-third area criterion of 8.6.9.2.1 is not considered a story, it is permitted, therefore, to have 100 percent of its exit access within the communicating area run back through the story below.

- (8) Each occupant not in the communicating space has access to not less than one exit without having to enter the communicating space.

Subsection 8.6.6 recognizes a vertical opening that is exempt from the normal enclosure requirements of 8.6.5 under the following two conditions:

- (1) Use of the provision is not specifically prohibited by the pertinent occupancy chapter for the occupancy type in question.
- (2) All the alternative protection provisions of 8.6.6(1) through (8) are met.

The following paragraphs explain and illustrate the provisions of 8.6.6(1) through (8).

(a) The vertical space cannot connect or communicate among more than three stories, and all connected stories are required to be contiguous to each other. However, the building housing the vertical opening in question is permitted to be more than three stories in height. For example, the vertical opening might communicate among floors one through three of a six-story building. See Exhibit 8.15.

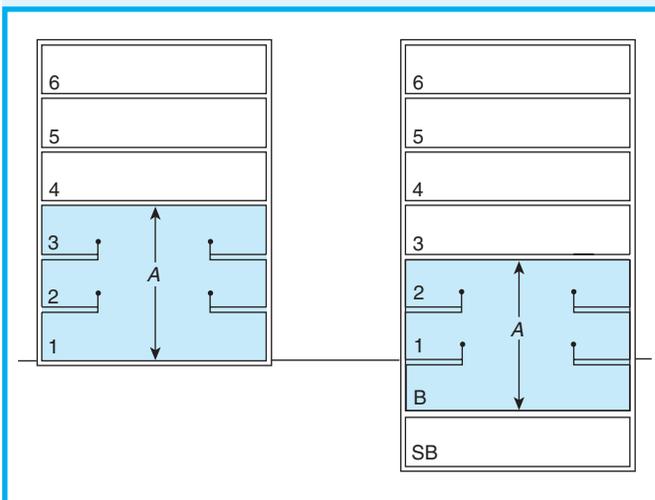

Exhibit 8.15 Permitted location of three-story vertical opening.

The provisions of 8.6.6 are often referred to as the “mini-atrium” requirements. Because they are limited to a maximum three-story vertical opening, the requirements are not as stringent as those of 8.6.7, which apply to atria that can involve vertical openings that communicate among 50 or 100 stories or more. A two- or three-story atrium can be adequately protected by the requirements of 8.6.6 without having to resort to the requirements of 8.6.7. The fact that a two- or three-story space is labeled as an atrium on building plans does not necessarily mean that it must be protected by the requirements of 8.6.7. A two- or three-story vertical opening, regardless of whether or not it is called an atrium, should be allowed to be protected per the requirements of 8.6.6, provided that doing so is not prohibited by the occupancy chapter(s) involved and the requirements of 8.6.6(1) through (8) are met.

(b) The lowest of the maximum three communicating floor levels must be at, or not more than one level below, the street level. In other words, the vertical opening can communicate among only the first, second, and third floors or among the basement, first,

and second floors. See space A in Exhibit 8.15. As previously mentioned, additional building floor levels might be present either above or below the floors involving the vertical opening, but these additional floors cannot be left open to the vertical opening. The more stringent set of provisions for atria per 8.6.7 should be considered where it is necessary or desirable either to have more than three levels open or to locate the communicating levels such that the lowest level does not meet the placement requirement with respect to street level.

(c) The communicating space includes all of the areas within the vertical opening itself and all of the adjoining areas left open to the vertical opening, as well as those areas not separated by minimum 1-hour fire resistance-rated barriers. The communicating space must be open and unobstructed so that occupants of the space will be aware of fire and smoke conditions emanating from any part of the communicating space prior to the time that such conditions become a hazard.

The provisions of 8.6.6 were originally written as an exception to the enclosure requirements for vertical openings in 8.6.2 to recognize typical mercantile occupancy construction practices, which left partial, mezzanine-like floors open to the main street-level shopping floor below. These arrangements were sufficiently open so that, where coupled with the other provisions of the exception, they allowed sufficient time for the necessary awareness of emergency conditions and for occupants to use the egress system. These provisions were not intended to be used for an unenclosed stair. The size of the small opening created by an unenclosed stair is insufficient to provide occupants on all levels connected by the stair with the needed degree of awareness.

Between the two extremes of vast amounts of openness (as in the case of the mezzanine-like floors described in the previous paragraph) and little or no openness (as depicted by the unenclosed stair), judging sufficient openness becomes difficult. Through the use of the equivalency concept addressed in Section 1.4, some authorities having jurisdiction have allowed complete automatic smoke detection systems with proper occupant notification features to be substituted for the openness and unobstructedness required by 8.6.6(3) for awareness and early warning purposes.

(d) The communicating space must be separated from the remainder of the building by fire barriers with a minimum 1-hour fire resistance rating. Once the boundaries of the communicating space are es-

tablished, based on determining how much area is open enough [per the requirement of 8.6.6(3) just discussed] to permit awareness and early warning, then areas outside these boundaries must be separated from the communicating space associated with the vertical opening by barriers with a minimum 1-hour fire resistance rating. If the building is fully sprinklered, the barriers are permitted to be nonrated but must resist the passage of smoke and meet the other smoke barrier requirements of Section 8.5. It is assumed that the sprinkler system will control the fire and make fire resistance-rated barriers unnecessary. The smoke barriers will control the limited smoke, under sprinklered conditions, and help maintain a tenable means of egress route.

For example, consider a hotel building with fingerlike guest room wings fanning out from the vertical opening. It can be assumed that the guest room wing corridors will need separation from the vertical opening, because occupants in the corridor on the second or third floor will not be readily aware of a fire on the first floor before it becomes a hazard to their safety. The required 1-hour separation can be provided, while maintaining the perception of openness, by isolating the guest room wings from the vertical opening through the use of pairs of cross-corridor doors held open with automatic release devices. See Exhibit 8.16.

(e) If the communicating space [the vertical opening itself and all adjoining areas open to it as described in item (c)] has *ordinary hazard* contents (as explained in Section 6.2 of this Code, as opposed to

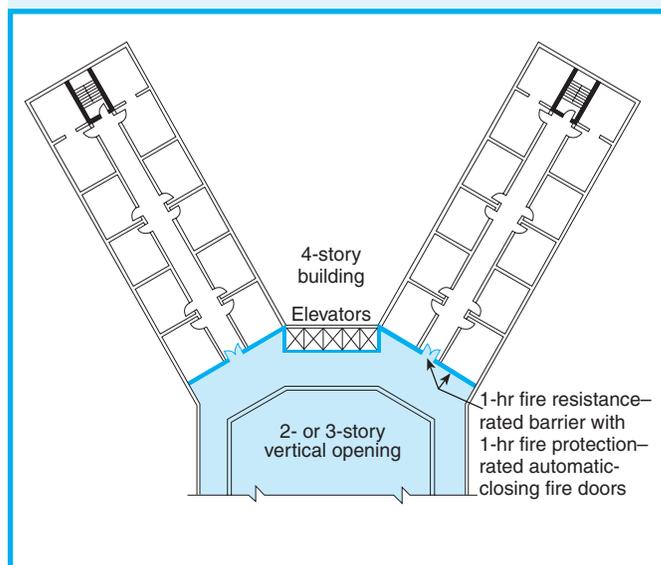

Exhibit 8.16 Separation of two- or three-story communicating space from remainder of building.

(the definition of *ordinary hazard occupancies* in NFPA 13, *Standard for the Installation of Sprinkler Systems*³¹), all areas within the confines of the communicating space must be sprinklered. If the contents are *low hazard* (again, as explained in Section 6.2 of this Code, rather than *light hazard* as defined in NFPA 13), no sprinkler system is required by 8.6.6. However, as intended by Section 6.2, most occupancies are classified as ordinary hazard. Because only low hazard and ordinary hazard contents are addressed in 8.6.6(5), high hazard contents are prohibited from any communicating spaces recognized by 8.6.6.

Although sprinkler system protection is required with ordinary hazard contents, only the communicating space (as previously defined) needs to be sprinklered, according to 8.6.6. The sprinkler system should cover all areas within the boundaries established by the 1-hour fire barriers that are required by 8.6.6(4). See Exhibit 8.16.

In Exhibit 8.16, the cross-corridor fire doors are held open by automatic release devices so that the corridor appears to be open to the communicating area of the vertical opening. Yet, because there are doors and a barrier at that location, it demarcates the boundary between the communicating space and the floor area outside the communicating space. Sprinkler protection must be provided for the vertical opening and the shaded adjoining areas up to the 1-hour barriers.

(f) Because all occupants within the communicating area might be exposed within a short time to the effects of a fire within the area, simultaneous evacuation capability needs to be provided. Thus, the combined occupant load for all spaces, on all levels, within the boundaries of the communicating area needs to be included when sizing the means of egress for the communicating area. This requirement is more stringent than the provision of 7.3.1.4, which exempts the accumulation of occupant loads from various floors.

(g) Per the requirements of 8.6.6(3) and 8.6.6(4), the communicating space is that space that is sufficiently open to the vertical opening to allow ready awareness of fire conditions on that and other levels within the communicating space. Areas that are remote enough from the vertical opening to lose the requisite awareness must be located on the other side of 1-hour fire resistance-rated fire barriers and are considered to be outside the communicating space. Thus, in a typical office building making use of the provisions of 8.6.6, for example, some occupants work and are normally stationed within the communicating space, while others work and are stationed out-

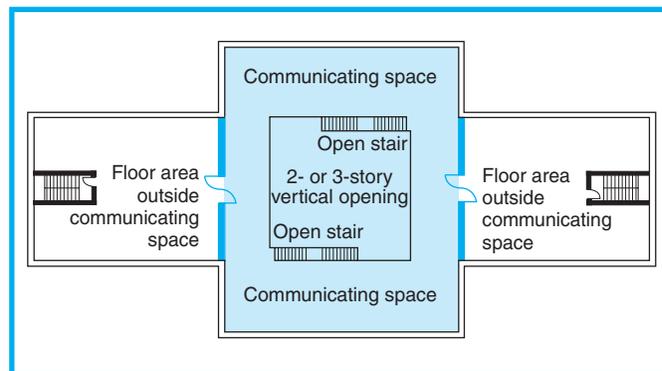

Exhibit 8.17 Exit access arrangement for building using the two- or three-story vertical opening provision.

side the communicating space. This arrangement is shown in Exhibit 8.17.

Occupants located within the communicating space must have access to at least one exit without having to traverse another story within the communicating space as per 8.6.6(7). The communicating space shown in Exhibit 8.17 would meet this requirement by allowing occupants to travel horizontally across the communicating space, pass through the fire doors in the fire-rated barrier into one of the building wings designated as “floor area outside the communicating space,” and continue to that wing’s enclosed exit stair. In other words, the occupants of the communicating space are not permitted to use the open stairs exclusively to travel to another level of the communicating space to reach the required exits.

In the example illustrated in Exhibit 8.17, assume that some occupants of the communicating space are farther from either of the enclosed exit stairs, which are located at each end of the building, than the travel distance allowed by other Code requirements. Further, assume that those same occupants of the communicating space can travel down the open stair and across the bottom floor of the vertical opening to an exterior exit door within the allowable travel distance limitation. The open stair, although it is not an exit, could be considered as exit access, and the door to the outside at the lowest level of the vertical opening could then be regarded as the nearest Code-complying exit for those occupants. Either of the enclosed exit stairs at the end of the building could then serve as the second exit for those occupants of the communicating space. The enclosed exit stairs would then serve the following three purposes, none of which would be as the primary exit for those occupants of the communicating space:

- (1) The stairs would satisfy the business occupancy chapters' requirements that the minimum two required exits occur on the floor.
- (2) Either stair would satisfy the requirement of 8.6.6(7) that the occupants of the communicating space have access to at least one exit without having to traverse another story within the communicating space.
- (3) Each stair would satisfy the requirement of 8.6.6(8), discussed in the commentary that follows, which mandates that each occupant not located within the communicating space is to have access to at least one exit without entering the communicating space.

(h) Although all occupants must have access to two separate exits, the occupants who are located on any of the maximum of three floors that are permitted to communicate with the vertical opening, but who are not within the communicating space (as illustrated in Exhibit 8.17 by the wings located at each end of the building), must be able to reach one of the two required exits without entering the communicating space. This requirement is satisfied by locating an enclosed exit stair within each of the floor areas outside the communicating space.

The provisions of 8.6.6 are permitted unless prohibited by an occupancy chapter. For an example of an occupancy that prohibits the two- or three-story vertical opening, see 18.3.1.5 and 19.3.1.5, which apply to health care occupancies. For an example of an occupancy that provides requirements in addition to those of 8.6.6(1) through (8), see 14.3.1.2 and 15.3.1.2, which apply to educational occupancies. Chapters 14 and 15 require that the entire building, rather than only the communicating space, be protected by a supervised automatic sprinkler system.

8.6.7* Atriums.

Unless prohibited by Chapter 12 through Chapter 42, an atrium shall be permitted, provided that the following conditions are met:

- (1) The atrium is separated from the adjacent spaces by fire barriers with not less than a 1-hour fire resistance rating with opening protectives for corridor walls, unless one of the following is met:
 - (a) The requirement of 8.6.7(1) shall not apply to existing, previously approved atriums.
 - (b) Any number of levels of the building shall be permitted to open directly to the atrium without enclosure based on the results of the engineering analysis required in 8.6.7(5).
- (2) Access to exits is permitted to be within the atrium, and exit discharge in accordance with 7.7.2 is permitted to be within the atrium.
- (3) The occupancy within the atrium meets the specifications for classification as low or ordinary hazard contents. (See 6.2.2.)
- (4) The entire building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (5)* For other than existing, previously approved atriums, an engineering analysis is performed that demonstrates that the building is designed to keep the smoke layer interface above the highest unprotected opening to adjoining spaces, or 1830 mm (72 in.) above the highest

- (c)* Glass walls and inoperable windows shall be permitted in lieu of the fire barriers where all the following are met:
 - i. Automatic sprinklers are spaced along both sides of the glass wall and the inoperable window at intervals not to exceed 1830 mm (72 in.).
 - ii. The automatic sprinklers specified in 8.6.7(1)(c)i are located at a distance from the glass wall not to exceed 305 mm (12 in.) and arranged so that the entire surface of the glass is wet upon operation of the sprinklers.
 - iii. The glass wall is of tempered, wired, or laminated glass held in place by a gasket system that allows the glass framing system to deflect without breaking (loading) the glass before the sprinklers operate.
 - iv. The automatic sprinklers required by 8.6.7(1)(c)i are not required on the atrium side of the glass wall and the inoperable windows where there is no walkway or other floor area on the atrium side above the main floor level.
 - v. Doors in the glass walls shall be glass or other material that resists the passage of smoke.
 - vi. Doors in the glass walls shall be self-closing or automatic-closing upon detection of smoke.

A.8.6.7(1)(c) The intent of the requirement for closely spaced sprinklers is to wet the atrium glass wall to ensure that the surface of the glass is wet upon operation of the sprinklers, with a maximum spacing of sprinklers of 1830 mm (72 in.) on centers. Provided that it can be shown that the glass can be wet by the sprinklers using a given discharge rate and that the 1830-mm (72-in.) spacing is not exceeded, the intent of the requirement is met. It is important that the entire glass area surface is wet. Due consideration should be given to the height of the glass panels and any horizontal members that may interfere with sprinkler wetting action.

floor level of exit access open to the atrium, for a period equal to 1.5 times the calculated egress time or 20 minutes, whichever is greater.

A.8.6.7(5) See NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*. The engineering analysis should include the following elements:

- (1) Fire dynamics, including fire size and location, materials likely to be burning, fire plume geometry, fire plume or smoke layer impact on means of egress, and tenability conditions during the period of occupant egress
- (2) Response and performance of building systems, including passive barriers, automatic detection and extinguishing, and smoke control
- (3) Response time required for building occupants to reach building exits, including any time required to exit through the atrium as permitted by 8.6.7(2)
- (6)* In other than existing, previously approved atriums, where an engineered smoke control system is installed to meet the requirements of 8.6.7(5), the system is independently activated by each of the following:
 - (a) The required automatic sprinkler system
 - (b) Manual controls that are readily accessible to the fire department

A.8.6.7(6) Activation of the ventilation system by manual fire alarms, extinguishing systems, and detection systems can cause unwanted operation of the system, and it is suggested that consideration be given to zoning of the activation functions so the ventilation system operates only when actually needed.

A.8.6.7 Where atriums are used, there is an added degree of safety to occupants because of the large volume of space into which smoke can be dissipated. However, there is a need to ensure that dangerous concentrations of smoke are promptly removed from the atrium, and the exhaust system needs careful design. For information about systems that can be used to provide smoke protection in these spaces, see the following:

- (1) NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*
- (2) *Design of Smoke Management Systems*

Atria are permitted in accordance with 8.6.7 unless prohibited by an occupancy chapter. Although no occupancy chapter currently prohibits atria, some require additional criteria. For example, health care occupancies prohibit the open floors addressed by 8.6.7(1)(b) from involving patient sleeping and treatment rooms. Thus, there would need to be, at a minimum, a smoke-resisting membrane, such as a glass

window, between the patient room and the atrium space.

Exhibits 8.18 and 8.19 illustrate a typical atrium.

The provisions of 8.6.7 address a vertical opening that communicates among more than the three floors addressed by the “mini-atrium” provisions of 8.6.6. Although the atrium provisions are not prohibited from being used for two- or three-story, atrium-like vertical openings, the provisions of 8.6.6 should adequately protect a two- or three-story “mini-atrium.” The design professional should be allowed to protect such areas in accordance with the less stringent provisions of 8.6.6, provided that doing so is not prohibited by the occupancy chapter in question. For example, the ___3.1 subsections of the health care occupancy Chapters 18 and 19, which address the protection of vertical openings, prohibit the use of the mini-atrium provisions of 8.6.6. Thus, in health care occupancies, a two- or three-story atrium-like vertical opening is allowed only if it meets all criteria of 8.6.7 applicable to large atria. For certain designs, 8.6.6 is not desirable due to its restriction on exit access within the vertical opening. For example, a

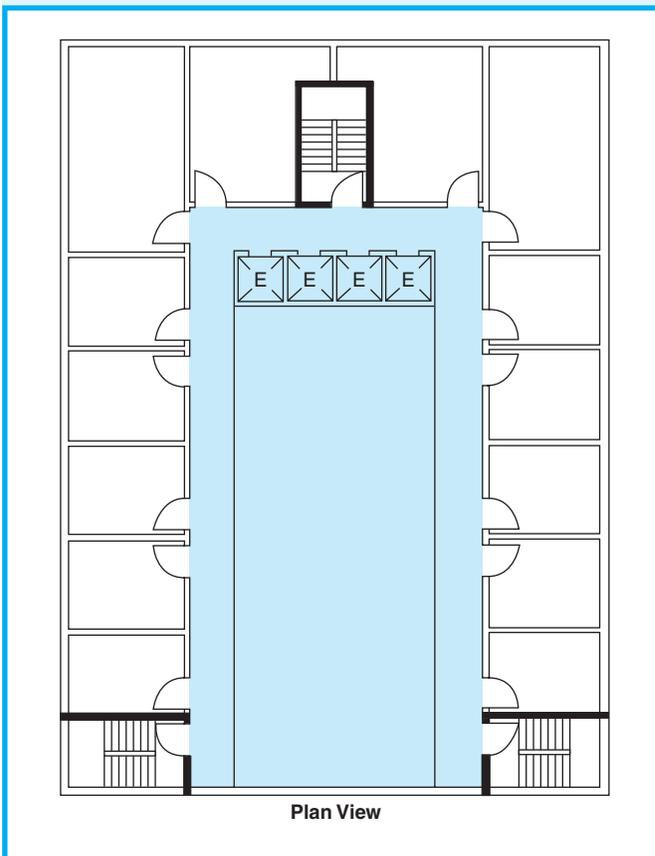

Exhibit 8.18 Plan view of a typical atrium.

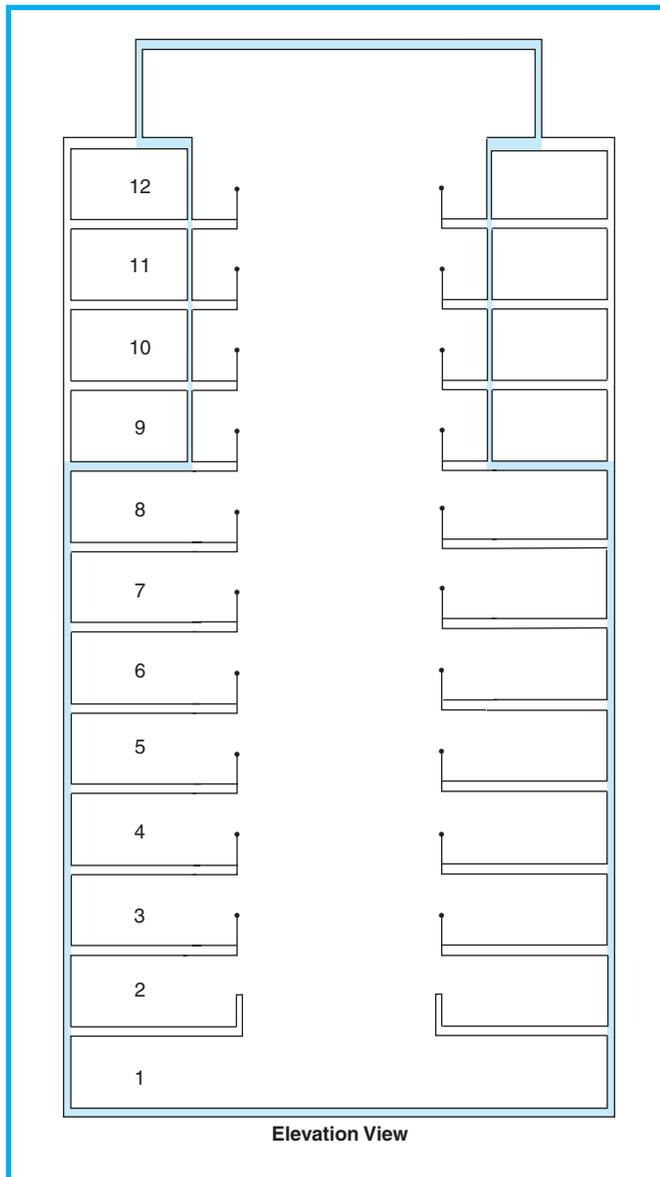

Exhibit 8.19 Elevation view of a typical atrium.

three-story hotel would prefer to use the more stringent provisions of 8.6.7 because they would permit the guest rooms to have exit access through the atrium, whereas 8.6.6 would not allow exit access to be solely through the mini-atrium.

The protection provisions of 8.6.7(1) through (6) are explained and illustrated in the paragraphs that follow.

(a) In accordance with the requirements of 8.6.5(1), a vertical opening of four or more stories in new construction generally must be separated from the rest of the building by an enclosure of 2-hour fire resistance-rated construction. However, the atrium

provisions work together as an overall package in allowing the construction that separates other areas of the building from the atrium to be reduced to a 1-hour fire resistance rating. Further, the doors in the 1-hour atrium fire barrier are permitted to be 20-minute fire protection-rated assemblies as allowed for corridor doors. Thus, the intent of the 1-hour separation requirement is mainly to provide a carefully constructed smoke-resistant barrier.

Per 8.6.7(1)(b), any number of levels is permitted to be left open to the atrium based on the engineering analysis required in 8.6.7(5). In Exhibit 8.20, levels 2 through 5 have been left open to the atrium. (In Exhibit 8.19, the open levels occur on floors 1 through 8.) Some occupancy chapters modify the atrium requirements as needed to afford the users of those occupancies the level of life safety needed. For example, for health care occupancies, Chapters 18 and 19 limit the location of the open levels allowed by 8.6.7(1)(b) so that patient treatment and sleeping rooms are not left open to the atrium.

To allow visual contact between the atrium and floors that have not been proven by engineering analysis to warrant openness, 8.6.7(1)(c) exempts the 1-hour rated separation if a smoke-resisting separation is provided. The use of glass walls, vision panels,

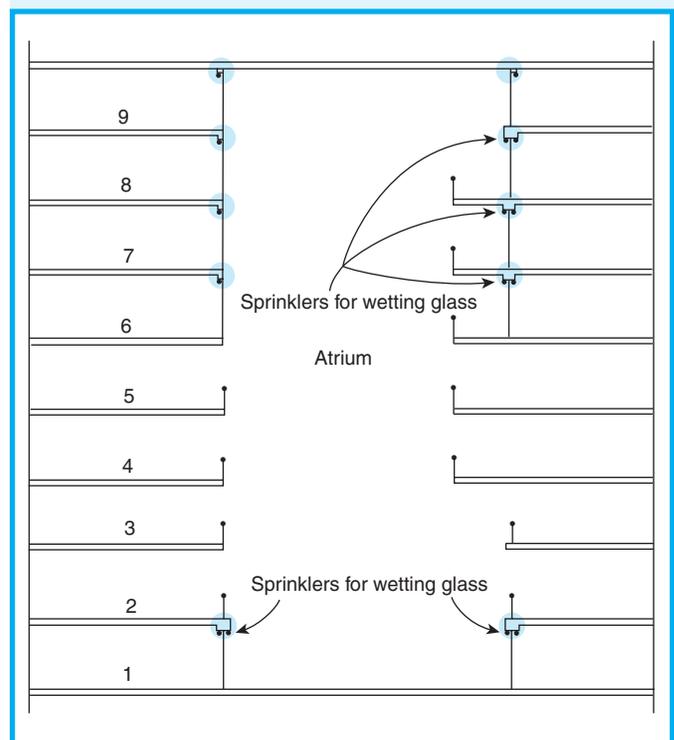

Exhibit 8.20 Floor levels open to atrium.

and windows in lieu of actual 1-hour fire resistance-rated construction is recognized by 8.6.7(1)(c). The intent of the requirement for directing closely spaced sprinklers at the glass walls is explained by A.8.6.7(1)(c).

The concept of wetting the glass that is exposed to a fire, without specifying a water application rate, is similar to boiling water in a Pyrex® container over an open flame. As long as there is some water present to absorb the heat, the glass itself does not reach excessive temperatures that would cause failure. To ensure that water will reach the surface of the glass, window blinds and draperies must not be placed between the line of closely spaced sprinklers and the glass. Careful design will allow for the sprinklers to be placed close enough to the glass so that blinds and draperies can be installed using normal installation practice.

The allowance to omit lines of closely spaced sprinklers on the atrium side of glass walls, which are to be used in lieu of 1-hour fire resistance-rated barriers, is intended to apply to the floor levels above the atrium main floor level. In other words, if glass walls are used on the main floor level in lieu of a 1-hour enclosure, sprinklers must be installed on both sides of the glass at that level, because combustibles might be placed on the floor on the atrium side of the glass. A similar condition occurs on levels 6, 7, and 8 where combustibles could be placed on the balcony floor adjacent to the glass. See Exhibit 8.20.

(b) The exit stairs must be enclosed in accordance with the exit enclosure requirements of 7.1.3.2, although they are allowed to be within the communicating space and located so as to require building occupants to walk through the communicating space of the atrium in order to gain access to them. Exhibit 8.18 shows three such exit stair enclosures located within the communicating space, with all occupants of the floor required to walk within the communicating space across the interior exit access balcony of that floor in order to gain access to the stairs. Up to 50 percent of those three exits—that is, one exit in the given example—is permitted to discharge occupants from upper or lower floors through the level of exit discharge in accordance with 7.7.2, thus forcing some occupants to walk across the floor of the atrium to reach a door to the outside. The stringent requirements of 8.6.7(1) through (6) ensure an adequate overall life safety package, allowing the exit access and as much as half of the exit discharge to be within the atrium.

(c) The occupancy within the communicating

space [the vertical opening and all floor areas left open to the vertical opening, such as balcony-like walking surfaces and the levels allowed to be left completely open via the provisions of 8.6.7(1)(b)] is limited to low hazard or ordinary hazard contents as addressed in 6.2.2. High hazard contents are thus prohibited from being placed within the communicating space but could be within hazardous area rooms surrounded by fire resistance-rated walls in accordance with the provisions of Section 8.7. Because the provisions of 8.6.7(4) require that the building be completely protected by an approved, supervised automatic sprinkler system, the presence of only low hazard contents within the communicating space does not exempt the space from the sprinkler requirement. However, under the mini-atrium provisions of 8.6.6, such an exemption is allowed.

(d) The entire building, not only the communicating space involving the atrium opening, must be protected by an approved, supervised automatic sprinkler system meeting the requirements of Section 9.7. Assuming that the atrium is located in a hotel building of five or more stories, for example, the provisions of Section 9.7 require the use of NFPA 13, *Standard for the Installation of Sprinkler Systems*.

(e) An engineered smoke control or smoke removal system acceptable to the authority having jurisdiction has been required since the atrium provisions were first introduced into the *Life Safety Code* in the 1981 edition. As advisory, but nonmandatory, information, the appendix of earlier editions suggested that, depending on atrium height and volume, either four or six air changes per hour could provide the smoke exhaust rate needed to meet the tenability conditions intended by the requirement for atrium smoke control.

The guideline for six air changes per hour came to be considered law by many AHJs and was thus accepted as the norm by many system designers. AHJs then subjected such systems to acceptance testing using smoke bombs that produce cold smoke, which does not have the heat, buoyancy, and entrainment of air from a real fire. The acceptance criteria were further complicated by those who mistakenly believed that the intent of the smoke control requirement was, for example, that no smoke be visible within the atrium at the end of a 10-minute test. Designers found that, to ensure that the acceptance test could be passed, the system should provide approximately 10 to 12 air changes per hour. In effect, atrium smoke control systems were typically designed to pass the acceptance test with no consideration or

assurance of effective smoke control under fire conditions. NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*, warns that a system designed in accordance with NFPA 92B and capable of providing the intended smoke management might not pass smoke bomb tests³². Conversely, it is possible for a system that is incapable of providing the intended smoke management to pass smoke bomb tests. Because of the impracticality of conducting real fire tests within an atrium, the acceptance tests described in NFPA 92B are directed at those aspects of smoke management systems that can be verified through direct measurement.

Using performance-based criteria, 8.6.7(5) requires that an engineering analysis be performed to demonstrate that smoke will be managed for the time needed to evacuate the building. To accomplish this, 8.6.7(5) requires the analysis to prove that the smoke layer interface will be maintained above the highest unprotected opening to adjoining spaces, or 1830 mm (72 in.) above the highest floor level of exit access open to the atrium for a time equal to 1.5 times the calculated egress time or 20 minutes, whichever is greater. For a protect-in-place occupancy, such as health care, the evacuation time is considered to be infinite, which means that the smoke control performance criteria must be maintained indefinitely.

In Exhibit 8.19, floors 1 through 8 are open to the atrium and floors 9 through 12 use the atrium balconies for exit access. The engineering analysis will most likely determine that a high-capacity smoke management system will be needed to meet the performance-based criteria for maintaining the smoke layer interface 1830 mm (72 in.) above the walking surface of the 12th-floor exit access balcony (the highest floor level with exit access in the atrium). The smoke control system will need to begin removing smoke early in the fire, because there is little accumulation capacity in the space above the 12th floor and beneath the ceiling of the atrium. Contrast this situation with that shown in Exhibit 8.21 in which floors 10 through 12 do not use the atrium for exit access. Although a smoke control system will be needed to meet the performance-based smoke control criteria, the system might be of a less aggressive design, given that the smoke can bank down from the ceiling of the atrium to below the 10th floor before affecting occupant egress.

NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*, quantifies the physics associated with atrium smoke control and presents methodologies for system design in an understandable and useful format. The guidelines of NFPA 92B

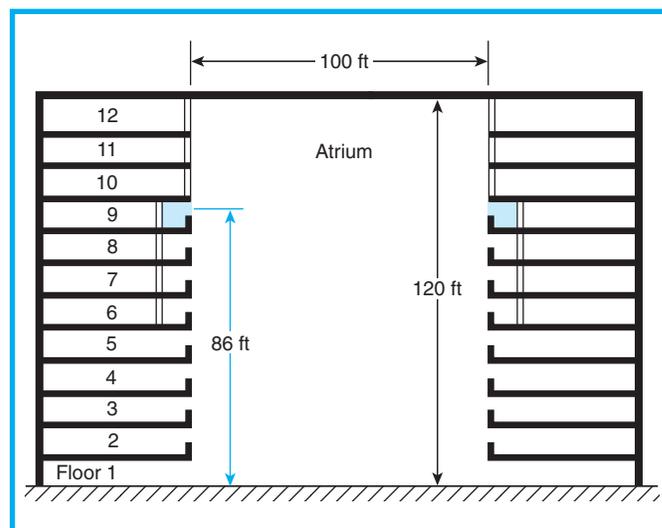

Exhibit 8.21 Twelve-story atrium for which smoke control is to be provided.

allow the system designer to design a system and prepare the associated documentation for the AHJ to assess for adequacy in meeting the performance criteria of 8.6.7(5). For example, the designer and the AHJ agree that an acceptable design must provide for the level of smoke-filling to be maintained at least 1830 mm (72 in.) above the highest floor level open to the atrium and the highest floor level used for exit access within the atrium for a minimum of 20 minutes after actuation of the fire alarm system.

The following example, which is illustrated in Exhibit 8.21, makes use of the guidelines of NFPA 92B in designing a smoke management system that meets the smoke-filling criterion agreed to by the designer and the AHJ.

The proposed atrium building is to be 12 stories in height, with the fifth floor as the highest level open to the atrium and the ninth floor as the highest walking level within the atrium. Further, the atrium ceiling is to be 36.6 m (120 ft) above the floor; the atrium opening is to be rectangular with horizontal dimensions of 30.4 m × 61 m (100 ft × 200 ft); and the atrium is to be furnished with upholstered furniture and wood and plastic tables characteristic of the fire loading typically associated with a business occupancy.

Note that the following example and analysis use the formulae from those portions of NFPA 92B that use the conventional U.S. Customary units (for example, feet, square feet, Btu per second, pounds per cubic foot, cubic feet per minute). Although it is standard practice within this handbook to provide metric or SI units, SI equivalents are not provided in

the calculations that follow. Rather, the reader is referred to Appendix D of NFPA 92B, where SI unit forms of all 24 equations used in the guide are available.

If the designer prefers to install spot smoke detectors for activation of the smoke control system and initiation of the building fire alarm at the top of the atrium only, the designer would need to determine if smoke will reach the ceiling or stratify at a given distance below the ceiling in the case of the selected design fire. Stratification occurs when the temperature of the rising plume equals the temperature of the surrounding air and the fire has insufficient energy to “push” the smoke layer any higher.

Computational methods, which are beyond the scope of this analysis, are available for determining the potential for stratification below the atrium ceiling. For example, in an atrium that is known to have a discrete ambient temperature change at a given elevation above the floor level (perhaps due to solar loading), the designer can determine the height at which the fire plume centerline temperature equals the ambient temperature. Stratification can be assumed to occur at that height.

To further compound the issue, detection of smoke by spot-type detectors at ceiling heights greater than 30 ft requires its own engineering analysis, which is also beyond the scope of this example. For such analyses, consult Schifiliti and Pucci’s “Fire Detection Modeling, State of the Art.”³³

Stratification is not a concern after the smoke management system activates, because the natural buoyancy of the smoke (or lack thereof) will be negligible compared to the pressure differences and air movement created by the system. Stratification can, however, have a significant adverse effect on the time to system initiation from the start of the fire. The designer might wish to design the detection system for activation of the smoke management system in a manner that ensures prompt detection regardless of the ambient conditions in the atrium at the time of the fire. Projected-beam smoke detectors, which are capable of measuring the light obscuration caused by smoke particles, can be arranged to quickly detect either a developing smoke layer or the rising smoke plume. In either case, a series of beam detectors is to be installed at strategic points within the atrium. Projected-beam smoke detectors can be arranged to provide a highly reliable means of detecting a fire within the atrium in its early stages. In all cases, the requirements of NFPA 72, *National Fire Alarm Code*, and the detector manufacturer’s installation guidelines should be followed.

For the remainder of this exercise, it is assumed that the atrium is provided with projected-beam smoke detectors arranged to activate the smoke management system and initiate the building fire alarm relatively quickly following the onset of fire, and before the smoke level descends to within 6 ft of the highest level of exit access open to the atrium.

Having equated the furniture arrangement as typical of the combustible loading associated with a business occupancy, the designer feels comfortable assuming a typical heat-release rate per unit floor area of 20 Btu/ft²-sec, which realistically translates to a design fire heat-release rate, Q , from steady fire of 5000 Btu/sec. The convective portion of the heat-release rate, Q_c , can be estimated as 70 percent of the heat-release rate, Q .

The designer next calculates the volumetric exhaust rate required to keep smoke 86 ft above the atrium floor (that is, 6 ft above the highest walking level in the atrium, which in this case is the ninth floor balcony whose floor is at the 80-ft elevation). From the guidance offered in NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*, the designer locates the design fire in the center of the floor of the atrium so as to keep the fire away from the walls and thus create the worst-case condition. With the fire at the center of the atrium floor, an axisymmetric fire plume is expected for which air is entrained from all sides and along the entire height of the plume until the plume becomes submerged in the smoke layer (see Exhibit 8.22). This leads the

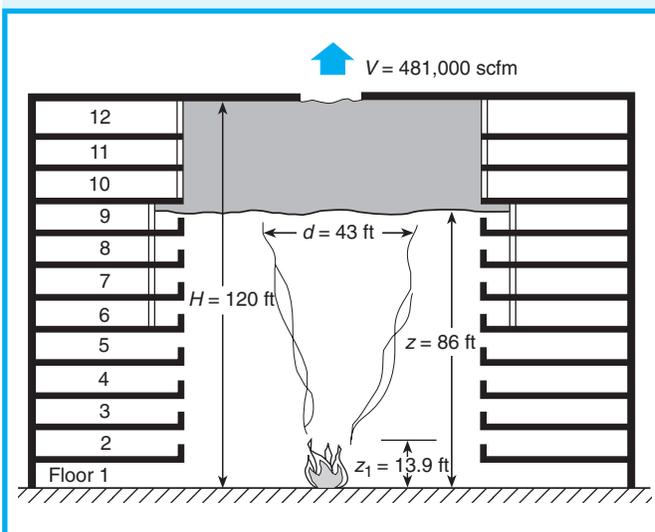

Exhibit 8.22 Axisymmetric fire plume and associated smoke interface.

designer to the use of equation 7 of NFPA 92B to determine the flame height:

$$z_l = 0.533Q_c^{2/5}$$

where:

z_l = limiting elevation (ft)

Q_c = convective portion of heat-release rate (Btu/sec), established previously as 70 percent of the heat-release rate, Q

In this case,

$$\begin{aligned} Q_c &= 0.7(5000 \text{ Btu/sec}) \\ &= 3500 \text{ Btu/sec} \end{aligned}$$

Substituting gives

$$\begin{aligned} z_l &= 0.533(3500)^{2/5} \\ &= 13.9 \text{ ft} \end{aligned}$$

With the design interface of the smoke layer at 86 ft above the floor level, the flame height is less than the design smoke layer height. Thus, equation 8 in 3.8.1.2 of NFPA 92B, which follows, can be used to determine the smoke production rate at the height of the smoke layer interface:

$$m = [0.022Q_c^{1/3} z^{5/3}] + 0.0042Q_c \quad (\text{for } z > z_l)$$

where:

m = smoke production rate at height of smoke layer interface (lb/sec)

Q_c = convective portion of heat-release rate (Btu/sec)

z = height above the fuel (ft)

In this case,

$$\begin{aligned} Q_c &= 3500 \text{ Btu/sec, as developed in previous calculations} \\ z &= 86 \text{ ft (that is, 6 ft above the 80-ft walking surface)} \end{aligned}$$

Substituting gives

$$\begin{aligned} m &= 0.022(3500)^{1/3}(86)^{5/3} + 0.0042(3500) \\ &= 574 \text{ lb/sec} \end{aligned}$$

If the smoke exhaust rate is equal to the smoke production rate, the smoke layer depth will be stabilized at the design height (that is, the 86-ft elevation) and, thus, all balconies and areas open to the atrium will remain tenable as the fire continues to burn.

Before converting the smoke production rate to a volumetric flow rate, it is necessary to determine the temperature rise above ambient of the smoke at time of venting in order to establish the density of the smoke during the vented stage. As explained by

the last note in Table 3.5 of NFPA 92B, the maximum temperature rise will occur if the total heat loss factor is equal to zero. Use the vented stage temperature rise formula from Table 3.5, simplified by setting the total heat loss factor equal to zero, to determine ΔT as follows:

$$\Delta T = 60 \frac{Q_c}{(\rho c V)}$$

which, through use of equation 22 of Section 3.11 of NFPA 92B, can be reduced to

$$\Delta T = \frac{Q_c}{mc}$$

where:

ΔT = temperature rise above ambient of smoke at time of venting ($^{\circ}\text{F}$)

Q_c = 3500 Btu/sec, as developed in previous calculations

m = 574 lb/sec, as developed in previous calculations

c = 0.24 Btu/lb- $^{\circ}\text{F}$ specific heat of smoke, assuming smoke equals air

Substituting gives

$$\begin{aligned} \Delta T &= \frac{3500}{574(0.24)} \\ &= 25^{\circ}\text{F} \end{aligned}$$

Assuming ambient temperature of 68 $^{\circ}\text{F}$, the temperature of smoke is $T_s = 25 + 68 = 93^{\circ}\text{F}$.

Using an alternate form of the equation shown in A.3.11 of NFPA 92B, the density of smoke at 93 $^{\circ}\text{F}$ can be calculated as follows:

$$\rho = \rho_o \frac{T_o}{T_s}$$

where:

ρ = density of heated smoke

ρ_o = 0.075 (see A.3.11 of NFPA 92B)

T_o = 68 + 460

T_s = 93 + 460

Substituting gives

$$\begin{aligned} \rho &= 0.075 \left(\frac{68 + 460}{93 + 460} \right) \\ &= 0.0716 \text{ lb/ft}^3 \end{aligned}$$

The smoke production rate can be converted to a volumetric flow rate using equation 22 from Section 3.11 of NFPA 92B as follows:

$$V = 60 \frac{m}{\rho}$$

where:

m = smoke production rate, 574 lb/sec as calculated

ρ = density of heated smoke, 0.0716 lb/ft³ as calculated

Substituting gives

$$\begin{aligned} V &= 60(574 / 0.0716) \\ &= 481,000 \text{ scfm} \end{aligned}$$

The preceding calculations assume that the smoke plume has not widened to contact the walls of the atrium prior to reaching the design interface height of 86 ft above the atrium floor in this example. As a plume rises, it also widens. If the plume were to contact all of the walls of the atrium prior to reaching the ceiling, the smoke interface would be considered as occurring at the height of contact with all of the surrounding walls. No additional smoke generation can be assumed to occur above that height, because additional air entrainment into the plume is considered to be negligible above the point of contact. To check if the widening plume has contacted the walls of the atrium, equation 16 from 3.8.4 of NFPA 92B can be used to predict the total plume diameter, d , at the interface height, z , as follows:

$$\begin{aligned} d &= 0.5z \\ &= 0.5(86) \\ &= 43 \text{ ft} \end{aligned}$$

Thus, in this 100 ft × 200 ft atrium area, the smoke does not contact the walls prior to reaching the design interface height of 86 ft. Mechanical systems capable of extracting approximately 480,000 scfm are then designed. The substantiation package is submitted to the authority having jurisdiction for approval.

Acceptance testing of the system then involves verifying the function of the system components in the intended sequence for varying initiation scenarios. In addition, the system should be evaluated by measuring the following:

- (1) Total volumetric flow rate
- (2) Airflow velocities
- (3) Airflow direction
- (4) Door-opening forces (forces permitted by the Code should not be exceeded when the smoke management system is operating)
- (5) Pressure differences
- (6) Ambient temperature

If the measurements are within the previously agreed-upon system design specifications, the system should be deemed as passing. Note again that

no reference is made to the use of subjective test criteria such as cold smoke bombs. The measurements are obtained objectively and can be performed by professional mechanical, HVAC, or fire protection engineers. NFPA 92A, *Recommended Practice for Smoke-Control Systems*³⁴, and NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*, offer detailed guidance on the equipment needed and procedures for conducting acceptance tests on engineered smoke management systems.

(f) The provisions of 8.6.7(6) address the activation of mechanical systems that might be designed to meet the performance-based smoke management requirements of 8.6.7(5). In some buildings that have large atrium openings, but no upper floors open to the atrium, and no exit access on those upper floors through the atrium, and that are used by ambulatory occupants, it might be possible to meet smoke control criteria without any mechanical systems by allowing the large atrium to accumulate smoke above the heads of all atrium occupants. The purpose of the engineering analysis required by 8.6.7(5) is to determine what, if any, mechanical smoke control is needed. Alternatively, tenability of the means of egress might be able to be maintained through passive ventilation of the atrium. The required engineering analysis should evaluate several protection scenarios.

As addressed by A.8.6.7(6), automatic activation of the atrium smoke management system, especially upon initiation of the building alarm system via operation of a manual fire alarm box, could result in the activation of the smoke management system in the incorrect mode. For example, a building occupant walking along the sixth floor exit access balcony within the atrium might see flames and smoke on the third floor, which is open to the atrium. The occupant might walk to the exit stair enclosure on the sixth floor and operate the manual fire alarm box. The building fire alarm system might incorrectly assume that the fire is on the sixth level. The third floor, which is the actual fire floor, might incorrectly be identified as a non-fire floor. The smoke management system might positively pressurize the third floor and move large volumes of air across the third-floor opening into the atrium in an effort to keep smoke from entering the third-floor communicating space. In reality, the smoke management system would accomplish exactly the opposite of what it was designed to do; it would spread the smoke and other products of combustion from the third floor fire into the atrium. The sixth floor would mistakenly be negatively pressurized (exhausted) and would pull in the smoke and

gases from the third floor fire via the atrium. For this reason, NFPA 92A and NFPA 92B recommend arranging smoke management systems to activate only via automatic initiating devices, such as smoke detectors and automatic sprinklers. However, controls for manual operation of the system by the fire department are required by 8.6.7(6)(b). Smoke management systems should not be arranged to activate via manual fire alarm boxes that are accessible to building occupants.

The manual controls required by 8.6.7(6)(b) must be readily accessible to the responding fire department personnel so that the smoke management system's mode of operation can be overridden and tailored to the specific needs of the emergency responders. These and other concepts on effective smoke management are covered in NFPA 92A, *Recommended Practice for Smoke-Control Systems*, and NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*.

8.6.8 Convenience Openings.

8.6.8.1 A vertical opening serving as other than an exit enclosure, connecting only two adjacent stories, and piercing only one floor shall be permitted to be open to one of the two stories.

Paragraph 8.6.8.1 recognizes a maximum two-story exit access stair that is separated from one of the two floors but not both. The separating barrier will keep the effects of a fire on one of the two levels from spreading to the other floor. Because the exit access stair is not an exit, this arrangement does not violate the requirements of 7.1.3.2 pertaining to exit enclosures. Exhibit 8.23 illustrates this provision. As an alternative, the stair could be separated from floor 3 and open to floor 2.

8.6.8.2 Where permitted by Chapter 12 through Chapter 42, unenclosed vertical openings not concealed within the building construction shall be permitted as follows:

- (1) Such openings shall connect not more than two adjacent stories (one floor pierced only).
- (2) Such openings shall be separated from unprotected vertical openings serving other floors by a barrier complying with 8.6.5.
- (3) Such openings shall be separated from corridors.
- (4)* Such openings shall not serve as a required means of egress.

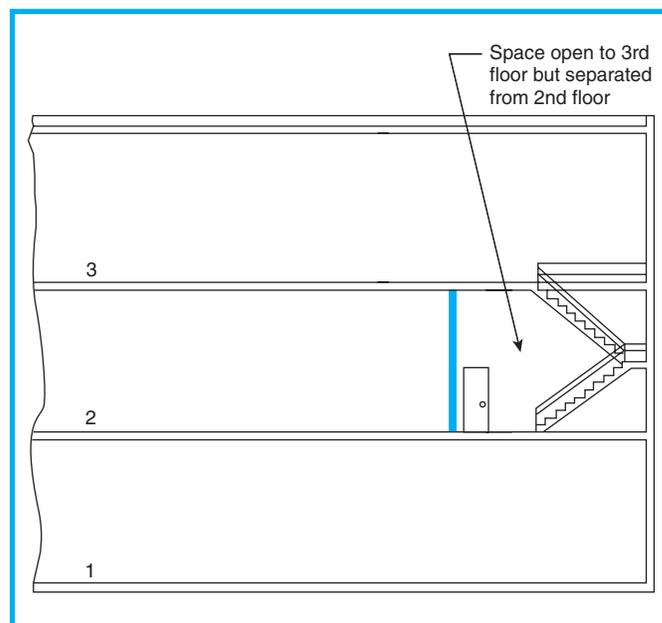

Exhibit 8.23 Vertical opening protection by fire barrier at one floor level only.

A.8.6.8.2(4) This requirement prohibits means of egress down or up the convenience opening. It does not prohibit means of escape from running down or up the convenience opening within residential dwelling units.

The provisions of 8.6.8.2 address a convenience opening, often taking the form of a nonrequired stair, which many of the occupancy chapters have recognized for many years. Prior to the 1997 edition of the *Code*, occupancy chapters specified the detailed criteria contained in 8.6.8.2(1) through (4). The provisions now appear in 8.6.8.2 with the conditional statement “where permitted by Chapter 12 through Chapter 42.” Therefore, any occupancy chapter can reference the provisions of 8.6.8.2 without having to repeat the detailed criteria. For example, in 38.3.1.1, which applies to new business occupancies, the detailed criteria have been dropped and 38.3.1.1(1) permits “unenclosed vertical openings in accordance with 8.6.8.2.” This permits, for example, a two-level office or reference library in an office building to have an unenclosed convenience stair.

The application of 38.3.1.1(1) is restricted by 8.6.8.2(1) to two adjacent levels only. The opening must be separated from other vertical openings serving other floors per 8.6.8.2(2); this requirement prevents the linking of individual openings that would otherwise create a means for spreading the effects of

fire among multiple floors. The areas connected by the opening must be separated from corridors per 8.6.8.2(3). The stairs are not permitted to be part of the means of egress per 8.6.8.2(4). The space would be required to have access to exits on both levels so occupants would not have to rely on the open stair as part of the required means of egress. One possible application of these provisions is shown in Exhibit 8.24.

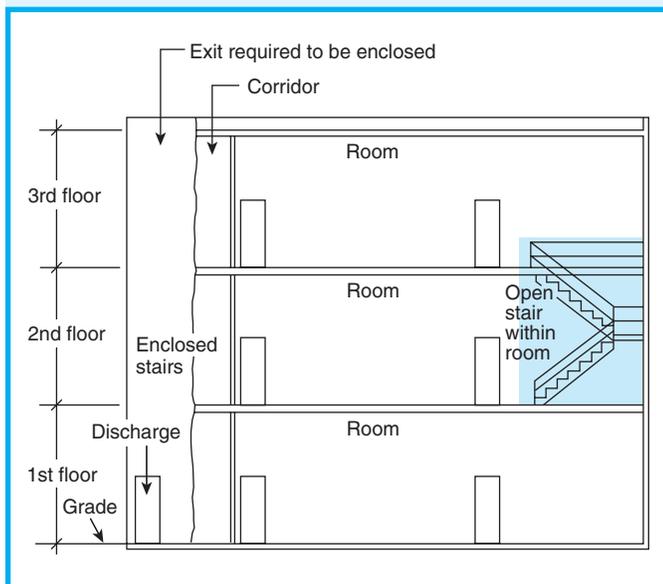

Exhibit 8.24 Elevation view of unenclosed two-story stair serving as a convenience opening.

8.6.8.3 For other than existing hoistways in existing buildings, elevator cars located within a building shall be enclosed as follows:

- (1) Where there are three or fewer elevator cars in a building, they shall be permitted to be located within the same hoistway enclosure.
- (2) Where there are four elevator cars in the building, they shall be divided in such a manner that not less than two separate hoistway enclosures are provided.
- (3) Where there are more than four elevator cars in the building, the number of elevator cars located within a single hoistway enclosure shall not exceed four.

The requirements addressed by 8.6.8.3 help to ensure that smoke and fire in an elevator hoistway will not prevent the use of all elevators in any building that has four or more elevators. If a building has four elevators, a maximum of three elevators are allowed within the same elevator hoistway or shaft. If the

building has more than four elevators, no more than four elevators can be in one shaft. If smoke and fire prevent the use of the elevators within one hoistway, an elevator in another hoistway might be usable. Because of the maximum limit of four elevators per hoistway, a building with 9 to 12 elevators must have a minimum of three hoistways.

The requirements of 8.6.8.3 mesh well with the high-rise building requirements of 11.8.4.2, which apply to standby power. The required standby power system must be connected to at least one elevator serving all floors of the building. Additionally, elevator standby power must be transferable to any elevator. If the hoistway containing the elevator initially powered by the standby power system becomes untenable, the switching requirement will allow for an elevator in a different hoistway to be placed back into service.

8.6.8.4 Service openings for conveyors, elevators, and dumbwaiters, where required to be open on more than one story at the same time for purposes of operation, shall be provided with closing devices in accordance with 7.2.1.8.

8.6.8.5 Any escalators and moving walks serving as a required exit in existing buildings shall be enclosed in the same manner as exit stairways. (See 7.1.3.2.)

Where used as an exit, an escalator must be completely enclosed with fire-rated construction, including entrance and discharge doors. It is rare to find an escalator enclosed in such a manner. Escalators located within the required means of egress in existing buildings that maintain compliance with the Code usually make use of one of the provisions of 8.6.8.6 to avoid creating an unprotected vertical opening. By doing so they are classified as exit access. Note that 7.2.7 prohibits escalators from constituting any part of the required means of egress in new buildings. Thus, in new construction, an escalator can be installed but is not recognized as satisfying the requirements for exit access, exit, or exit discharge.

8.6.8.6 Any escalators and moving walks not constituting an exit shall have their floor openings enclosed or protected as required for other vertical openings, unless otherwise permitted by the following:

- (1) The requirement of 8.6.8.6 shall not apply to escalators in large open areas, such as atriums and enclosed shopping malls.

- (2)* In buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7, escalator and moving walk openings shall be permitted to be protected in accordance with the method detailed in NFPA 13, *Standard for the Installation of Sprinkler Systems*, or in accordance with a method approved by the authority having jurisdiction.

A.8.6.8.6(2) The intent is to place a limitation on the size of the opening to which the protection applies. The total floor opening should not exceed twice the projected area of the escalator or moving walk at the floor. Also, the arrangement of the opening is not intended to circumvent the requirements of 8.6.7.

As with any opening through a floor, the openings around the outer perimeter of the escalators should be considered as vertical openings. The sprinkler draftstop installation is intended to provide adequate protection for these openings, provided that the criteria of NFPA 13, *Standard for the Installation of Sprinkler Systems*, as well as the area criteria described in the preceding paragraph, are met.

- (3) In buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7, escalator and moving walk openings shall be permitted to be protected by rolling steel shutters appropriate for the fire resistance rating of the vertical opening as follows:
- (a) The shutters shall close automatically and independently of each other upon smoke detection and sprinkler operation.
 - (b) A manual means of operating and testing the operation of the shutter shall be provided.
 - (c) The shutters shall be operated not less than once a week to ensure that they remain in proper operating condition.
 - (d) The shutters shall operate at a speed not to exceed 0.15 m/s (30 ft/min) and shall be equipped with a sensitive leading edge.
 - (e) The leading edge shall arrest the progress of a moving shutter and cause it to retract a distance of approximately 150 mm (6 in.) upon the application of a force not exceeding 90 N (20 lbf) applied to the surface of the leading edge.
 - (f) The shutter, following the retraction specified in 8.6.8.6(3)(e), shall continue to close.
 - (g) The operating mechanism for the rolling shutter shall be provided with standby power complying with the provisions of NFPA 70, *National Electrical Code*[®].

The provisions of 8.6.8.6 provide that new escalators (which cannot be part of the means of egress) and

existing escalators not serving as exits (see 8.6.8.5) need not be enclosed if certain provisions are met.

The sprinkler-draft curtain method is detailed in NFPA 13, *Standard for the Installation of Sprinkler Systems*. It consists of surrounding the escalator opening, in an otherwise fully sprinklered building, with a 460-mm- (18-in.-) deep draft stop located on the underside of the floor to which the escalator ascends. This draft stop serves to delay the heat, smoke, and combustion gases developed in the early stages of a fire on that floor from entering into the escalator well. A row of closely spaced automatic sprinklers located outside of the draft stop also surrounds the escalator well. As sprinklers along this surrounding row are individually activated by heat, their water discharge patterns combine to create a water curtain. A typical installation is shown in Exhibit 8.25. In combination with the sprinkler system in the building, this system should delay fire spread effectively and allow time for evacuation.

Prior editions of the *Code* detailed several methods that permitted the use of unenclosed escalators in completely sprinklered buildings where the escalators were not used as exits. In addition to the sprinkler-draft curtain or rolling shutter methods, the authority having jurisdiction might consider one of the following when evaluating existing buildings:

- (1) Sprinkler-vent method
- (2) Spray nozzle method
- (3) Partial enclosure method

The following discussion details these three methods.

Sprinkler-Vent Method. Under the conditions specified, escalator or moving walk openings are permitted to be protected by the sprinkler-vent method, which consists of a combination of an automatic fire or smoke detection system, an automatic exhaust system, and an automatic water curtain. This combination of fire protection and system design is required to meet the following criteria and be approved by the authority having jurisdiction.

- (a) The exhaust system should be capable of creating a downdraft through the escalator or moving walk floor opening. The downdraft should have an average velocity of not less than 1.5 m/s (300 ft/min) under normal conditions for a period of not less than 30 minutes. This requirement can be met by providing an air intake from the outside of the building above the floor opening. The test of the system under “normal” conditions requires that the velocity of the

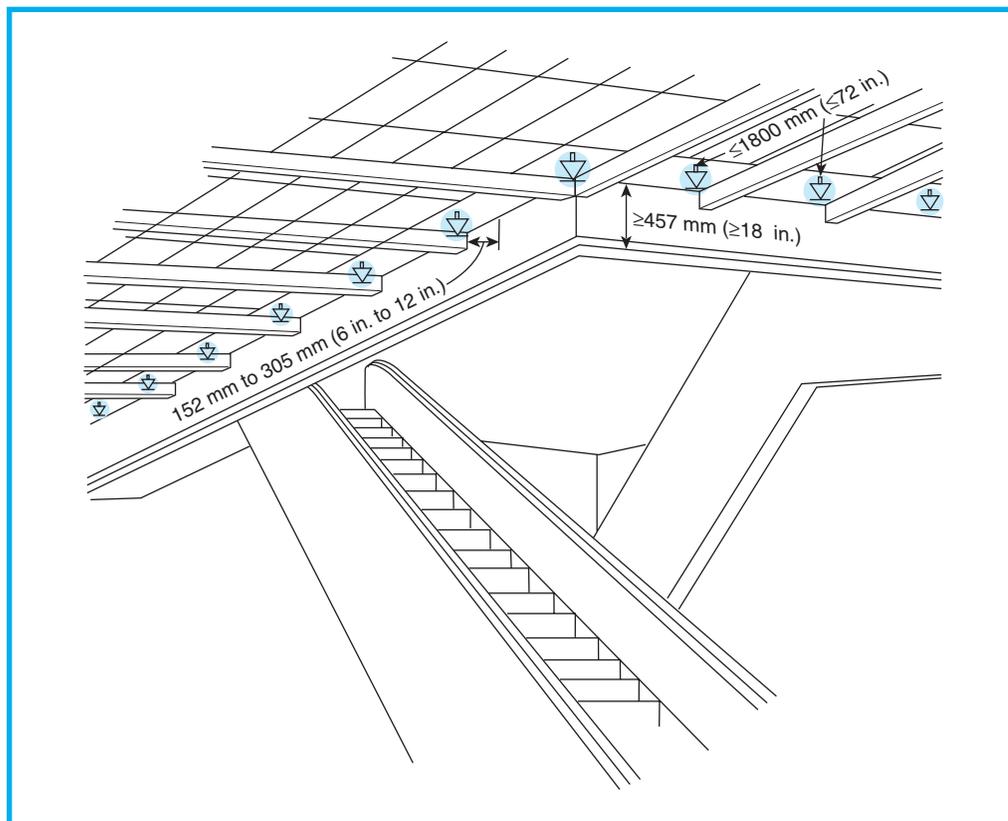

Exhibit 8.25 Sprinklers around an escalator opening.

downdraft be developed when windows or doors on the several stories normally used for ventilation are open. The size of the exhaust fan and exhaust ducts must be sufficient to meet such ventilation conditions. Experience indicates that fan capacity should be based on a rating of not less than $8.3 \text{ m}^3/\text{sec}/\text{m}^2$ ($500 \text{ ft}^3/\text{min}/\text{ft}^2$) of moving stairway opening to obtain the $1.5\text{-m}/\text{sec}$ ($300\text{-ft}/\text{min}$) velocity required. If the building is provided with an air conditioning system arranged to be automatically shut down in the event of fire, the test condition should be met with the air conditioning system shut down. The $1.5\text{-m}/\text{sec}$ ($300\text{-ft}/\text{min}$) downdraft through the opening provides for the testing of the exhaust system without requiring the expansion of air that would be present under actual fire conditions.

(b) Operation of the exhaust system for any floor opening should be initiated by an approved device on the involved story and should use one of the following means, in addition to a manual means, for operating and testing the system:

- (1) Heat detectors (fixed-temperature, rate-of-rise, or a combination of both)

- (2) Waterflow in the sprinkler system
- (3) Approved, supervised smoke detection located so that the presence of smoke is detected before it enters the stairway

(c) Electric power supply to all parts of the exhaust system and its control devices should be designed and installed for maximum reliability. The electric power supply provision of NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*³⁵, can be used as a guide to design and installation features that help to ensure maximum reliability.

(d) Any fan or duct used in connection with an automatic exhaust system should be of the approved type and should be installed in accordance with the applicable standards in Chapter 2 and Annex B.

(e) Periodic tests should be made of the automatic exhaust system, at least quarterly, to maintain the system and the control devices in good working condition.

- (f) The water curtain should be formed by open sprinklers or by spray nozzles located and spaced to

form a complete and continuous barrier along all exposed sides of the floor opening and to reach from the ceiling to the floor. Water discharge for the water curtain should be not less than approximately 0.6 L/sec/lineal m (3 gal/min/lineal ft) of water curtain, measured horizontally around the opening.

(g) The water curtain should operate automatically from thermal-responsive elements of a fixed-temperature type. These elements should be located with respect to the ceiling/floor opening so that the water curtain actuates upon the advance of heat toward the escalator or moving walk opening.

(h) Every automatic exhaust system (including all motors, controls, and automatic water curtain system) should be electrically supervised in an approved manner that is similar to that specified for automatic sprinkler system supervision.

Spray Nozzle Method. Under the conditions specified, escalator openings are permitted to be protected by the spray nozzle method, which consists of a combination of an automatic fire or smoke detection system and a system of high-velocity water spray nozzles. This combination of fire protection and system design should meet the following criteria and be approved by the authority having jurisdiction.

(a) Spray nozzles should be of the open type and should have a solid conical spray pattern with discharge angles between 45 and 90 degrees. The number of nozzles, their discharge angles, and their location should be such that the escalator or moving walk opening between the top of the wellway housing and the treadway will be completely filled with dense spray on operation of the system.

(b) The number and size of nozzles and water supply should be sufficient to deliver a discharge of 1.4 L of water/m²/sec (2 gal of water/ft²/min) through the wellway, with the area to be figured perpendicular to the treadway. See Exhibit 8.26.

(c) Spray nozzles should be located to take full advantage of the cooling and counterdraft effect. They should be positioned so that the centerline of spray discharge is as closely in line as possible with the slope of the escalator or moving walk, not more than an angle of 30 degrees with the top slope of the wellway housing. Nozzles should also be positioned so that the centerline of discharge is at an angle of not more than 30 degrees from the vertical sides of the wellway housing.

(d) Spray nozzles should discharge at a minimum pressure of 172 kPa (25 lb/in.²). Water supply piping is permitted to be taken from the sprinkler

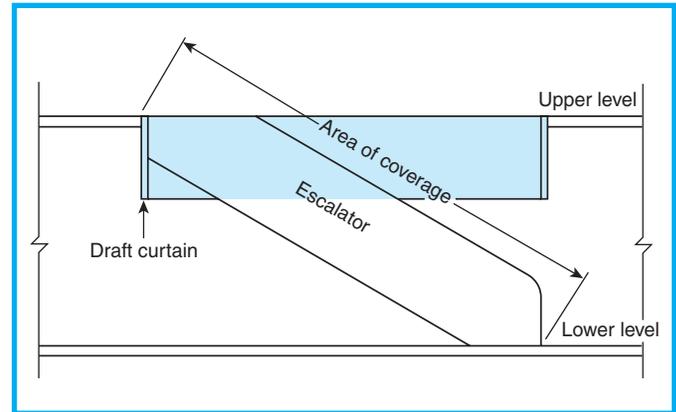

Exhibit 8.26 Area of coverage for spray nozzle method of protecting escalator openings.

system, provided that an adequate supply of water is available for the spray nozzles and that the water pressure at the sprinkler farthest from the supply riser is not reduced beyond the required minimum. Water supply taken from the sprinkler system is designed to provide protection from life hazards to the wellway opening during the exit period but is not to be relied on to provide an effective floor cutoff.

(e) Control valves should be readily accessible to minimize water damage.

(f) A noncombustible or limited-combustible draft curtain should be provided that extends at least 510 mm (20 in.) below and around the opening, and a solid noncombustible wellway housing at least 1520 mm (60 in.) long, measured parallel to the handrail and extending from the top of the handrail enclosure to the soffit of the stairway or ceiling above, should also be provided at each escalator floor opening. Where necessary, spray nozzles should be protected against mechanical damage or tampering that might interfere with proper discharge. See Exhibit 8.27.

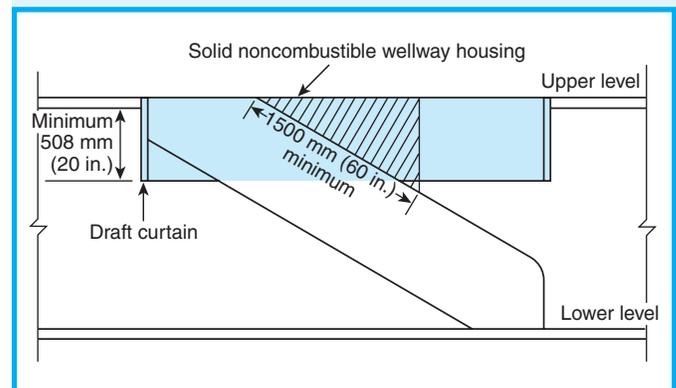

Exhibit 8.27 The draft curtain and wellway housing method of protecting vertical openings.

(g) The spray nozzle system should operate automatically from thermal-response elements of the fixed-temperature type and be located with respect to the ceiling/floor opening so that the spray nozzle system actuates upon the advance of heat toward the escalator opening. Supervised smoke detection located in or near the escalator opening is permitted to be used to sound an alarm. The spray nozzle system should also be provided with manual means of operation. It is not desirable to have smoke detectors activate the spray nozzles; safeguards against accidental discharge must be provided to prevent both panic and property damage.

(h) Control valves for the spray nozzle system and approved smoke detection or thermostatic devices should be electrically supervised in accordance with the applicable provisions of 9.7.2.

Partial Enclosure Method. Under the conditions specified, escalator or moving walk openings are permitted to be protected by a partial enclosure, or so-called kiosk, designed to provide an effective barrier to the spread of smoke from floor to floor. This method of fire protection should meet the following criteria and be approved by the AHJ.

(a) Partial enclosure construction should provide fire resistance equivalent to that specified for stairway enclosures in the same building, with openings therein protected by approved, self-closing fire doors. The openings also are permitted to be of approved wired-glass and metal frame construction with wired-glass panel doors.

(b) Fire doors are permitted to be equipped with an electric opening mechanism, which opens the door automatically upon the approach of a person. The mechanism should return the door to its closed position upon any interruption of electric current supply, and it should be adjusted so that the pressures generated by a fire will not cause the door to open.

8.6.9 Mezzanines.

8.6.9.1 General.

8.6.9.1.1 A mezzanine shall not be included as a story for the purpose of determining the allowable number of stories in a building.

8.6.9.1.2 Multilevel residential housing areas in detention and correctional occupancies in accordance with Chapter 22 and Chapter 23 shall be exempt from the provisions of 8.6.9.2 and 8.6.9.3.

8.6.9.2 Area Limitations.

8.6.9.2.1 The aggregate area of mezzanines located within a room, other than those located in special purpose industrial occupancies, shall not exceed one-third the open area of the room in which the mezzanines are located. Enclosed space shall not be included in a determination of the size of the room in which the mezzanine is located.

8.6.9.2.2 No limit on the number of mezzanines in a room shall be required.

8.6.9.2.3 For purposes of determining the allowable mezzanine area, the aggregate area of the mezzanines shall not be included in the area of the room.

8.6.9.3 Openness. Mezzanines shall be in accordance with 8.6.9.3.1 or 8.6.9.3.2.

8.6.9.3.1 All portions of a mezzanine, other than walls not more than 1065 mm (42 in.) high, columns, and posts, shall be open to and unobstructed from the room in which the mezzanine is located, unless the occupant load of the aggregate area of the enclosed space does not exceed 10.

8.6.9.3.2 A mezzanine having two or more means of egress shall not be required to open into the room in which it is located if not less than one of the means of egress provides direct access from the enclosed area to an exit at the mezzanine level.

The mezzanine provisions of 8.6.9 were developed for the 1991 edition of the *Code*. They are based on a report prepared by the Board for the Coordination of the Model Codes (BCMC) in an attempt to standardize the treatment of mezzanines among three former U.S. regional building code officials' organizations and NFPA.

The aggregate area of a mezzanine within a room must not exceed one-third the open area (the unenclosed space) of the room in which the mezzanine is located. The area of the mezzanine is not considered to be part of the total open area of the room for the purposes of this calculation. For other purposes, the area of the mezzanine is considered part of the area of the room. Because a mezzanine is limited to such size, it is exempted from being counted as a building story—thus affecting the applicability of *Code* requirements based on the number of building stories or floors.

Exhibit 8.28 illustrates the use of the one-third area rule for determining whether a level is a mezzanine. A 93-m² (1000-ft²) partial level is positioned above a 279-m² (3000-ft²) main room. This is depicted in the plan view at the top of the figure. Because the

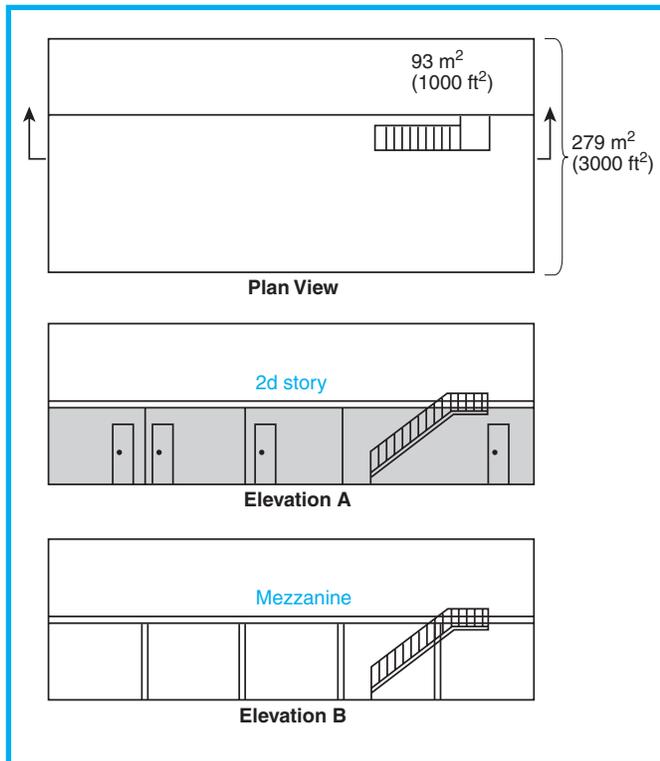

Exhibit 8.28 Determining whether partial upper level meets one-third area rule to qualify as a mezzanine.

one-third area rule compares the area of the upper level to the *open* area of the room in which the partial floor level is located, only the unenclosed space of the room is used in the calculation. In elevation A in Exhibit 8.28, the space below the partial floor level is enclosed. The enclosed area beneath the partial upper level is not counted in the area of the main floor. In this case, the area of the upper level is approximately half the area of the open space on the main room below. The size of this area exceeds the one-third allowance, which means that the partial upper level is considered a floor and not a mezzanine. Contrast this arrangement with the arrangement shown in elevation B in Exhibit 8.28. In this case, the space below the partial floor level is open to the main room. The 93-m² (1000-ft²) area of the partial floor level is compared to the full 279-m² (3000-ft²) area of the room below. The one-third area rule is met and the upper level is considered a mezzanine, provided that the other provisions of 8.6.9 are met.

The openness requirements of 8.6.9.3 are intended to provide the mezzanine occupants with a degree of awareness of fire conditions on the floor below that is equivalent to the awareness of the occupants of the fire floor. Because the mezzanine sits

above the floor of which it is considered a part, untenable smoke concentrations and the associated loss of visibility due to smoke obscuration might affect the mezzanine level before similarly affecting the floor below. In the same way that openness and awareness are required via the mini-atrium provisions of 8.6.6(3), the occupants of the mezzanine should be alerted to a fire in any part of the two-level space before the fire becomes a hazard to their safety.

In recognition of such openness, the *Code* treats the mezzanine no differently than an area or room on the level below the mezzanine. If the mezzanine depicted in Exhibit 8.29 were located in a business occupancy, for example, it would be required to follow the same exit access arrangement rules of any other room on the floor below. Thus, if all occupants could travel across the mezzanine, down the open stair to the room below, and as far across the floor of that room as necessary to reach a point where they had access to two different egress paths, and if that total distance did not exceed the allowable common path of travel [that is, 23 m (75 ft), or 30 m (100 ft) if sprinklered per 38.2.5.3, for the new business occupancy in this example], a single exit access from the mezzanine to the floor below would be allowed. If the allowable common path of travel were exceeded, the mezzanine would require a second, remote exit access.

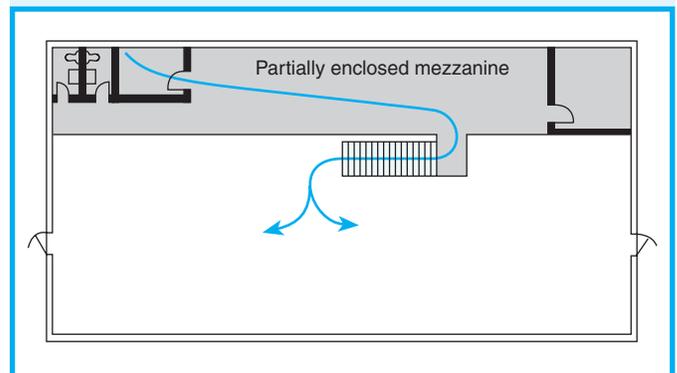

Exhibit 8.29 Open mezzanine.

Paragraph 8.6.9.3.1 recognizes that walls not more than 1065 mm (42 in.) high can serve as guards to prevent falls over the open side of a mezzanine but are low enough to achieve the openness requirement. See 7.2.2.4 for guardrail requirements.

A limited amount of enclosed space on the mezzanine is also permitted by 8.6.9.3.1 to allow for toilet rooms, limited storage, small offices, and similar

areas normally separated from the open area of the mezzanine. In Exhibit 8.29, the mezzanine is partially enclosed such that the total occupant load of all enclosed rooms does not exceed 10 persons. This permits a partially enclosed mezzanine to use all the benefits available to a fully open mezzanine.

Paragraph 8.6.9.3.2 exempts a mezzanine from being open to the room in which it is located if the occupants of the mezzanine are provided with at least two means of egress and if one of those means of egress provides direct access to an exit at the mezzanine level. This provision permits the mezzanine in Exhibit 8.30 to be enclosed, because one of its two means of egress provides access from the mezzanine directly into an exit stair enclosure that discharges to the outside. Occupants of the mezzanine are then judged as being adequately safe from a fire on the level below because, even if they learn about that fire later than they would have if the mezzanine were open, one of their means of egress does not require them to return through the room below.

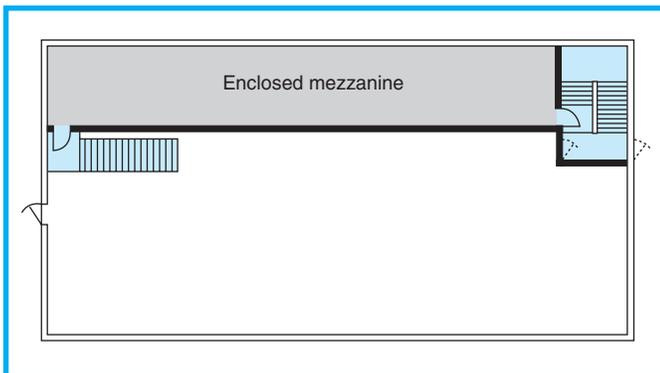

Exhibit 8.30 Enclosed mezzanine.

8.6.10 Concealed Spaces and Draft Stops.

8.6.10.1 Any concealed combustible space in which building materials having a flame spread index greater than Class A are exposed shall be draftstopped as follows:

- (1) Every exterior and interior wall and partition shall be firestopped at each floor level, at the top story ceiling level, and at the level of support for roofs.
- (2) Every unoccupied attic space shall be subdivided by draftstops into areas not to exceed 280 m² (3000 ft²).
- (3) Any concealed space between the ceiling and the floor or roof above shall be draftstopped for the full depth of the space along the line of support for the floor or roof structural members and, if necessary, at other locations to form areas not to exceed 93 m² (1000 ft²) for any

space between the ceiling and floor, and 280 m² (3000 ft²) for any space between the ceiling and roof.

8.6.10.2 The requirements of 8.6.10.1 shall not apply where any of the following conditions are met:

- (1) Where the space is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7
- (2) Where concealed spaces serve as plenums (*see NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems*)
- (3) Where the installation is an existing installation

8.6.10.3 Draftstopping materials shall be not less than 13-mm (½-in.) thick gypsum board, 12-mm (½-in.) thick plywood, or other approved materials that are adequately supported.

8.6.10.4 The integrity of all draftstops shall be maintained.

The vertical spread of fire through shafts, chases, and hollow wall construction and the horizontal spread of fire through plenums and open attics are phenomena common to many serious fires. Where such spaces are protected with automatic sprinklers, the risk of unseen fires is minimized. Certain additional precautions are required where automatic sprinkler protection is not installed in new buildings, and where the materials used have a flame spread rating of more than 25 (that is, other than Class A interior finish).

Draftstopping of attic spaces is particularly important in shopping centers composed of one story and an attic and in two-story apartment buildings or row houses. Experience has shown that fires starting in one of these occupancy units frequently breaks into the attic space, spreads through the attic, and travels down into adjoining units.

Numerous fires in garden-type apartments have demonstrated two common weaknesses that relate to the lack of adequate firestopping and draftstopping. The following two areas are frequently not firestopped:

- (1) Between the underside of the roof deck and the top of fire barriers that do not extend through the roofline
- (2) Inside the pipe chase that contains the plumbing vent stack

The vent stack is of particular concern, because it frequently is located between two mirror-image apartment units and interconnects all the floors of the apartment building. A fire that travels into this

concealed space can spread to the attic and soon involve the entire structure.

The term *draft stop* is defined in 3.3.49 as “a continuous membrane used to subdivide a concealed space to restrict the passage of smoke and heat.”

8.6.10.5 In existing buildings, firestopping and draftstopping shall be provided as required by Chapter 12 through Chapter 42.

An example of an occupancy chapter requirement for firestopping is found in 19.1.6.8, which requires firestopping between the basement and first floor in existing health care occupancies.

Section 8.7 Special Hazard Protection

8.7.1 General.

8.7.1.1* Protection from any area having a degree of hazard greater than that normal to the general occupancy of the building or structure shall be provided by one of the following means:

- (1) Enclosing the area with a fire barrier without windows that has a 1-hour fire resistance rating in accordance with Section 8.3
- (2) Protecting the area with automatic extinguishing systems in accordance with Section 9.7
- (3) Applying both 8.7.1.1(1) and 8.7.1.1(2) where the hazard is severe or where otherwise specified by Chapter 12 through Chapter 42

A.8.7.1.1 Areas requiring special hazard protection include, but are not limited to, areas such as those used for storage of combustibles or flammables, areas housing heat-producing appliances, or areas used for maintenance purposes.

The effects of fire originating in hazardous areas are minimized by isolating those areas that have a high potential for fire or a high fuel load in accordance with 8.7.1.1. The occupancy chapters identify the particular hazards against which protection is to be provided and generally address them in subsection ___3.2 of each occupancy chapter. With each new edition of the *Code*, additional occupancy chapters reformat this subsection to include a list of typical hazardous areas and the required level of associated protection. For example, see Table 22.3.2.1, which is applicable to hazardous areas in new detention and correctional

occupancies. This subsection addresses the fundamental fire protection concept of either protecting against known hazards via automatic extinguishment systems or isolating known hazards by means of fire-rated construction. The authority having jurisdiction is responsible for determining the criteria that define a hazardous area.

8.7.1.2 In new construction, where protection is provided with automatic extinguishing systems without fire-resistive separation, the space protected shall be enclosed with smoke partitions in accordance with Section 8.4, unless otherwise permitted by one of the following conditions:

- (1) Where mercantile occupancy general storage areas and stockrooms are protected by automatic sprinklers in accordance with Section 9.7
- (2) Where hazardous areas in industrial occupancies are protected by automatic extinguishing systems in accordance with 40.3.2

The provisions of 8.7.1.2 require a smoke-resisting enclosure, which includes both surrounding wall barriers and opening protectives such as self-closing doors, where the allowance of 8.7.1.1(2) is used, to protect the hazardous area with automatic sprinkler protection in lieu of a fire-rated enclosure. The smoke-resisting enclosure, although it lacks mandated fire resistance rating, will help to contain the smoke generated prior to sprinkler activation and subsequent to fire control. This concept is illustrated in Exhibit 8.31.

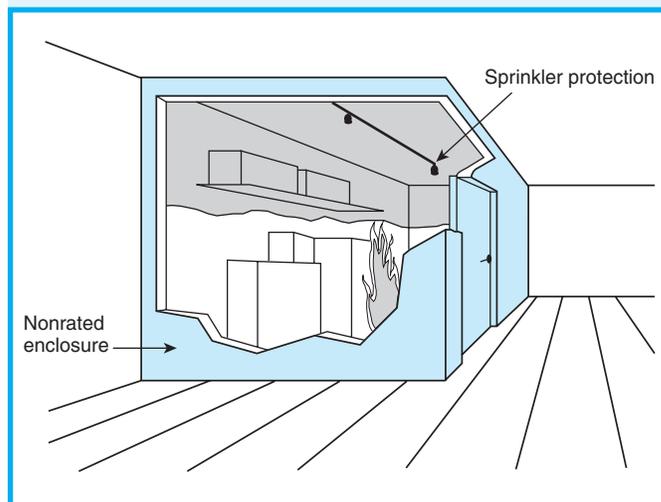

Exhibit 8.31 Sprinkler-protected hazardous contents area.

Paragraph 8.7.1.2(1) permits omission of the additional smoke-resisting enclosure or separation for general storage areas in mercantile occupancies that are protected by automatic sprinklers. For example, in a shoe store, a sprinklered shoe storage area could be left open to the sales area. The clerk might go behind a partial-height partition without going through a door opening to get shoes. Another example is a department store, which usually positions its general storage rooms behind floor-to-ceiling wall barriers at the rear of the store along exterior walls. In this case, double-acting doors (that is, those that can swing both into and out of the storage room) that might not adequately resist the passage of smoke as required by 8.7.1.2 could be used if the storage area were sprinklered.

The provision of 8.7.1.2(2) exempts hazardous areas in industrial occupancies from the additional smoke-resisting enclosure requirement if those areas are protected by automatic extinguishing systems. The nonhazardous areas might not be sprinklered, but the protected hazardous areas can be left open to the nonhazardous areas.

8.7.1.3 Doors in barriers required to have a fire resistance rating shall have a $\frac{3}{4}$ -hour fire protection rating and shall be self-closing or automatic-closing in accordance with 7.2.1.8.

8.7.2* Explosion Protection.

Where hazardous processes or storage is of such a character as to introduce an explosion potential, an explosion venting system or an explosion suppression system specifically designed for the hazard involved shall be provided.

A.8.7.2 For details, see NFPA 68, *Guide for Venting of Deflagrations*.

If a potential hazard is of an explosive nature, explosion venting or an explosion suppression system is required. NFPA 68, *Guide for Venting of Deflagrations*³⁶, contains details of acceptable venting systems; NFPA 69, *Standard on Explosion Prevention Systems*³⁷, covers suppression systems. NFPA 654, *Standard for the Prevention of Fire and Dust Explosions from the Manufacturing, Processing, and Handling of Combustible Particulate Solids*³⁸, is useful where explosive dusts are encountered.

8.7.3 Flammable Liquids and Gases.

8.7.3.1 The storage and handling of flammable liquids or gases shall be in accordance with the following applicable standards:

- (1) NFPA 30, *Flammable and Combustible Liquids Code*
- (2) NFPA 54, *National Fuel Gas Code*
- (3) NFPA 58, *Liquefied Petroleum Gas Code*

8.7.3.2* No storage or handling of flammable liquids or gases shall be permitted in any location where such storage would jeopardize egress from the structure, unless otherwise permitted by 8.7.3.1.

A.8.7.3.2 NFPA 58, *Liquefied Petroleum Gas Code*, permits portable butane-fueled appliances in restaurants and in attended commercial food catering operations where fueled by not in excess of two 0.28-kg (10-oz) LP-Gas capacity, nonrefillable butane containers having a water capacity not in excess of 0.4 kg (1.08 lb) per container. Containers are required to be directly connected to the appliance, and manifolded containers is not permitted. Storage of cylinders is also limited to 24 containers, with an additional 24 permitted where protected by a 2-hour fire resistance-rated barrier.

8.7.4 Laboratories.

8.7.4.1 Laboratories that use chemicals shall comply with NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*, unless otherwise modified by other provisions of this *Code*.

8.7.4.2 Laboratories in health care occupancies and medical and dental offices shall comply with NFPA 99, *Standard for Health Care Facilities*.

8.7.5* Hyperbaric Facilities.

All occupancies containing hyperbaric facilities shall comply with NFPA 99, *Standard for Health Care Facilities*, Chapter 19, unless otherwise modified by other provisions of this *Code*.

A.8.7.5 While the scope of NFPA 99, *Standard for Health Care Facilities*, is limited to health care occupancies, it is the intent that this requirement be applied to hyperbaric facilities used in all occupancies.

Hyperbaric facilities are starting to appear in a variety of occupancies, in addition to health care. For example, hyperbaric chambers have been installed in amusement centers and physical fitness centers and have been promoted as health-enhancing aids. Paragraph 8.7.5 extends the use of the provisions of NFPA 99, *Standard for Health Care Facilities*³⁹, to hyperbaric facilities regardless of occupancy classification.

CHAPTER 9

Building Service and Fire Protection Equipment

As the title indicates, Chapter 9 divides the types of equipment commonly found in buildings into two categories: building service and fire protection. For the most part, the requirements for building service equipment are handled by direct reference to another code or standard with little or no modification or additional requirements in the occupancy chapters. The result is that compliance with the referenced document is required in order for the building to achieve overall compliance with the *Life Safety Code*. Fire protection systems, particularly fire alarm and automatic sprinkler systems, are handled quite differently. For these systems, the *Code* presents a menu of general provisions that are used in conjunction with the installation standards. To apply these provisions, a specific requirement from another section of the *Code* must require their use. For example, 9.6.2.1 addresses alarm system signal initiation and 12.3.4.2 mandates the use of those provisions for alarm systems in new assembly occupancies.

The features that maintain a building safe from fire are varied and work in combination to provide protection for the occupants under a range of potentially adverse conditions. This chapter addresses those systems that help either to maintain a safe environment or to keep the occupants safe from the effects of a fire.

Section 9.6 identifies types of fire alarm initiating and notification systems. The fire alarm system plays an important role in notifying the building occupants of a fire as well as summoning help from outside sources such as the fire department.

Section 9.7 applies to systems or features used to provide an active method for controlling the effects of a fire. These systems and features include automatic systems (such as sprinkler systems) as well as man-

ual systems (such as standpipes and portable fire extinguishers).

Note that the type of system required, and the conditions under which that system is required, are mandated by the occupancy chapters.

Section 9.1 Utilities

9.1.1 Gas.

Equipment using gas and related gas piping shall be in accordance with NFPA 54, *National Fuel Gas Code*, or NFPA 58, *Liquefied Petroleum Gas Code*, unless such installations are approved existing installations, which shall be permitted to be continued in service.

Although the referenced documents do not specify whether gas piping is allowed to pass through an exit enclosure, such as an enclosed stair, other provisions of the *Life Safety Code* apply. For example, see the provisions of 7.1.3.2.1(5) and 7.1.3.2.1(6) and the commentary following 7.1.3.2.1(7). These provisions stress that the only openings permitted in the enclosure walls between an exit and other building spaces are those needed to provide access into the exit from any normally occupied space and those needed to provide access out of the exit at the level of exit discharge. In other words, only those openings used by an occupant to enter and leave the exit enclosure are permitted. Gas piping cannot pass through exit enclosure walls. Conversely, the *Code* does not prohibit the installation of gas piping in elevator shafts, dumbwaiters, or chutes. However, these areas are clearly

prohibited from containing gas piping by NFPA 54, *National Fuel Gas Code*¹. Thus, the *Code* and the reference document are used together to address installation safety and life safety.

9.1.2 Electrical Systems.

Electrical wiring and equipment shall be in accordance with NFPA 70, *National Electrical Code*[®], unless such installations are approved existing installations, which shall be permitted to be continued in service.

Because electrical wiring might require a complicated system or array involving many specifications and design details, the *Code* does not repeat them; rather, it references NFPA 70, *National Electrical Code*^{®2}, for design and installation guidance.

The *Life Safety Code* requirements for emergency lighting, addressed by Section 7.9 and, in particular, by 7.9.2.2 with respect to independence of the emergency lighting source and distribution network, exceed the more general guidelines of NFPA 70. See the commentary throughout Section 7.9.

9.1.3 Emergency Generators.

Emergency generators, where required for compliance with this *Code*, shall be tested and maintained in accordance with NFPA 110, *Standard for Emergency and Standby Power Systems*.

9.1.4 Stored Electrical Energy Systems.

Stored electrical energy systems shall be maintained in accordance with NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems*.

Section 9.2 Heating, Ventilating, and Air-Conditioning

9.2.1 Air-Conditioning, Heating, Ventilating Ductwork, and Related Equipment.

Air-conditioning, heating, ventilating ductwork, and related equipment shall be in accordance with NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, or NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems*, as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service.

For the proper installation of HVAC systems, 9.2.1 refers the *Code* user to NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*³. For occupancies with small overall volumes, such as one- and two-family dwellings, the *Code* refers the user to NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems*⁴.

For example, NFPA 90A addresses fire damper requirements for both ductwork and air transfer grilles that penetrate fire resistance-rated barriers. NFPA 90A also prohibits means of egress corridors in health care, detention and correctional, and residential occupancies from being used as a portion of a supply, return, or exhaust air system serving adjoining areas. Exhibit 9.1 identifies some of the areas where fire dampers and smoke dampers would be required by NFPA 90A.

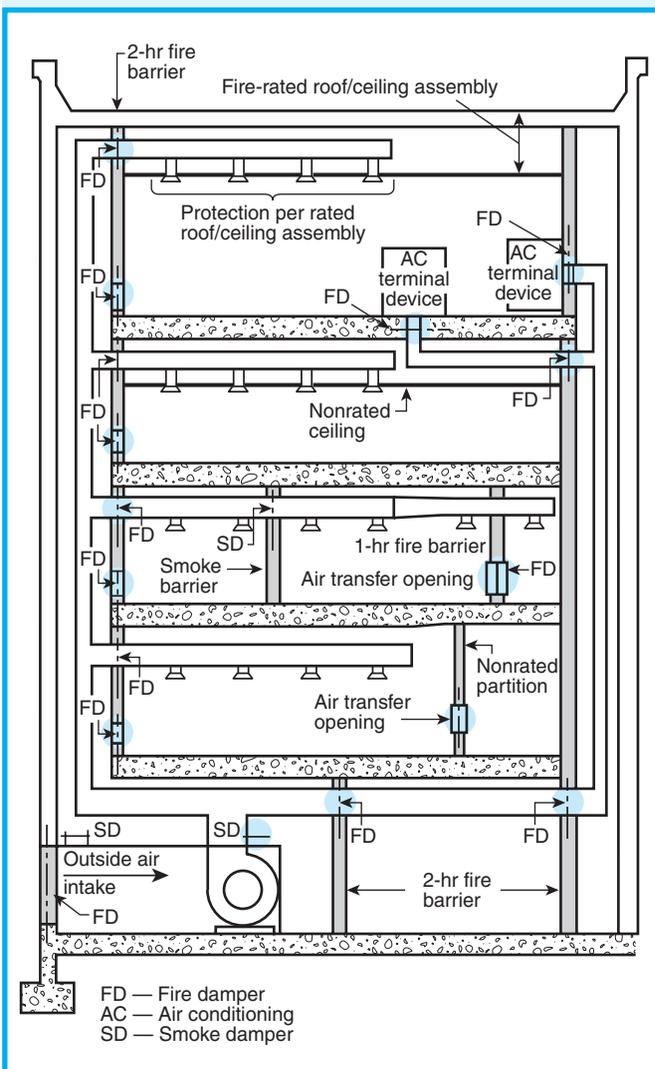

Exhibit 9.1 Partition and fire barrier penetration protection.

9.2.2 Ventilating or Heat-Producing Equipment.

Ventilating or heat-producing equipment shall be in accordance with NFPA 91, *Standard for Exhaust Systems for Air Conveying of Vapors, Gases, Mists, and Noncombustible Particulate Solids*; NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel-Burning Appliances*; NFPA 31, *Standard for the Installation of Oil-Burning Equipment*; NFPA 54, *National Fuel Gas Code*; or NFPA 70, *National Electrical Code*[®], as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service.

9.2.3 Commercial Cooking Equipment.

Commercial cooking equipment shall be in accordance with NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*, unless such installation are approved existing installations, which shall be permitted to be continued in service.

The occupancy chapters that address the protection of commercial cooking equipment do so in the provisions for the protection of hazards. To understand the intent of the *Code*, close attention must be paid to the manner in which the protection is addressed.

For example, for health care occupancies, 18.3.2.5.2 states that domestic cooking equipment used for food-warming or limited cooking is not required to be protected, nor must the space be segregated from the rest of the building. For day-care occupancies, a similar provision appears in 16.3.2.5; however, this provision requires the approval of the authority having jurisdiction to exempt protection and segregation of domestic cooking equipment (the term *approved* is defined as acceptable to the AHJ). Paragraph 22.3.2.3, which applies to detention and correctional occupancies, permits a kitchen to be open to the rest of a building only if protection in accordance with 9.2.3 is provided for the cooking facilities.

In occupancy chapters that do not refer to the protection of cooking facilities, NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*⁵, needs to be consulted to determine the criteria that define commercial cooking equipment and its appropriate required protection.

9.2.4 Ventilating Systems in Laboratories Using Chemicals.

Ventilating systems in laboratories using chemicals shall be in accordance with NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*, or NFPA 99, *Standard for Health Care Facilities*, as appropriate.

NFPA 45, *Standard on Fire Protection for Laboratories Using Chemicals*⁶, contains requirements for construction, ventilation, and fire protection in laboratory buildings, as well as for units and work areas in all buildings. Additional requirements for laboratories in health care occupancies are found in NFPA 99, *Standard for Health Care Facilities*⁷. The requirements of both documents are to be applied in laboratories in health care facilities.

Section 9.3 Smoke Control

9.3.1* Where required by the provisions of another section of this *Code*, smoke control systems shall be installed, inspected, tested, and maintained in accordance with nationally recognized standards, engineering guides, or recommended practices.

A.9.3.1 For guidance on designing, installing, acceptance testing, periodic testing, and maintaining engineered smoke-control systems, see the following (*see A.23.3.1.3 for existing detention and correctional occupancies*):

- (1) NFPA 92A, *Recommended Practice for Smoke-Control Systems*
- (2) NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*
- (3) NFPA SPP-53, *Smoke Control in Fire Safety Design*
- (4) *Design of Smoke Management Systems*
- (5) ASHRAE *Guideline 5: Guideline for Commissioning Smoke Management Systems*

The provision of 9.3.1 does not itself require smoke control systems; it mandates that, if such systems are installed for *Code* compliance, an approved maintenance and testing program must be provided to ensure operational integrity. A combination public address system and emergency occupant notification system is used routinely and any problems with the system will be readily apparent; a smoke control system dedicated to emergency use only will not be subject to daily use. Therefore, maintenance and testing of smoke control systems are necessary.

Some *Code* requirements, such as those applicable to atria in 8.6.7, indirectly mandate smoke control systems via performance-based language that requires tenable smoke conditions during egress.

Paragraph A.9.3.1 provides references to advise users of material that is available to assist in the design of smoke control systems.

The reference documents that provide design

guidance cannot be mandatorily referenced because they themselves do not contain mandatory requirements. NFPA 92A, *Recommended Practice for Smoke-Control Systems*⁸, addresses smoke control systems that use barriers, airflows, and pressure differences to confine the smoke of a fire to the zone of fire origin and thus maintain a tenable environment in other zones. The guidelines of NFPA 92A can be used to create a smokeproof enclosure using the stair pressurization method described in 7.2.3.9. The document also covers smoke control for elevator hoistways by employing the following methods either singly or in combination:

- (1) Fire floor exhaust
- (2) Elevator lobby pressurization
- (3) Smoketight elevator lobby construction
- (4) Elevator hoistway pressurization

NFPA 92A also addresses, in detail, zoned smoke control under which a building can be divided into a number of smoke control zones. Each zone is separated from the others by partitions, floors, and doors that can be closed to inhibit the movement of smoke. A smoke control zone can consist of one or more floors, or a floor can consist of more than one smoke control zone. Some arrangements of smoke control zones are depicted in Exhibit 9.2. The smoke zones are indicated by minus signs — negative pressurization or exhaust — and positively pressurized spaces are indicated by plus signs. All nonsmoke zones might be pressurized as in illustrations (a) and (c), or only those nonsmoke zones that are adjacent to the smoke zone might be pressurized as in illustrations (b) and (d). In illustration (e), the smoke zone has been limited to a portion of a floor.

The subject of maintaining tenable conditions within large zones of fire origin (such as atria and shopping malls) is addressed by NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*⁹. NFPA 92B provides technical data relevant to the design, installation, testing, operation, and maintenance of smoke management systems in buildings with large-volume spaces. These systems manage smoke within the space where the fire exists or between spaces not separated by smoke barriers. The guidelines of NFPA 92B can be used to implement smoke management systems that help to maintain a tenable environment in the means of egress from large-volume building spaces during the time required for evacuation. The guide also addresses the control and reduction of the smoke migration between the fire area and adjacent spaces. The com-

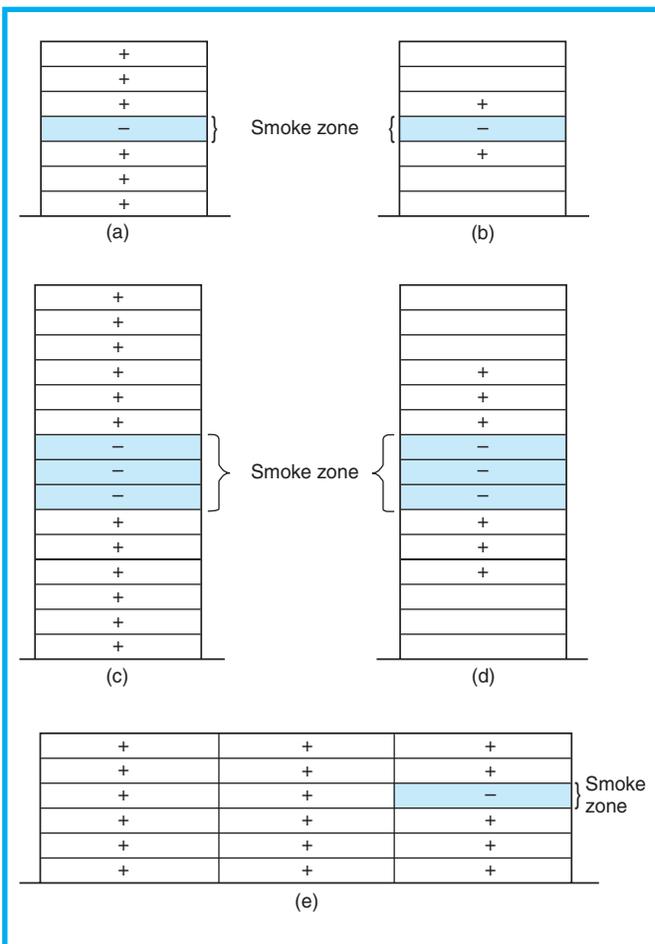

Exhibit 9.2 Smoke control zone arrangement.

mentary following A.8.6.7(6) on atrium smoke control draws extensively from the theories and protection strategies presented in NFPA 92B. In the example cited in that commentary, a volumetric exhaust rate was calculated following a detailed analysis of the physics associated with fire growth and smoke generation. This analysis concerns a particular atrium building configuration in which the exhaust rate keeps smoke from descending from the ceiling level to a level lower than head height of persons on the highest floor of the building open to the atrium. The summation of the exercise is detailed in Exhibit 8.22 and generalized in Exhibit 9.3.

Although NFPA 92A and NFPA 92B cannot be referenced mandatorily by the *Code*, they should be used in the design, installation, testing, operation, and maintenance of smoke control systems covered by their scope statements. Because of the complex nature in which numerous building systems can be

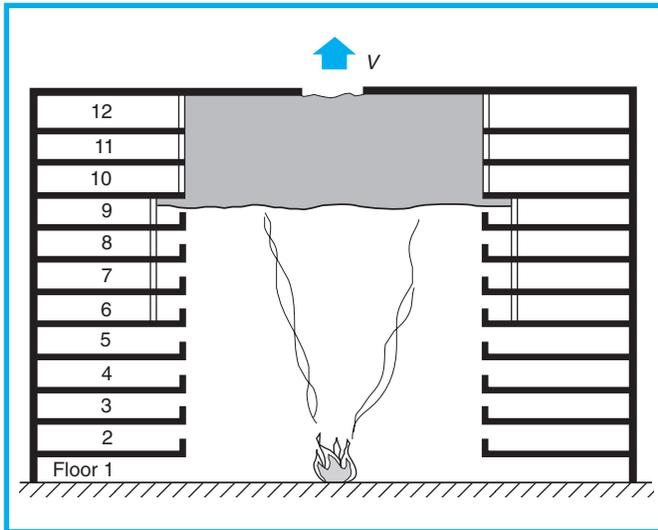

Exhibit 9.3 Control of smoke layer.

incorporated, smoke control systems are subject to special inspections in accordance with Section 9.8, as mandated by 9.3.3.

9.3.2 The engineer of record shall clearly identify the intent of the system, the design method used, the appropriateness of the method used, and the required means of inspecting, testing, and maintaining the system.

9.3.3 Acceptance testing shall be performed by a special inspector in accordance with Section 9.8.

9.3.4 Smoke Control System Operation.

9.3.4.1 Floor- or zone-dependent smoke control systems shall be automatically activated by sprinkler waterflow or smoke detection systems.

9.3.4.2 Means for manual operation of smoke control systems shall be provided at an approved location.

Section 9.4 Elevators, Escalators, and Conveyors

9.4.1* General.

An elevator, other than an elevator in accordance with 7.2.13, shall not be considered a component in a required means of egress but shall be permitted as a component in an accessible means of egress.

A.9.4.1 Under certain conditions, elevators are recognized as means of egress.

The use of elevators for emergency evacuation purposes where operated by trained emergency service personnel (for example, building personnel, fire personnel) should be utilized in the building evacuation program. Elevators are normally capable of manual, in-car fire fighter operation (Phase II) after elevator recall (Phase I). In addition, there usually are two or more shafts wherever there are more than three elevators, which further enhances the possibilities for elevator use during a fire emergency where operated by trained personnel.

In high-rise buildings, in towers, or in deep underground spaces where travel over considerable vertical distance on stairs can cause persons incapable of such physical effort to collapse before they reach the street exit, stairways are permitted to be used for initial escape from the immediate area of danger, and elevators are permitted to be used to complete the travel to the street.

It can be reasonably assumed that in all buildings of sufficient height to indicate the need for elevators, elevators will be provided for normal use; for this reason, no requirements for mandatory installation of elevators are included in the *Code*.

For additional information on elevators, see ASME A17.1, *Safety Code for Elevators and Escalators*, and ASME A17.3, *Safety Code for Existing Elevators and Escalators*.

In much earlier *Code* editions, the egress capacity of elevators was calculated based on the assumption that three average elevators were roughly equivalent to the formerly used single unit of stairway exit width. Because of this assumption, elevators were accepted as required egress components under certain limited conditions. No such credit has been given since 1956 because of some inherent characteristics that might make elevators unsuitable for emergency exit use. These characteristics are accentuated in modern automatic elevators where no operator is available to exercise judgment in the control of the elevator in case of fire or other emergency. The reasons that elevators are not credited as part of the required means of egress are summarized as follows.

(a) People seeking to escape from a fire by using an elevator might have to wait at the elevator door for some time; during that time they might be exposed to fire or smoke, or they might become panicked.

(b) Automatic elevators travel to floors by responding to pressed buttons, both in the elevator car and in elevator lobbies. Because this operation cannot be canceled once a button is pressed, it is possible for an elevator descending from floors above a fire to stop automatically at the floor of the fire. The doors

will open automatically, thus exposing occupants to fire and smoke.

A further consideration is that an elevator shaft will act as a built-in “chimney” in a multi-story building. Unless positively pressurized with respect to the fire floor, the shaft can carry heat and smoke from a fire and expose passengers to hazardous levels of both—even if the elevator does not stop at the fire floor and continues to function. An elevator moving within its shaft enclosure might act as a piston within a cylinder and push the smoke and fire gases to floors not initially involved.

(c) Modern elevators will not operate until the doors are fully closed. In an emergency, a large number of people might try to crowd into an elevator, preventing the doors from closing and preventing the elevator from operating.

(d) Any power failure, such as the burnout of electric supply cables during a fire, might render the elevators inoperative or might cause people to become trapped in elevators stopped between floors. Under fire conditions, there might not be enough time to rescue the trapped occupants through emergency escape hatches or doors.

Exhibit 9.4 is an example of an appropriate elevator placard to notify occupants that an elevator is unsuitable for emergency egress use.

Recognizing the viability of elevators to facilitate the movement of people, the *Code* has, in recent edi-

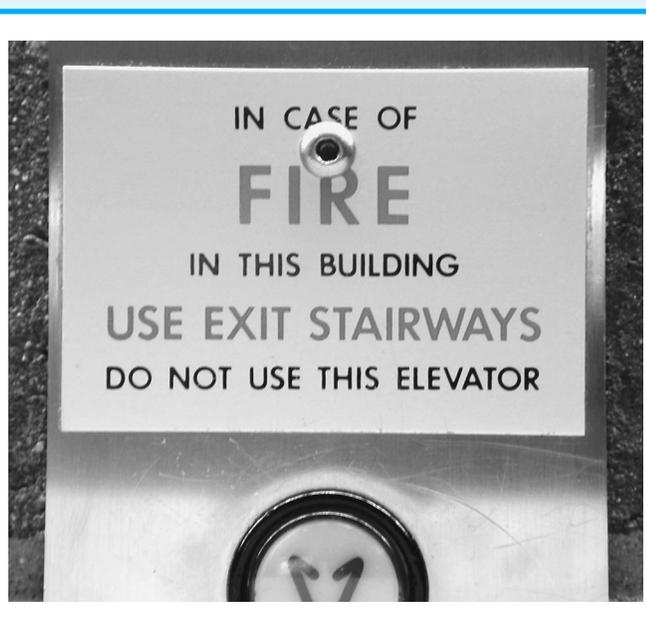

Exhibit 9.4 Elevator placard.

tions, added guidelines addressing the use of elevators in limited circumstances. The following are four circumstances under which an elevator can be part of a building’s evacuation plan.

(a) An elevator can be used in a high-rise building for assisting in a staged evacuation. Though it cannot be used as a component of the means of egress, an elevator can be a useful tool in the evacuation of a high-rise building.

(b) An elevator can be used as a means of evacuating people from an area of refuge. Elevators are an effective means of transporting people with severe mobility impairments. The criteria for the use of elevators for evacuation from an area of refuge are established in 7.2.12.2.4. Also see the commentary on 7.2.12.

(c) In underground assembly occupancies, the *Code* might require an elevator or escalator for the purposes of assisting in an emergency evacuation in an upward direction. An example of the *Code* requiring an elevator to be used under emergency conditions can be found in 12.4.3.3, which requires each level of a new assembly occupancy with a floor level more than 9140 mm (360 in.) below the level of exit discharge to be divided into at least two smoke compartments. Per 12.4.3.3.2, each compartment must be provided with a mechanical means of moving people vertically, such as an elevator or escalator. These requirements are in addition to those of Section 11.7, which addresses underground and limited access structures. In Exhibit 9.5, an escalator is used in smoke zone A and an elevator is used in smoke zone B to meet the requirements of 12.4.3.3.2.

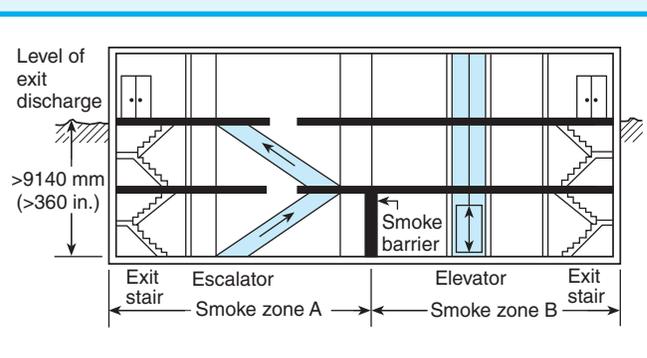

Exhibit 9.5 Elevator and escalator use in underground assembly occupancy.

(d) In special types of towers (typically air traffic control towers), the *Code* recognizes the use of an elevator as a secondary means of egress. See the commentary on 7.2.13.

9.4.2 Code Compliance.

For elevator installations, the *Code* requires compliance with either of the following:

- (1) ASME A17.1, *Safety Code for Elevators and Escalators*¹⁰
- (2) ASME A17.3, *Safety Code for Existing Elevators and Escalators*¹¹

The *Code* additionally requires that a sprinkler system, if installed, meet the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*¹². ASME A17.1 permits sprinklers in elevator hoistways and machine rooms in accordance with NFPA 13 subject to the following provisions:

- (1) All risers and returns are to be located outside these spaces.
- (2) Branch lines in the hoistway are to supply only the sprinklers on that level.
- (3) A means for disconnecting the main line power supply to the affected elevator automatically upon or prior to the application of water from sprinklers located in the machine room or hoistway is to be provided as follows:
 - a. The means must be independent of the elevator control and cannot be self-resetting.
 - b. The activation of sprinklers outside the hoistway or machine room is not to disconnect the main line power supply.
 - c. Smoke detectors are not to be used to activate sprinklers in these spaces or to disconnect the main line power supply.

ASME A17.1 and ASME A17.3 are also referenced because the *Code* recognizes the use of elevators and escalators under limited conditions and because fire fighters might need to use elevators during fire suppression efforts. Compliance with these documents makes it possible to recall elevators to the ground floor or other pre-designated floor during a fire, thus taking the elevators out of service. The provisions also permit fire fighters to manually override the controls and use the elevators as necessary.

9.4.2.1 Except as modified herein, new elevators, escalators, dumbwaiters, and moving walks shall be in accordance with the requirements of ASME A17.1, *Safety Code for Elevators and Escalators*.

9.4.2.2 Except as modified herein, existing elevators, escalators, dumbwaiters, and moving walks shall conform to the requirements of ASME A17.3, *Safety Code for Existing Elevators and Escalators*.

9.4.3 Fire Fighters' Emergency Operations.

9.4.3.1 All new elevators shall conform to the fire fighters' emergency operations requirements of ASME A17.1, *Safety Code for Elevators and Escalators*.

9.4.3.2 All existing elevators having a travel distance of 7620 mm (300 in.) or more above or below the level that best serves the needs of emergency personnel for fire fighting or rescue purposes shall conform to the fire fighters' emergency operations requirements of ASME A17.3, *Safety Code for Existing Elevators and Escalators*.

Because an elevator stopping at a fire floor (intentionally or unintentionally) is an extreme hazard, the *Code* mandates compliance with the fire fighters' emergency operations requirements of ASME A17.1 and ASME A17.3 in both new and existing buildings. The fire fighters' emergency operations requirements establish elevator recall activated by smoke detection in each elevator lobby and in associated elevator machine rooms. A three-position, key-operated switch, normally located in the main lobby at the elevator, controls the recall function. The requirements mandate specific functions for the "on," "off," and "bypass" positions of this switch. The requirements also provide for *emergency in-car operations* or what is often referred to as *fire fighters' service*. Fire fighters' service requires a three-position, key-operated switch in each elevator car. The functions of the "on," "off," and "hold" positions are specified in the elevator code. For specific details, refer to ASME A17.1. Explanatory material on these rules can be found in the *ASME Handbook A17.1*¹³.

Supplement 4 of this *Life Safety Code Handbook* contains extracts from ASME A17.1 regarding this issue as well as commentary from the *ASME Handbook A17.1*.

9.4.4 Number of Cars.

The number of elevator cars permitted in a hoistway shall be in accordance with 8.6.8.3.

9.4.5* Elevator Machine Rooms.

Elevator machine rooms that contain solid-state equipment for elevators, other than existing elevators, having a travel distance exceeding 15 m (50 ft) above the level of exit discharge or exceeding 9150 mm (360 in.) below the level of exit discharge shall be provided with independent ventilation or air-conditioning systems required to maintain temperature during fire fighters' service operation for elevator operation (*see 9.4.3*). The operating temperature shall be established by the elevator equipment manufacturer's speci-

fications. When standby power is connected to the elevator, the machine room ventilation or air-conditioning shall be connected to standby power.

A.9.4.5 Continued operation of solid-state elevator equipment is contingent on maintaining the ambient temperature in the range specified by the elevator manufacturer. If the machine room ventilation/air conditioning is connected to the general building system, and that system is shut down during a fire, the fire department might lose the use of elevators due to excessive heat in the elevator machine room.

The intent of the requirement for a ventilation or air conditioning system to help keep the elevator controls operable is explained in 9.4.5 and A.9.4.5. For many typical installations, this can be accomplished by installing an independent through-the-wall air conditioning unit. Regardless of shutdown of the building's HVAC system, the independent unit will continue to run, provided that its power supply is not interrupted.

9.4.6 Elevator Testing.

Elevators shall be subject to periodic inspections and tests as specified in ASME A17.1, *Safety Code for Elevators and Escalators*. All elevators equipped with fire fighters' emergency operations in accordance with 9.4.3 shall be subject to a monthly operation with a written record of the findings made and kept on the premises as required by ASME A17.1, *Safety Code for Elevators and Escalators*.

Because of the emphasis placed on elevators by the *Code*, it is important to provide an appropriate level of elevator testing to help ensure that they can be used by persons with mobility impairment and trained personnel under fire and other emergency conditions.

9.4.7 Openings.

Conveyors, elevators, dumbwaiters, and pneumatic conveyors serving various stories of a building shall not open to an exit.

Openings in exit enclosures are strictly limited by the provisions of 7.1.3.2.1(5) to doors that provide access to the exit from normally occupied spaces and means to leave the exit enclosure. Elevators and other conveyors are not considered normally occupied areas. Additionally, an elevator, with its associated cables, controls, and mechanical equipment, would introduce a quantity of combustibles into an exit enclosure

that conflicts with the objective of making the exit enclosure a safe place free of combustibles.

Section 9.5 Rubbish Chutes, Incinerators, and Laundry Chutes

9.5.1 Enclosure.

9.5.1.1 Rubbish chutes and laundry chutes shall be separately enclosed by walls or partitions in accordance with the provisions of Section 8.3.

9.5.1.2 Inlet openings serving chutes shall be protected in accordance with Section 8.3.

9.5.1.3 The doors of chutes specified in 9.5.1.2 shall open only to a room that is designed and used exclusively for accessing the chute opening.

9.5.1.4 The room used for accessing the chute opening shall be separated from other spaces in accordance with Section 8.7.

9.5.1.5 The requirements of 9.5.1.1 through 9.5.1.4 shall not apply where otherwise permitted by the following:

- (1) Existing installations having properly enclosed service chutes and properly installed and maintained service openings shall be permitted to have inlets open to a corridor or normally occupied space.
- (2) Rubbish chutes and laundry chutes shall be permitted to open into rooms not exceeding 37 m² (400 ft²) that are used for storage, provided that the room is protected by automatic sprinklers.

Laundry chutes are often associated with a laundry/storage room. The provision of 9.5.1.5(2) allows chutes to open into such rooms, provided that the room does not exceed 37 m² (400 ft²) in area. Without this provision, the user might interpret the words "used exclusively" (see 9.5.1.3) as limiting the use of that room to serving the chute only.

9.5.2 Installation and Maintenance.

Rubbish chutes, laundry chutes, and incinerators shall be installed and maintained in accordance with NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment*, unless such installations are approved existing installations, which shall be permitted to be continued in service.

Shafts containing waste and linen chutes must be enclosed according to the requirements for the pro-

tection of vertical openings found in Section 8.6. The installation of the chute itself must meet the requirements of NFPA 82, *Standard on Incinerators and Waste and Linen Handling Systems and Equipment*¹⁴.

Additional concerns regarding chutes opening to other parts of the building need to be addressed. For convenience, service openings for loading are usually located to be accessible from corridors on the upper floors of the building. However, these corridors also serve as exit access, and a fire in the chute with an open loading door could result in the obstruction of the corridor by smoke and other products of combustion. To address this hazard, the *Code* and NFPA 82 require the construction of service opening rooms to form a buffer between the chute and the building space. The special hazard protection provisions in Section 8.7 for the separation of the service opening are referenced in 9.5.1.4. The result is a room that is separated from the rest of the building by construction with a 1-hour fire resistance rating or protected with an automatic extinguishing system. The door to this room is required to have a $\frac{3}{4}$ -hour fire protection rating. Exhibit 9.6 illustrates the protection arrangement required for waste and linen chutes by NFPA 82.

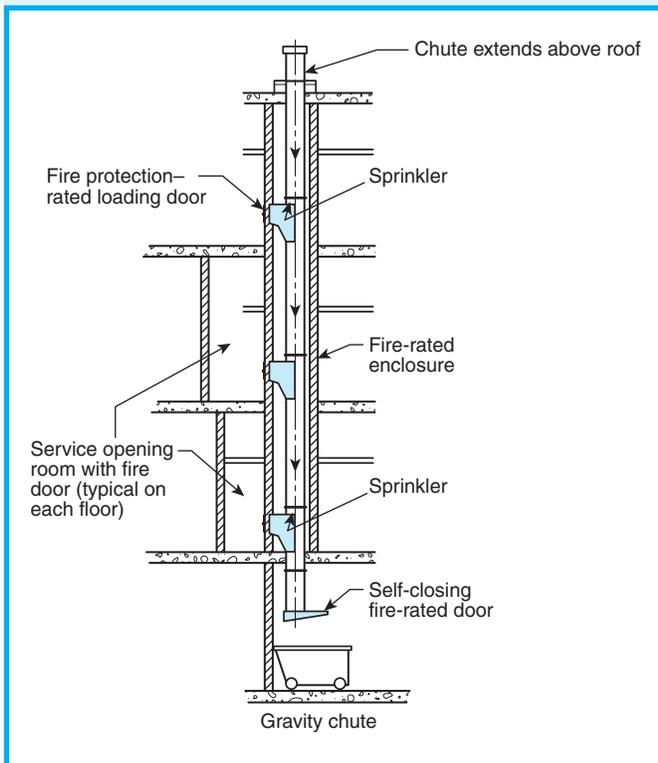

Exhibit 9.6 Protection of waste and linen chutes.

Additionally, NFPA 82 requires the service opening room to be sized to maintain a minimum 150-mm (6-in.) clearance between the open chute loading door and the closed room door. Exhibit 9.7 illustrates the measurement of this clearance.

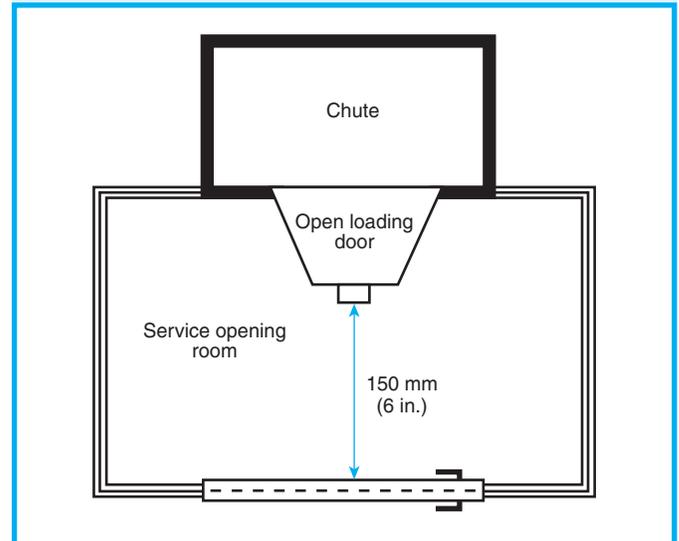

Exhibit 9.7 Clearance in service opening room.

Section 9.6 Fire Detection, Alarm, and Communications Systems

Supplement 2 of this handbook provides additional information regarding fire detection, alarm, and communications systems.

9.6.1* General.

A.9.6.1 The provisions of Section 9.6 cover the basic functions of a complete fire alarm system, including fire detection, alarm, and communications. These systems are primarily intended to provide the indication and warning of abnormal conditions, the summoning of appropriate aid, and the control of occupancy facilities to enhance protection of life.

Some of the provisions of Section 9.6 originated with *NFPA 72*[®], *National Fire Alarm Code*[®]. For purposes of this *Code*, some provisions of Section 9.6 are more stringent than those of *NFPA 72*[®], *National Fire Alarm Code*[®], which should be consulted for additional details.

The provision for early warning of fire accompanied by notification of appropriate authorities is a key ele-

ment of a fire protection program. Where people are involved, protective signaling carries even greater importance. The intent of A.9.6.1 is to provide guidance on establishing objectives for the performance of the fire alarm system and to allow individual system designs to address occupancy-specific variables.

Certain occupancies might not be required to have a fire alarm system at all. In industrial and storage occupancies, for example, the number of occupants in the facility or the hazard classification of the contents of the building determines whether an alarm system is required. In educational, mercantile, and business occupancies, there are usually enough people present (at least during a part of the day) to discover an incipient fire. For these occupancies, the *Code* imposes less rigid requirements for fire alarm systems than it does for certain other occupancies. Conversely, for health care occupancies, the provisions for the fire alarm system are quite detailed with respect to notification and emergency functions such as smoke door operation.

9.6.1.1 The provisions of Section 9.6 shall apply only where specifically required by another section of this *Code*.

Section 9.6 applies only where specifically referenced by another section of the *Code*. Primarily, such references appear in the occupancy chapters. Careful attention to the specific references in the occupancy chapters is necessary, as they might contain additional modifications or exceptions to Section 9.6. For example, 12.3.4.1 for new assembly occupancies contains a general reference to all the requirements of 9.6.1; however, it also contains a provision that exempts voice communication or public address systems from complying with 9.6.1, provided that they meet the requirements of 12.3.4.3.4.

9.6.1.2 Fire detection, alarm, and communications systems installed to make use of an alternative permitted by this *Code* shall be considered required systems and shall meet the provisions of this *Code* applicable to required systems.

The provisions of 9.6.1.2 remind the user that a fire detection, alarm, or associated communications system that is installed to take advantage of a *Code* alternative becomes a required system and is subject to the same requirements as any other required system, including maintenance. An example of this is a new

business occupancy that is not required to have a fire alarm system on the basis of the thresholds established in 38.3.4.1. If, for security reasons, delayed-egress locks are to be installed, they would have to meet the provisions of 7.2.1.6.1. Paragraph 7.2.1.6.1(1) requires that the locks automatically release upon the activation of an approved, supervised automatic sprinkler system in accordance with Section 9.7; activation of any heat detector; or activation of not more than two smoke detectors of an approved, supervised automatic fire detection system installed in accordance with Section 9.6. If a fire alarm is utilized to automatically release a delayed egress lock, the fire alarm system becomes a required system and must be installed and maintained in accordance with Section 9.6.

9.6.1.3 A fire alarm system required for life safety shall be installed, tested, and maintained in accordance with the applicable requirements of NFPA 70, *National Electrical Code*[®], and NFPA 72[®], *National Fire Alarm Code*[®], unless it is an approved existing installation, which shall be permitted to be continued in use.

9.6.1.4 All systems and components shall be approved for the purpose for which they are installed.

Approval of both the system as a whole and its individual components is required. Such approval is granted by the authority having jurisdiction. See the definition of *approved* in 3.2.1. Substantiating data could be provided in the form of test reports, approvals or listings issued by organizations such as FM Global or Underwriters Laboratories Inc., or testing or evaluation by another recognized source.

9.6.1.5 Fire alarm system installation wiring or other transmission paths shall be monitored for integrity in accordance with 9.6.1.3.

A broken or short-circuited wire between a fire alarm system initiating device (for example, a smoke detector) and the central control equipment will render the device inoperative without necessarily providing notification of the malfunction. Monitoring of the system installation wiring will result in an audible and visible trouble signal on the fire alarm control panel indicating a circuit break or ground and allow for corrective action to be taken. The intent of 9.6.1.5 is not to override the provisions for supervision in the

codes referenced in 9.6.1.3, but only to highlight those requirements or to mandate them where the referenced codes might provide that such supervision is optional.

9.6.1.6* To ensure operational integrity, the fire alarm system shall have an approved maintenance and testing program complying with the applicable requirements of NFPA 70, *National Electrical Code*[®], and NFPA 72[®], *National Fire Alarm Code*[®].

A.9.6.1.6 Records of conducted maintenance and testing and a copy of the certificate of compliance should be maintained.

The operational integrity of a fire alarm system cannot be ensured without proper maintenance and testing. Thus, the *Code* requires that an approved—that is, acceptable to the authority having jurisdiction—maintenance and testing program be operational on an ongoing basis. An important part of the program is retention of system acceptance records and subsequent operational test records so comparisons can be made to initial system specifications.

9.6.1.7* Where a required fire alarm system is out of service for more than 4 hours in a 24-hour period, the authority having jurisdiction shall be notified, and the building shall be evacuated or an approved fire watch shall be provided for all parties left unprotected by the shutdown until the fire alarm system has been returned to service.

A.9.6.1.7 A fire watch should at least involve some special action beyond normal staffing, such as assigning an additional security guard(s) to walk the areas affected. These individuals should be specially trained in fire prevention and in occupant and fire department notification techniques, and they should understand the particular fire safety situation for public education purposes. (*Also see NFPA 601, Standard for Security Services in Fire Loss Prevention.*)

A fire alarm system might be shut down for any number of reasons during the life of a building. Some shutdowns are preplanned, controlled, and of short duration, such as during periodic testing and maintenance. Others might be preplanned and of longer duration, such as during times of building or system renovation. Emergency shutdown of the system can be the result of power failure, fire, or other physical damage and might result in a short or lengthy shutdown to repair the system. Advance planning should

help ensure that the system, or most of the system, can be restored to service despite the scope of the renovation or the extent of an unexpected impairment. If the alarm system is required by the *Code* or if it was installed to make use of one of the alternatives offered by the *Code*, it must be in good, operable condition for the building to be considered *Code*-compliant.

Instead of designating a building with an inoperative alarm system as noncompliant and prohibiting occupancy under all conditions in accordance with the provisions of 4.6.10.1, 9.6.1.7 differentiates between those alarm system impairments that last less than 4 hours within a 24-hour period and those that last longer. Continued occupancy of a building that has an alarm system impairment of more than 4 hours cumulative within any 24-hour period can be tolerated only if a fire watch acceptable to the authority having jurisdiction is provided. Such lengthy impairments generally indicate a situation that involves a problem more serious in nature than typical system maintenance or testing.

It is the intent of the *Code* that the fire watch result in a heightened awareness of the building's operations and environment. Individuals selected for the fire watch should be able to recognize fire hazards and know the procedures for occupant and fire department notification and occupant evacuation in an emergency.

When developing a plan to address system shutdown, it is important to consider the nature of the shutdown, the location, the increased hazards that are involved, and the necessary actions to mitigate the hazards. The authority having jurisdiction should be involved in the development of such a plan.

A parallel requirement in 9.7.6 addresses sprinkler system impairments.

9.6.1.8 For the purposes of this *Code*, a complete fire alarm system shall provide functions for initiation, notification, and control, which shall perform as follows:

- (1) The initiation function provides the input signal to the system.
- (2) The notification function is the means by which the system advises that human action is required in response to a particular condition.
- (3) The control function provides outputs to control building equipment to enhance protection of life.

9.6.1.9 All required documentation regarding the design of fire detection, alarm, and communications systems and the procedures for maintenance, inspection, and testing of fire

detection, alarm, and communications systems shall be maintained at an approved, secured location for the life of the system.

9.6.1.10 Testing and maintenance records required by *NFPA 72®*, *National Fire Alarm Code®*, shall be maintained at an approved, secured location.

9.6.2 Signal Initiation.

9.6.2.1 Where required by other sections of this *Code*, actuation of the complete fire alarm system shall be initiated by, but shall not be limited to, any or all of the following means:

- (1) Manual fire alarm initiation
- (2) Automatic detection
- (3) Extinguishing system operation

Manual initiation is a requirement common to all occupancies that require the installation of a fire alarm system. Initiation by automatic detection or extinguishing system operation is permitted to serve in lieu of manual initiation for some occupancies. In some cases, initiation by automatic detection or extinguishing system operation might be required by an occupancy chapter. For example, new educational occupancies are not generally required to have an automatic sprinkler system; however, if such a system is installed, 14.3.4.2.2 requires alarm system initiation by operation of the sprinkler system in addition to the manual means. In new health care occupancies, automatic sprinklers are required, and 18.3.4.2.1 states that initiation of the alarm system is to be by manual means and sprinkler system waterflow alarms. In new Class A mercantile occupancies, a fire alarm system and an automatic sprinkler system are required. However, 36.3.4.2 only requires initiation by manual means. Alarm initiation by means of sprinkler system activation is permitted by 36.3.4.2(3) to serve in lieu of manual initiation, but it is not required.

Where both manual and automatic means for alarm system initiation are used, they should be complementary. If one system becomes inoperative—perhaps due to poor maintenance, abuse, or mechanical failure—the second will provide backup support.

9.6.2.2 Manual fire alarm boxes shall be approved for the particular application and shall be used only for fire-protective signaling purposes. Combination fire alarm and guard's tour stations shall be acceptable.

9.6.2.3 A manual fire alarm box shall be provided in the natural exit access path near each required exit from an area, unless modified by another section of this *Code*.

9.6.2.4* Additional manual fire alarm boxes shall be located so that, on any given floor in any part of the building, no horizontal distance on that floor exceeding 60 m (200 ft) shall need to be traversed to reach a manual fire alarm box.

A.9.6.2.4 It is not the intent of 9.6.2.4 to require manual fire alarm boxes to be attached to movable partitions or to equipment, nor is it the intent to require the installation of permanent structures for mounting purposes only.

In a large open area such as a convention hall, it would be impractical to require the installation of manual fire alarm boxes on mounting posts in the middle of the floor. However, it would be reasonable to apply the maximum spacing requirements to boxes located on the perimeter wall of the space.

9.6.2.5 For fire alarm systems using automatic fire detection or waterflow detection devices, not less than one manual fire alarm box shall be provided to initiate a fire alarm signal. The manual fire alarm box shall be located where required by the authority having jurisdiction.

9.6.2.6* Each manual fire alarm box on a system shall be accessible, unobstructed, and visible.

A.9.6.2.6 Manual fire alarm boxes can include those with key-operated locks for detention areas or psychiatric hospitals, manual fire alarm boxes in areas where explosive vapors or dusts might be a hazard, or manual fire alarm boxes in areas with corrosive atmospheres. The appearance of manual fire alarm boxes for special uses often differs from those used in areas of normal occupancy. Manual fire alarm boxes, such as those with locks, that are located in areas where the general public has limited access might need to have signage advising persons to seek assistance from staff in the event a fire is noted.

Paragraphs 9.6.2.3 through 9.6.2.6 establish the criteria for the placement of manual fire alarm boxes. The intent is to provide maximum visibility and easy access to increase the probability that building occupants will initiate an alarm as they exit the building. If alarm boxes are not located conveniently or are obstructed from view, it is unlikely that an occupant will look for one. Exhibit 9.8 illustrates two possible locations for a manual fire alarm box; one is appropriate, the other is not. A typical manual fire alarm box is shown in Exhibit 9.9.

The requirement of 9.6.2.5 is also found in *NFPA*

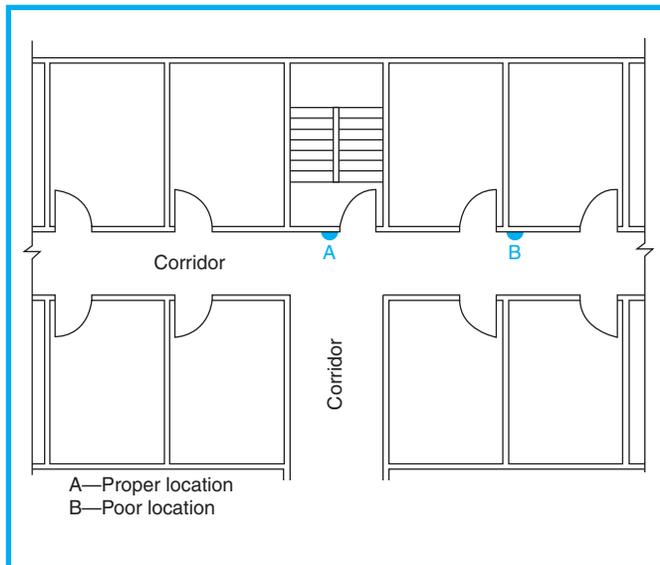

Exhibit 9.8 Manual fire alarm box location.

Exhibit 9.9 Typical manual fire alarm box. (Source: Protectowire; photo courtesy of Mammoth Fire Alarms, Inc., Lowell, MA)

72,[®] *National Fire Alarm Code*^{®15}, and is restated in the *Life Safety Code* for additional emphasis. This requirement would affect initiation arrangement for occupancies that permit alarm initiation by automatic detection or extinguishing system operation in lieu of manual initiation. For example, a business occupancy using either 38.3.4.2(2) or 38.3.4.2(3) for alarm initiation still would be required to have one manual fire alarm box in the building in a location approved by the authority having jurisdiction.

9.6.2.7 Where a sprinkler system provides automatic detection and alarm system initiation, it shall be provided with an approved alarm initiation device that operates when the flow of water is equal to or greater than that from a single automatic sprinkler.

9.6.2.8 Where a total (complete) coverage smoke detection system is required by another section of this *Code*, automatic detection of smoke in accordance with *NFPA 72*[®], *National Fire Alarm Code*[®], shall be provided in all occupiable areas, common areas, and work spaces in environments that are suitable for proper smoke detector operation.

9.6.2.9 Where a partial smoke detection system is required by another section of this *Code*, automatic detection of smoke in accordance with *NFPA 72*[®], *National Fire Alarm Code*[®], shall be provided in all common areas and work spaces, such as corridors, lobbies, storage rooms, equipment rooms, and other tenantless spaces in environments that are suitable for proper smoke detector operation. Selective smoke detection unique to other sections of this *Code* shall be provided as required by those sections.

Paragraphs 9.6.2.8 and 9.6.2.9 use the terms *total (complete) coverage smoke detection system* and *partial smoke detection system* to provide standard specifications to be used throughout the *Code* wherever these systems are required. The term *selective smoke detection* varies in meaning and relies on another provision of the *Code* to specify the intent. For example, existing, non-sprinklered limited care facilities are required by 19.3.4.5.1 to have a corridor smoke detection system. The system is unique to existing limited care facilities and does not meet the specifications of *total (complete)* or *partial* as addressed by 9.6.2.8 or 9.6.2.9.

9.6.2.10 Smoke Alarms.

Smoke alarms need to be positioned correctly. If they are too close to a wall/ceiling intersection, particularly over a door, air currents might cause heat and smoke to bypass the unit completely. Likewise, their location with respect to a dropped beam or other construction can have a similar nullifying effect. Problems can arise where partitions are moved without regard to the location of existing detectors. These problems are illustrated in Exhibit 9.10. *NFPA 72, National Fire Alarm Code*, provides extensive guidance in this area.

9.6.2.10.1 Where required by another section of this *Code*, single-station and multiple-station smoke alarms shall be in

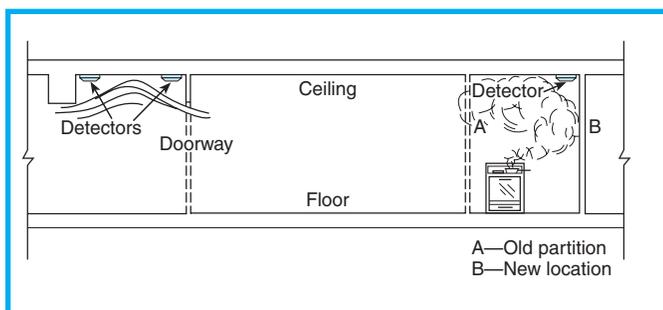

Exhibit 9.10 Detector location problems to be avoided.

accordance with *NFPA 72®*, *National Fire Alarm Code®*. System smoke detectors in accordance with *NFPA 72®*, *National Fire Alarm Code®*, and arranged to function in the same manner as single-station or multiple-station smoke alarms shall be permitted in lieu of smoke alarms.

The provisions of 9.6.2.10.1 reference the use of *NFPA 72* where single-station and multiple-station smoke alarms that are not part of a fire alarm system are used. See the commentary following 9.6.2.10.2 through 9.6.2.10.4.

The term *single station* is often misunderstood. *Single station* means that the alarm that senses smoke also sounds an integral sounding device but does not ring a general alarm.

The term *multiple-station* refers to smoke alarms that are interconnected such that when one alarm senses smoke, all the interconnected devices sound their integral alarms. Interconnected multiple-station smoke alarms are typically used within individual dwelling units to alert sleeping occupants located in different rooms to a fire in the unit.

9.6.2.10.2 Smoke alarms, other than battery-operated devices as permitted by other sections of this *Code*, or battery-operated devices complying with 9.6.1.3 and the low-power wireless system requirements of *NFPA 72®*, *National Fire Alarm Code®*, shall receive their operating power from the building electrical system.

Single-station and multiple-station smoke alarms, unless exempted by 9.6.2.10.2, must receive their operating power from the building's electrical system; they must not rely solely on battery power. This provision is based on the experience that battery-operated detectors do not provide the reliability with respect to uninterrupted power supply that building electrical

system power provides. Batteries are often removed to avoid nuisance alarms caused by kitchen or bathroom vapors or for use in other devices, such as radios and electronic toys; dead batteries are often not replaced. However, 9.6.2.10.2 permits the occupancy chapters to allow battery-operated, single-station smoke alarms. Such exemptions recognize battery-operated alarms in existing one- and two-family dwellings, in existing lodging or rooming houses, and, under certain conditions, in existing board and care facilities.

Paragraph 9.6.2.10.2 also clarifies that it is not the *Code's* intent to prohibit low-power wireless technology, in which a battery-operated alarm reports by radio transmission to an alarm panel, if such a device complies with *NFPA 72*, *National Fire Alarm Code*. In turn, *NFPA 72* requires such systems to indicate a missing battery or low battery power condition at the remotely located alarm system panel.

Compliance with the provisions of *NFPA 72* applicable to low-power wireless systems increases the power source reliability to a level comparable to that provided by connection to the building electrical service.

9.6.2.10.3* In new construction, where two or more smoke alarms are required within a dwelling unit, suite of rooms, or similar area, they shall be arranged so that operation of any smoke alarm shall cause the alarm in all smoke alarms within the dwelling unit, suite of rooms, or similar area to sound, unless otherwise permitted by the following:

- (1) The requirement of 9.6.2.10.3 shall not apply where permitted by another section of this *Code*.
- (2) The requirement of 9.6.2.10.3 shall not apply to configurations that provide equivalent distribution of the alarm signal.

A.9.6.2.10.3 A dwelling unit is that structure, area, room, or combination of rooms, including hotel rooms/suites, in which a family or individual lives. A dwelling unit includes living areas only and not common usage areas in multifamily buildings such as corridors, lobbies, and basements.

Audibility over background noises, such as running water, home appliances, and audio systems, with intervening doors closed between the occupants and the detector sounding device, is of key importance. In multistory or large-area living units, multiple smoke alarms should be interconnected so that the sensing of smoke by one sounds the alarms of all devices within that living unit.

9.6.2.10.4 The alarms shall sound only within an individual dwelling unit, suite of rooms, or similar area and shall not actuate the building fire alarm system, unless otherwise permitted by the authority having jurisdiction. Remote annunciation shall be permitted.

The intent behind requiring smoke detection within an individual living unit without requiring connection to the overall building alarm system is to provide notification of a smoke condition within a living unit to its occupants. Once the occupants egress their unit to the building's common areas, they can use the manual fire alarm boxes to sound the building alarm to notify occupants of other living units of the emergency.

Interconnection of living unit smoke alarms to the building alarm system often results in numerous nuisance alarms due to the detection of cooking or bathroom shower vapors. Nuisance alarms can lead to the deliberate disablement of the system and the resulting lack of early warning. Thus, a complete fire detection (versus smoke detection) system usually includes system smoke detection within building common areas and system heat detection within individual living units. Single-station smoke detectors are then still necessary within each living unit to afford the occupants of each unit early warning of smoke conditions within their unit.

9.6.2.11 Where required by Chapter 11 through Chapter 42, an automatic fire detection system shall be provided in hazardous areas for initiation of the signaling system.

9.6.3 Occupant Notification.

9.6.3.1 Occupant notification shall be provided to alert occupants of a fire or other emergency where required by other sections of this *Code*.

9.6.3.2 Occupant notification shall be in accordance with 9.6.3.3 through 9.6.3.11, unless otherwise provided in 9.6.3.2.1 through 9.6.3.2.4.

Note that 9.6.3.5 requires that occupant notification be provided by audible and visible signals. Thus, where an occupancy chapter requires an alarm system that provides occupant notification in accordance with Section 9.6, visible signal (as well as the traditional audible signal) must be provided. See also the modifications to the visible signal requirement in 9.6.3.5.1 through 9.6.3.5.6.

9.6.3.2.1* Elevator lobby, hoistway, and associated machine room smoke detectors used solely for elevator recall, and heat detectors used solely for elevator power shutdown, shall not be required to activate the building evacuation alarm if the power supply and installation wiring to such detectors are monitored by the building fire alarm system, and if the activation of such detectors results in an audible and visible alarm signal at a constantly attended location.

A.9.6.3.2.1 Elevator lobbies have been considered areas subject to unwanted alarms due to factors such as low ceilings and smoking. In the past several years, new features have become available to reduce this problem. These features are, however, not necessarily included in any specific installation.

9.6.3.2.2* Smoke detectors used solely for closing dampers or heating, ventilating, and air-conditioning system shutdown shall not be required to activate the building evacuation alarm.

A.9.6.3.2.2 The concept addressed is that detectors used for releasing service, such as door or damper closing and fan shutdown, are not required to sound the building alarm.

9.6.3.2.3* Detectors located at doors for the exclusive operation of automatic door release shall not be required to activate the building evacuation alarm.

A.9.6.3.2.3 The concept addressed is that detectors used for releasing service, such as door or damper closing and fan shutdown, are not required to sound the building alarm.

The provisions of 9.6.3.2.2 and 9.6.3.2.3 reaffirm that not all detectors are required to sound the building alarm simply because they are installed on the premises. Detectors used for releasing service, such as for the release of an automatic door hold-open device that allows a door to be self-closing in the presence of smoke, need only perform their intended function. In areas where smoke detection—complete with occupant notification via the building alarm system—is needed to provide the intended level of life safety, the *Code* will specifically require either a complete or partial smoke detection system. Interconnection with the building alarm should not be mandated in the hope of receiving additional detection coverage, because a detector might have been installed for another purpose, such as releasing service.

New health care occupancies, via 18.3.4.3.1, prohibit the use of 9.6.3.2.3. Thus, if a smoke detector is installed as part of an automatic door release (see 7.2.1.8.2), the activation of the detector must result in occupant notification through the building fire alarm system.

9.6.3.2.4 Detectors in accordance with 22.3.4.3.1(2) and 23.3.4.3.1(2) shall not be required to activate the building evacuation alarm.

9.6.3.3 Where permitted by Chapter 11 through Chapter 42, a presignal system shall be permitted where the initial fire alarm signal is automatically transmitted without delay to a municipal fire department, to a fire brigade (if provided), and to an on-site staff person trained to respond to a fire emergency.

Instead of immediately and automatically sounding a general alarm throughout the building, a presignal system delays the general alarm by sounding alarm devices initially in only an approved and constantly attended area. This area could be, for example, a fire brigade station, guard station, or similar location with trained staff who investigate the signal's origin and subsequently sound a general alarm if necessary.

A delay in sounding the general alarm is inherent in a presignal system, but the delay might do more harm than good in those occupancies with populations that are difficult to evacuate or protect. Therefore, the *Code* requires an occupancy chapter to specifically recognize a presignal system to permit its use. Most occupancies no longer permit presignal systems in new construction but continue to permit them in existing buildings. For example, 40.3.4.3.3 permits an existing presignal system in an industrial occupancy.

A presignal system used in accordance with the provisions of 9.6.3.3 is allowed to delay only the general occupant notification and must, at time of initiation, achieve immediate and automatic notification of emergency forces.

9.6.3.4 Where permitted by Chapter 11 through Chapter 42, a positive alarm sequence shall be permitted, provided that it is in accordance with *NFPA 72*[®], *National Fire Alarm Code*[®].

Given that smoke detector sensitivity should result in alarm system initiation sooner than that achieved by either heat detection or manual discovery and use of a pull station, 9.6.3.4 addresses positive alarm sequence, which has detailed requirements in *NFPA 72*, *National Fire Alarm Code*. Positive alarm sequence offers relief from nuisance alarms in buildings equipped with detection technology by allowing a delay in occupant notification. The detector senses smoke, automatically and without delay, sending an

alarm signal to a constantly attended location so that trained staff can investigate the origin of the signal. Positive alarm sequence includes all of the following features:

- (1) The signal received at the attended location must be acknowledged within 15 seconds, or immediate occupant notification (and emergency forces notification, if required) must occur.
- (2) Trained personnel have up to 180 seconds during the alarm investigation phase to evaluate the fire condition and reset the system; if the system is not reset within 180 seconds, immediate occupant notification (and emergency forces notification, if required) must occur.
- (3) If a second automatic fire detector is actuated during the investigation phase, immediate occupant notification (and emergency forces notification, if required) must occur.
- (4) If any other initiating device, such as a manual pull station, is actuated during the investigation phase, immediate occupant notification (and emergency forces notification, if required) must occur.
- (5) The system must provide a means to bypass the positive alarm sequence.

Positive alarm sequence is permitted only if an occupancy chapter specifically allows it by direct reference to 9.6.3.4. The following occupancies permit positive alarm sequence:

- (1) Assembly occupancies (12.3.4.3.1, 13.3.4.3.1)
- (2) Educational occupancies (14.3.4.3.1.2, 15.3.4.3.1.2)
- (3) Day care occupancies (16.3.4.3.2, 17.3.4.3.2)
- (4) Detention and correctional occupancies (22.3.4.3.1, 23.3.4.3.1)
- (5) Lodging or rooming house occupancies (26.3.3.3.2)
- (6) Hotels and dormitories (28.3.4.3.2, 29.3.4.3.2)
- (7) Apartment buildings (30.3.4.3.1, 31.3.4.3.1)
- (8) Mercantile occupancies (36.3.4.3.1, 37.3.4.3.1)
- (9) Business occupancies [38.3.4.3(1), 39.3.4.3(1)]
- (10) Industrial occupancies (40.3.4.3.2)
- (11) Storage occupancies (42.3.4.3.2, 42.8.3.4.3.2)

9.6.3.5 Unless otherwise provided in 9.6.3.5.1 through 9.6.3.5.6, notification signals for occupants to evacuate shall be audible and visible signals in accordance with *NFPA 72*[®], *National Fire Alarm Code*[®], and ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, or other means of notification ac-

ceptable to the authority having jurisdiction shall be provided.

9.6.3.5.1 Areas not subject to occupancy by persons who are hearing impaired shall not be required to comply with the provisions for visible signals.

Visible alarm devices, in addition to the audible alarms, are needed in buildings occupied by persons who are hearing impaired. The provision of 9.6.3.5.1 recognizes that not all buildings are subject to occupancy by those who are hearing impaired. For example, in a special hazard industrial occupancy where, due to employee safety concerns, an adequate hearing level has been judged to be a legitimate condition of employment, there should be no life safety need for visible signals in addition to the audible signals. As the provisions of the *Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities (ADAAG)*¹⁶ discussed in the commentary associated with 7.2.12 receive wider implementation or are expanded in scope, there will be few locations where it is certain that persons with hearing impairments will not be present.

9.6.3.5.2 Visible-only signals shall be provided where specifically permitted in health care occupancies in accordance with the provisions of Chapter 18 and Chapter 19.

9.6.3.5.3 Existing alarm systems shall not be required to comply with the provision for visible signals.

9.6.3.5.4 Visible signals shall not be required in lodging or rooming houses in accordance with the provisions of Chapter 26.

9.6.3.5.5 Visible signals shall not be required in exit stair enclosures.

9.6.3.5.6 Visible signals shall not be required in elevator cars.

Visible occupant notification appliances are not required to be installed in exit stairs or elevator cars as noted in 9.6.3.5.5 and 9.6.3.5.6, respectively. These provisions were added to the 2003 edition of the *Code* to recognize that once occupants enter an exit stair, they have reached a safe location and are in the process of egressing the building. Notification appliances in exit stair enclosures can create confusion and actually slow down the evacuation process. Likewise, if an occupant is in an elevator and the building alarm

activates, the elevator should be recalled to a designated floor (typically the street-level lobby). When the doors open, occupants will become aware of the alarm condition and proceed to egress the building. See also 9.6.3.6.5 and 9.6.3.6.6 for parallel provisions addressing audible notification appliances.

9.6.3.6 The general evacuation alarm signal shall operate in accordance with one of the methods prescribed by 9.6.3.6.1 through 9.6.3.6.4.

9.6.3.6.1 The general evacuation alarm signal shall operate throughout the entire building.

9.6.3.6.2* Where total evacuation of occupants is impractical due to building configuration, only the occupants in the affected zones shall be notified initially. Provisions shall be made to selectively notify occupants in other zones to afford orderly evacuation of the entire building.

A.9.6.3.6.2 To approve an evacuation plan to selectively notify building occupants, the authority having jurisdiction should consider several building parameters, including building compartmentation, detection and suppression system zones, occupant loads, and the number and arrangement of the means of egress.

In high-rise buildings, it is typical to evacuate the fire floor, the floor(s) above, and the floor immediately below. Other areas are then evacuated as the fire develops.

The provision of 9.6.3.6.2 normally applies to high-rise buildings. It provides for zoned, staged evacuation. This provision anticipates that the portions of the building that do not receive the initial alarm are separated from the areas of immediate emergency by adequate fire resistance-rated construction, such as the 2-hour fire separation that is usually provided between floors of high-rise buildings.

9.6.3.6.3 Where occupants are incapable of evacuating themselves because of age, physical or mental disabilities, or physical restraint, the private operating mode as described in *NFPA 72*[®], *National Fire Alarm Code*[®], shall be permitted to be used. Only the attendants and other personnel required to evacuate occupants from a zone, area, floor, or building shall be required to be notified. The notification shall include means to readily identify the zone, area, floor, or building in need of evacuation.

The provision of 9.6.3.6.3, which addresses the private operating mode for occupant notification, commonly

applies to health care occupancies and detention and correctional occupancies. It is common in these occupancies to use coded messages or a similar method to announce the location of a fire emergency throughout the facility. This allows all members of the emergency response team, regardless of current location within a potentially sprawling facility, to respond to their assigned emergency duties. For example, despite the fact that the facility engineer might be in a building remote from that having the emergency when the coded alarm sounds throughout the facility, the engineer will receive the proper notification to carry out the previously assigned task of checking the fire pump to ensure that it is ready to operate if needed.

9.6.3.6.4 In mall buildings in accordance with Chapter 36 and Chapter 37, notification within the mall shall be permitted in accordance with 36.4.4.4.3.1(3) and 37.4.4.4.3.1(3).

Paragraph 9.6.3.6.4 emphasizes that the provisions of Chapters 36 and 37 that apply to malls require an alarm system for the mall (the covered pedestrian walkway) rather than for the entire mall building, which includes both the mall and all attached tenant spaces. Each individual tenant space that is itself a Class A mercantile occupancy must also have an alarm system. Smaller tenant spaces are not required to have alarm systems. The alarm system required in the mall must sound throughout the pedestrian way but need not sound within the tenant spaces. The alarm system required in each Class A mercantile occupancy tenant space must sound within that tenant space but is not required to sound either in the smaller tenant spaces (which are exempt from the alarm system requirement) or in the mall.

9.6.3.6.5 The general evacuation signal shall not be required to operate in exit stair enclosures.

9.6.3.6.6 The general evacuation signal shall not be required to operate in elevator cars.

9.6.3.7 Audible alarm notification appliances shall be of such character and so distributed as to be effectively heard above the average ambient sound level that exists under normal conditions of occupancy.

The authority having jurisdiction needs to review carefully the types and locations of alarm-indicating appliances. Given that audibility above ambient sound level is of primary importance and that each

additional sounding device adds cost to a system, a balance should be maintained so that excessive costs are not incurred while the installation of sufficient devices for adequate audibility is ensured. The provision of sufficient devices is extremely important in hotels and apartment buildings. Sounding devices located in corridors might not be audible within living units, especially in new construction, due to increased levels of acoustical insulation.

In new hotels, it has become common to install alarm indicators within each guest room to meet the audibility requirement. With water running in the bathroom, the television operating on high volume, and the air-conditioning system in use, the horn or speaker within the room achieves the required occupant notification whereas a similar device located in the corridor might not. Additionally, the alarm device often used is a speaker that can produce an alarm tone or deliver a specific voice message. A speaker device is particularly useful in a high-rise building; although it is important to get an initial message to all rooms, different messages will also need to be sent to different parts of the building as part of a zoned evacuation plan.

9.6.3.8 Audible alarm notification appliances shall produce signals that are distinctive from audible signals used for other purposes in a given building.

Where the provisions of Chapters 12 through 42 require an evacuation alarm signal, the standard fire alarm evacuation signal described in *NFPA 72, National Fire Alarm Code*, should be used. The standard fire alarm evacuation signal is a three-pulse temporal pattern using any appropriate sound. This signal is illustrated in Exhibit 9.11. The pattern consists of an “on” phase (a) lasting 0.5 second followed by an “off” phase (b) lasting 0.5 second, for three successive “on” periods; these are followed by an “off” phase (c) lasting 1.5 seconds. The signal should be repeated for a period appropriate for the purposes of evacuation of the building but for not less than 180 seconds. A single-stroke bell or chime sounded at “on” intervals lasting 1 second, with a 2-second “off” interval after each third “on” stroke is permitted.

The manner of sounding alarms should be standardized to obtain uniformity throughout as large a geographic area as practicable so that people moving from one locality to another will not be misled and confused by differences in the manner of sounding alarms.

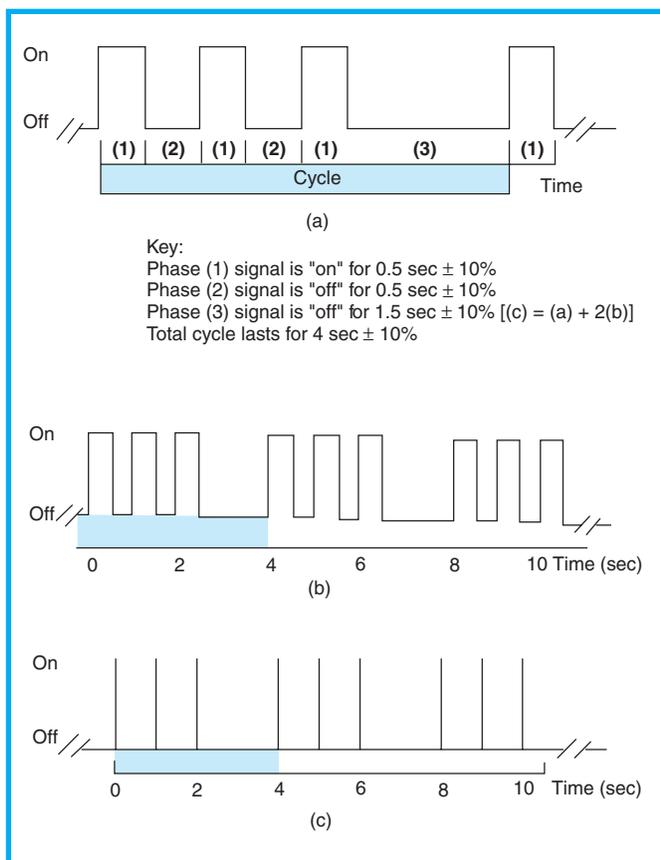

Exhibit 9.11 Standard fire alarm evacuation signal.

Two multiple-fatality fires in hotel occupancies that occurred in late 1978 and 1979 illustrate the need for standardized fire alarm signals with adequate audibility. In both incidents, which occurred in the middle of the night, many survivors reported not hearing any alarm device or mistaking the alarm for telephones or alarm clocks. An additional multiple-fatality fire in a hotel in 1978 illustrated the special problems with alarm notification where occupants are hearing impaired. In this fire, several elderly occupants removed hearing aids before going to bed, thus challenging the adequacy of the alarm's audibility.

9.6.3.9 Automatically transmitted or live voice evacuation or relocation instructions shall be permitted to be used to notify occupants and shall be in accordance with *NFPA 72*[®], *National Fire Alarm Code*[®].

Rather than specify additional requirements for recorded or live voice evacuation or relocation instructions, the *Code* mandatorily references *NFPA 72*,

National Fire Alarm Code, which contains the necessary requirements.

9.6.3.10 Unless otherwise permitted by another section of this *Code*, audible and visible fire alarm notification appliances shall comply with either 9.6.3.10.1 or 9.6.3.10.2.

An example of a use permitted by another section of the *Code*, as specified in 9.6.3.10, appears in 14.3.4.3.1.3 for educational occupancies. The fire alarm system in 14.3.4.3.1.3 is permitted to be used to designate class change, provided that the fire alarm signal is distinctively different from the class change signal and overrides all other use and such arrangement is acceptable to the authority having jurisdiction.

9.6.3.10.1 Audible and visible fire alarm notification appliances shall be used only for fire alarm system or other emergency purposes.

9.6.3.10.2 Voice communication systems shall be permitted to be used for other purposes, subject to the approval of the authority having jurisdiction, if the fire alarm system takes precedence over all other signals.

The provision of 9.6.3.10.2 requires the approval of the authority having jurisdiction to permit a voice communication system to be used for some other purpose. The system designer or building operator and the authority having jurisdiction should determine how susceptible the system is to deliberate tampering. For example, in a business occupancy where a combination emergency voice communication and daily background music system is installed with a speaker located in the ceiling directly over an employee's desk, it should be predicted that the constant, background music might irritate the employee to the point that the speaker will be muffled or otherwise disabled. Therefore, the requirement that the fire alarm system take precedence over all other signals becomes futile; a disabled speaker cannot deliver the required emergency message.

9.6.3.11 Alarm notification signals shall take precedence over all other signals.

9.6.4 Emergency Forces Notification.

9.6.4.1 Where required by another section of this *Code*, emergency forces notification shall be provided to alert the

municipal fire department and fire brigade (if provided) of fire or other emergency.

9.6.4.2 Where fire department notification is required by another section of this *Code*, the fire alarm system shall be arranged to transmit the alarm automatically via any of the following means acceptable to the authority having jurisdiction and shall be in accordance with *NFPA 72®*, *National Fire Alarm Code®*:

- (1) Auxiliary alarm system
- (2) Central station connection
- (3) Proprietary system
- (4) Remote station connection

The following is provided to help differentiate among the four alarm transmission methods for fire department notification in 9.6.4.2.

(a) *Auxiliary Alarm System.* An auxiliary alarm system is a system connected to a municipal fire alarm system for transmitting an alarm of fire to the public fire service communication center. Fire alarms from an auxiliary alarm system are received at the public fire service communication center on the same equipment and by the same methods as alarms transmitted manually from municipal fire alarm boxes located on streets.

(b) *Central Station Fire Alarm System.* A central station fire alarm system is a system or group of systems in which the operations of circuits and devices are signaled automatically to, recorded in, maintained by, and supervised from a listed central station staffed by competent and experienced servers and operators. Upon receipt of a signal, the staff take such action as is required. Such service is controlled and operated by a person or firm whose business is the furnishing, maintaining, and monitoring of supervised fire alarm systems.

(c) *Proprietary Fire Alarm System.* A proprietary fire alarm system is an installation of fire alarm systems that serves contiguous or noncontiguous properties under one ownership from a proprietary supervising station located at the protected property, where trained, competent personnel are in constant attendance. This system includes the proprietary supervising station; power supplies; signal initiating devices; initiating device circuits; signal notification appliances; equipment for the automatic, permanent, visual recording of signals; and equipment for initiating the operation of emergency building control services.

(d) *Remote Station Fire Alarm System.* A remote

station fire alarm is a system installed to transmit alarm, supervisory, and trouble signals from one or more protected premises to a remote supervising station location at which appropriate action is taken.

Fire alarm equipment installed for the notification of occupants of a building, in localities under the protection of a regularly organized fire department or private fire brigade, can be arranged to provide the automatic transmission of alarms. These alarms can be transmitted directly or through an approved central station office to the fire department or fire brigade upon operation of an alarm-sending station or system. Where no such connection is provided, a fire alarm box arranged to signal the fire department could be installed at the main entrance to the building, at the telephone switchboard, or somewhere outside the building. The alarm box must be plainly visible during day or night and must be conveniently accessible from the main entrance. While this arrangement is desirable, it is not required by 9.6.4.2 unless specified by the occupancy chapter.

9.6.4.3 For existing installations where none of the means of notification specified in 9.6.4.2(1) through 9.6.4.2(4) is available, an approved plan for notification of the municipal fire department shall be permitted.

The extensive availability of reliable communications systems has limited the necessity for this provision (formerly permitted for all occupancies) to existing installations only.

9.6.5 Emergency Control.

9.6.5.1 A fire alarm and control system, where required by another section of this *Code*, shall be arranged to actuate automatically the control functions necessary to make the protected premises safer for building occupants.

9.6.5.2 Where required by another section of this *Code*, the following functions shall be actuated by the complete fire alarm system:

- (1) Release of hold-open devices for doors or other opening protectives

Doors are permitted by 7.2.1.8.2 to be automatic-closing if (among other requirements) the detection of smoke automatically releases the device holding the door open, thus allowing the door to become self-closing. The provisions of 7.2.1.8.2 do not require the

building alarm system to release the doors. The health care occupancy chapters are more stringent on the subject and require that the automatic closing of doors is also to occur upon initiation of the building's required fire alarm system (see 18.2.2.2.6 and 19.2.2.2.6). This is an example of an occupancy chapter mandating 9.6.5.2(1) as a requirement that is needed in addition to 7.2.1.8.2.

- (2) Stairwell or elevator shaft pressurization
- (3) Smoke management or smoke control systems

Manual fire alarm boxes generally should not be used to activate smoke control systems other than stair tower pressurization systems due to the likelihood of a person signaling an alarm from a location outside the smoke zone of fire origin. Such alarm initiation could put the smoke management system in an undesirable mode of operation and cause it to spread smoke from one zone to another, rather than restrict it. For additional guidance on the subject, see the following:

- (1) NFPA 92A, *Recommended Practice for Smoke-Control Systems*
- (2) NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*

- (4) Emergency lighting control

New special amusement buildings are addressed in 12.4.7. Those that operate in reduced lighting levels (for example, a haunted house amusement) must, upon actuation of the required automatic smoke detection system or the required automatic sprinkler system, increase illumination in the means of egress to at least the minimum level required by Section 7.8. The requirements applicable to special amusement buildings augment the concept of using the alarm system to initiate an emergency control function by mandating that conflicting or confusing sounds and visuals stop upon actuation of the required automatic smoke detection system or the required automatic sprinkler system. Thus, in a haunted house amusement, all audible and visual special effects would cease upon alarm so as not to confuse the patrons. A fire alarm horn or strobe might not be recognized if forced to compete with the background special effects common to such an occupancy.

- (5) Unlocking of doors

For an example of a *Code* requirement for the activation of the alarm system to unlock a door, see the provisions for delayed-egress door locking addressed by 7.2.1.6.1.

9.6.5.3 The functions specified in 9.6.5.2 shall be permitted to be actuated by any fire alarm and control system where otherwise not required by this *Code*. Additionally, such a fire alarm and control system shall be permitted to recall elevators, as required by Section 9.4, if the activation of the system for such recall is by means of the elevator lobby, hoistway, or associated machine room detectors only.

ASME A17.1, *Safety Code for Elevators and Escalators*, and ASME A17.3, *Safety Code for Existing Elevators and Escalators* (which are referenced mandatorily by Section 9.4), prohibit the recall of elevators by detectors other than those installed in the elevator lobbies, hoistways, and associated elevator machine room. Recall by other detectors can lead to numerous nuisance recalls under conditions where it would be safe to operate elevators. To avoid having elevators taken out of service every time any building system detector senses smoke, the recall feature is often deliberately disabled. ASME A17.1 and ASME A17.3 impose the recall restriction to keep the recall feature operational. These provisions are restated in 9.6.5.3, which permits the elevator lobby and machine room detectors to be part of the building detection, alarm, and communications system.

9.6.5.4* Installation of emergency control devices shall be in accordance with *NFPA 72®*, *National Fire Alarm Code®*. The performance of emergency control functions shall not impair the effective response of all required alarm notification functions.

A.9.6.5.4 Control devices (fire alarm relays) can be located at a motor control center that is located floors away from the device to be activated, such as air-handling units and exhaust fans located on the roof. The requirement for monitoring for integrity only applies to the installation wiring between the fire alarm control unit and the auxiliary fire alarm relay. It does not apply to the wiring between the auxiliary fire alarm relay and the emergency control device (for example, motor stop/start control relay) or between the emergency control device and the equipment to be controlled

(for example, air-handling units and exhaust fans). For example, although the auxiliary fire alarm relay is required be located within 915 mm (36 in.) of the emergency control device, there is no limit specified for the distance between the emergency control device and the equipment to be controlled.

9.6.6 Location of Controls.

Operator controls, alarm indicators, and manual communications capability shall be installed in a control center at a convenient location acceptable to the authority having jurisdiction.

At times it is not practical, either physically or from a security standpoint, to locate control centers adjacent to an entrance. For example, control centers for proprietary fire alarm systems designed in accordance with *NFPA 72, National Fire Alarm Code*, for reasons of security, often need to be located away from public areas. Thus, the *Code* does not require that control centers be located adjacent to an entrance. However, because the controls are intended to be used by the fire department, they need to be located in a position approved by the authority having jurisdiction.

9.6.7 Annunciation.

Subsection 9.6.7 establishes provisions applicable to alarm annunciation, which are then referenced by other sections of the *Code* as part of the overall life safety package needed for specific occupancies. Alarm annunciation allows trained individuals—such as building engineers, security and safety officers, and responding fire service personnel—to read the indicator lamps or alphanumeric displays of an annunciator unit to identify circuits, associated building locations, and conditions that warrant attention or investigation.

9.6.7.1 Where alarm annunciation is required by another section of this *Code*, it shall comply with 9.6.7.2 through 9.6.7.7.

9.6.7.2 Alarm annunciation at the control center shall be by means of audible and visible indicators.

Alarm annunciation at the control center, as specified in 9.6.7.2, must be by means of audible as well as visible indicators to capture the attention of the trained attendant, who might have numerous job

functions within or near the control center that might distract attention from the annunciator unit.

9.6.7.3 For the purposes of alarm annunciation, each floor of the building, other than floors of existing buildings, shall be considered as not less than one zone, unless otherwise permitted by 9.6.7.4.3, 9.6.7.4.4, or another section of this *Code*.

9.6.7.4 If a floor area exceeds 2090 m² (22,500 ft²), additional fire alarm zoning shall be provided, and the length of any single fire alarm zone shall not exceed 91 m (300 ft) in any direction, except as provided in 9.6.7.4.1 through 9.6.7.4.4 or otherwise modified by another section of this *Code*.

9.6.7.4.1 Where permitted by another section of this *Code*, fire alarm zones shall be permitted to exceed 2090 m² (22,500 ft²), and the length of a zone shall be permitted to exceed 91 m (300 ft) in any direction.

9.6.7.4.2 Where the building is protected by an automatic sprinkler system in accordance with 9.7.1.1(1), the area of the fire alarm zone shall be permitted to coincide with the allowable area of the sprinkler system.

9.6.7.4.3 Where the building is protected by an automatic sprinkler system in accordance with 9.7.1.1(2), the sprinkler system shall be permitted to be annunciated on the fire alarm system as a single zone.

9.6.7.4.4 Where the building is protected by an automatic sprinkler system in accordance with 9.7.1.1(3), the sprinkler system shall be permitted to be annunciated on the fire alarm system as a single zone.

Paragraphs 9.6.7.4.1 through 9.6.7.4.4 provide a choice of zone locations and zone sizes for meaningful annunciation. In a new multiple-story building required to have alarm annunciation by another section of the *Code*, 9.6.7.3 would not allow two or more floors to be considered as a single zone unless the building is a residential occupancy, sprinklered in accordance with *NFPA 13R, Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*¹⁷, or *NFPA 13D, Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*¹⁸, in which case the sprinkler system is permitted to be annunciated as a single zone. In buildings other than those sprinklered in accordance with *NFPA 13R* or *NFPA 13D*, floors must be annunciated separately, otherwise an alarm condition would be annunciated as originating in a zone that includes multiple floors and, thus, would

not identify the specific location of the fire. Such a situation might delay the investigation and associated emergency response effort. Existing alarm annunciation systems are exempted from the requirement of 9.6.7.3 so as not to unfairly render existing *Code*-complying installations abruptly noncompliant, thereby avoiding the need for major alterations or a complete replacement of the alarm system.

Residential sprinkler systems in accordance with NFPA 13R and NFPA 13D commonly utilize a so-called “birdcage” piping configuration, in which the sprinkler branch lines are run vertically through the building, rather than horizontally, providing an economical design alternative. (The resulting piping network resembles a birdcage, thus the name.) With such a configuration, however, it is not practical to provide waterflow devices for every floor since each branch line typically serves multiple floors. Therefore, a single waterflow device is provided on the supply piping ahead of the branch lines resulting in the sprinkler system being annunciated as a single zone. While such an arrangement might increase the time required for emergency responders to locate the fire, it is considered a reasonable alternative for residential occupancies not exceeding four stories in height utilizing NFPA 13R- or NFPA 13D-compliant sprinkler systems.

It is further specified in 9.6.7.4 that no one zone for alarm annunciation purposes, even if it is located entirely on one floor of the building, should be so large that it delays identification of the location from which the alarm was initiated. The permitted zone size, 2090 m² (22,500 ft²), is intended to coordinate with the maximum permitted smoke compartment size in health care and detention and correctional occupancies. The maximum zone area and zone dimensional criteria are modified by 9.6.7.4.2 for fully sprinklered buildings, allowing the alarm system zoning to coincide with the area of the sprinkler system zone. Depending on the sprinkler system’s design, this might result in a zone as large as 4831 m² (52,000 ft²). This requirement helps to achieve consistency in reporting alarms from signaling system devices and from sprinkler system waterflow to the annunciator unit. Although a sprinkler system might be designed and installed by parties other than those who design and install fire alarm systems, the coordination of these two systems is needed during the design phase for them to complement each other.

9.6.7.5 A system trouble signal shall be annunciated at the control center by means of audible and visible indicators.

9.6.7.6 A system supervisory signal shall be annunciated at the control center by means of audible and visible indicators.

Alarm system trouble signals and supervisory signals must be annunciated at the control center by both audible and visible indicators in accordance with 9.6.7.5 and 9.6.7.6 to help ensure that personnel in attendance will pay attention to the indication and act appropriately. Trouble signals indicate such conditions as a circuit break or ground occurring in the fire alarm system wiring. Supervisory signals indicate a problem with the supervision of sprinkler systems, such as a closed valve. Supervisory signals can also be associated with the supervision of other extinguishing systems and equipment or the maintenance features of other fire protection systems.

9.6.7.7 Where the system serves more than one building, each building shall be annunciated separately.

Section 9.7 Automatic Sprinklers and Other Extinguishing Equipment

Supplement 3 of this handbook contains additional information on sprinklers and automatic sprinkler systems.

9.7.1 Automatic Sprinklers.

9.7.1.1* Each automatic sprinkler system required by another section of this *Code* shall be in accordance with one of the following:

- (1) NFPA 13, *Standard for the Installation of Sprinkler Systems*
- (2) NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*
- (3) NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*

A.9.7.1.1 For a discussion of the effectiveness of automatic sprinklers as well as a general discussion on automatic sprinklers, see the NFPA *Fire Protection Handbook*. Where partial sprinkler protection is permitted by another section of this *Code*, the limited area systems provisions of NFPA 13, *Standard for the Installation of Sprinkler Systems*, should apply.

The *Code* requirements for automatic sprinklers are based on the sprinkler experience record, which shows that, where installed properly, a sprinkler system is the most effective tool for protecting and safeguarding against loss of life and property. Occupants of a building who are aware of the presence of sprinkler protection can feel secure that any fire will be detected and fought at its origin and that an alarm will be sounded. The alarm will provide time for occupants to evacuate a burning building before fire can cut off their escape.

Numerous myths exist regarding the operation of automatic sprinklers. Some are reinforced by misrepresentations in the news media or the entertainment industry. The following facts should serve to debunk these myths:

- (1) Sprinkler systems do not operate when smoke detectors operate.
- (2) All sprinklers in the building do not operate simultaneously unless specifically designed to do so (such as the case of a deluge system protecting an unusual hazard).
- (3) Sprinklers do not spray water that has been superheated by the fire, resulting in the scalding of building occupants.
- (4) Sprinkler system operation does not cause drowning or electrocution of building occupants.
- (5) Sprinkler system operation does not increase the amount of smoke generated by the fire; rather, it dramatically reduces the generation of smoke and other hazardous products of combustion.

Automatic sprinkler systems remain the single most effective means of controlling fire spread for the widest range of buildings and areas. It is for this reason that the *Code* contains numerous modifications to requirements based on the presence sprinklers.

NFPA 13, *Standard for the Installation of Sprinkler Systems*, covers installation details for standard automatic sprinkler systems. In the interest of both life safety from fire and the protection of property, it will generally be beneficial to provide a complete standard automatic sprinkler installation to protect the entire property. Sprinklers prove beneficial even in situations where the *Code* requires sprinklers only for the isolation and protection of hazardous contents areas.

NFPA 13 is the authoritative source for sprinkler systems with respect to design, installation, and character and adequacy of water supply. Even though there are usually some areas in a building where fires

are more likely to start than others, it is impossible to predict where a fire might start and protect only those areas. Thus, where sprinklers are installed, they should be installed throughout a building. The basic requirements of NFPA 13 for spacing, locating, and positioning sprinklers are based on principles that include sprinkler installation throughout the building—including combustible concealed spaces. The *Life Safety Code*, however, in an effort to promote the use of sprinkler systems by reducing the costs, allows sprinklers to be omitted from small closets and bathrooms in various residential occupancies but considers those occupancies to be fully sprinklered. For an example, see 29.3.5.5, which applies to existing hotels.

NFPA 13 provides for the installation of systems of various types that are appropriate for the individual building protected, subject to the approval of the authority having jurisdiction.

NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, was developed after extensive research that included full-scale fire tests. NFPA 13D introduced the concept of a quick-response residential sprinkler. Unlike its industrial standard spray sprinkler counterpart, which is inherently slow to fuse its relatively massive eutectic solder element, a quick-response, residential sprinkler operates very quickly once its rated temperature is reached. It begins controlling a fire early in its growth. In addition to being quick to respond, residential sprinklers (as mandated by NFPA 13D) have a specifically designed spray pattern that delivers water to nearly the full height of the walls of small rooms that are characteristic of residential occupancies.

NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, was first published in 1989. NFPA 13R addresses residential sprinklers, which include the quick-response sprinkler technology described in the preceding paragraph. NFPA 13R thus extends the technological and economic benefits of an NFPA 13D-type system to larger residential buildings while mandating additional requirements that are commensurate with increased building size. The requirements help to ensure improved protection against injury and life loss to building occupants, including those within the room of fire origin.

NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*¹⁹, provides information on required maintenance procedures.

9.7.1.2 Sprinkler piping serving not more than six sprinklers for any isolated hazardous area shall be permitted to be connected directly to a domestic water supply system having a capacity sufficient to provide 6.1 mm/min (0.15 gpm/ft²) throughout the entire enclosed area. An indicating shutoff valve, supervised in accordance with 9.7.2 or NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall be installed in an accessible, visible, location between the sprinklers and the connection to the domestic water supply.

The general provisions of Section 8.7 for special hazard protection—in combination with the specific requirements of subsection 8.3.2 of each occupancy chapter—make extensive use of sprinklering hazardous contents rooms in otherwise nonsprinklered buildings. Such sprinklers are permitted by 9.7.1.2 to be supplied by the domestic water supply and its associated distribution piping. The domestic water supply must provide sufficient quantities of water at the appropriate pressures to deliver a sprinkler discharge density of 6.1 mm/min (0.15 gpm/ft²) within the hazardous contents room. For a 9.3-m² (100-ft²) room, the water supply would have to provide at least 57 L/min (15 gpm) at the pressure appropriate to such a discharge from a specific size and model of sprinkler. Additionally, the provisions of 9.7.1.2 can be used (in lieu of a devoted sprinkler system piping network and water supply) only if any given room requires six or fewer sprinklers for adequate protection, based on the spacing and location rules of the applicable installation standards referenced in 9.7.1.1. Another hazardous contents room on the same floor, or in some other part of the building, can obtain its protection by repeating a similar maximum six-sprinkler installation in accordance with 9.7.1.2.

9.7.1.3* In areas protected by automatic sprinklers, automatic heat-detection devices required by other sections of this *Code* shall not be required.

A.9.7.1.3 Properly designed automatic sprinkler systems provide the dual function of both automatic alarms and automatic extinguishment. Dual function is not provided in those cases where early detection of incipient fire and early notification of occupants are needed to initiate actions in behalf of life safety earlier than can be expected from heat-sensitive fire detectors.

Because the operation of an automatic sprinkler system is initiated by a heat-sensing device and works on the same principle as an automatic heat detection

and alarm system, a sprinkler system is judged to be capable of serving the same purpose. Even though some sprinkler systems do not sound an alarm on activation, most do. Furthermore, although a particular sprinkler system might not sound an alarm, it does begin immediate extinguishment; this is a feature that is at least as valuable, if not more so, than a system that sounds an alarm only.

Detection of smoke, on the other hand, can be accomplished at the incipient stages of a fire and give rise to an earlier warning than that provided by heat detection, so smoke detection is considered in a somewhat different light. One school of thought is that a system that starts suppression of a fire immediately upon detection is better than one that simply detects the fire and sounds an alarm, even though the latter is quicker in the initiation of signal indication. Others believe, however, that an early alarm is more advantageous. The first group is concerned with the immediate suppression or containment of fire; it might take considerable time for fire fighters to arrive. The second group stresses immediate notification of occupants. The *Code* recognizes the values of both strategies, and strives for a balanced approach to occupant protection by requiring, in some occupancies, both early warning and automatic suppression systems, depending on the characteristics of the occupants. The extent of protection provided should be commensurate with the ability of the occupants, as a group, to evacuate or relocate to a safe location within the building before the egress routes become unusable from the effects of a fire.

9.7.1.4 Automatic sprinkler systems installed to make use of an alternative permitted by this *Code* shall be considered required systems and shall meet the provisions of this *Code* that apply to required systems.

The provisions of 9.7.1.4 remind the user that an automatic sprinkler system voluntarily installed as a *Code* alternative is considered a required system; therefore, it is subject to the same requirements (including maintenance) that apply to a sprinkler system specifically mandated by the *Code*. For example, if an occupancy that does not require a sprinkler system does allow the use of the delayed-egress door lock addressed by 7.2.1.6.1, and if the designer or building operator meets one of the unlocking provisions of 7.2.1.6.1 via the installation of an approved, supervised automatic sprinkler system, the sprinkler sys-

tem is considered a required system. Therefore, the system must meet all requirements that apply to a similar system installed to comply with the *Code* in addition to those of the alternative system, such as delayed-egress door locking.

9.7.2 Supervision.

Supervision is not required by 9.7.2. The requirements of 9.7.2 apply where a supervised automatic sprinkler system is specified by the *Code*.

9.7.2.1* Supervisory Signals. Where supervised automatic sprinkler systems are required by another section of this *Code*, supervisory attachments shall be installed and monitored for integrity in accordance with *NFPA 72®*, *National Fire Alarm Code®*, and a distinctive supervisory signal shall be provided to indicate a condition that would impair the satisfactory operation of the sprinkler system. System components and parameters that shall be monitored shall include, but shall not be limited to, control valves, fire pump power supplies and running conditions, water tank levels and temperatures, tank pressure, and air pressure on dry-pipe valves. Supervisory signals shall sound and shall be displayed either at a location within the protected building that is constantly attended by qualified personnel or at an approved, remotely located receiving facility.

A.9.7.2.1 *NFPA 72®*, *National Fire Alarm Code®*, provides details of standard practice in sprinkler supervision. Subject to the approval of the authority having jurisdiction, sprinkler supervision is also permitted to be provided by direct connection to municipal fire departments or, in the case of very large establishments, to a private headquarters providing similar functions. *NFPA 72®*, *National Fire Alarm Code®*, covers such matters.

Where municipal fire alarm systems are involved, reference should also be made to *NFPA 1221, Standard for the Installation, Maintenance, and Use of Emergency Services Communications Systems*.

One reason why the automatic sprinkler system has attained a high level of satisfactory performance and response to fire conditions is that, through supervision, it can be kept in operative condition. Of course, keeping the system operative depends on routine maintenance and the owner's willingness to repair the system when there are indications of impairment. Features of the system such as the following can be automatically monitored:

- (1) Opening and closing of water control valves
- (2) Power supplies for required fire pumps
- (3) Water tank level

If an undesirable situation develops, a signal is annunciated in the protected building or relayed to a monitoring facility.

A supervisory system will also indicate or activate a waterflow alarm. In addition to being transmitted to an alarm monitoring agency, the waterflow alarm can be transmitted directly to the fire department. The signals for electrical and mechanical problems need not burden the fire department unnecessarily, yet those indicating a fire can be received directly.

For additional information on supervisory signal transmission, see the commentary following 9.6.7.6.

9.7.2.2 Alarm Signal Transmission. Where supervision of automatic sprinkler systems is provided in accordance with another provision of this *Code*, waterflow alarms shall be transmitted to an approved, proprietary alarm-receiving facility, a remote station, a central station, or the fire department. Such connection shall be in accordance with 9.6.1.3.

9.7.3 Other Automatic Extinguishing Equipment.

9.7.3.1 In any occupancy where the character of the fuel for fire is such that extinguishment or control of fire is accomplished by a type of automatic extinguishing system in lieu of an automatic sprinkler system, such system shall be installed in accordance with the appropriate standard, as determined in accordance with Table 9.7.3.1.

Use of special types of extinguishing systems is a matter of engineering judgment on the part of the designer, working in collaboration with the owner and the authority having jurisdiction. The *NFPA* standards listed in Table 9.7.3.1 provide mandatory requirements for the installation and maintenance of such alternative systems.

9.7.3.2 If the extinguishing system is installed in lieu of a required, supervised automatic sprinkler system, the activation of the extinguishing system shall activate the building fire alarm system, where provided. The actuation of an extinguishing system that is not installed in lieu of a required, supervised automatic sprinkler system shall be indicated at the building fire alarm system, where provided.

The activation of a specialized extinguishing system—installed in lieu of a required supervised auto-

Table 9.7.3.1 Fire Suppression System Installation Standards

Fire Suppression System	Installation Standard
Low-expansion foam systems	NFPA 11, <i>Standard for Low-Expansion Foam</i>
Medium- and high-expansion foam systems	NFPA 11A, <i>Standard for Medium- and High-Expansion Foam Systems</i>
Carbon dioxide systems	NFPA 12, <i>Standard on Carbon Dioxide Extinguishing Systems</i>
Halon 1301 systems	NFPA 12A, <i>Standard on Halon 1301 Fire Extinguishing Systems</i>
Water spray fixed systems	NFPA 15, <i>Standard for Water Spray Fixed Systems for Fire Protection</i>
Deluge foam-water sprinkler systems	NFPA 16, <i>Standard for the Installation of Deluge Foam-Water Sprinkler and Foam-Water Spray Systems</i>
Dry chemical systems	NFPA 17, <i>Standard for Dry Chemical Extinguishing Systems</i>
Wet chemical systems	NFPA 17A, <i>Standard for Wet Chemical Extinguishing Systems</i>
Water mist systems	NFPA 750, <i>Standard on Water Mist Fire Protection Systems</i>
Clean agent extinguishing systems	NFPA 2001, <i>Standard on Clean Agent Fire Extinguishing Systems</i>

matic sprinkler system—must activate the building fire alarm system per 9.7.3.2. This system provides early warning to building occupants so that necessary action, probably evacuation, can occur. If the specialized extinguishing system is not serving as a substitute for the required supervised automatic sprinkler system, its activation need only be indicated at the fire alarm control panel or remote annunciator. A kitchen exhaust hood and duct extinguishing system is an example of specialized extinguishing systems not serving as a substitute for a required supervised automatic sprinkler system. The operation of a kitchen exhaust hood and duct extinguishing system would have to be indicated at the fire alarm panel but would not have to result in the activation of audible and visible occupant notification signals.

9.7.4 Manual Extinguishing Equipment.

9.7.4.1* Where required by the provisions of another section of this *Code*, portable fire extinguishers shall be installed, inspected, and maintained in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

A.9.7.4.1 For a description of standard types of extinguishers and their installation, maintenance, and use, see NFPA 10, *Standard for Portable Fire Extinguishers*. The labels of recognized testing laboratories on extinguishers provide evidence of tests indicating the reliability and suitability of the extinguisher for its intended use. Many unlabeled extinguishers are offered for sale that are substandard by reason of insufficient extinguishing capacity, questionable reliability, or ineffective extinguishing agents for fires in ordinary combustible materials or because they pose a personal hazard to the user.

Portable extinguishers are required throughout health care, ambulatory health care, detention and correctional, mercantile, and business occupancies but only in the hazardous areas of nonsprinklered hotels, nonsprinklered apartment buildings, and large board and care occupancies. Where the *Code* requires portable extinguishers, the number, types, and locations required are beyond the scope of the *Code*. Such requirements can be found in NFPA 10, *Standard for Portable Fire Extinguishers*²⁰.

9.7.4.2 Where required by the provisions of another section of this *Code*, standpipe and hose systems shall be provided in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*. Where standpipe and hose systems are installed in combination with automatic sprinkler systems, installation shall be in accordance with the appropriate provisions established by NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 14, *Standard for the Installation of Standpipe and Hose Systems*.

The *Code* has requirements for standpipes only in some of the individual occupancy chapters. For example, standpipes are required on stages of assembly occupancies and in detention and correctional occupancies. Standpipe provisions also appear as part of the Section 11.8 menu of provisions applicable to high-rise buildings (see 11.8.2.2). The following occupancy chapters mandatorily reference all of Section 11.8 and thus specify standpipe requirements for new high-rise buildings:

- (1) New assembly occupancies (12.4.4)
- (2) New educational occupancies (14.4.2)
- (3) New day-care centers (16.4.2)
- (4) New health care occupancies (18.4.2)
- (5) New detention and correctional occupancies (22.4.3)
- (6) New hotels and dormitories (28.4.1)
- (7) New apartment buildings (30.4.1)
- (8) New business occupancies (38.4.2)

9.7.5 Maintenance and Testing.

All automatic sprinkler and standpipe systems required by this *Code* shall be inspected, tested, and maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

9.7.6* Sprinkler System Shutdown.

A.9.7.6 A fire watch should at least involve some special action beyond normal staffing, such as assigning an additional security guard(s) to walk the areas affected. These individuals should be specially trained in fire prevention and in the use of fire extinguishers and occupant hose lines, in notifying the fire department, in sounding the building fire alarm, and in understanding the particular fire safety situation for public education purposes. Some authorities having jurisdiction require fire fighters to be assigned to the area, with direct radio communication to the local fire department. (Also see NFPA 601, *Standard for Security Services in Fire Loss Prevention*.)

9.7.6.1 Where a required automatic sprinkler system is out of service for more than 4 hours in a 24-hour period, the authority having jurisdiction shall be notified, and the building shall be evacuated or an approved fire watch shall be provided for all parties left unprotected by the shutdown until the sprinkler system has been returned to service.

9.7.6.2 Sprinkler impairment procedures shall comply with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

A sprinkler system might be shut down for any number of reasons during the life of a building. Some shutdowns are preplanned, controlled, and of short duration, such as those during periodic testing and maintenance. Others might be preplanned and of longer duration, such as shutdowns during times of building or system renovation. Emergency shutdown of the system can be the result of fire or other physical damage and might result in a short or lengthy shutdown to repair the system. Advance planning should

help ensure that the system, or most of the system, can be restored to service despite the scope of the renovation or the extent of an unexpected impairment. If the sprinkler system is required by the *Code*, or if it was installed to make use of one of the alternatives offered by the *Code*, it must be in good, operable condition for the building to be considered *Code* compliant.

Instead of designating a building with an inoperative sprinkler system as noncompliant and prohibiting occupancy under all conditions in accordance with the provisions of 4.6.10.1, 9.7.6.1 differentiates between those sprinkler system impairments that last less than 4 hours within a 24-hour period and those that last longer. Continued occupancy of a building that has a sprinkler system impairment of more than 4 hours cumulative within any 24-hour period can be tolerated only if a fire watch acceptable to the authority having jurisdiction is provided. Such lengthy impairments generally indicate a situation that involves a problem more serious in nature than typical system maintenance or testing.

It is the intent of the *Code* that the fire watch result in a heightened awareness of the building's operations and environment. Individuals selected for the fire watch should be able to recognize fire hazards and know the procedures for occupant and fire department notification and occupant evacuation in an emergency.

When developing a plan to address system shutdown, it is important to consider the nature of the shutdown, the location, the increased hazards that are involved, and the necessary actions to mitigate the hazards. The authority having jurisdiction should be involved in the development of these plans.

A parallel requirement in 9.6.1.7 addresses fire alarm system impairments.

9.7.7 Documentation.

All required documentation regarding the design of the fire protection system and the procedures for maintenance, inspection, and testing of the fire protection system shall be maintained at an approved, secured location for the life of the fire protection system.

9.7.8 Record Keeping.

Testing and maintenance records required by NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*, shall be maintained at an approved, secured location.

Section 9.8 Special Inspections and Tests

9.8.1 Where required by another section of this *Code*, special inspections and tests shall be performed to verify the operation of the fire protection system in its final condition for acceptance by the authority having jurisdiction.

9.8.2 The design documents shall provide the procedures and methods to be used and items subject to special inspections and tests.

9.8.3 The special inspector shall submit an inspection and test report to the authority having jurisdiction and registered design professional in responsible charge.

Section 9.8 addressing special inspections and tests was added to the 2003 edition of the *Code* to recognize the complex nature of certain life safety systems in buildings. Where required by another section of the *Code*, special inspections must be performed and design and test documentation must be provided to the authority having jurisdiction to ensure the system will perform as intended during a fire. Currently, only engineered smoke management systems must be submitted to special inspections and tests as required by 9.3.3 to ensure all relevant parties (building owner's representative, design professional, and authority having jurisdiction) understand the goals and objectives of the system — for example, to maintain the means of egress tenable for a given time period to facilitate evacuation — and the required performance criteria to achieve the stated goals — for example, the pressure differences needed between smoke zones (among other performance criteria). See NFPA 92A, *Recommended Practice for Smoke-Control Systems*, and NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*, for additional details on smoke control system design.

CHAPTER 10

Interior Finish, Contents, and Furnishings

Historically, many fire fatalities have been attributed to the quick spread of fire. Often the fire spread occurs along the expanses of exposed wall and ceiling coverings and via the contents of the building. Such was the case with The Station nightclub fire in West Warwick, Rhode Island, which happened at the time this chapter was being revised. In that fire, pyrotechnics ignited acoustical foam wall surfaces, resulting in a rapidly developing fire and the death of 100 people.

Chapter 10 establishes basic requirements for interior wall, ceiling, and floor finish and for furnishings and contents. This chapter specifies a menu of protection options, which are mandated to varying degrees by specific occupancy chapters. However, some of the requirements of this chapter apply to all occupancies.

Section 10.2 provides requirements for interior finish, which includes wall, ceiling, and floor finishes. The concept behind the requirements is to slow the flame spread across these finish surfaces to allow additional time for occupants to relocate within, or evacuate from, a building. The fire characteristics of interior finish can play a dramatic role in life safety when a fire occurs.

Section 10.3 addresses the contents and furnishings in a building. Very few occupancy chapters mandate the use of the provisions of this section. The occupancies for which the regulation of furnishings and contents is part of the overall life safety scheme involve occupants who are nonambulatory, who are otherwise restrained or detained, or who are asleep. Contrast this application with the provisions for interior finish that are mandated by all of the occupancy chapters.

Section 10.1 General

Interior finish has been a significant factor in rapid flame spread in many of the deadliest U.S. fires of recent decades. The following are a few examples of such fires.

In June 1989, five people died on the floor of origin of an “intense, rapidly developing fire on the sixth floor of an office building” in Atlanta, Georgia¹. In this fire, “. . . the fire spread was so fast that the blaze in the corridor had burned itself out by the time fire fighters entered the sixth floor about seven minutes after the initial alarm . . . This is not the first time that multiple layers of wall coverings have been identified as a contributing factor in a fire . . . It is evident that this condition existed in the Atlanta building, that the materials in those layers contributed to the total load in the corridor, and that it is likely they contributed to the rate of fire spread.”

Regarding the 1986 Dupont Plaza Hotel fire (see Exhibit 10.1) in which 96 people died: “Under the NFPA *Life Safety Code*, interior finish in all ballrooms, including the room of origin, should have been Class A or Class B. The wall finish of the room of origin contributed to the rapid fire growth.”²

In the 1981 Las Vegas Hilton Hotel fire, combustible carpeting on the walls and ceilings of elevator lobbies contributed to horizontal fire spread on the floor of origin and vertical spread involving 22 floors. Eight people died.³

In a 1978 Holiday Inn fire that killed 10 people, “lightweight plywood paneling in stairway did not meet *Life Safety Code*, was involved early in fire, and produced rapid growth and spread.” In a 1979 Holi-

Exhibit 10.1 Dupont Plaza Hotel Fire, in which rapid fire growth was, in part, due to wall finish in room of origin.

day Inn fire that also killed 10 people, “carpeting and some wall covering in corridors had excessively high flame-spread properties.”⁴

In a 1972 Springfield, Illinois, convalescent nursing home fire that killed 10 of the 41 patients, “the wood-panel finish accelerated fire spread . . . Combustible interior finish—especially interior finish such as the wood paneling in this facility—should not be allowed where infirm people are housed . . . The paneling on the stairway had completely burned away, permitting fire spread into the first floor through holes in the plaster.”⁵

Regarding the 1970 Pioneer International Hotel fire where 28 died:

Under the NFPA *Life Safety Code*, interior finish in all ballrooms, including the room of origin, corridors and stairs were carpeted (100 percent acrylic), with two layers of padding under carpet in corridors and carpeting extending 22 inches up the walls. Above the carpeted areas of the wall were sections of wood, wallpaper, and plastic-laminated plywood. Interior finish contributed to fire.⁶

10.1.1 Application.

The interior finish, contents, and furnishings provisions set forth in this chapter shall apply to new construction and existing buildings.

Highly combustible interior wall and ceiling finishes and easily ignited contents and furnishings are repeatedly reported as factors in fire spread in various occupancies. The repeated contribution of these factors to fire spread demonstrates the need to apply Chapter 10 requirements to both new construction and existing buildings.

10.1.2 Automatic Sprinkler Systems.

Where another provision of this chapter requires an automatic sprinkler system, the automatic sprinkler system shall be installed in accordance with the subparagraph of 9.7.1.1 as permitted by the applicable occupancy chapter.

The protection provided by automatic sprinklers, especially with respect to preventing flashover, is recog-

nized via certain exemptions in Chapter 10. For example, in locations protected by automatic sprinklers, 10.2.8.1 permits the use of Class C interior wall and ceiling finish materials where Class B would otherwise be required. It is important that the sprinkler system be designed and installed in accordance with the proper standard. Paragraph 10.1.2 relegates the appropriate sprinkler system installation standard to the applicable occupancy chapter.

10.1.3 Definitions.

The following is a list of terms used in this chapter:

- (1) **Contents and Furnishings.** See 3.3.36.
- (2) **Flashover.** See 3.3.85.
- (3) **Interior Finish.** See 3.3.120.

The faster a fire develops, the greater the threat it represents to the occupants of a building and the more difficult it will be to control. Wall and ceiling surfaces of a building have a major influence on how fast a fire develops. In establishing restrictions for the use of interior finish materials, the *Code's* intention is to prevent entirely, or at least limit, the spread of fire across the interior surfaces of a building.

Any large fire within a building represents a threat to occupants. A successful fire protection strategy attempts to limit the size of fires. Any interior finish that acts as a "fuse" to spread flame and involve objects remote from the point of origin, or that contributes fuel to the early growth of a fire and causes a large fire, is undesirable. The restrictions found in the *Code* for wall and ceiling finishes vary, depending on the occupancy characteristics. Where occupants are immobile or where security measures restrict freedom of movement (as in health care facilities or detention and correctional facilities), conservative interior finish limits are set. In contrast, more relaxed limits are allowed in industrial or storage occupancies where occupants are assumed to be alert and mobile.

Interior finishes are the interior surfaces of a building that are generally secured in place. Thus, wall, ceiling, and column coverings are considered interior wall and ceiling finishes. The surfaces of movable walls or folding partitions would also be treated as interior finishes. However, the *Code* allows the authority having jurisdiction to exercise judgment in determining the criteria that constitute interior finish. For example, a tapestry would not normally be considered interior finish. However, a large tapestry

that is secured to and covers a major portion of a wall could promote the rapid growth of fire and might warrant regulation. See the definition of *interior finish* in 3.3.120.

Furnishings (including high-backed, plastic-upholstered restaurant booths) are not normally considered as interior finish, even in cases where the furnishings are fixed in place. See the definition of *contents and furnishings* in 3.3.36.

- (4) **Interior Ceiling Finish.** See 3.3.120.1.
- (5) **Interior Floor Finish.** See 3.3.120.2.

Interior floor finish includes both exposed surfaces of structural floor systems and decorative floor treatments, such as wood flooring, carpet, or other resilient flooring materials. Coverings on stair risers and treads are regulated as interior floor finish, even though risers involve vertical applications. This regulation recognizes that floor coverings on stair risers and treads will perform similarly to other floor surfaces during a fire. See the definition of *interior floor finish* in 3.3.120.2.

- (6) **Interior Wall Finish.** See 3.3.120.3.

Section 10.2* Interior Finish

A.10.2 The requirements pertaining to interior finish are intended to restrict the spread of fire over the continuous surface forming the interior portions of a building.

10.2.1 General.

10.2.1.1 Classification of interior finish materials shall be in accordance with tests made under conditions simulating actual installations, provided that the authority having jurisdiction shall be permitted to establish the classification of any material on which a rating by standard test is not available, unless otherwise provided in 10.2.1.2.

10.2.1.2 Materials applied directly to the surface of walls and ceilings in a total thickness of less than 0.9 mm ($\frac{1}{8}$ in.) shall be exempt from tests simulating actual installation if they meet the requirements of Class A interior wall or ceiling finish when tested in accordance with 10.2.3 using inorganic reinforced cement board as the substrate material.

Paragraph 10.2.1.2 addresses the issue of thin coverings, which was covered in earlier editions of the

Code by a simply worded, performance-based criterion that was difficult to use and enforce. The *Code* recognized that thin coverings [those less than 0.9 mm (1/28 in.) in thickness] with surface burning characteristics no greater than that of paper would not significantly affect the fire performance of the basic wall or ceiling material. If assurance were provided that such a thin covering had surface burning characteristics no greater than those of paper, the thin material would not be subject to regulation as an interior finish. Therefore, the material's flame spread rating wasn't needed, which, in turn, meant that no fire testing was required. The problem was that, without running fire tests, it was impossible to determine whether a thin material had surface burning characteristics that were greater than those of paper.

The wording of 10.2.1.2 was new to the 2000 edition of the *Code*. It no longer exempts thin materials from testing, but it does exempt thin material from testing with the actual substrate or backing material that will be used in the final installed state. If there were no exemption, thin materials such as paint (whose liquid suspension state dries to become a thin layer of material) and wallpaper would be required to be fire tested in combination with numerous backing materials. A complete set of test results, representative of the many forms of substrates in common use, would be prohibitively expensive to collect. Paragraph 10.2.1.2 permits the material to be tested with only inorganic reinforced cement board.

Thermally thin coverings such as paint and wallpaper coverings, where secured to a noncombustible substrate such as inorganic reinforced cement board, will not significantly alter the performance of the substrate during a fire. However, thicker coverings, such as multiple layers of wallpaper, can and have contributed to rapid fire growth. For example, multi-

ple layers of wall coverings contributed to rapid fire growth in the multiple-death fire in the Holiday Inn in Cambridge, Ohio, which occurred on July 31, 1979.⁷

The exemption mandated by 10.2.1.2 has the effect of requiring any wall or ceiling covering of more than 0.9 mm (1/28 in.) in thickness to undergo the full test series required of other interior finish materials so as to be representative of actual installations.

For proper evaluation and classification, assemblies of materials must be tested as they will actually be installed. For example, the performance of thermally thin coverings is altered by the nature of the substrate over which they are installed.⁸ Adhesives might also be an important factor in performance. In the case of composites (such as textile wall coverings over gypsum board), the adhesive should be sufficient to maintain a bond between the "finish" and the substrate. However, excess adhesive might contribute to a fire. Tests of textile wall coverings have shown that changing adhesives, or simply changing the application rate for the same adhesive, might significantly alter product performance.⁹ Tests to qualify assemblies should use adhesives and application rates similar to actual installations.

Similarly, a product that undergoes testing in intimate contact with a mineral board should be installed in contact with a mineral board or similar substrate. Also, where products are tested in intimate contact with a substrate, results might be altered if the product is installed with air space behind the covering.

10.2.2* Use of Interior Finishes.

A.10.2.2 Table A.10.2.2 provides a compilation of the interior finish requirements of the occupancy chapters (Chapter 12 through Chapter 42) of this *Code*.

Table A.10.2.2 Interior Finish Classification Limitations

Occupancy	Exits	Exit Access Corridors	Other Spaces
Assembly — New			
>300 occupant load	A I or II	A or B I or II	A or B
≤300 occupant load	A I or II	A or B I or II	A, B, or C
Assembly — Existing			
>300 occupant load	A	A or B	A or B
≤300 occupant load	A	A or B	A, B, or C
Educational — New	A I or II	A or B I or II	A or B; C on low partitions†
Educational — Existing	A	A or B	A, B, or C

Table A.10.2.2 Continued

Occupancy	Exits	Access to Exits	Other Spaces
Day-Care Centers — New	A I or II	A I or II	A or B
Day-Care Centers — Existing	A or B	A or B	A or B
Day-Care Homes — New	A or B I or II	A or B	A, B, or C
Day-Care Homes — Existing	A or B	A, B, or C	A, B, or C
Health Care — New	A	A B on lower portion of corridor wall†	A B in small individual rooms†
Health Care — Existing	A or B	A or B	A or B
Detention and Correctional — New (sprinklers mandatory)	A or B I or II	A or B I or II	A, B, or C
Detention and Correctional — Existing	A or B I or II	A or B I or II	A, B, or C
1- and 2-Family Dwellings, Lodging or Rooming Houses	A, B, or C	A, B, or C	A, B, or C
Hotels and Dormitories — New	A I or II	A or B I or II	A, B, or C
Hotels and Dormitories — Existing	A or B I or II†	A or B I or II†	A, B, or C
Apartment Buildings — New	A I or II	A or B I or II	A, B, or C
Apartment Buildings — Existing	A or B I or II†	A or B I or II†	A, B, or C
Residential, Board and Care — (See Chapter 32 and Chapter 33)

Notes:

1. Class A interior wall and ceiling finish — flame spread 0–25, (new) smoke developed 0–450.
2. Class B interior wall and ceiling finish — flame spread 26–75, (new) smoke developed 0–450.
3. Class C interior wall and ceiling finish — flame spread 76–200, (new) smoke developed 0–450.
4. Class I interior floor finish — critical radiant flux, not less than 0.45 W/cm².
5. Class II interior floor finish — critical radiant flux, not less than 0.22 W/cm² but less than 0.45 W/cm².
6. Automatic sprinklers — where a complete standard system of automatic sprinklers is installed, interior wall and ceiling finish with flame spread rating not exceeding Class C is permitted to be used in any location where Class B is required and with rating of Class B in any location where Class A is required; similarly, Class II interior floor finish is permitted to be used in any location where Class I is required, and no critical radiant flux rating is required where Class II is required. These provisions do not apply to new detention and correctional occupancies.
7. Exposed portions of structural members complying with the requirements for heavy timber construction are permitted.

†See corresponding chapters for details.

10.2.2.1 Requirements for interior wall and ceiling finish shall apply as follows:

- (1) Where specified elsewhere in this *Code* for specific occupancies (see *Chapter 7* and *Chapter 11* through *Chapter 42*)
- (2) As specified in 10.2.4

10.2.2.2* Requirements for interior floor finish shall apply under any of the following conditions:

- (1) Where floor finish requirements are specified elsewhere in the *Code*
- (2)* Where carpet or carpet-like material not meeting the requirements of ASTM D 2859, *Flammability of Finished Textile Floor Covering Materials*, is used

A.10.2.2.2(2) Compliance with Title 16 CFR 1630, *Standard for the Surface Flammability of Carpets and Rugs* (FFI-70), is considered equivalent to compliance with ASTM D 2859.

- (3) Where the fire performance of the floor finish cannot be demonstrated to be equivalent to floor finishes with a critical radiant flux of at least 0.1 W/cm²
- (4) Where the fire performance of the floor finish is unknown

A.10.2.2.2 This paragraph recognizes that traditional finish floors and floor coverings such as wood flooring and resilient floor coverings have not proved to present an unusual hazard.

Experience has shown that traditional floor coverings, such as wood flooring and resilient tile, do not contribute to the early growth of fire. Paragraph 10.2.2.2 has the effect of exempting traditional floor coverings from the restrictions that would otherwise be applicable. However, the authority having jurisdiction can require substantiation of the performance of any unfamiliar floor covering. For example, imitation wood floors made of plastic, artificial turf, artificial surfaces of athletic fields, and certain types of carpeting are products that might merit substantiation. Where the AHJ judges that a floor covering warrants testing and substantiation, or where an occupancy chapter imposes restrictions, the floor covering would be treated as interior floor finish. It would, therefore, be regulated on the basis of tests conducted in accordance with the flooring radiant panel test required in 10.2.7.

10.2.3* Interior Wall or Ceiling Finish Testing and Classification.

Interior wall or ceiling finish that is required elsewhere in this *Code* to be Class A, Class B, or Class C shall be classified

based on test results from NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, except as indicated in 10.2.3.1 or 10.2.3.2.

A.10.2.3 See A.10.2.4.1.

Flame spread and smoke development are both recorded in the results of a test conducted in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*¹⁰. This document is also known as ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*¹¹. The test is also referred to generically as the “room tunnel test.” Fuel contribution values have not been recorded as a required part of the test procedure for many years.

10.2.3.1 Exposed portions of structural members complying with the requirements for Type IV(2HH) construction in accordance with NFPA 220, *Standard on Types of Building Construction*, shall be exempt from testing and classification in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Type IV(2HH) construction has traditionally been called “heavy timber construction.” Exposed surfaces of the structural members, such as wood columns, beams, and girders, meet the definition of interior wall and ceiling finish. All heavy timber structural members are required to be of substantial thickness as detailed in NFPA 220, *Standard on Types of Building Construction*¹². Thus, none are thermally thin, so they do not present the concerns addressed in the commentary that follows 10.2.1.2. Paragraph 10.2.3.1 recognizes that exposed surfaces of heavy timber structural members can be safely used where Class A, Class B, or Class C interior finish is required. Such wood members often have flame spread ratings in the range of 76 to 200 and, therefore, are classified as Class C interior finish. The exemption is based on the fact that the structural members are located at intervals and do not constitute a continuous surface that allows flame to spread, for example, across a ceiling.

10.2.3.2 Interior wall and ceiling finish tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, and meeting the conditions of 10.2.3.7.3 shall be permitted to be used where interior wall and ceiling finish is required to be Class A in accordance with NFPA 255,

Standard Method of Test of Surface Burning Characteristics of Building Materials.

Paragraph 10.2.3.2 permits testing in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*¹³, for both interior wall finish and interior ceiling finish. Such testing represents an improvement over testing in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*. It was developed specifically to measure the following:

- (1) Whether flashover occurs
- (2) Extent of flame spread and burning relative to the realistically mounted sample
- (3) Peak rate of heat release
- (4) Smoke obscuration throughout the test

Note that 10.2.3.2 does not require testing per NFPA 286; rather, it offers this test procedure as an alternative to that of the more traditional NFPA 255.

10.2.3.3 For fire retardant coatings, see 10.2.6.

10.2.3.4* Products required to be tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, shall be classified as follows in accordance with their flame spread and smoke development, except as indicated in 10.2.3.4.1.

A.10.2.3.4 It has been shown that the method of mounting interior finish materials may affect actual performance. Where materials are tested in intimate contact with a substrate to determine a classification, such materials should be installed in intimate contact with a similar substrate. Such details are especially important for “thermally thin” materials. For further information, see NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Some interior wall and ceiling finish materials, such as fabrics not applied to a solid backing, do not lend themselves to a test made in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*. In these cases, the large-scale test outlined in NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, is permitted to be used.

Prior to 1978, the test report described by NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, included an evaluation of the fuel contribution as well as the flame spread rating and the smoke development value. However, it is now recognized that the measurement on which the fuel contribution is based does

not provide a valid measure. Therefore, although the data are recorded during the test, the information is no longer normally reported. Classification of interior wall and ceiling finish thus relies only on flame spread index and smoke development value.

The 450 smoke development value limit is based solely on obscuration. (See A.10.2.4.1.)

- (1) Class A interior wall and ceiling finish shall be characterized by the following:
 - (a) Flame spread, 0–25
 - (b) Smoke development, 0–450
 - (c) No continued propagation of fire in any element thereof when so tested
- (2) Class B interior wall and ceiling finish shall be characterized by the following:
 - (a) Flame spread, 26–75
 - (b) Smoke development, 0–450
- (3) Class C interior wall and ceiling finish shall be characterized by the following:
 - (a) Flame spread, 76–200
 - (b) Smoke development, 0–450

Samples are tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, as mandated by 10.2.3.4, using a noncombustible backing. Specimens are tested with adhesives and joints and under other conditions that simulate the actual installation of a product in a building. NFPA 255 provides a general indication of product performance only if the product is installed in a fashion similar to that which has been tested. Available data demonstrate that the performance of interior finish materials varies, depending on mounting conditions.¹⁴ For example, a product installed over a combustible substrate tends to propagate fire more readily than would be typical of the same product installed over a noncombustible substrate.

Further, a wall covering installed with air space behind the covering tends to spread flame more readily than one installed in contact with a noncombustible substrate. Therefore, mounting techniques must be carefully considered in the evaluation of probable product performance.

Consider decorative fabric hung in front of a wall surface, covering a significant portion of that wall. The loosely hanging fabric creates a continuous surface that can spread flame; thus, the fabric should comply with the requirements for interior finish. Testing in accordance with NFPA 255, which reports a flame spread rating and smoke development value that can be used to classify interior finish per 10.2.3.4, would not provide meaningful information in this

example. However, testing per NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*¹⁵, might help the authority having jurisdiction judge the safety of hanging fabrics that constitute interior finish.

NFPA 701 describes procedures for intermediate-scale and large-scale tests. The choice of the applicable test method is determined in part by the weight of the material per unit area. Tests using NFPA 701 involve applying a flame to a vertically positioned sample for a specified time. Upon removal of the flame-producing burner, the sample must self-extinguish and must not have charred beyond a specified distance in order to pass the test. Additionally, with the intermediate-scale test, a specified maximum percent weight loss cannot be exceeded. The test in NFPA 701 should help in evaluating the installation, although a strict Class A, Class B, or Class C determination of interior finish classification, per 10.2.3.4, cannot be made.

10.2.3.4.1 Existing interior finish shall be exempt from the smoke development criteria of 10.2.3.4.

Interior wall and ceiling finish classifications in accordance with 10.2.3.4 are based mainly on flame spread ratings with an additional requirement that smoke development not exceed a common value of 450, regardless of the class into which the material falls based on flame spread. Flame spread ratings offer a general indication of the speed with which fire might

spread across the surface of a material. In assessing the hazard posed by a material on the basis of flame spread, it is assumed that a person might be close to the fire and would be directly exposed to the energy associated with the actual flames. By contrast, the purpose of smoke development ratings is to address obscuration of the egress path by smoke. Thus, an interior wall and ceiling finish material with a low smoke development value should provide better visibility in a given egress route than a material with a high smoke development value. Given that the smoke development value is a cumulative measurement over the prescribed test duration, it is based on both quantity and rate of smoke liberation.

The *Code* requires the use of specific classes of interior wall and ceiling finish materials, which are differentiated by their allowable flame spread rating, based on consideration of their installed location within the building, the building's egress paths, and the occupancy in question. Different classes of interior finish materials are specified for an office area, for example, as opposed to an exit stair enclosure or exit access corridor. The different classes recognize that, when escaping a building, people must move away from the flames while traveling through the means of egress toward an exit. The classes of interior finishes that are considered acceptable within an open office, therefore, are different from those that are required for exit enclosures. Similarly, occupancies used by those who are mobility impaired have stricter interior finish requirements than occupancies used by fully ambulatory occupants. For example, although both hospitals and hotels provide sleeping accommodations, interior finish requirements for hospitals are more stringent because hospital patients are less capable of self-preservation.

The same smoke development limit is used for all three flame spread classifications. This limit recognizes that smoke generated during a fire might affect visibility both in the vicinity of and remote from the fire. Large buildings can be quickly filled with smoke as a result of a fire. An upper limit has been established, therefore, that applies to interior finish materials, regardless of their location.

Per 10.2.3.4.1, existing buildings are exempted from the smoke development limitation. In existing buildings, interior finish materials are restricted only on the basis of flame spread. *Life Safety Code* editions prior to 1976 did not regulate interior finish materials based on smoke development. As a general rule, the replacement of existing materials only because they were previously approved exclusively on the basis of flame spread is not warranted.

The smoke development limit of 450 was determined on the basis of research conducted by Underwriters Laboratories Inc. A 140-m³ (5000-ft³) room was filled with smoke from the tunnel test chamber. The room was equipped with illuminated exit signs. The time required to reach various stages of exit sign obscuration was recorded and compared to the smoke development rating for the different materials involved. The report states that “materials having smoke developed ratings above 325 showed ‘good’ to ‘marginal’ visibility—scale readings of 3 to 4.8—in a few cases; other materials produced conditions of ‘marginal’ to obscuration in the six-minute period.”¹⁶

Considering both time and smoke levels, the limit of 450 on smoke ratings as used in the *Code* has been judged to be reasonable. It should be emphasized that there is no direct relationship between flame spread and smoke development. For example, in the report referenced in the previous paragraph, one material had a flame spread rating of 490 and a smoke development factor of 57, while another had a flame spread rating of 44 and a smoke development factor of 1387.

The smoke development limit of 450 is based solely on the level of obscuration. Although not addressed by the requirements for interior finishes, other important factors used in evaluating materials on the basis of smoke generation are the effects of irritability and toxicity caused by gases. Smoke might also act as an irritant, further reducing visibility, and might, in addition, have a debilitating physiological effect on people attempting to escape from a building. Such effects are not evaluated by the current smoke development limit. Previous editions of the *Code* allowed the authority having jurisdiction to regulate products presenting an “unreasonable life hazard due to the character of the products of decomposition.” This provision was deleted in the 1988 edition of the *Code* due to the unenforceable nature of the requirement. The adverse physiological effects on the human body caused by exposure to heat and the effects of inhaling hot gases should also be considered as part of an overall hazard risk assessment and should be considered separately from the interior finish requirements of Section 10.2.

10.2.3.5 The classification of interior finish specified in 10.2.3.4 shall be that of the basic material used by itself or in combination with other materials.

10.2.3.6 Wherever the use of Class C interior wall and ceiling finish is required, Class A or Class B shall be permitted. Where Class B interior wall and ceiling finish is required, Class A shall be permitted.

Paragraph 10.2.3.6 recognizes that the *Code* sets minimum criteria. An interior finish material that performs better than that specifically prescribed by *Code* is always permitted.

10.2.3.7* Products tested in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*, shall comply with the criteria of 10.2.3.7.1 or 10.2.3.7.2. Products tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, shall comply with the criteria of 10.2.3.7.3.

A.10.2.3.7 The methodology specified in NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*, includes provisions for measuring smoke obscuration. Such measurement is considered desirable, but the basis for specific recommended values is not currently available. (See A.10.2.4.1.)

10.2.3.7.1* The following criteria shall be met when using method A of the test protocol of NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*:

- (1) Flame shall not spread to the ceiling during the 40-kW exposure.
- (2) During the 150-kW exposure, the following criteria shall be met:
 - (a) Flame shall not spread to the outer extremities of the sample on the 2440 mm × 3660 mm (96 in. × 144 in.) wall.
 - (b) The specimen shall not burn to the outer extremities of the 610-mm (24-in.) wide samples mounted vertically in the corner of the room.
 - (c) Burning droplets that are judged to be capable of igniting the textile wall covering or that persist in burning for 30 seconds or more shall not be formed and dropped to the floor.
 - (d) Flashover shall not occur.
 - (e) The maximum instantaneous net peak rate of heat release shall not exceed 300 kW.

A.10.2.3.7.1 See A.10.2.3.7 and A.10.2.4.1.

10.2.3.7.2 The following conditions shall be met when using method B of the test protocol of NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*:

- (1) Flame shall not spread to the ceiling during the 40-kW exposure.

- (2) During the 150-kW exposure, the following criteria shall be met:
- Flame shall not spread to the outer extremities of the sample on the 2440 mm × 3660 mm (96 in. × 144 in.) wall.
 - Flashover shall not occur.

Exhibit 10.3 illustrates the equipment required for testing in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*.

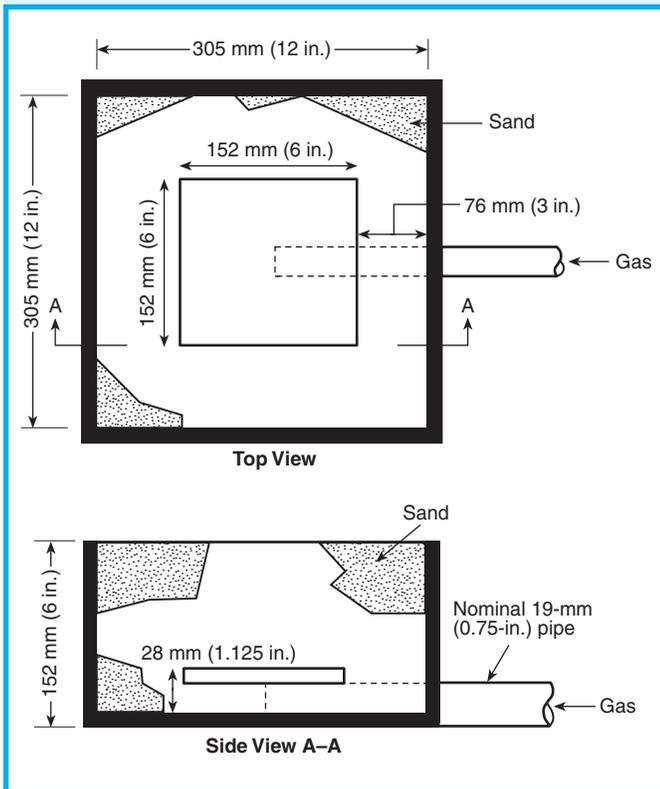

Exhibit 10.3 Schematic of gas burner required by NFPA 265.

10.2.3.7.3 The following conditions shall be met when using the test protocol of NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*:

- Flames shall not spread to the ceiling during the 40-kW exposure.
- During the 160-kW exposure, the following criteria shall be met:
 - Flame shall not spread to the outer extremities of the sample on the 2440 mm × 3660 mm (96 in. × 144 in.) wall.
 - Flashover shall not occur.
- For new installations, the total smoke released throughout the test shall not exceed 1000 m².

10.2.4* Specific Materials.

A.10.2.4 Surface nonmetallic raceway products, as permitted by NFPA 70, *National Electrical Code*[®], are not interior finishes.

10.2.4.1* Textile Wall and Textile Ceiling Materials. The use of textile materials on walls or ceilings shall comply with one of the following conditions:

- Textile materials having a Class A rating (*see 10.2.3.4*) shall be permitted on the walls or ceilings of rooms or areas protected by an approved automatic sprinkler system.
- Textile materials having a Class A rating (*see 10.2.3.4*) shall be permitted on partitions that do not exceed three-quarters of the floor-to-ceiling height or do not exceed 2440 mm (96 in.) in height, whichever is less.
- Textile materials having a Class A rating (*see 10.2.3.4*) shall be permitted to extend not more than 1220 mm (48 in.) above the finished floor on ceiling-height walls and ceiling-height partitions.
- Previously approved existing installations of textile material having a Class A rating (*see 10.2.3.4*) shall be permitted to be continued to be used.
- Textile materials shall be permitted on walls and partitions where tested in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*. (*See 10.2.3.7.*)

Prior to the 1988 edition of the *Code*, the danger of carpetlike textile coverings used on walls and ceilings was recognized and regulated by a requirement that only Class A tufted or napped, carpetlike materials be used, even in a sprinklered building. In 1981, eight people died at the nonsprinklered Las Vegas Hilton Hotel when a fire began in an elevator lobby and was fueled by carpetlike, textile wall and ceiling finishes that did not meet the qualifications for Class A interior finish.¹⁷ Other than the textile wall and ceiling finish materials, sheer sunscreen material at the window, and a cushioned seat pad on a metal bench, there was little combustible material to fuel the fire in the elevator lobby. See Exhibit 10.4. Yet, the elevator lobby went to flashover, the fire broke out the windows and climbed to a nearly identical elevator lobby on the floor above, and the events repeated themselves in a leap frog fashion from the 8th floor through the 24th floor. See Exhibit 10.5.

Research sponsored by the American Textile

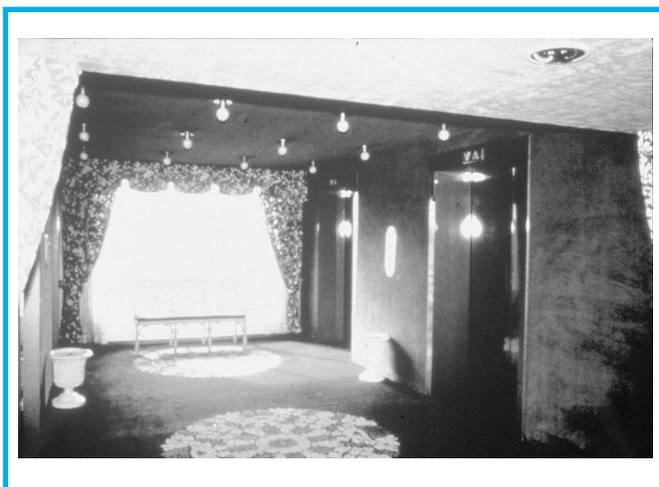

Exhibit 10.4 Elevator lobby with carpetlike textile wall and ceiling finish material.

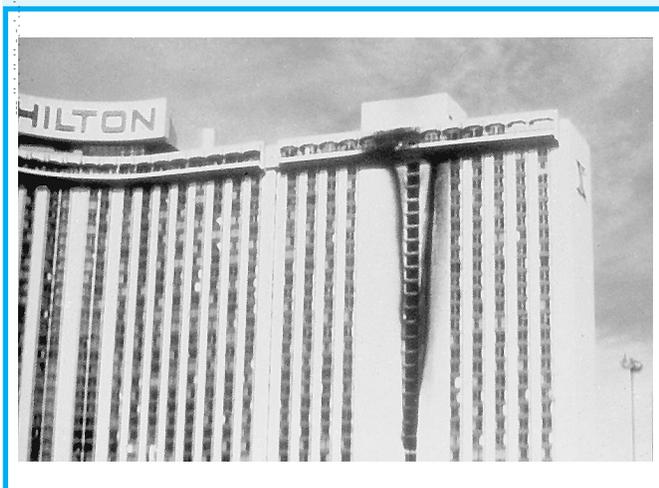

Exhibit 10.5 Resulting fire spread involving elevator lobbies on 8th through 24th floors.

Manufacturers Institute (ATMI) and conducted by the Fire Research Laboratory of the University of California at Berkeley between March 1985 and January 1986 was described in the report “Room Fire Experiments of Textile Wall Coverings.”¹⁸ This research demonstrated that consideration of only the flame spread rating, as measured by NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, might not reliably predict the fire behavior of textile wall and ceiling coverings. Test results indicate that not all Class A textile wall coverings are alike with respect to their potential for producing room flashover; some are capable of producing room flashover when subjected to an ignition source scenario that models a small fuel item (such

as a wastebasket) igniting a chair or similar furnishing, others are not. Simply requiring textile wall coverings to be classified as Class A interior wall and ceiling finishes does not ensure the level of life safety intended by the *Code*.

The testing at the University of California was conducted in a 2440 mm × 3660 mm × 2440 mm (96 in. × 144 in. × 96 in.) high room using a gas diffusion burner as an ignition source. Products undergoing evaluation—various textile wall coverings—were applied to the walls; the gas diffusion burner and ignition source were placed in the corner of the room. Two of the 16 products tested—one a tufted wall covering, the other a woven wall covering—were known to have flame spread ratings of 25 or less when tested in accordance with NFPA 255. When tested in the room-corner procedure, these two products readily spread flame and caused the fire in the test room to grow quickly to a large size, causing full room involvement—that is, flashover. Concerns about the performance of these low flame spread textile wall coverings led to the requirement of 10.2.4.1(5) for full-scale room-corner testing to qualify products for use in nonsprinklered buildings.

The tests revealed that the method of mounting, including adhesive and application rate, can be critically important to product fire performance. Changing the application rate of the same adhesive or changing the adhesive can cause a product that is assumed to be safe to exhibit unsatisfactory performance.

Caution should be exercised when using combinations of textile wall and ceiling coverings. Experience has shown that combinations of textile wall and ceiling coverings might result in intense burning.¹⁹ The University of California testing included only wall coverings; research conducted at the Illinois Institute of Technology Research Institute indicates that flame spread is more likely to occur with combinations of combustible wall and ceiling coverings than in those situations involving only combustible wall coverings or only combustible ceiling coverings.²⁰ Therefore, full-scale room-corner testing, using an appropriately sized ignition source, is necessary to substantiate the performance of textile wall and ceiling coverings.

With the publication of NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*²¹, a nationally recognized room-corner fire test to be used specifically for textile wall coverings became available. Its use is addressed in 10.2.3.7, 10.2.3.7.1, 10.2.3.7.2, and 10.2.4.1(5). Paragraphs

10.2.4.1(1) through 10.2.4.1(4) address other conditions under which textile wall coverings are permitted to be used.

A.10.2.4.1 Previous editions of the *Code* have regulated textile materials on walls and ceilings using NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*. Full-scale room/corner fire test research has shown that flame spread indices produced by NFPA 255 might not reliably predict all aspects of the fire behavior of textile wall and ceiling coverings.

NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*, and NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, both known as room-corner tests, were developed for assessing the fire and smoke obscuration performance of textile wall coverings and interior wall and ceiling finish materials, respectively. As long as an interior wall or ceiling finish material is tested by NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*, or by NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, as appropriate, using a mounting system, substrate, and adhesive (if appropriate) that are representative of actual use, the room-corner test provides an adequate evaluation of a product's flammability and smoke obscuration behavior. Manufacturers, installers, and specifiers should be encouraged to use NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*, or NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, as appropriate—but not both—because each of these standard fire tests has the ability to characterize actual product behavior, as opposed to data generated by tests using NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, which only allows comparisons of one product's performance with another. If a manufacturer or installer chooses to test a wall finish in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, additional testing in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, is not necessary.

The test results from NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations. Ac-

tual test results, for heat, smoke, and combustion product release from NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*, and from NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, are suitable for use as input into fire models for performance-based design.

10.2.4.2* Expanded Vinyl Wall or Ceiling Coverings. The use of expanded vinyl wall or ceiling coverings shall comply with one of the following conditions:

A.10.2.4.2 Expanded vinyl wall covering consists of a woven textile backing, an expanded vinyl base coat layer, and a nonexpanded vinyl skin coat. The expanded base coat layer is a homogeneous vinyl layer that contains a blowing agent. During processing, the blowing agent decomposes, which causes this layer to expand by forming closed cells. The total thickness of the wall covering is approximately 1.4 mm to 1.8 mm (0.055 in. to 0.070 in.).

- (1) Materials having a Class A rating (*see 10.2.3.4*) shall be permitted on the walls or ceilings of rooms or areas protected by an approved automatic sprinkler system.
- (2) Materials having a Class A rating (*see 10.2.3.4*) shall be permitted on partitions that do not exceed three-quarters of the floor-to-ceiling height or do not exceed 2440 mm (96 in.) in height, whichever is less.
- (3) Materials having a Class A rating (*see 10.2.3.4*) shall be permitted to extend not more than 1220 mm (48 in.) above the finished floor on ceiling-height walls and ceiling-height partitions.
- (4) Existing installations of materials with the appropriate wall finish classification for the occupancy involved, and with classification in accordance with the provisions in 10.2.3.4, shall be permitted to be continued to be used.
- (5) Materials shall be permitted on walls and partitions where tested in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*. (*See 10.2.3.7.*)
- (6) Materials shall be permitted on walls, partitions, and ceilings where tested in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*. (*See 10.2.3.7.*)

The provisions of 10.2.4.2, which address expanded vinyl wall coverings (described in A.10.2.4.2), are similar to those of 10.2.4.1, which are applicable to textile wall coverings.

10.2.4.3 Cellular or Foamed Plastic. Cellular or foamed plastic materials shall not be used as interior wall and ceiling finish unless specifically permitted by 10.2.4.3.1 or 10.2.4.3.2.

10.2.4.3.1 Cellular or foamed plastic materials shall be permitted where subjected to fire tests that substantiate their combustibility characteristics for the use intended under actual fire conditions using large-scale tests performed on a finished foamed plastic assembly of the maximum thickness intended for use that is related to the actual end-use configuration.

10.2.4.3.2 Cellular or foamed plastic shall be permitted for trim not in excess of 10 percent of the wall or ceiling area, provided that it is not less than 320 kg/m³ (20 lb/ft³) in density, is limited to 13 mm (½ in.) in thickness and 100 mm (4 in.) in width, and complies with the requirements for Class A or Class B interior wall and ceiling finish as described in 10.2.3.4; however, the smoke rating shall not be limited.

The prohibition of 10.2.4.3 on the use of foamed plastics within buildings is based on actual fire experience in which foamed plastics have contributed to very rapid fire development.²² It is also acknowledged that tunnel testing per NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, or the equivalent ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, (see 10.2.3.4) might not accurately assess the potential hazard of plastics in general. Therefore, if cellular or foamed plastics are to be used within a building, their use should be substantiated on the basis of full-scale fire tests or fire testing that simulates conditions of actual use.

Paragraph 10.2.4.3.2 permits the limited use of cellular or foamed plastics as a substitute for traditional wood trim, assuming their performance under fire exposure will be comparable to that of wood. To control the mass of the material that can be used, limits have been established on width and thickness. The intent in establishing a minimum density of 320 kg/m³ (20 lb/ft³) is to prohibit the use of lightweight [16 kg/m³ to 48 kg/m³ (1 lb/ft³ to 3 lb/ft³)] readily available, foamed plastics as trim.

Limiting plastic trim to Class A or Class B materials, in combination with the 10 percent area limit for walls and ceilings, imposes a greater restriction than that which applies to wood. This limitation ensures that the performance of the plastic trim will be equivalent or superior to that of more traditional materials.

In establishing the 10 percent limit, it is intended

that the trim will be used around doors and windows or at the junction of walls and ceilings. Therefore, the trim will be uniformly distributed throughout the room. There would be a significant difference in the probable performance of wall and ceiling finish if the 10 percent limit were concentrated in one area.

10.2.4.4* Light-Transmitting Plastics. Light-transmitting plastics shall be permitted to be used as interior wall and ceiling finish if approved by the authority having jurisdiction.

A.10.2.4.4 Light-transmitting plastics are used for a variety of purposes, including light diffusers, exterior wall panels, skylights, canopies, glazing, and the like. Previous editions of the *Code* have not addressed the use of light-transmitting plastics. Light-transmitting plastics will not normally be used in applications representative of interior finishes. Accordingly, NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, can produce test results that might or might not apply.

Light-transmitting plastics are regulated by the United States model building codes; see, for example, the *Uniform Building Code*, the *Standard Building Code*, and the *National Building Code*. Model building codes provide adequate regulation for most applications of light-transmitting plastics. Where an authority having jurisdiction determines that a use is contemplated that differs from uses regulated by model building codes, light-transmitting plastics in such applications can be substantiated by fire tests that demonstrate the combustibility characteristics of the light-transmitting plastics for the use intended under actual fire conditions.

Building code provisions typically regulate light-transmitting plastics. Paragraph 10.2.4.4 gives the authority having jurisdiction the ability to regulate light-transmitting plastics; A.10.2.4.4 offers guidance for such regulation.

10.2.4.5 Decorations and Furnishings. Decorations and furnishings that do not meet the definition of interior finish as defined in 3.3.120 shall be regulated by the provisions of Section 10.3.

10.2.5 Trim and Incidental Finish.

Interior wall and ceiling finish not in excess of 10 percent of the aggregate wall and ceiling areas of any room or space shall be permitted to be Class C materials in occupancies where interior wall and ceiling finish of Class A or Class B is required.

Subsection 10.2.5 is intended to allow the use of wood trim around doors and windows as a decoration or as functional molding (such as for chair rails). Wood trim must meet the criteria for Class C materials. See 10.2.4.3.2 for restrictions applicable to plastic trim. Where such trim is used in rooms or spaces requiring the use of Class A or Class B materials, the trim is permitted to constitute not more than 10 percent of the aggregate wall or ceiling area, to ensure that the trim will be more or less uniformly distributed throughout the room or space. If the trim is concentrated in a single, sizable, continuous pattern (for example, on one wall of a room), the materials could contribute to rapid fire growth.

10.2.6* Fire-Retardant Coatings.

A.10.2.6 Fire-retardant coatings need to be applied to surfaces properly prepared for the material, and application needs to be consistent with the product listing. Deterioration of coatings applied to interior finishes can occur due to repeated cleaning of the surface or painting over applied coatings.

10.2.6.1* The required flame spread or smoke development classification of existing surfaces of walls, partitions, columns, and ceilings shall be permitted to be secured by applying approved fire-retardant coatings to surfaces having higher flame spread ratings than permitted. Such treatments shall comply with the requirements of NFPA 703, *Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*.

A.10.2.6.1 It is the intent of the *Code* to mandate interior wall and ceiling finish materials that obtain their fire performance and smoke developed characteristics in their original form. However, in renovations, particularly those involving historic buildings, and in changes of occupancy, the required fire performance or smoke developed characteristics of existing surfaces of walls, partitions, columns, and ceilings might have to be secured by applying approved fire-retardant coatings to surfaces having higher flame spread ratings than permitted. Such treatments should comply with the requirements of NFPA 703, *Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*. When fire-retardant coatings are used, they need to be applied to surfaces properly prepared for the material, and application needs to be consistent with the product listing. Deterioration of coatings applied to interior finishes can occur due to repeated cleaning of the surface or painting over applied coatings, but permanency must be assured in some appropriate fashion. Fire-retardant coatings must possess the desired degree of permanency and be maintained

so as to retain the effectiveness of the treatment under the service conditions encountered in actual use.

10.2.6.2 Fire-retardant coatings shall possess the desired degree of permanency and shall be maintained so as to retain the effectiveness of the treatment under the service conditions encountered in actual use.

Fire-retardant paints, coatings, and penetrants are sometimes used to improve the flame spread ratings of materials or assemblies used as interior finishes within buildings. Fire-retardant treatments are permitted to be used to satisfy the flame spread requirements only for existing interior finish materials within existing buildings.

Fire retardants are generally a surface treatment that—through intumescence or other chemical reaction—will delay the ignition and slow the flame spread of a material. The nature of the material to which the treatment has been applied is not changed. Fire exposures of sufficient duration or intensity can ultimately cause a treated material to burn. Therefore, as a rule, materials with favorable intrinsic performance characteristics are preferred over those that achieve a satisfactory level of performance through the use of externally applied treatments. However, external treatments, where properly applied and maintained, can be effective in achieving reasonable fire performance.

Fire-retardant paints, coatings, and penetrants must be applied in strict accordance with the manufacturer's instructions. Most fire-retardant coatings require an application rate that is three-to-four times greater than that of ordinary paints. Application is usually done by brush, spray, immersion, or pressure treatment. The treatment should be reapplied or renewed at regular intervals. Treatments that might be removed by regular maintenance, washing, or cleaning procedures will require periodic examination and reapplication to maintain the required level of performance.

The use of fire retardants can improve the performance of some materials from Class C to Class B; similarly, Class B materials can, in some cases, be upgraded to Class A. Likewise, materials having flame spread ratings in excess of 200 can sometimes be upgraded to Class C.

In approving fire-retardant treatments, the authority having jurisdiction should take into consideration that in reducing flame spread, some fire-retardant treatments increase a material's capacity for smoke generation.

10.2.7 Interior Floor Finish Testing and Classification.

10.2.7.1 Carpet and carpet-like interior floor finishes shall comply with ASTM D 2859, *Standard Test Method for Flammability of Finished Textile Floor Covering Materials*.

10.2.7.2* Floor coverings, other than carpet for which 10.2.2.2 establishes requirements for fire performance, shall have a minimum critical radiant flux of 0.1 W/cm².

A.10.2.7.2 The fire performance of some floor finishes has been tested, and traditional finish floors and floor coverings such as wood flooring and resilient floor coverings have not proved to present an unusual hazard.

10.2.7.3* Interior floor finishes shall be classified in accordance with 10.2.7.4 based on test results from NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*.

A.10.2.7.3 The flooring radiant panel provides a measure of a floor covering's tendency to spread flames where located in a corridor and exposed to the flame and hot gases from a room fire. The flooring radiant panel test method is to be used as a basis for estimating the fire performance of a floor covering installed in the building corridor. Floor coverings in open building spaces and in rooms within buildings merit no further regulation, provided that it can be shown that the floor covering is at least as resistant to spread of flame as a material that meets the U.S. federal flammability standard 16 CFR 1630, *Standard for the Surface Flammability of Carpets and Rugs* (FF 1-70). All carpeting sold in the U.S. since 1971 is required to meet this standard and, therefore, is not likely to become involved in a fire until a room reaches or approaches flashover. Therefore, no further regulations are necessary for carpet other than carpet in exitways and corridors.

It has not been found necessary or practical to regulate interior floor finishes on the basis of smoke development.

Full scale fire tests and fire experience have shown floor coverings in open building spaces merit no regulation beyond the United States federally mandated DOC FF 1-70 "pill test." This is because floor coverings meeting the FF 1-70 will not spread flame significantly until a room fire approaches flashover. At flashover the spread of flame across a floor covering will have minimal impact on the already existing hazard. The minimum critical radiant flux of a floor covering that will pass the FF 1-70 has been determined to be approximately 0.04 watts/cm² (Tu, King-Mon and Davis, Sanford, *Flame Spread of Carpet Systems Involved in Room Fires*, NFSIR 76-1013, Center for Fire Research, National Bureau of Standards, June 1976). The flooring radiant panel is only able to determine critical radiant flux values to 0.1

watts/cm². This provision will prevent use of a noncomplying material, which may create a problem, especially when the *Code* is used outside the U.S. where U.S. Federal regulation FF-1 (16 CFR 1630) is not mandated.

Experience and full-scale fire test data have shown that floor coverings of modest resistance to flame spread are unlikely to become involved in the early growth of a fire. The testing of flooring materials in accordance with 10.2.7.1 and 10.2.7.2 is relatively easy to accomplish. The tests help to identify floor finish materials that have a modest resistance to flame spread.

Where floor coverings are regulated by the occupancy chapters, the evaluation is to be based on tests conducted in accordance with NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*²³, also known as ASTM E 648, *Standard Test Method for Critical Radiant Flux of Floor-Covering Systems Using a Radiant Heat Energy Source*²⁴. The flooring radiant panel test was specifically developed to evaluate the tendency of a floor covering to propagate flame.

Fire tests conducted by the National Bureau of Standards (now the National Institute of Standards and Technology) demonstrate that carpet that passes the federal flammability standard 16 CFR 1630, *Standard for the Surface Flammability of Carpets and Rugs*²⁵ (also known as FF 1-70 or the pill test) is not likely to become involved in a fire until a room reaches or approaches flashover.²⁶ Since all carpet manufactured for sale in the United States has been required since April 1971 to meet the pill test, no further regulation is necessary for carpet located within rooms.

On the other hand, it has been shown that floor coverings might propagate flame under the influence of a sizable exposure fire. For example, it has been shown that carpet located in a corridor might spread flame when subjected to the energy emanating from the doorway of a room fully developed in fire. The fire discharges flame and hot gases into the corridor, causing a radiant heat energy exposure to the floor. It has been shown that the level of energy radiating onto the floor is a significant factor in determining whether progressive flaming will occur. NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, measures the minimum energy required on the floor covering to sustain flame, measured in W/cm². This minimum value is the *critical radiant flux*. The flooring radiant panel test, therefore, measures a floor covering's tendency to spread flames where located in

a corridor and exposed to flame and hot gases from a room fire.

Interior floor finishes should be tested as proposed for use. For example, if a carpet is to be used with a separate underlayment, the carpet should be tested as such. The flooring radiant panel test specifies that a carpet is permitted to be tested using either the standard underlayment specified in NFPA 253 or the actual underlayment proposed for use. Data generated using the standard underlayment is intended to allow the tested carpet to be used over any other underlayment. Where assembly tests are conducted with other than the standard underlayment, the results of such tests are valid only for the specific combination tested.

Floor coverings are not regulated on the basis of smoke generation. Smoke development limits are not believed to be practical or necessary because floor coverings generally will not contribute to a fire until the fire has grown to large proportions. The minimal benefits achieved by imposing smoke development limits do not usually warrant such regulation. In addition, it is not considered practical to regulate on the basis of smoke development, because no regulatory test method that exists has been shown to be capable of producing data that correlates with the performance of products in actual fires.

10.2.7.4 Interior floor finishes shall be classified as follows in accordance with the critical radiant flux ratings:

- (1) Class I interior floor finish shall be characterized by a critical radiant flux not less than 0.45 W/cm² as determined by the test described in 10.2.7.3.
- (2) Class II interior floor finish shall be characterized by a critical radiant flux not less than 0.22 W/cm² but less than 0.45 W/cm² as determined by the test described in 10.2.7.3.

The greater its critical radiant flux value, the greater the resistance of a floor finish to flame propagation. Thus, a Class I interior floor finish with a critical radiant flux of 0.45 W/cm² or greater should perform better under fire conditions than a Class II interior floor finish material with its lesser critical radiant flux value range of 0.22 W/cm² to less than 0.45 W/cm². Contrast this classification with that of interior wall and ceiling interior finish materials in 10.2.3.4, in which higher flame spread ratings generally denote poorer performance under fire conditions.

10.2.7.5 Wherever the use of Class II interior floor finish is required, Class I interior floor finish shall be permitted.

10.2.8 Automatic Sprinklers.

10.2.8.1 Unless specifically prohibited elsewhere in this *Code*, where an approved automatic sprinkler system is in accordance with Section 9.7, Class C interior wall and ceiling finish materials shall be permitted in any location where Class B is required, and Class B interior wall and ceiling finish materials shall be permitted in any location where Class A is required.

10.2.8.2 Unless specifically prohibited elsewhere in this *Code*, where an approved automatic sprinkler system is in accordance with Section 9.7, Class II interior floor finish shall be permitted in any location where Class I interior floor finish is required, and where Class II is required, no critical radiant flux rating shall be required.

Fire testing and actual fire experience have shown that automatic sprinklers prevent flame spread across the surface of a wall, ceiling, or floor covering. Flame spread limits (applicable to interior wall and ceiling finishes) and critical radiant flux limits (applicable to interior floor finishes) are more lenient in areas protected by an automatic sprinkler system. However, there is a value beyond which the potential for flame spread becomes unacceptably high. For example, in occupancies with the most lenient interior finish requirements, which include fully sprinklered buildings, interior wall and ceiling finishes must meet the criteria for Class C materials.

Section 10.3 Contents and Furnishings

Section 10.3 provides a detailed menu of provisions that apply to contents and furnishings (for example, draperies, upholstered furniture, and mattresses) that can be adopted singly, in various combinations, or in their entirety in accordance with an occupancy's individual operating features requirements. These requirements typically appear in Section ___7 of an occupancy chapter. For example, the provisions for detention and correctional occupancies (22.7.4 and 23.7.4) make extensive, mandatory use of all provisions outlined in the Section 10.3 menu. Provisions for residential board and care occupancies (32.7.5, 33.7.5, A.32.7.5, and A.33.7.5) make mandatory and advisory use of various menu items contained in Section 10.3.

10.3.1* Where required by the applicable provisions of this *Code*, draperies, curtains, and other similar loosely hanging furnishings and decorations shall be flame resistant as demonstrated by testing in accordance with NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*.

A.10.3.1 Testing per NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, applies to textiles and films used in a hanging configuration. If the textiles and films are to be applied to surfaces of buildings or backing materials as interior finishes for use in buildings, they should be treated as interior wall and ceiling finishes in accordance with Section 10.2 of this *Code*, and they should then be tested for flame spread rating and smoke development values in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, or for flame spread and flashover in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls*.

The test results from NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations.

The testing requirements of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, measure the level of hazard posed by draperies and other loosely hanging fabrics and films. NFPA 701 describes procedures for intermediate-scale and large-scale tests. The choice of the applicable test method is determined, in part, by the weight of the material per unit area. Both tests involve applying a flame to a vertically positioned sample for a specified time. Upon removal of the flame-producing burner, the sample must self-extinguish and must not have charred beyond a specified distance in order to pass the test. Additionally, with the intermediate-scale test, a specified maximum percent weight loss cannot be exceeded.

Exhibit 10.6 illustrates a representative test setup from NFPA 701.

10.3.2* Where required by the applicable provisions of this *Code*, upholstered furniture and mattresses shall be resistant to a cigarette ignition (that is, smoldering) in accordance with the following:

- (1) Where required by the applicable provisions of this *Code*, the components of the upholstered furniture,

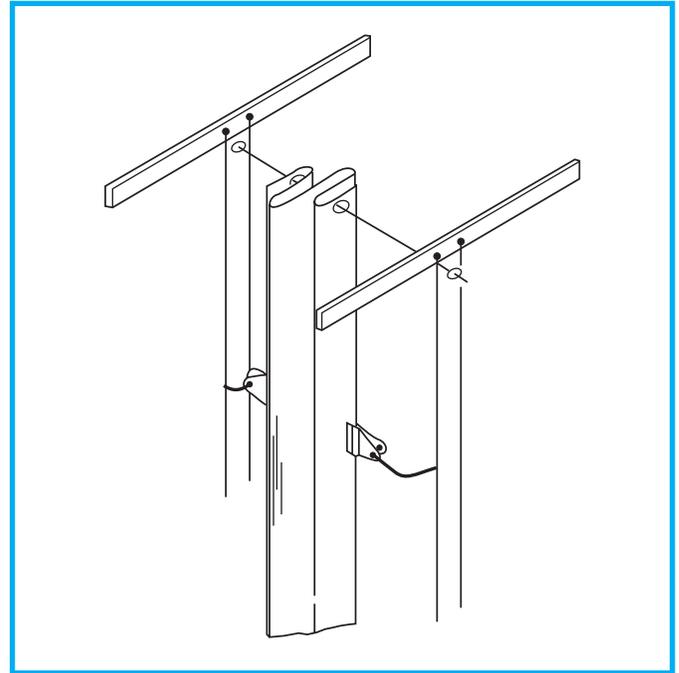

Exhibit 10.6 Test sample in loosely hanging fabric.

unless located in rooms or spaces protected by an approved automatic sprinkler system, shall meet the requirements for Class I when tested in accordance with NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*.

- (2) Where required by the applicable provisions of this *Code*, mocked-up composites of the upholstered furniture, unless located in rooms or spaces protected by an approved automatic sprinkler system, shall have a char length not exceeding 38 mm (1½ in.) when tested in accordance with NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*.
- (3)* Where required by the applicable provisions of this *Code*, mattresses, unless located in rooms or spaces protected by an approved automatic sprinkler system, shall have a char length not exceeding 51 mm (2 in.) when tested in accordance with Part 1632 of the *Code of Federal Regulations* 16.

A.10.3.2(3) Regardless of sprinkler protection provided, U.S. federal regulations require mattresses in the United States to comply with 16 CFR 1632.

A.10.3.2 The Class I requirement associated with testing per NFPA 260, *Standard Methods of Tests and Classification*

System for Cigarette Ignition Resistance of Components of Upholstered Furniture; the char length of not more than 38 mm (1.5 in.) required with testing per NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*; and the char length of not more than 51 mm (2 in.) required in FF4-72, *Standard for the Flammability of Mattresses*, are indicators that the furniture item or mattress is resistant to a cigarette ignition. Although rooms or spaces protected by an approved automatic sprinkler system are exempt from cigarette ignition resistance testing, a fire that smolders for an excessive period of time without flaming can reduce the tenability within the room or area of fire origin without developing the temperatures necessary to operate automatic sprinklers.

The test results from NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*, and NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*, are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations.

The provisions of 10.3.2 address ignition by cigarettes or other smoldering sources in an attempt to reduce the incidence of fires involving upholstered furniture and mattresses. Such ignition sources can smolder for considerable periods before producing flaming ignition.

The following two NFPA fire test methods address the cigarette ignition resistance of upholstered furniture:

- (1) NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*²⁷
- (2) NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*²⁸

One federal test method that is specified for judging the cigarette ignition resistance of mattresses is 16 CFR 1632, *Standard for the Flammability of Mattresses and Mattress Pads*²⁹.

When purchasing upholstered furniture, consumers should check for flammability labeling. See Exhibit 10.7 for a representative flammability tag found on upholstered furniture.

NFPA 260 tests individual components of upholstered furniture, such as cover fabric, interior fabric, welt cord, filling/padding, decking materials, and barrier materials. Specimens of the component to be

tested are assembled with specimens of standardized materials to create a miniature horizontal base panel and vertical panel tester, a mocked-up arrangement that simulates the junction and surrounding area of a seat cushion and back cushion in a piece of upholstered furniture. Standardizing all the components of the mocked-up tester, except the component being tested, allows the test to measure the ignition resistance of the test component. Components that meet the test criteria are designated as Class I materials. Components that do not meet the test criteria are designated as Class II materials. Upholstered furniture constructed from components that individually received a Class I designation is judged to be resistant to cigarette ignition without testing the actual combination of materials. Cigarette ignition-resistant upholstered furniture can also be constructed using Class II cover fabric materials over conventional polyurethane foam cushions, if a Class I barrier material is used between the Class II fabric and the conventional foam cushion.

NFPA 261 tests a mocked-up assembly consisting of all the actual components that will be used to construct the piece of upholstered furniture, rather than testing the components individually. The test procedure specifies that a char length is to be measured and reported. There are no pass/fail criteria within the document, so 10.3.2(2) specifies that the char length not exceed 38 mm (1½ in.) if the mocked-up assembly is to be considered resistant to cigarette ignition.

NFPA 260 and NFPA 261 address the cigarette ignition resistance of upholstered furniture; 16 CFR 1632 addresses the cigarette ignition resistance of mattresses. For this test method, 10.3.2(3) establishes that a char length not exceeding 51 mm (2 in.) qualifies the mattress as resistant to cigarette ignition.

10.3.3* Where required by the applicable provisions of this Code, upholstered furniture, unless the furniture is located in a building protected throughout by an approved automatic sprinkler system, shall have limited rates of heat release when tested in accordance with ASTM E 1537, *Standard Method for Fire Testing of Real Scale Upholstered Furniture Items*, as follows:

- (1) The peak rate of heat release for the single upholstered furniture item shall not exceed 250 kW.
- (2) The total energy released by the single upholstered furniture item during the first 5 minutes of the test shall not exceed 40 MJ.

A.10.3.3 The intent of the provisions of 10.3.3 is as follows.

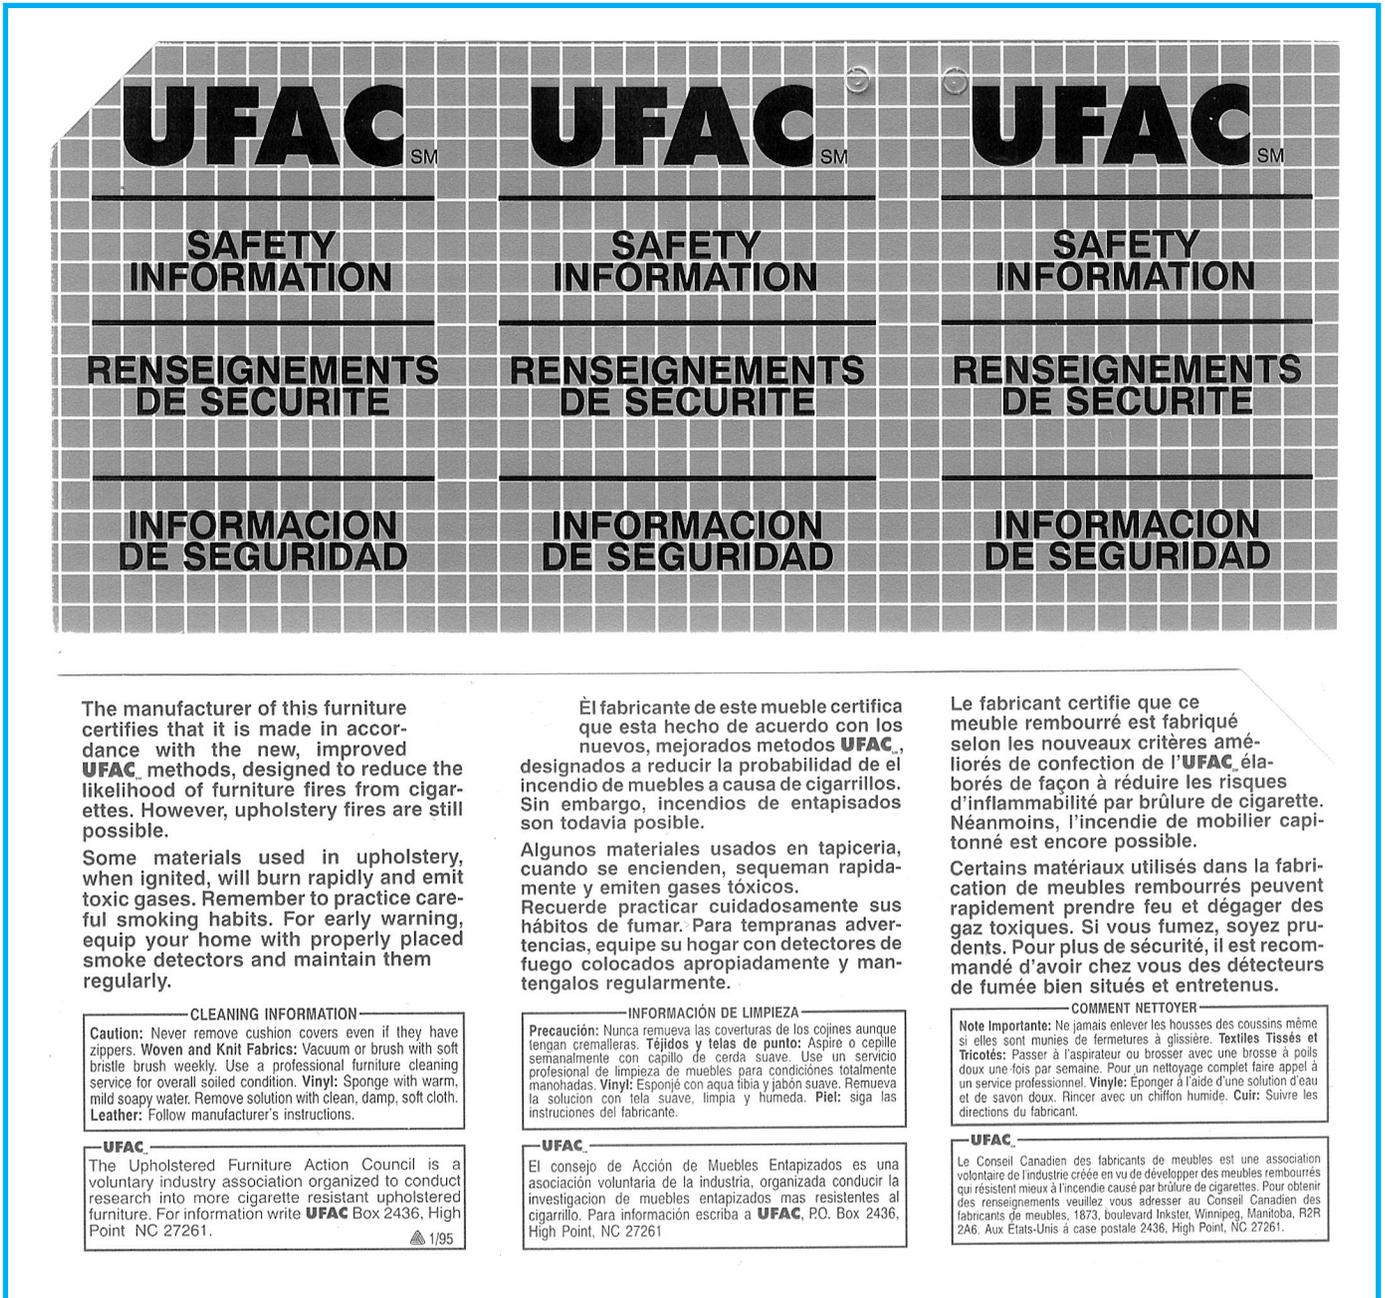

Exhibit 10.7 Upholstered furniture flammability tag. (Photo courtesy of American Furniture Manufacturers Association and the Upholstered Furniture Action Council.)

- (1) The peak heat release rate of not more than 250 kW by a single upholstered furniture item was chosen based on maintaining a tenable environment within the room of fire origin. The sprinkler exception was developed because the sprinkler system helps to maintain tenable conditions even if the single upholstered furniture item were to have a peak rate of heat release in excess of 250 kW.
- (2) The total energy release of not more than 40 MJ by the single upholstered furniture item during the first 5 minutes of the test was established as an additional safeguard to protect against the adverse conditions that would be created by an upholstered furniture item that released its heat in other than the usual measured scenario. During the test for measurement of rate of heat release, the instantaneous heat release value usually

peaks quickly and then quickly falls off so as to create a triangle-shaped curve. In the atypical case, if the heat release were to peak and remain steady at that elevated level, as opposed to quickly falling off, the 250-kW limit would not ensure safety. Again, only a sprinkler exception is permitted in lieu of the test because of the ability of the sprinkler system to control the fire.

Actual test results for heat, smoke, and combustion product release from ASTM E 1537, *Standard Method of Fire Testing of Real Scale Upholstered Furniture Items*, might be suitable for use as input into fire models for performance-based design.

The provisions of 10.3.2 address only one important property of upholstered furniture and mattresses—their resistance to cigarette ignition. The provisions of 10.3.3 and 10.3.4 supplement those provisions by addressing rates of heat release. Different combustible materials vary in their potential to produce heat. Some plastic materials, for example, have twice as much potential heat per weight of material as wood. However, if a material with twice the potential heat were to burn only half as fast as a material with lower potential, the two materials would liberate about the same amount of heat during any given period and create approximately equivalent hazards. If one material with a heat potential approximately equal to another material were to burn twice as fast as the other, it would liberate about twice as much heat during any given period and, thus, create a greater hazard than the slower burning material. Therefore, the property of a material or group of materials expressed by a rate of heat release is important in regulating the combustibility of upholstered furniture and mattresses for use in nonsprinklered areas.

Paragraph A.10.3.3 adequately describes the intent of the rates of heat release provisions, which is to prevent any single furniture item from causing room flashover. The material in that paragraph also explains how automatic sprinklers, in certain cases, can serve in lieu of a low rate of heat release.

10.3.4* Where required by the applicable provisions of this *Code*, mattresses, unless the mattress is located in a building protected throughout by an approved automatic sprinkler system, shall have limited rates of heat release when tested in accordance with ASTM E 1590, *Standard Method for Fire Testing of Real Scale Mattresses*, as follows:

- (1) The peak rate of heat release for the mattress shall not exceed 250 kW.
- (2) The total energy released by the mattress during the first 5 minutes of the test shall not exceed 40 MJ.

A.10.3.4 The intent of the provisions of 10.3.4 is as follows.

- (1) The peak heat release rate of not more than 250 kW by a single mattress was chosen based on maintaining a tenable environment within the room of fire origin. The sprinkler exception was developed because the sprinkler system helps to maintain tenable conditions even if the single mattress were to have a peak rate of heat release in excess of 250 kW.
- (2) The total energy release of not more than 40 MJ by the single mattress during the first 5 minutes of the test was established as an additional safeguard to protect against the adverse conditions that would be created by a mattress that released its heat in other than the usual measured scenario. During the test for measurement of rate of heat release, the instantaneous heat release value usually peaks quickly and then quickly falls off so as to create a triangle-shaped curve. In the atypical case, if the heat release were to peak and remain steady at that elevated level, as opposed to quickly falling off, the 250-kW limit would not ensure safety. Again, only a sprinkler exception is permitted in lieu of the test because of the ability of the sprinkler system to control the fire.

Actual test results for heat, smoke, and combustion product release from NFPA 267, *Standard Method of Test for Fire Characteristics of Mattresses and Bedding Assemblies Exposed to Flaming Ignition Source*, and ASTM E 1590, *Standard Method for Fire Testing of Real Scale Mattresses*, might be suitable for use as input into fire models for performance-based design.

See the commentary following A.10.3.3.

10.3.5* Furnishings or decorations of an explosive or highly flammable character shall not be used.

A.10.3.5 Christmas trees not effectively flame-retardant treated, ordinary crepe paper decorations, and pyroxylin plastic decorations might be classified as highly flammable.

The *Code* relies on the authority having jurisdiction to exercise judgment in determining the materials that are of an explosive or highly flammable nature.

10.3.6 Fire-retardant coatings shall be maintained to retain the effectiveness of the treatment under service conditions encountered in actual use.

See NFPA 703, *Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*³⁰.

10.3.7* Where required by the applicable provisions of this *Code*, furnishings and contents made with foamed plastic materials that are unprotected from ignition shall have a heat release rate not exceeding 100 kW when tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*.

A.10.3.7 UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, is not intended for evaluating interior wall and ceiling finish materials.

Actual test results for heat, smoke, and combustion product release from UL 1975 might be suitable for use as input into fire models intended for performance-based design.

CHAPTER 11

Special Structures and High-Rise Buildings

Section 11.1 General Requirements

Chapter 11 is formatted differently from the other chapters of the *Code*. It is the last of the core chapters that precedes the occupancy chapters. Its scope is potentially applicable to all occupancies. Each subsection is targeted to specific special structures or *unusual* surroundings within which a *usual* occupancy might exist. The facilities to which Chapter 11 provisions might be applied range from a refinery petroleum-cracking plant to an air-traffic control tower. While the life safety and functional use considerations of these properties might, at times, seem to conflict, Chapter 11 provides the necessary guidance to make them safe as well as functional.

Examples of usual occupancies housed in unusual surroundings or special structures include a large convention center located on a pier, so that the facility is surrounded by water on three sides, and a moderately sized restaurant located on an upper level of an air-traffic control tower. Exhibit 11.1 is an example of usual occupancies in an unusual surrounding. An authority having jurisdiction should ensure that any engineered solutions to the special structure's inherent egress deficiencies provide an overall level of life safety equivalent to that specified by the requirements of the occupancy chapter that applies to the structure's use. In some cases, a structure might be so unusual that the only practical option is a complete performance-based design in accordance with Chapter 5.

Chapter 11 also regulates water-surrounded structures, vehicles and vessels, and limited-access (referred to as *windowless* in previous editions of the *Code*) and underground structures. These provisions apply regardless of the occupancy classification. For

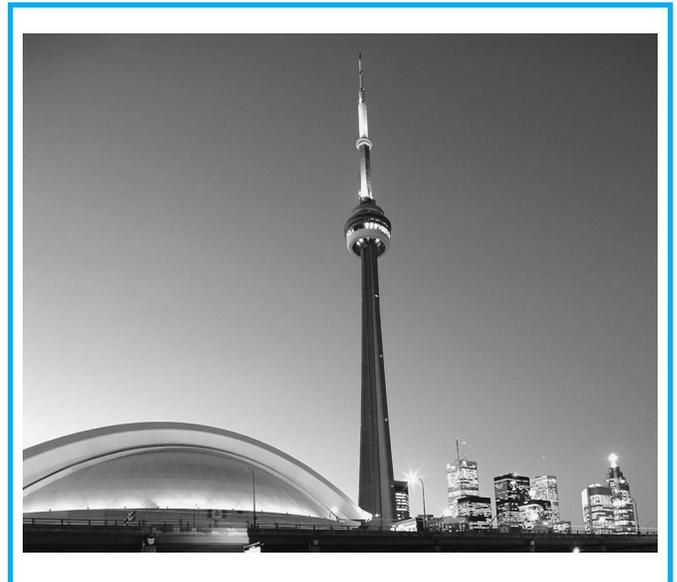

Exhibit 11.1 The CN Tower in Toronto.

example, a permanently moored ship that is used as a restaurant must comply with Chapter 12 or 13 for assembly occupancies, as appropriate, by virtue of the language in 11.6.2.

Section 11.8 presents a series of unique provisions applicable to high-rise buildings. The various occupancy chapters might mandate the use of some, all, or none of those provisions.

The last three sections of Chapter 11 were introduced in the 2000 edition of the *Code*. They provide a series of requirements applicable to tents and membrane structures. Similar requirements were originally contained in NFPA 102, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*¹. However, the requirements as they appear

in this *Code* (and in *NFPA 5000™*, *Building Construction and Safety Code™2*) are more comprehensive and current, because NFPA 102 has not been updated since 1995.

11.1.1 Application.

The requirements of Section 11.1 through Section 11.11 apply to occupancies regulated by Chapter 12 through Chapter 42 that are in a special structure. The applicable provisions of Chapter 12 through Chapter 42 shall apply, except as modified by this chapter. Section 11.8 applies to high-rise buildings only where specifically required by Chapter 12 through Chapter 42.

Occupancies in special structures pose a special challenge to life safety. Sections 11.1 through 11.6 are intended to supplement the requirements of occupancy Chapters 12 through 42; their provisions might serve as requirements that must be satisfied in addition to those found in the applicable occupancy chapter. For example, 11.5.3 contains additional provisions that apply to a pier used for other than cargo handling or storage. Therefore, in the case of an amusement pier, the requirements of Chapter 12 or 13 for assembly occupancies would apply, as well as those of 11.5.3.

The provisions of Chapter 11 also might take the form of a modification of a requirement that is permitted to be used for an occupancy in a special structure but that would not be allowed in a usual structure housing the same occupancy. For example, if a business occupancy is housed in a tower, 11.3.2.4.1 permits a single exit from the tower, under a strict set of conditions. However, if a similar business occupancy is located on an upper floor of a multistory building that is not a tower, Chapter 38 or 39 would require that two exits be provided on the floor housing the business occupancy. In other words, Chapter 11 might offer an exemption based on the inherent difficulty of providing two remote exits from a tower. Yet, the exemption isn't a waiver that ignores life safety; rather, the exemption provides criteria and limitations that ensure a safe means of tolerating a single exit.

In addition to the provisions applicable to an occupancy via its appropriate occupancy chapter (Chapters 12 through 42), occupancies housed in limited-access and underground structures must comply with the provisions of Section 11.7, which include the following:

- (1) Complete automatic sprinkler protection unless certain criteria are met (see 11.7.3.4)
- (2) Emergency lighting
- (3) Smoke venting (in underground structures only; see 11.7.4.4)
- (4) Directional signage for egress paths (in underground structures only; see 11.7.4.5)

An occupancy in a high-rise building must comply with the requirements of Section 11.8 only to the degree specified by the applicable occupancy chapter. For example, for new hotels, 28.4.1 requires compliance with the full package of high-rise building provisions of Section 11.8; for new mercantile occupancies, 36.4.2 requires only sprinkler systems in accordance with 11.8.2.1 rather than the complete high-rise package. For most existing buildings, the applicable occupancy chapter does not make mandatory use of any of the provisions of Section 11.8—although some require existing high-rise buildings to be sprinklered in accordance with Section 9.7 rather than 11.8.2.

Although the *Code* provisions present an essentially complete package of requirements for life safety, the provision of adequate means of egress from many special structures requires unique solutions. In many instances, engineered solutions will supplement the minimum provisions of Chapter 11 and the applicable occupancy chapter. However, the unique character of a structure should not become an excuse for reducing safety to life. The *Code* user is cautioned to exercise careful judgment when determining the egress requirements for special structures.

11.1.2 Multiple Occupancies.

See 6.1.14.

11.1.3 Definitions.

See the defined terms within each special structure section.

11.1.4 Classification of Occupancy.

Occupancies regulated by Chapter 12 through Chapter 42 that are in special structures shall meet the requirements of those chapters, except as modified by this chapter.

11.1.5 Classification of Hazard of Contents.

Classification of hazard of contents shall be in accordance with Section 6.2.

11.1.6 Minimum Construction Requirements.

Minimum construction requirements shall be in accordance with the applicable occupancy chapter.

11.1.7 Occupant Load.

The occupant load of special structures shall be based on the use of the structure as regulated by Chapter 12 through Chapter 42.

11.1.8 Automatic Sprinkler Systems.

Where another provision of this chapter requires an automatic sprinkler system, the automatic sprinkler system shall be installed in accordance with the subparts of 9.7.1.1 as permitted by the applicable occupancy chapter.

Section 11.2 Open Structures

11.2.1 Application.

11.2.1.1 General. The provisions of Section 11.1 shall apply.

11.2.1.2 Definition—Open Structure. See 3.3.217.6.

11.2.2* Means of Egress.

A.11.2.2 Escape chutes, controlled descent devices, and elevators are permitted to provide escape routes in special structures; however, they should not be substituted for the provisions of this *Code*.

11.2.2.1 General. The means of egress provisions of the applicable occupancy, Chapter 12 through Chapter 42, shall apply, except as modified by 11.2.2.2 through 11.2.2.10.

11.2.2.2 Means of Egress Components.

11.2.2.2.1 Fire Escape Ladders. Open structures that are designed for occupancy by not more than three persons shall be permitted to be served by fire escape ladders complying with 7.2.9.

11.2.2.3 Capacity of Means of Egress. Open structures shall be exempt from the requirements for capacity of means of egress.

Paragraph 11.2.2.3 recognizes the multiple means of egress paths available from open structures, such as those found in petrochemical and process industries. An open structure is actually an access platform to the equipment it surrounds or supports. Normal oc-

cupancy is very limited in number and occasional in frequency. If a fire blocks one means of egress, a number of alternate means of egress remain available. An escape route is provided by the fixed means of egress, and rescue is possible from any portion of the structure by use of the emergency procedures of fire-fighting personnel. The potential for exposure of portions of the structure not involved in a fire is minimal, because, in open platforms, flames, heat, and smoke are safely dispersed directly into the atmosphere and not into the uninvolved portions of the structure.

11.2.2.4 Number of Means of Egress.

11.2.2.4.1 The grade level of open structures, which by their very nature contain an infinite number of means of egress, shall be exempt from the requirements for number of means of egress.

11.2.2.4.2 Open structures occupied by not more than three persons, with travel distance of not more than 61 m (200 ft), shall be permitted to have a single exit.

11.2.2.5 Arrangement of Means of Egress. (No modifications.)

11.2.2.6 Travel Distance to Exits. Open structures shall be exempt from travel distance limitations.

11.2.2.7 Discharge from Exits. Open structures permitted to have a single exit per 11.2.2.4 shall be permitted to have 100 percent of the exit discharge through areas on the level of exit discharge.

11.2.2.8 Illumination of Means of Egress. Open structures shall be exempt from illumination of means of egress requirements.

11.2.2.9 Emergency Lighting. Open structures shall be exempt from emergency lighting requirements.

11.2.2.10 Marking of Means of Egress. Open structures shall be exempt from marking of means of egress requirements.

11.2.3 Protection.

11.2.3.1 Protection of Vertical Openings. Open structures shall be exempt from protection of vertical opening requirements.

11.2.3.2 Protection from Hazards. Every open structure, other than those structures with only occasional occupancy, shall have automatic, manual, or other protection that is

appropriate to the particular hazard and that is designed to minimize danger to occupants in case of fire or other emergency before they have time to use the means of egress.

11.2.3.3 Interior Finish. (No modifications.)

11.2.3.4 Detection, Alarm, and Communications Systems. Open structures shall be exempt from requirements for detection, alarm, and communications systems.

11.2.3.5 Extinguishing Requirements. (No modifications.)

Section 11.3 Towers

11.3.1 Application.

11.3.1.1 General. The provisions of Section 11.1 shall apply.

11.3.1.2 Definition—Tower. See 3.3.224.

11.3.1.3 Use of Accessory Levels.

11.3.1.3.1 Sprinklered Towers. In towers protected throughout by an automatic sprinkler system in accordance with Section 9.7, the levels located below the observation level shall be permitted to be occupied only for the following uses that support tower operations:

- (1) Electrical and mechanical equipment rooms, including emergency power, radar, communications, and electronics rooms
- (2)* Incidental accessory uses

A.11.3.1.3.1(2) The incidental accessory uses are intended to apply to small office spaces or lounge areas and similar uses that are used by tower employees.

11.3.1.3.2 Nonsprinklered Towers. The levels located within a tower below the observation level and the equipment room for that level in nonsprinklered towers shall not be occupied.

11.3.2 Means of Egress.

11.3.2.1 General. The means of egress provisions of the applicable occupancy chapter, Chapter 12 through Chapter 42, shall apply, except as modified by 11.3.2.2 through 11.3.2.10.

11.3.2.2 Means of Egress Components.

11.3.2.2.1 Fire Escape Ladders. Towers, such as forest fire observation or railroad signal towers, that are designed for occupancy by not more than three persons shall be permitted to be served by fire escape ladders complying with 7.2.9.

11.3.2.2.2 Elevators. Towers subject to occupancy by not more than 90 persons shall be permitted to use elevators in the means of egress in accordance with 7.2.13.

11.3.2.3 Capacity of Means of Egress.

11.3.2.3.1 Means of egress for towers shall be provided for the number of persons expected to occupy the space.

11.3.2.3.2 Spaces not subject to human occupancy because of machinery or equipment shall be excluded from consideration.

11.3.2.4* Number of Means of Egress.

A.11.3.2.4 The Washington Monument in Washington, DC, is an example of a tower where it would be impracticable to provide a second stairway.

11.3.2.4.1 Towers shall be permitted to have a single exit if the following conditions are met:

- (1) The tower shall be subject to occupancy by fewer than 25 persons.
- (2) The tower shall not be used for living or sleeping purposes.
- (3) The tower shall be of Type I, Type II, or Type IV construction. (*See 8.2.1.*)
- (4) The tower interior wall and ceiling finish shall be Class A or Class B.
- (5) No combustible materials shall be located within the tower, under the tower, or within the immediate vicinity of the tower, except necessary furniture.
- (6) No high hazard occupancies shall be located within the tower or within its immediate vicinity.
- (7) Where the tower is located above a building, the single exit from the tower shall be provided by one of the following:
 - (a) An exit enclosure separated from the building with no door openings to or from the building
 - (b) An exit enclosure leading directly to an exit enclosure serving the building, with walls and door separating the exit enclosures from each other, and another door allowing access to the top floor of the building that provides access to a second exit serving that floor

Paragraph 11.3.2.4.1 permits a single means of egress from a tower if additional criteria are met. Determination of the total occupant load of a tower should be based on the actual number of people expected to occupy the facility [see 11.3.2.4.1(1)]. Limitations on the combustibility and interior finish of the structure are established, so that the potential exposure of the tower occupants to fire is minimal. Types I, II, and IV

construction [see 11.3.2.4.1(3)] are defined in NFPA 220, *Standard on Types of Building Construction*³.

One difficulty associated with the requirements for exits in towers is the accurate determination of the level of exposure of the tower to combustible materials under, or in the immediate vicinity of, the structure. The authority having jurisdiction and other Code users should use careful judgment to ensure that arbitrary limitations are not established that excessively restrict the use of the tower. For example, a forest fire tower is usually located in a clearing in a large forest. The proximity of trees to the tower could be interpreted as constituting combustible materials in the immediate vicinity of the tower. Reasonable clearances between the tower and forest—such as a clear space of 15 m to 30 m (50 ft to 100 ft)—could be considered adequate separation for the life safety of the tower's occupants. Similar judgment is required where evaluating the clearance between high-hazard occupancies and towers.

The provisions of 11.3.2.4.1(7) are illustrated in Exhibit 11.2. Where the tower is located above a building, special precautions must be taken to prevent use of the tower's single means of egress from being compromised by a fire in the building below. In Exhibit 11.2, illustration (a), the single exit stair enclosure for the tower is separated from the building by rated construction in accordance with 7.1.3.2. Additionally, the single exit stair enclosure for the tower has no openings to the floors of the building above which the tower is positioned, thus preventing a fire on the building floors from entering the enclosure.

In Exhibit 11.2, illustration (b), the single exit stair positioned above the building serves the tower. It provides direct access to the exit stair enclosure on the left, which also serves the building floors. If a fire prevents the use of the exit stair enclosure on the left, the tower stair permits tower occupants to traverse the top floor of the building and access a second exit stair enclosure on the right.

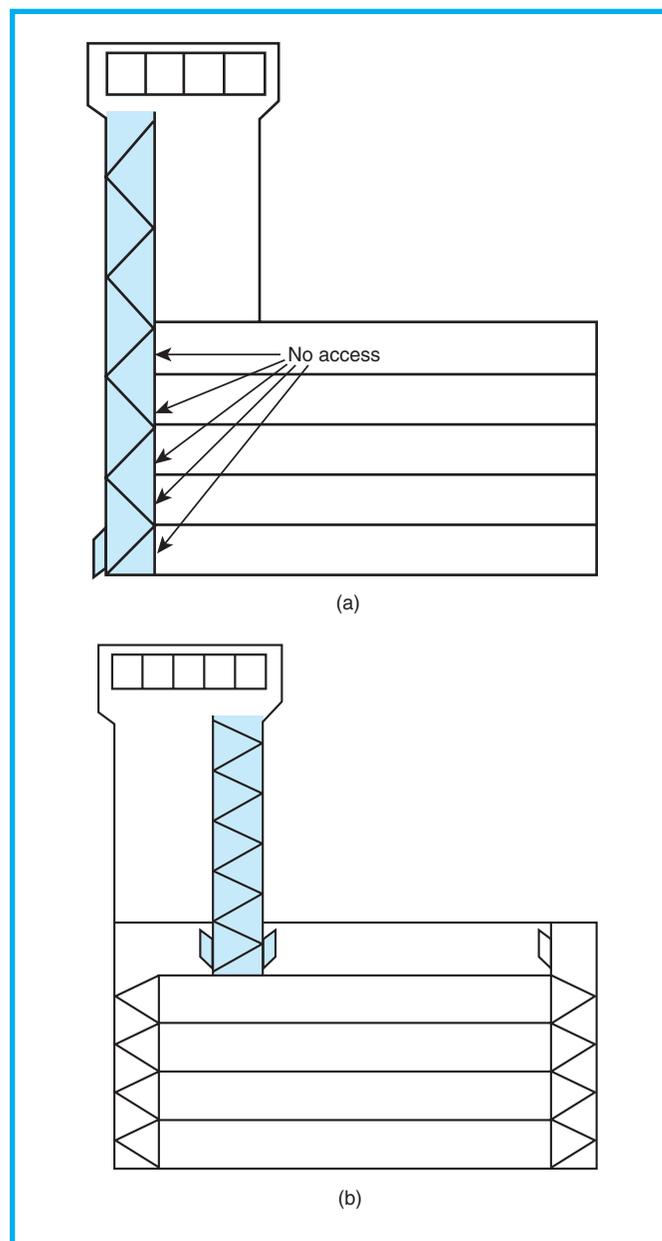

Exhibit 11.2 Single exit from a tower.

11.3.2.4.2 Towers with 360-degree line-of-sight requirements shall be permitted to have a single means of egress for a distance of travel not exceeding 23 m (75 ft), or 30 m (100 ft) if the tower is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

11.3.2.5 Arrangement of Means of Egress. (No modifications.)

11.3.2.6 Travel Distance to Exits. Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from travel distance limitations.

11.3.2.7 Discharge from Exits. Towers permitted to have a single exit per 11.3.2.4 shall be permitted to have 100 percent of the exit discharge through areas on the level of exit discharge.

11.3.2.8 Illumination of Means of Egress. Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from illumination of means of egress requirements.

11.3.2.9 Emergency Lighting.

11.3.2.9.1 Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from emergency lighting requirements.

11.3.2.9.2 Locations not routinely inhabited by humans shall be exempt from emergency lighting requirements.

11.3.2.9.3 Structures occupied only during daylight hours, with windows arranged to provide the required level of illumination of all portions of the means of egress during such hours, shall be exempt from emergency lighting requirements where approved by the authority having jurisdiction.

11.3.2.10 Marking of Means of Egress.

11.3.2.10.1 Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from marking of means of egress requirements.

11.3.2.10.2 Locations not routinely inhabited by humans shall be exempt from marking of means of egress requirements.

11.3.3 Protection.

11.3.3.1 Protection of Vertical Openings.

11.3.3.1.1 Towers where ladders are permitted by 11.3.2.2.1 shall be exempt from protection of vertical opening requirements.

11.3.3.1.2 In towers where the support structure is open and there is no occupancy below the top floor level, stairs shall be permitted to be open with no enclosure required, or fire escape stairs shall be permitted.

11.3.3.2 Protection from Hazards. Every tower, other than structures with only occasional occupancy, shall have automatic, manual, or other protection that is appropriate to the particular hazard and that is designed to minimize danger to occupants in case of fire or other emergency before they have time to use the means of egress.

11.3.3.3 Interior Finish. (No modifications.)

11.3.3.4 Detection, Alarm, and Communications Systems. Towers designed for occupancy by not more than three persons shall be exempt from requirements for detection, alarm, and communications systems.

11.3.3.5 Extinguishing Requirements. (No modifications.)

11.3.3.6 Corridors. (No modifications.)

Section 11.4 Water-Surrounded Structures

11.4.1 Application.

11.4.1.1 General. The provisions of Section 11.1 and Section 11.4 shall apply to those structures that are not under

the jurisdiction of the U.S. Coast Guard and not designed and arranged in accordance with U.S. Coast Guard regulations.

11.4.1.2 Definition—Water-Surrounded Structure. See 3.3.217.12.

11.4.2 Means of Egress.

11.4.2.1 General. The means of egress provisions of the applicable occupancy chapter, Chapter 12 through Chapter 42, shall apply, except as modified by 11.4.2.2 through 11.4.2.10.

11.4.2.2 Means of Egress Components. (No modifications.)

11.4.2.3 Capacity of Means of Egress. Spaces in water-surrounded structures that are not subject to human occupancy because of machinery or equipment shall be exempt from the requirements for capacity of means of egress.

11.4.2.4 Number of Means of Egress. (No modifications.)

11.4.2.5 Arrangement of Means of Egress. (No modifications.)

11.4.2.6 Travel Distance to Exits. (No modifications.)

11.4.2.7 Discharge from Exits. Structures permitted to have a single exit per the applicable occupancy chapter shall be permitted to have 100 percent of the exit discharge through areas on the level of exit discharge.

11.4.2.8 Illumination of Means of Egress. (No modifications.)

11.4.2.9 Emergency Lighting.

11.4.2.9.1 Locations not routinely inhabited by humans are exempt from emergency lighting requirements.

11.4.2.9.2 Structures occupied only during daylight hours, with windows arranged to provide the required level of illumination of all portions of the means of egress during such hours, shall be exempt from emergency lighting requirements where approved by the authority having jurisdiction.

11.4.2.10 Marking of Means of Egress. Locations not routinely inhabited by humans shall be exempt from marking of means of egress requirements.

11.4.3 Protection.

11.4.3.1 Protection of Vertical Openings. (No modifications.)

11.4.3.2 Protection from Hazards. Every water-surrounded structure, other than structures with only occasional

occupancy, shall have automatic, manual, or other protection that is appropriate to the particular hazard and that is designed to minimize danger to occupants in case of fire or other emergency before they have time to use the means of egress.

11.4.3.3 Interior Finish. (No modifications.)

11.4.3.4 Detection, Alarm, and Communications Systems. (No modifications.)

11.4.3.5 Extinguishing Requirements. (No modifications.)

11.4.3.6 Corridors. (No modifications.)

Section 11.5* Piers

A.11.5 For further information on pier fire protection, see NFPA 307, *Standard for the Construction and Fire Protection of Marine Terminals, Piers, and Wharves*.

11.5.1 Application.

The provisions of Section 11.1 shall apply.

11.5.2 Number of Means of Egress.

Piers used exclusively to moor cargo vessels and to store material shall be exempt from number of means of egress requirements where provided with proper means of egress from structures thereon to the pier and a single means of access to the mainland, as appropriate to the pier's arrangement.

The intent of 11.5.2 is to recognize the open nature of a pier and to equate a pier with a public way for purposes of egress arrangement. Note that 11.5.2 applies mainly to cargo and storage piers, which are occupied by a limited number of people, the majority of whom are accustomed to the arrangement of piers. The risk to life safety is considered minimal under these conditions, and one means of egress is acceptable.

11.5.3 Arrangement of Means of Egress.

Piers not meeting the requirements of 11.5.2 and occupied for other than cargo handling and storage shall have means of egress arranged in accordance with Chapter 12 through Chapter 42. In addition, one of the following measures shall be provided on piers extending over 46 m (150 ft) from shore to minimize the possibility that fire under or on the pier blocks the escape of occupants to shore:

- (1) The pier shall be arranged to provide two separate ways to travel to shore, such as by two well-separated walkways or independent structures.
- (2) The pier deck shall be open, fire resistive, and set on noncombustible supports.
- (3) The pier shall be open, unobstructed, and not less than 15 m (50 ft) in width if less than 150 m (500 ft) long, or its width shall be not less than 10 percent of its length if more than 150 m (500 ft) long.
- (4) The pier deck shall be provided with an approved automatic sprinkler system in accordance with Section 9.7 for combustibile substructures and all superstructures. Such sprinkler system shall be supervised where required by the applicable occupancy chapter (Chapter 12 through Chapter 42).

The provisions of 11.5.3 apply to pier structures other than those structures waived by 11.5.2. Note that these provisions must be applied in addition to those contained in Chapters 12 through 42 for piers that exceed 46 m (150 ft) in length. The provisions of 11.5.3(1) through (4) are not required to be applied in total; in other words, the pier is required to comply with only one of the four subparts.

Section 11.6* Vehicles and Vessels

A.11.6 Fire safety information for manufactured home parks is found in NFPA 501A, *Standard for Fire Safety Criteria for Manufactured Home Installations, Sites, and Communities*.

11.6.1 Vehicles.

Where immobile, attached to a building, or permanently fixed to a foundation, and where subject to human occupancy, the following vehicles shall comply with the requirements of this *Code* that are appropriate to buildings of similar occupancy:

- (1) Trailers
- (2) Railroad cars
- (3) Streetcars
- (4) Buses
- (5) Conveyances similar to those in 11.6.1(1) through 11.6.1(4)

11.6.2 Vessels.

Any ship, barge, or other vessel permanently fixed to a foundation or mooring, or unable to get underway by means of its own power, and occupied for purposes other than navigation shall be subject to the requirements of this *Code* that apply to buildings of similar occupancy.

Section 11.7 Underground and Limited Access Structures

11.7.1 Application.

The provisions of Section 11.1 shall apply.

11.7.2* Definitions.

The following is a list of terms used in Section 11.7:

- (1) **Underground Structure.** See 3.3.217.11.
- (2) **Limited Access Structure.** See 3.3.217.3.

A.11.7.2 It is not the intent that emergency access openings be readily openable from the exterior by the public but that they can easily be opened with normal fire department equipment.

The provision of emergency access openings for ventilation and rescue exempts stories below the level of exit discharge from classification as underground. In Exhibit 11.3, the basement is not considered to be underground if the following conditions apply:

- (1) Openings are provided on at least two sides
- (2) Openings are located entirely above the adjoining grade level
- (3) Openings comprise a minimum of 1.9 m² (20 ft²) per 15 lineal m (50 lineal ft) of walls
- (4) X = minimum width of 560 mm (22 in.) of unobstructed opening
 Y = minimum height of 610 mm (24 in.) of unobstructed opening

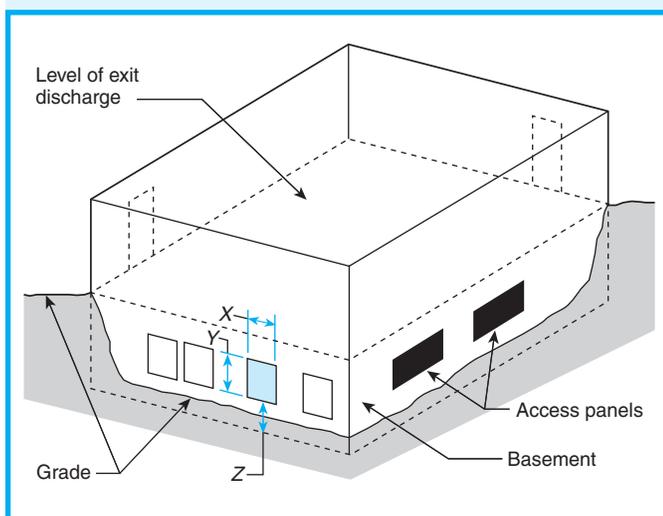

Exhibit 11.3 Emergency access openings.

- Z = maximum of 1120 mm (44 in.) from floor to bottom of opening
- (5) Openings are readily identifiable
 - (6) Openings are readily openable

As explained in A.11.7.2, access openings need not be readily opened from the exterior by the public. Rather, they need to be opened easily from the outside by the fire department, using equipment normally carried on fire apparatus. They should also be easily opened from the interior by building occupants.

Openings are permitted in the form of a window, a door, or an access panel.

Note that a structure is not considered to be a limited-access structure if certain provisions are made for emergency access openings for ventilation and rescue. The provisions are more stringent for multistory structures than for single-story structures.

11.7.3 Special Provisions for Underground and Limited Access Structures.

11.7.3.1 A structure or portion of a structure that does not have openings in compliance with 11.7.3.1(A) and 11.7.3.1(B) shall be designated as a limited access structure and shall comply with 11.7.3.4 and 11.7.3.5.

(A) Single-Story Structures. Single-story structures shall have grade level doors or emergency access openings in accordance with 11.7.3.2 on two sides of the building, spaced not more than 38 m (125 ft) apart on the exterior walls.

(B) Multiple-Story Structures. Multiple-story structures shall comply with the following:

- (1) The story at grade level shall comply with 11.7.3.1(A).
- (2) Other stories shall be provided with emergency access openings in accordance with 11.7.3.2 on two sides of the building, spaced not more than 9140 mm (360 in.) apart.

11.7.3.2 Emergency access openings shall consist of a window, panel, or similar opening that complies with all of the following:

- (1) The opening shall have dimensions of not less than 560 mm (22 in.) in width and 610 mm (24 in.) in height and shall be unobstructed to allow for ventilation and rescue operations from the exterior.
- (2) The bottom of the opening shall be not more than 1120 mm (44 in.) above the floor.
- (3) The opening shall be readily identifiable from both the exterior and interior.
- (4) The opening shall be readily openable from both the exterior and interior.

11.7.3.3 A structure or portion of a structure shall not be considered an underground structure if the story is provided, on not less than two sides, with not less than 1.9 m² (20 ft²) of emergency access opening located entirely above the adjoining grade level in each 15 lineal m (50 lineal ft) of exterior enclosing wall area.

11.7.3.4 Underground and limited access structures, and all areas and floor levels traversed in traveling to the exit discharge, shall be protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7, unless such structures meet one of the following criteria:

- (1) They have an occupant load of 50 or fewer persons in new underground or limited access portions of the structure.
- (2) They have an occupant load of 100 or fewer persons in existing underground or limited access portions of the structure.
- (3) The structure is a single-story underground or limited access structure that is permitted to have a single exit per Chapter 12 through Chapter 42, with a common path of travel not greater than 15 m (50 ft).

11.7.3.5 Underground or limited access portions of structures and all areas traversed in traveling to the exit discharge, other than in one- and two-family dwellings, shall be provided with emergency lighting in accordance with Section 7.9.

11.7.4 Additional Provisions for Underground Structures.

11.7.4.1 A structure or portion of a structure shall not be considered an underground structure if the story is provided, on not less than two sides, with not less than 1.9 m² (20 ft²) of emergency access opening located entirely above the adjoining grade level in each 15 lineal m (50 lineal ft) of exterior enclosing wall area.

11.7.4.2 The requirements of 11.7.3 shall apply.

11.7.4.3 Exits from underground structures with an occupant load of more than 100 persons in the underground portions of the structure and having a floor used for human occupancy located more than 9140 mm (360 in.) below the lowest level of exit discharge, or having more than one level located below the lowest level of exit discharge, shall meet the following criteria:

- (1) Exits shall be cut off from the level of exit discharge per 7.1.3.2.
- (2) Exits shall be provided with outside smoke-venting facilities or other means to prevent the exits from becoming charged with smoke from any fire in the areas served by the exits.

11.7.4.4 The underground portions of an underground structure, other than an existing underground structure, shall be provided with approved automatic smoke venting in accordance with Section 9.3 where the underground structure has the following features:

- (1) An occupant load of more than 100 persons in the underground portions of the structure
- (2) A floor level used for human occupancy located more than 9140 mm (360 in.) below the lowest level of exit discharge, or having more than one level located below the lowest level of exit discharge
- (3) Combustible contents, combustible interior finish, or combustible construction

11.7.4.5 Exit stair enclosures in underground structures having a floor level used for human occupancy located more than 9140 mm (360 in.) below the lowest level of exit discharge, or having more than one level located below the lowest level of exit discharge, shall be provided with signage in accordance with 7.2.2.5.4 at each floor level landing traversed in traveling to the exit discharge. The signs shall include a chevron-shaped indicator to show direction to the exit discharge.

The provisions contained in 11.7.1 through 11.7.4.5 that regulate life safety in underground and limited-access buildings are minimal. The intent of those provisions is to supplement, not to provide a means of circumventing, the life safety provisions contained in other chapters of the *Code*. If the building under consideration is a limited-access structure or located underground and—due to its occupancy classification—subject to stricter requirements than those contained in Section 11.7, the stricter provisions of the *Code* must be applied. For example, the provisions of 12.4.3—which apply to new assembly occupancies located in limited-access or underground buildings or portions thereof—require that each level more than 9140 mm (360 in.) below the level of exit discharge be equipped with a mechanical means of moving occupants vertically, such as an elevator or escalator. Section 11.7 has no such requirement.

Limited-access and underground structures pose special risks to life safety, because the buildings cannot be easily vented of products of combustion. In an area from which there is no direct access to the outside and where there are no windows to permit outside fire department rescue operations and ventilation, fire or smoke might cause occupants to panic. Therefore, additional corrective measures, such as complete automatic sprinkler protection and auto-

matic smoke-venting systems, must be provided where necessary to ensure an adequate level of life safety.

The provisions of 11.7.4.5 address the need for cues to guide occupants toward the exit and level of exit discharge. Traveling upward in an exit stair might appear illogical, because most egress from buildings involves downward travel within an exit stair enclosure. However, the direction of travel chosen by an occupant can depend on how the occupant entered the building. Paragraph 11.7.4.5 requires signs to be provided within the exit stair enclosure to direct occupants to the exit discharge. The directional indicator must be of the same chevron design as required by 7.10.6.2.

Section 11.8 High-Rise Buildings

Section 11.8 does not itself require that any special provisions be applied to high-rise buildings. Instead, it provides a menu of options for high-rise buildings that can be wholly or partially mandated by other *Code* sections. For example, Chapters 12, 14, 16, 17, 18, 28, 30, and 38 (which apply to new assembly occupancies, new educational occupancies, new and existing day-care occupancies, new health care occupancies, new hotels and dormitories, new apartment buildings, and new business occupancies, respectively) require high-rise buildings to comply with the entire package of requirements contained in Section 11.8. Chapter 22 (which applies to new detention and correctional occupancies) requires high-rise buildings to comply with the provisions of 11.8.2, which require sprinklers and standpipes. Chapters 15, 36, 40, and 42 (for existing educational occupancies, new mercantile occupancies, industrial occupancies, and storage occupancies, respectively) require that new high-rise buildings be sprinklered in accordance with 11.8.2.1.

Exhibit 11.4 illustrates the criteria under which a building is classified as high-rise as specified by the definition of *high-rise building* in 3.3.27.7. Measurement of the vertical distance criterion begins at ground level on the lowest side of the building that provides fire department vehicle access and ends at the floor of the highest occupiable story. If the vertical distance measurement made in this manner exceeds 23 m (75 ft), the building is considered to be high-rise.

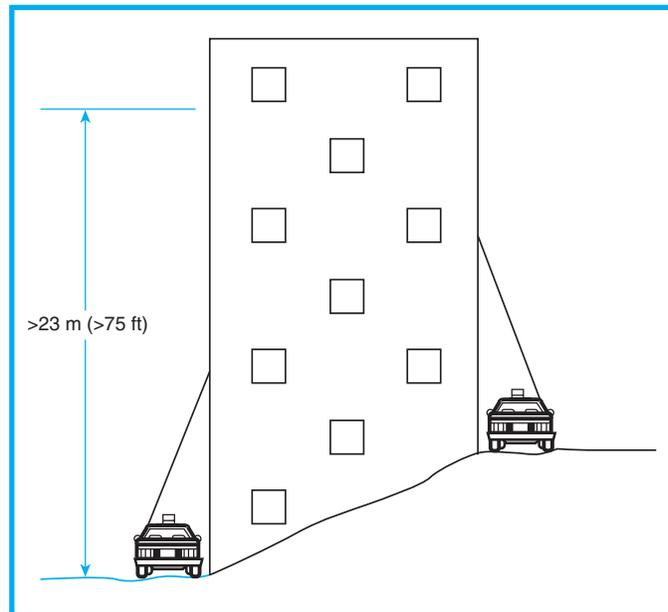

Exhibit 11.4 Determining if building is high-rise in accordance with the 23-m (75-ft) criterion.

The 23-m (75-ft) criterion used for defining a high-rise building was first added to the 1988 edition of the *Code*. Previously, individual occupancy chapters set their own criteria. Business and health care occupancies used provisions similar to the 23-m (75-ft) criterion, while residential occupancies used a six-story criterion. The current method establishes consistency for use throughout the *Code*. The current criteria have been accepted fairly well throughout the United States, but some local jurisdictions set a lower height at which high-rise building provisions apply. Although the definition does not include buildings less than 23 m (75 ft) in height, such buildings can experience the same challenges as true high-rise buildings, because they are set back over a larger one-story section out of reach of fire department ladders. Although the definition does not address the subject completely, it provides a generally acceptable method for determining whether a building is a high-rise building.

High-rise buildings pose several problems as follows:

- (1) Potential for wide distribution of smoke to all floors due to significant stack effect (that is, natural draft) within stair towers and other tall shafts
- (2) Difficulty in evacuation
- (3) Difficulty experienced by fire service personnel in reaching the fire

11.8.1 General.

11.8.1.1 Where required by Chapter 12 through Chapter 42, the provisions of Section 11.8 shall apply to high-rise buildings as defined in 3.3.27.7.

11.8.1.2 In addition to the requirements of Section 11.8, compliance with all other applicable provisions of this *Code* shall be required.

11.8.2 Extinguishing Requirements.

11.8.2.1* High-rise buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7. A sprinkler control valve and a waterflow device shall be provided for each floor.

A.11.8.2.1 Where an occupancy chapter (Chapter 12 through Chapter 42) permits the omission of sprinklers in specific spaces, such as small bathrooms and closets in residential occupancies, the building is still considered to be protected throughout for the purposes of 11.8.2.1.

11.8.2.2 High-rise buildings shall be protected throughout by a Class I standpipe system in accordance with Section 9.7.

Paragraph 11.8.2.2 expands the menu of provisions that can be mandated for high-rise buildings—in accordance with the various occupancy chapters—to include standpipes. Exhibit 11.5 illustrates an example of a typical standpipe.

Although the *Life Safety Code* has traditionally considered standpipes mainly as property protection devices, limited mandatory standpipe requirements for life safety purposes have been included for many editions of the *Code*. Standpipes are required on stages in assembly occupancies and in detention and correctional occupancies (see 12.4.5.12, 13.4.5.12, 22.3.5.5, and 23.3.5.5). These requirements are based on the following:

- (1) Occupants will not be able to leave the fire area immediately either due to the presence of large numbers of people, as is characteristic of an assembly occupancy, or because doors to the outside will not be unlocked, as might be expected in a detention and correctional occupancy.
- (2) Trained personnel will be present early in the fire development to make effective use of the standpipe and hose.

Standpipes in high-rise buildings can serve to increase life safety, as well as property protection, because of the lengthy evacuation times associated

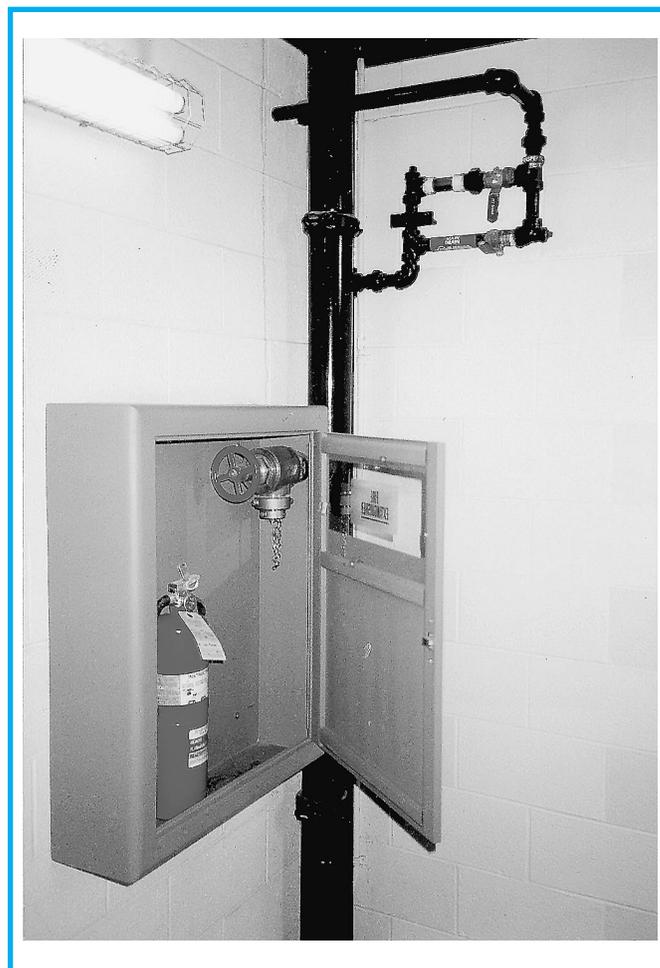

Exhibit 11.5 Typical combination sprinkler/standpipe system with a 64-mm (2½-in.) fire department valve.

with tall buildings. In many cases, fire emergency plans advise occupants who are not in immediate danger of exposure to fire to remain within the building to allow responding fire service personnel better access to the standpipes within the exit stair enclosures. Use of standpipes at that time supplements the operation of the required automatic sprinkler system.

11.8.3 Detection, Alarm, and Communications Systems.

11.8.3.1* A fire alarm system using an approved, emergency voice/alarm communication system shall be installed in accordance with Section 9.6.

A.11.8.3.1 The need for voice communication can be based on a decision regarding staged or partial evacuation versus total evacuation of all floors. The determination of need is a function of occupancy classification and building height.

11.8.3.2 Two-way telephone service shall be in accordance with 11.8.3.2(A) and 11.8.3.2(B):

(A) Two-way telephone communication service shall be provided for fire department use. This system shall be in accordance with *NFPA 72®*, *National Fire Alarm Code®*. The communications system shall operate between the central control station and every elevator car, every elevator lobby, and each floor level of exit stairs.

(B) The requirement of 11.8.3.2(A) shall not apply where the fire department radio system is approved as an equivalent system.

11.8.4 Emergency Lighting and Standby Power.

11.8.4.1 Emergency lighting in accordance with Section 7.9 shall be provided.

11.8.4.2 Requirements for standby power shall be as specified in 11.8.4.2(A) through 11.8.4.2(D).

(A)* Class I, Type 60, standby power in accordance with Article 701 of *NFPA 70*, *National Electrical Code®*, and *NFPA 110*, *Standard for Emergency and Standby Power Systems*, shall be provided.

A.11.8.4.2(A) The Class 1, Type 60, standby power required by 11.8.4.2(A) is established in accordance with the provisions of Table 2.2.2 and Table 2.2.3 of *NFPA 110*, *Standard for Emergency and Standby Power Systems*. The last class identification in Table 2.2.3 is for those emergency power systems that might have a different minimum running time requirement than those shown in the table. Therefore, it is the intent that the standby power required by 11.8.4.2(A) have an operation of not less than 1 hour running time before refueling is required.

(B) The standby power system shall have a capacity and rating sufficient to supply all equipment required to be connected by 11.8.4.2(D).

(C) Selective load pickup and load shedding shall be permitted in accordance with *NFPA 70*, *National Electrical Code®*.

(D) The standby power system shall be connected to the following:

- (1) Fire alarm system
- (2) Electric fire pump
- (3) Central control station equipment and lighting
- (4) Not less than one elevator serving all floors, with standby power transferable to any elevator
- (5) Mechanical equipment for smokeproof enclosures
- (6) Mechanical equipment required to conform with the requirements of Section 9.3

11.8.5* Central Control Station.

A central control station shall be provided in a location approved by the fire department. The control station shall contain the following:

- (1) Voice fire alarm system panels and controls
- (2) Fire department two-way telephone communication service panels and controls where required by another section of this *Code*
- (3) Fire detection and fire alarm system annunciation panels
- (4) Elevator floor location and operation annunciators
- (5) Sprinkler valve and waterflow annunciators
- (6) Emergency generator status indicators
- (7) Controls for any automatic stairway door unlocking system
- (8) Fire pump status indicators
- (9) A telephone for fire department use with controlled access to the public telephone system

A.11.8.5 It is not the intent of the paragraph to require any of the equipment in the list, other than the telephone for fire department use, but only to provide the controls, panels, annunciators, and similar equipment at this location if the equipment is provided or required by another section of the *Code*.

Section 11.9 Permanent Membrane Structures

The material in Section 11.9 was transferred into the *Code* from *NFPA 102*, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*, so that all the provisions for life safety needed for a permanent membrane structure reside in this *Code*. Other material from *NFPA 102* that is specific to assembly seating was moved to the assembly occupancy chapters—Chapters 12 and 13. The provisions applicable to permanent membrane structures are included in Chapter 11 because they can apply to any occupancy.

11.9.1 Application.

11.9.1.1 General. The provisions of Section 11.1 shall apply.

11.9.1.2 Use of Membrane Roofs. Membrane roofs shall be used in accordance with the following:

- (1) Membrane materials shall not be used where fire resistance ratings are required for walls or roofs.

- (2) Where every part of the roof, including the roof membrane, is not less than 6100 mm (240 in.) above any floor, balcony, or gallery, a noncombustible or limited-combustible membrane shall be permitted to be used as the roof in any type of construction.
- (3) With approval of the authority having jurisdiction, membrane materials shall be permitted to be used where every part of the roof membrane is sufficiently above every significant fire potential such that the imposed temperature cannot exceed the capability of the membrane, including seams, to maintain its structural integrity.

11.9.1.3 Testing. Testing of membrane materials for compliance with the requirements of Section 11.9 for use of the categories of noncombustible and limited-combustible materials shall be performed on weathered-membrane material as defined in 3.3.

11.9.1.4 Flame Spread Classification. Flame spread of all membrane materials exposed within the structure shall be Class A in accordance with Section 10.2.

11.9.1.5 Roof Covering Classification. Roof membranes shall have a roof covering classification, as required by the applicable building codes, when tested in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.

11.9.1.6 Flame Resistance.

11.9.1.6.1 All membrane structure fabric shall be flame resistant in accordance with 10.3.1.

11.9.1.6.2 One of the following shall serve as evidence that the fabric materials have the required flame resistance:

- (1) The authority having jurisdiction shall require a certificate or other evidence of acceptance by an organization acceptable to the authority having jurisdiction.
- (2) The authority having jurisdiction shall require a report of tests made by other inspection authorities or organizations acceptable to the authority having jurisdiction.

11.9.1.6.3 Where required by the authority having jurisdiction, confirmatory field tests shall be conducted using test specimens from the original material, which shall have been affixed at the time of manufacture to the exterior of the structure.

11.9.2 Tensioned-Membrane Structures.

11.9.2.1 The design, materials, and construction of the building shall be based on plans and specifications prepared

by a licensed architect or engineer knowledgeable in tensioned-membrane construction.

11.9.2.2 Material loads and strength shall be based on physical properties of the materials verified and certified by an approved testing laboratory.

11.9.2.3 The membrane roof for structures in climates subject to freezing temperatures and ice buildup shall be composed of two layers separated by an air space through which heated air can be moved to guard against ice accumulation. As an alternative to the two layers, other approved methods that protect against ice accumulation shall be permitted.

11.9.2.4 Roof drains shall be equipped with electrical elements to protect against ice buildup that can prevent the drains from functioning. Such heating elements shall be served by on-site standby electrical power in addition to the normal public service. As an alternative to such electrical elements, other approved methods that protect against ice accumulation shall be permitted.

11.9.3 Air-Supported and Air-Inflated Structures.

11.9.3.1 General. In addition to the general provisions of 11.9.1, the requirements of 11.9.3 shall apply to air-supported and air-inflated structures.

11.9.3.2 Pressurization (Inflation) System. The pressurization system shall consist of one or more operating blower units. The system shall include automatic control of auxiliary blower units to maintain the required operating pressure. Such equipment shall meet the following requirements:

- (1) Blowers shall be powered by continuous-rated motors at the maximum power required.
- (2) Blowers shall have personnel protection, such as inlet screens and belt guards.
- (3) Blower systems shall be weather protected.
- (4) Blower systems shall be equipped with backdraft check dampers.
- (5) Not less than two blower units shall be provided, each of which has capacity to maintain full inflation pressure with normal leakage.
- (6) The blowers shall be designed to be incapable of over-pressurization.
- (7) The auxiliary blower unit(s) shall operate automatically if there is any loss of internal pressure or if an operating blower unit becomes inoperative.
- (8) The design inflation pressure and the capacity of each blower system shall be certified by a professional engineer.

11.9.3.3 Standby Power System.

11.9.3.3.1* A fully automatic standby power system shall be provided. The system shall be either an auxiliary engine generator set capable of running the blower system or a supplementary blower unit that is sized for 1 times the normal operating capacity and is powered by an internal combustion engine.

A.11.9.3.3.1 The requirements of this paragraph can be considered as a Class 4, Type 60 system per NFPA 110, *Standard for Emergency and Standby Power Systems*.

11.9.3.3.2 The standby power system shall be fully automatic to ensure continuous inflation in the event of any failure of the primary power. The system shall be capable of operating continuously for a minimum of 4 hours.

11.9.3.3.3 The sizing and capacity of the standby power system shall be certified by a professional engineer.

11.9.4 Maintenance and Operation.

11.9.4.1 Instructions in both operation and maintenance shall be transmitted to the owner by the manufacturer of the tensioned-membrane, air-supported, or air-inflated structure.

11.9.4.2 Annual inspection and required maintenance of each structure shall be performed to ensure safety conditions. At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer.

11.9.5 Services.

11.9.5.1 Fired Heaters.

11.9.5.1.1 Only labeled heating devices shall be used.

11.9.5.1.2 Fuel-fired heaters and their installation shall be approved by the authority having jurisdiction.

11.9.5.1.3 Containers for liquefied petroleum gases shall be installed not less than 1525 mm (60 in.) from any temporary membrane structure and shall be in accordance with the provisions of NFPA 58, *Liquefied Petroleum Gas Code*.

11.9.5.1.4 Tanks shall be secured in the upright position and protected from vehicular traffic.

11.9.5.2 Electric Heaters.

11.9.5.2.1 Only labeled heaters shall be permitted.

11.9.5.2.2 Heaters shall be connected to electricity by electric cable that is suitable for outside use and is of sufficient size to handle the electrical load.

Section 11.10 Temporary Membrane Structures

The material in Section 11.10 was transferred into the Code from NFPA 102, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*, so that all the provisions for life safety needed for a temporary membrane structure reside in this Code. Other material from NFPA 102 that is specific to assembly seating was moved to the assembly occupancy chapters—Chapters 12 and 13. The provisions applicable to temporary membrane structures are included in Chapter 11 because they can apply to any occupancy.

11.10.1 Application.

11.10.1.1 General. The provisions of Section 11.1 shall apply.

11.10.1.2 Required Approval. Membrane structures designed to meet all the requirements of Section 11.10 shall be permitted to be used as temporary buildings subject to the approval of the authority having jurisdiction.

11.10.1.3 Alternative Requirements. Temporary tensioned-membrane structures shall be permitted to comply with Section 11.11 instead of Section 11.10.

11.10.1.4 Roof Covering Classification. Roof membranes shall have a roof covering classification, as required by the applicable building codes, when tested in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.

11.10.1.5 Flame Resistance.

11.10.1.5.1 All membrane structure fabric shall be flame resistant in accordance with 10.3.1.

11.10.1.5.2 One of the following shall serve as evidence that the fabric materials have the required flame resistance:

- (1) The authority having jurisdiction shall require a certificate or other evidence of acceptance by an organization acceptable to the authority having jurisdiction.
- (2) The authority having jurisdiction shall require a report of tests made by other inspection authorities or organizations acceptable to the authority having jurisdiction.

11.10.1.5.3 Where required by the authority having jurisdiction, confirmatory field tests shall be conducted using test specimens from the original material, which shall have been affixed at the time of manufacture to the exterior of the structure.

11.10.2 Fire Hazards.

11.10.2.1 The ground enclosed by any temporary membrane structure, and the ground for a reasonable distance but for not less than 3050 mm (120 in.) outside of such a structure, shall be cleared of all flammable or combustible material or vegetation that is not used for necessary support equipment. The clearing work shall be accomplished to the satisfaction of the authority having jurisdiction prior to the erection of such a structure. The premises shall be kept free from such flammable or combustible materials during the period for which the premises are used by the public.

11.10.2.2 Where prohibited by the authority having jurisdiction, smoking shall not be permitted in any temporary membrane structure.

11.10.3 Fire-Extinguishing Equipment.

Portable fire-extinguishing equipment of approved types shall be furnished and maintained in temporary membrane structures in such quantity and in such locations as directed by the authority having jurisdiction.

11.10.4 Tensioned-Membrane Structures.

11.10.4.1 The design, materials, and construction of the building shall be based on plans and specifications prepared by a licensed architect or engineer knowledgeable in tensioned-membrane construction.

11.10.4.2 Material loads and strength shall be based on physical properties of the materials verified and certified by an approved testing laboratory.

11.10.4.3 The membrane roof for structures in climates subject to freezing temperatures and ice buildup shall be composed of two layers separated by an air space through which heated air can be moved to guard against ice accumulation. As an alternative to the two layers, other approved methods that protect against ice accumulation shall be permitted.

11.10.4.4 Roof drains shall be equipped with electrical elements to protect against ice buildup that can prevent the drains from functioning. Such heating elements shall be served by on-site standby electrical power in addition to the normal public service. As an alternative to such electrical elements, other approved methods that protect against ice accumulation shall be permitted.

11.10.5 Air-Supported and Air-Inflated Structures.

11.10.5.1 General. In addition to the general provisions of 11.10.1, the requirements of 11.10.5 shall apply to air-supported and air-inflated structures.

11.10.5.2 Pressurization (Inflation) System. The pressurization system shall consist of one or more operating blower units. The system shall include automatic control of auxiliary blower units to maintain the required operating pressure. Such equipment shall meet the following requirements:

- (1) Blowers shall be powered by continuous-rated motors at the maximum power required.
- (2) Blowers shall have personnel protection, such as inlet screens and belt guards.
- (3) Blower systems shall be weather protected.
- (4) Blower systems shall be equipped with backdraft check dampers.
- (5) Not less than two blower units shall be provided, each of which has capacity to maintain full inflation pressure with normal leakage.
- (6) The blowers shall be designed to be incapable of over-pressurization.
- (7) The auxiliary blower unit(s) shall operate automatically if there is any loss of internal pressure or if an operating blower unit becomes inoperative.
- (8) The design inflation pressure and the capacity of each blower system shall be certified by a professional engineer.

11.10.5.3 Standby Power System.

11.10.5.3.1 A fully automatic standby power system shall be provided. The system shall be either an auxiliary engine generator set capable of running the blower system or a supplementary blower unit that is sized for 1 times the normal operating capacity and is powered by an internal combustion engine.

11.10.5.3.2 The standby power system shall be fully automatic to ensure continuous inflation in the event of any failure of the primary power. The system shall be capable of operating continuously for a minimum of 4 hours.

11.10.5.3.3 The sizing and capacity of the standby power system shall be certified by a professional engineer.

11.10.6 Maintenance and Operation.

11.10.6.1 Instructions in both operation and maintenance shall be transmitted to the owner by the manufacturer of the tensioned-membrane, air-supported, or air-inflated structure.

11.10.6.2 Annual inspection and required maintenance of each structure shall be performed to ensure safety conditions. At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer.

11.10.7 Services.

11.10.7.1 Fired Heaters.

11.10.7.1.1 Only labeled heating devices shall be used.

11.10.7.1.2 Fuel-fired heaters and their installation shall be approved by the authority having jurisdiction.

11.10.7.1.3 Containers for liquefied petroleum gases shall be installed not less than 1525 mm (60 in.) from any temporary membrane structure and shall be in accordance with the provisions of NFPA 58, *Liquefied Petroleum Gas Code*.

11.10.7.1.4 Tanks shall be secured in the upright position and protected from vehicular traffic.

11.10.7.2 Electric Heaters.

11.10.7.2.1 Only labeled heaters shall be permitted.

11.10.7.2.2 Heaters used inside a temporary membrane structure shall be approved.

11.10.7.2.3 Heaters shall be connected to electricity by electric cable that is suitable for outside use and is of sufficient size to handle the electrical load.

Section 11.11 Tents

The material in Section 11.11 was transferred into the Code from NFPA 102, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*, so that all the provisions for life safety needed for a tent reside in this Code. Other material from NFPA 102 that is specific to assembly seating was moved to the assembly occupancy chapters—Chapters 12 and 13. The provisions applicable to tents are included in Chapter 11 because they can apply to any occupancy.

11.11.1 General.

11.11.1.1 The provisions of Section 11.1 shall apply.

11.11.1.2 Tents shall be permitted only on a temporary basis.

11.11.1.3 Tents shall be erected to cover not more than 75 percent of the premises, unless otherwise approved by the authority having jurisdiction.

11.11.2 Flame Resistance.

11.11.2.1 All tent fabric shall be flame resistant in accordance with 10.3.1.

11.11.2.2 One of the following shall serve as evidence that the tent fabric materials have the required flame resistance:

- (1) The authority having jurisdiction shall require a certificate or other evidence of acceptance by an organization acceptable to the authority having jurisdiction.

- (2) The authority having jurisdiction shall require a report of tests made by other inspection authorities or organizations acceptable to the authority having jurisdiction.

11.11.2.3 Where required by the authority having jurisdiction, confirmatory field tests shall be conducted using test specimens from the original material, which shall have been affixed at the time of manufacture to the exterior of the tent.

11.11.3 Location and Spacing.

11.11.3.1 There shall be a minimum of 3050 mm (120 in.) between stake lines.

11.11.3.2 Adjacent tents shall be spaced to provide an area to be used as a means of emergency egress. Where 3050 mm (120 in.) between stake lines does not meet the requirements for means of egress, the distance necessary for means of egress shall govern.

11.11.3.3 Tents not occupied by the public and not used for the storage of combustible material shall be permitted to be erected less than 3050 mm (120 in.) from other structures where the authority having jurisdiction deems such close spacing to be safe from hazard to the public.

11.11.3.4 Tents, each not exceeding 112 m² (1200 ft²) in ground area and located in fairgrounds or similar open spaces, shall not be required to be separated from each other, provided that safety precautions meet the approval of the authority having jurisdiction.

11.11.3.5 The placement of tents relative to other structures shall be at the discretion of the authority having jurisdiction, with consideration given to occupancy, use, opening, exposure, and other similar factors.

11.11.4 Fire Hazards.

11.11.4.1 The ground enclosed by any tent, and the ground for a reasonable distance but for not less than 3050 mm (120 in.) outside of such a tent, shall be cleared of all flammable or combustible material or vegetation that is not used for necessary support equipment. The clearing work shall be accomplished to the satisfaction of the authority having jurisdiction prior to the erection of such a tent. The premises shall be kept free from such flammable or combustible materials during the period for which the premises are used by the public.

11.11.4.2 Where prohibited by the authority having jurisdiction, smoking shall not be permitted in any tent.

11.11.5 Fire-Extinguishing Equipment.

Portable fire-extinguishing equipment of approved types shall be furnished and maintained in tents in such quantity

and in such locations as directed by the authority having jurisdiction.

11.11.6 Services.

11.11.6.1 Fired Heaters.

11.11.6.1.1 Only labeled heating devices shall be used.

11.11.6.1.2 Fuel-fired heaters and their installation shall be approved by the authority having jurisdiction.

11.11.6.1.3 Containers for liquefied petroleum gases shall be installed not less than 1525 mm (60 in.) from any tent and shall be in accordance with the provisions of NFPA 58, *Liquefied Petroleum Gas Code*.

11.11.6.1.4 Tanks shall be secured in the upright position and protected from vehicular traffic.

11.11.6.2 Electric Heaters.

11.11.6.2.1 Only labeled heaters shall be permitted.

11.11.6.2.2 Heaters used inside a tent shall be approved.

11.11.6.2.3 Heaters shall be connected to electricity by electric cable that is suitable for outside use and is of sufficient size to handle the electrical load.

CHAPTERS 12 and 13

New and Existing Assembly Occupancies

Chapters 12 and 13 are the first of the numerous occupancy chapters that address a specific building use. The occupancy chapters of the *Code* work together with the core chapters to implement the basic and fundamental requirements of the core chapters as appropriate to a specific use. The requirements for assembly occupancies are based on protecting concentrations of occupants in a building or area.

The occupant load factors for assembly uses (see Table 7.3.1.2) accurately reflect the large numbers of occupants in a given area that are characteristic of such use. Large numbers of occupants present unique challenges, such as arranging and designing the egress facilities to move the occupants efficiently and quickly. In addition, there are issues that must be balanced, such as sloping the floor to achieve line-of-sight for audience spectators (for example, in theater performances, sporting events, or concerts) without creating aisle stairs that are too steep to use effectively.

The level of life safety mandated by Chapters 12 and 13 addresses many conditions that are often taken for granted by the public. The exit access from occupant seating areas to aisles in a movie theater, for example, is regulated by these chapters, as is the arrangement of tables and chairs in a restaurant (see 12/13.2.5.7). This is done to provide a reasonable egress path if a fire occurs.

Sections 12/13.4 address special provisions and contain a series of specific and unique rules for assembly occupancies. The concept of smoke-protected assembly seating (see 12/13.4.2) is intended to provide a realistic egress capacity for an assembly occupancy that performs under fire conditions as if it were outdoors. This concept departs somewhat from the prescriptive rules usually imposed on an occupancy.

The use of smoke-protected assembly seating, however, requires a life safety evaluation that addresses many aspects associated with the potential threat to the large number of occupants.

Other special subjects addressed in Sections 12/13.4 include stages and platforms (12/13.4.5), projection rooms (12/13.4.6), special amusement buildings (12/13.4.7), grandstands (12/13.4.8), folding and telescopic seating (12/13.4.9), and airport loading walkways (12/13.4.10).

Assembly occupancies include, but are not limited to, buildings or portions of buildings used for gatherings of 50 or more people for such purposes as deliberation, worship, entertainment, eating, drinking, amusement, or awaiting transportation. Assembly occupancies also include special amusement buildings (such as a fun house amusement structure) regardless of occupant load (see 12/13.4.7). Examples of assembly occupancies include the following if they have an occupant load of at least 50 persons:

- (1) Armories
- (2) Assembly halls
- (3) Auditoriums
- (4) Bowling establishments
- (5) Churches
- (6) Club rooms
- (7) Conference rooms
- (8) Courtrooms
- (9) Dance halls
- (10) Discotheques
- (11) Drinking establishments
- (12) Exposition halls
- (13) Gymnasiums
- (14) Libraries
- (15) Mortuary chapels

CHAPTER 12 • New

- (16) Motion picture theaters
- (17) Multilevel play structures (regardless of occupant load)
- (18) Museums
- (19) Nightclubs
- (20) Pool rooms
- (21) Recreation piers
- (22) Restaurants
- (23) Skating rinks
- (24) Theaters

Passenger stations and terminals of air, surface, underground, and marine public transportation facilities are also considered assembly occupancies. If the jurisdiction enforcing the *Code* has adopted NFPA 130, *Standard for Fixed Guideway Transit and Passenger Rail Systems*, requirements for transit stations might fall under NFPA 130 rather than this *Code*. See NFPA 130 for additional details.

CHAPTER 13 • Existing

Also note that 14/15.1.1.2(3) requires classrooms having a capacity of 50 or more persons to comply with the requirements of the assembly occupancy chapters.

Assembly occupancies with an occupant load of fewer than 50 persons (except for special amusement buildings) are considered incidental to the predominant occupancy in which they are located. For example, a small conference room in an office area is considered part of the overall business occupancy. A freestanding small diner with an occupant load of fewer than 50 persons is normally assigned a mercantile occupancy classification. Regardless of occupancy classification, the occupant load for areas of assembly use should be calculated based on the use of the space, not the occupancy classification, using the occupant load factors of Table 7.3.1.2.

Section 12.1 General Requirements

12.1.1 Application.

The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as an assembly occupancy (*see 1.3.1*)
- (2) Additions made to, or used as, an assembly occupancy (*see 4.6.7*)
- (3) Alterations, modernizations, or renovations of existing assembly occupancies (*see 4.6.8*)
- (4) Existing buildings or portions thereof upon change of occupancy to an assembly occupancy (*see 4.6.12*)

13.1 General Requirements.

13.1.1 Application.

13.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as assembly occupancies, unless otherwise specified by 13.1.1.2. (*See 3.3.152.2 for definition of assembly occupancy; see also 12.1.1.*)

13.1.1.2 An existing building housing an assembly occupancy established prior to the effective date of this *Code* shall be permitted to be approved for continued use if it conforms to or is made to conform to the provisions of this *Code* to the extent that, in the opinion of the authority having jurisdiction, reasonable life safety against the hazards of fire, explosion, and panic is provided and maintained.

13.1.1.3 Additions to existing buildings shall conform to the requirements for new construction.

13.1.1.4 Existing portions of buildings shall be upgraded if the addition results in an increase in the required minimum number of separate means of egress in accordance with 7.4.1.2.

13.1.1.5 Existing portions of the structure shall not be required to be modified, provided that both of the following are met:

- (1) The new construction has not diminished the fire safety features of the facility.

CHAPTER 12 • New

CHAPTER 13 • Existing

The provisions for new assembly occupancies are addressed in Chapter 12; the provisions for existing assembly occupancies are addressed in Chapter 13.

If some part of an existing building of another occupancy type is reclassified as an assembly occupancy, that portion of the building housing the assembly occupancy must comply with Chapter 12 for new assembly occupancies, even though it is located in an existing building (see 4.6.10).

Paragraph 13.1.1.3 mandates that additions to existing assembly occupancies meet the requirements for new construction (see 4.6.7). Per 13.1.1.4, if construction of an addition causes the occupant load to increase to the point that 7.4.1.2 would require an increase in the required minimum number of separate means of egress, the existing portion of the building must be modified to meet the requirements for new construction.

12.1.2 Multiple Occupancies.

12.1.2.1 General. Multiple occupancies shall be in accordance with 6.1.14.

12.1.2.2* Simultaneous Occupancy. Exits shall be sufficient for simultaneous occupancy of both the assembly occupancy and other parts of the building, except where the authority having jurisdiction determines that the conditions are such that simultaneous occupancy will not occur.

A.12.1.2.2 Example. An assembly room for the residents of a detention occupancy will not normally be subject to simultaneous occupancy.

The provision of 12/13.1.2.2 that exempts exits from the simultaneous occupancy requirement should be used judiciously, with all possible uses being considered before it is judged whether simultaneous occupancy will occur. For example, a school gymnasium might normally be used only by the school occupants;

- (2) The addition does not result in an increase in the required minimum number of separate means of egress in accordance with 7.4.1.2.

13.1.1.6 An assembly occupancy in which an occupant load increase results in an increase in the required minimum number of separate means of egress, in accordance with 7.4.1.2, shall meet the requirements for new construction.

The provisions of 13.1.1.6 are similar to those of 13.1.1.4 in that, if the occupant load increases so that an increase in the required minimum number of separate means of egress is mandated by 7.4.1.2, the existing building must be modified to comply with the requirements of Chapter 12 for new assembly occupancies. Paragraph 13.1.1.4 addresses such changes occurring as a result of an addition; 13.1.1.6 encompasses such situations as renovation of an existing building or a higher occupant load being granted by the authority having jurisdiction under the provisions of 7.3.1.3. (For example, large dining tables might be replaced by small cocktail tables, permitting a larger occupant load even though the building size has not increased.)

13.1.2 Multiple Occupancies.

13.1.2.1 General. Multiple occupancies shall be in accordance with 6.1.14.

13.1.2.2* Simultaneous Occupancy. Exits shall be sufficient for simultaneous occupancy of both the assembly occupancy and other parts of the building, except where the authority having jurisdiction determines that the conditions are such that simultaneous occupancy will not occur.

A.13.1.2.2 Example. An assembly room for the residents of a detention occupancy will not normally be subject to simultaneous occupancy.

however, it might be used by an outside group during school hours, such as occurs when school gymnasiums function as polling locations on Election Day. See Exhibit 12/13.1. A means of egress system sized to accommodate simultaneous occupancy provides maximum flexibility in the use of the building.

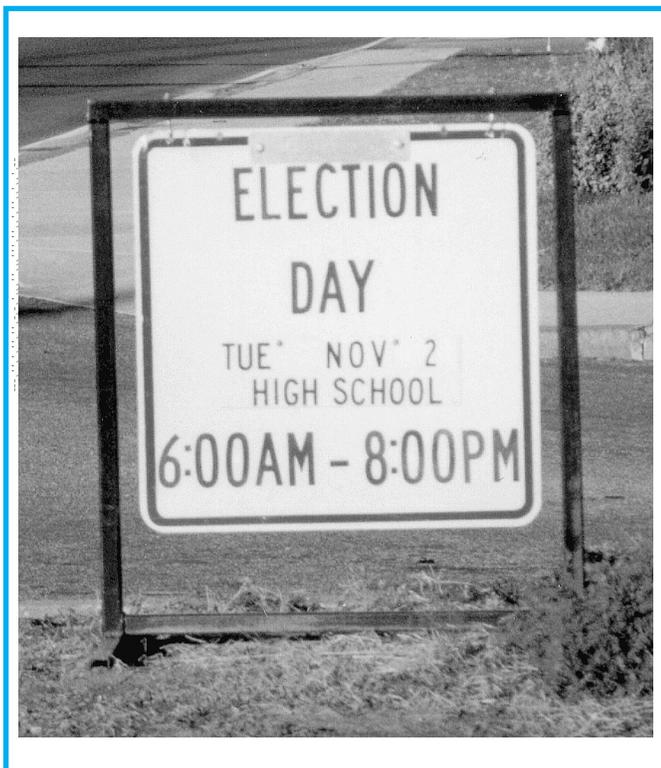

Exhibit 12/13.1 Use of school building for simultaneous mixed occupancy purposes.

12.1.2.3 Assembly and Mercantile Occupancies in Mall Buildings.

12.1.2.3.1 The provisions of Chapter 12 shall apply to the assembly occupancy tenant space.

12.1.2.3.2 The provisions of 36.4.4 shall be permitted to be used outside the assembly occupancy tenant space.

Subsection 12/13.1.2.3 addresses the common situation in which mall buildings include assembly occupancies in addition to mercantile and other occupancies. The assembly occupancies are required to comply with the requirements of Chapters 12 and 13 up to the point in the egress system at which the occupants reach the mall. The remainder of the egress path—which passes through the mall and exit discharge to the public way—is addressed in the mercantile occupancy chapters in the specialized mall building provisions of 36/37.4.4. Subsection 36/37.4.4

13.1.2.3 Assembly and Mercantile Occupancies in Mall Buildings.

13.1.2.3.1 The provisions of Chapter 13 shall apply to the assembly occupancy tenant space.

13.1.2.3.2 The provisions of 37.4.4 shall be permitted to be used outside the assembly occupancy tenant space.

requires that egress from the mall be sufficient for an occupant load based on the gross leasable area of the overall mall building, not a calculation directly related to the area of only the mall (that is, the covered pedestrian way that connects the various stores and assembly areas). Although this calculation method does not take into consideration the actual number of persons sent into the mall from the assembly occupancy, it is reliable. The concept is addressed in the commentary following 36/37.4.4.8(4).

CHAPTER 12 • New

12.1.3* Definitions.

A list of terms used in this chapter follows:

- (1) **Aisle Accessway.** See 3.3.8.
- (2) **Exhibit.** See 3.3.58.
- (3) **Exhibitor.** See 3.3.59.
- (4) **Exposition.** See 3.3.65.
- (5) **Exposition Facility.** See 3.3.69.1.
- (6) **Festival Seating.** See 3.3.188.1.
- (7) **Flow Time.** See 3.3.88.
- (8) **Fly Gallery.** See 3.3.89.
- (9) **Gridiron.** See 3.3.96.
- (10) **Legitimate Stage.** See 3.3.210.1.
- (11) **Life Safety Evaluation.** See 3.3.126.
- (12) **Multilevel Play Structure.** See 3.3.217.5.
- (13) **Multipurpose Assembly Occupancy.** See 3.3.152.2.1.
- (14) **Pinrail.** See 3.3.165.
- (15) **Platform.** See 3.3.166.
- (16) **Proscenium Wall.** See 3.3.229.2.
- (17) **Regular Stage.** See 3.3.210.2.
- (18) **Smoke-Protected Assembly Seating.** See 3.3.188.4.
- (19) **Special Amusement Building.** See 3.3.27.10.
- (20) **Stage.** See 3.3.210.
- (21) **Temporary Platform.** See 3.3.166.1.

A.12.1.3 An understanding of the term *accessory room* might be useful to the enforcer of the *Code*, although the term is not used within the *Code*. An accessory room includes a dressing room, the property master's work and storage rooms, the carpenter's room, or similar rooms necessary for legitimate stage operations.

The terms in 12/13.1.3 have special meanings with respect to assembly occupancies. The commentary that follows addresses some of the terms. For definitions of all these terms, see Chapter 3.

The term *aisle accessway* is that part of the exit access (typically the row space occupied by one's legs and feet) located between where an occupant sits and an aisle. See 12/13.2.5.5 and 12/13.2.5.7.

The definitions of the terms *exhibit*, *exhibitor*, *exposition*, and *exposition facility* relate to the provisions in 12/13.7.4. The terms are consistent with terms used by the exposition industry.

Festival seating is addressed in 12/13.2.5.4.1.

The term *flow time* is used in the technical literature on egress and is important to understand in relation to the *Code's* requirements for the capacity of means of egress. Flow time is the time taken by a crowd to pass, for example, through a doorway during

CHAPTER 13 • Existing

13.1.3* Definitions.

A list of terms used in the chapter follows:

- (1) **Aisle Accessway.** See 3.3.8.
- (2) **Exhibit.** See 3.3.58.
- (3) **Exhibitor.** See 3.3.59.
- (4) **Exposition.** See 3.3.65.
- (5) **Exposition Facility.** See 3.3.69.1.
- (6) **Festival Seating.** See 3.3.188.1.
- (7) **Flow Time.** See 3.3.88.
- (8) **Fly Gallery.** See 3.3.89.
- (9) **Gridiron.** See 3.3.96.
- (10) **Legitimate Stage.** See 3.3.210.1.
- (11) **Life Safety Evaluation.** See 3.3.126.
- (12) **Multilevel Play Structure.** See 3.3.217.5.
- (13) **Pinrail.** See 3.3.165.
- (14) **Platform.** See 3.3.166.
- (15) **Proscenium Wall.** See 3.3.229.2.
- (16) **Regular Stage.** See 3.3.210.2.
- (17) **Smoke-Protected Assembly Seating.** See 3.3.188.4.
- (18) **Special Amusement Building.** See 3.3.27.10.
- (19) **Stage.** See 3.3.210.
- (20) **Temporary Platform.** See 3.3.166.1.

A.13.1.3 An understanding of the term *accessory room* might be useful to the enforcer of the *Code*, although the term is not used within the *Code*. An accessory room includes a dressing room, the property master's work and storage rooms, the carpenter's room, or similar rooms necessary for legitimate stage operations.

group egress. Flow time contributes to the total time needed to evacuate an area after an emergency is detected and an alarm is sounded. In the case of large assembly buildings, flow time is often the largest component of total evacuation time, which also includes the time taken to respond to an alarm before egress begins and to travel the length of an egress route. Although Chapters 12 and 13 of the *Code* do not specifically require flow time be used, the term is provided to help improve understanding of the nominal performance expected in complying with particular egress capacity requirements.

The term *life safety evaluation* is used in 12/13.1.7.3, 12/13.2.5.4.1(2), 12/13.4.1, and 12/13.4.2.2. See A.12/13.4.1.1 and A.12/13.4.1.3 in particular. A life safety evaluation addresses more than fire safety. A life safety evaluation considers all life safety hazards that could endanger occupants and require rapid egress

CHAPTER 12 • New

or other measures to maintain occupant safety. For example, fire might not be the most likely hazard in some large assembly facilities. Injuries and deaths might result from the actions of a large number of people occupying a limited space during normal occupancy conditions, such as when spectators become especially enthusiastic during an event. A sudden change in weather at an outdoor facility or a partial structural collapse might cause occupants to attempt to escape an area. Such situations must be taken into account during a life safety evaluation. In some cases, special expertise will be required to assess, design, or manage social and behavioral factors, in addition to fire and structural safety considerations. In general, the life safety evaluation requires a comprehensive understanding of occupant characteristics, especially if densely crowded conditions exist.

Multilevel play structures have become commonplace. Some are entities unto themselves and draw patrons strictly because of the amusement offered. Others are operated in conjunction with some other business, such as the play structures attached to fast food restaurants. Multilevel play structures are considered special amusement buildings. Special amusement buildings are assembly occupancies, regardless of occupant load. See 6.1.2.1 and 12/13.4.7.

The term *multipurpose assembly occupancy* is synonymous with the term *multipurpose room* as used in 12.3.5.2(2). Multipurpose rooms are often part of a school, office building, fellowship hall, or other occupancy.

The definition of the term *special amusement building*, which has application in the provisions of 12/

CHAPTER 13 • Existing

13.4.7, addresses both the structure of such buildings and their use. The structure might be a permanent building or a semi-trailer truck or other similar enclosure that is semipermanent or mobile. Special amusement buildings are designed to provide a full enclosure for patrons. Structures that are not fully enclosed (for example, a merry-go-round with a roof and no side walls) are not included in the definition. The definition also includes special amusement buildings within larger structures, such as an amusement building within a shopping mall. Theaters, movie houses, or similar public assembly occupancies used for amusement or entertainment are not defined as special amusement buildings.

The terms *stage* and *platform* are defined so as to differentiate between the two. The definition of stage should be examined in conjunction with the definition of platform. The critical features in defining a stage are hanging curtains, leg drops, and scenery. An arrangement without these features is most likely a platform. The intent is to include nontheatrical stages, such as those in many grade schools, under the definition of platform. However, many school stages are actually regular stages because they use scenery. Hanging curtains commonly used on platforms are normally used to conceal lighting or to provide a more aesthetic appearance. A potential problem is the arrangement commonly known as theater-in-the-round. For Code-application purposes, if a theater-in-the-round uses scenery, leg drops, or curtains suspended on or above it, it is considered a stage; if it uses only lighting with a valance to hide the electrical fixtures, it is a platform.

12.1.4* Classification of Occupancy.

See 6.1.2.

A.12.1.4 Assembly occupancy requirements should be determined on a room-by-room basis, a floor-by-floor basis, and a total building basis. The requirements for each room should be based on the occupant load of that room and the requirements for each floor should be based on the occupant load of that floor, but the requirements for the assembly building overall should be based on the total occupant load. Therefore, it is quite feasible to have several assembly occupancies with occupant loads of 300 or less grouped together in a single building. Such a building would be an assembly occupancy with an occupant load of over 1000.

13.1.4* Classification of Occupancy.

See 6.1.2.

A.13.1.4 Assembly occupancy requirements should be determined on a room-by-room basis, a floor-by-floor basis, and a total building basis. The requirements for each room should be based on the occupant load of that room and the requirements for each floor should be based on the occupant load of that floor, but the requirements for the assembly building overall should be based on the total occupant load. Therefore, it is quite feasible to have several assembly occupancies with occupant loads of 300 or less grouped together in a single building. Such a building would be an assembly occupancy with an occupant load of over 1000.

CHAPTER 12 • New

The 1994 edition of the *Code* was the last to subclassify assembly occupancies as Class A, Class B, or Class C. The subclassification scheme was based on the number of occupants and permitted requirements to be written for application to one or more of the subclasses. In subsequent editions of the *Code*, different requirements apply to different assembly

12.1.5 Classification of Hazard of Contents.

Contents of assembly occupancies shall be classified in accordance with the provisions of Section 6.2.

12.1.6 Minimum Construction Requirements.

The location of an assembly occupancy shall be limited as shown in Table 12.1.6, unless otherwise permitted by the following (*see* 8.2.1.):

- (1) This requirement shall not apply to outdoor grandstands of Type I or Type II construction.
- (2) This requirement shall not apply to outdoor grandstands of Type III, Type IV, or Type V construction that meet the requirements of 12.4.8.
- (3) This requirement shall not apply to grandstands of non-combustible construction supported by the floor in a building meeting the construction requirements of Table 12.1.6.
- (4) This requirement shall not apply to assembly occupancies within mall buildings in accordance with 36.4.4.

Unlike other occupancy chapter construction tables, Tables 12.1.6 and 13.1.6 are based on levels above the level of exit discharge (LED). Thus, in a normal building with the level of exit discharge at grade, the column headed “1” under “Number of Levels above LED” in Tables 12.1.6 and 13.1.6 refers to the second story of the building.

The 1942 Coconut Grove Night Club fire in Boston illustrated the effect of a combustible structure, combustible interior finish materials, and a multilevel configuration on the severity of a fire and its death count. The Beverly Hills Supper Club fire in 1977 also illustrated these consequences.² See Exhibit 12/13.2.

Based in part on the lessons learned from the Coconut Grove fire, the *Code* limits the number of persons in assembly occupancies located in buildings that are not of the highest fire-resistive construction types. Construction Types I(443), I(332), and II(222)

CHAPTER 13 • Existing

occupancies with different occupant loads. Such requirements explicitly state the occupant load threshold at which the particular requirement becomes applicable. For example, see the minimum construction requirements in Table 12/13.1.6 that apply, for a given construction type and given floor elevation level, to occupant loads of 300 or 1000.

13.1.5 Classification of Hazard of Contents.

Contents of assembly occupancies shall be classified in accordance with the provisions of Section 6.2.

13.1.6 Minimum Construction Requirements.

The location of an assembly occupancy shall be limited as shown in Table 13.1.6, unless otherwise permitted by the following (*see* 8.2.1.):

- (1) This requirement shall not apply to outdoor grandstands of Type I or Type II construction.
- (2) This requirement shall not apply to outdoor grandstands of Type III, Type IV, or Type V construction and that meet the requirements of 13.4.8.
- (3) This requirement shall not apply to grandstands of non-combustible construction supported by the floor in a building meeting the construction requirements of Table 13.1.6.
- (4) This requirement shall not apply to assembly occupancies within mall buildings in accordance with 37.4.4.

represent the most highly fire-resistive forms of construction. Their inherent structural stability under fire makes these construction types acceptable for any assembly occupancy. As the fire resistance of the structure diminishes from Type II(111) to Type V(000) construction, the location of assembly occupancies within the building and the permitted number of occupants are restricted. The construction types referenced in Tables 12.1.6 and 13.1.6 are based on NFPA 220, *Standard on Types of Building Construction*³. See 8.2.1.2 and Table A.8.2.1.2.

Note that Tables 12.1.6 and 13.1.6 address the location of the assembly occupancy in relation to the level of exit discharge (LED). For example, if the building in question were a 5-story, Type II(111) building with the level of exit discharge at the first floor, an assembly occupancy with an occupant load in excess of 1000 persons would be permitted to be

Table 12.1.6 Construction Type Limitations

Type of Construction	Below LED	LED	Number of Levels above LED			
			1	2	3	≥4
I(443)†‡§ I(332)†‡§ II(222)†‡§	Any assembly#	Any assembly	Any assembly	Any assembly	Any assembly	Any assembly; If OL > 300#
II(111)†‡§	Any assembly# Limited to 1 level below LED	Any assembly	Any assembly	Any assembly; If OL > 1000#	Assembly with OL ≤ 1000#	NP
III(211)‡ IV(2HH) V(111)	Any assembly# Limited to 1 level below LED	Any assembly	Any assembly	Any assembly; If OL > 300#	Assembly with OL ≤ 1000#	NP

III(200) V(000)	Assembly with OL ≤ 1000# Limited to 1 level below LED	Assembly with OL ≤ 1000	Assembly with OL ≤ 300#	NP	NP	NP

NP: Not permitted.

LED: Level of exit discharge.

OL: Occupant load.

Note: For the purpose of this table, a mezzanine is not counted as a level.

†Where every part of the structural framework of roofs in Type I or Type II construction is 6100 mm (240 in.) or more above the floor immediately below, omission of all fire protection of the structural members shall be permitted, including protection of trusses, roof framing, decking, and portions of columns above 6100 mm (240 in.).

#Where seating treads and risers serve as floors, such seating treads and risers shall be permitted to be of 1-hour fire resistance-rated construction. Structural members supporting seating treads and risers shall conform to the requirements of Table 12.1.6. Joints between seating tread and riser units shall be permitted to be unrated, provided that such joints do not involve separation from areas containing high hazard contents and the facility is constructed and operated in accordance with 12.4.2.

§In open-air fixed seating facilities, including stadia, omission of fire protection of structural members exposed to the outside atmosphere shall be permitted where substantiated by an approved engineering analysis.

#Permitted if all the following are protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7: (1) The level of the assembly occupancy, (2) any level below the level of the assembly occupancy, (3) in the case of an assembly occupancy located below the level of exit discharge, any level intervening between that level and the level of exit discharge, including the level of exit discharge

located on floors 1 through 3 but not on floors 4 and 5. Assembly occupancies with occupant loads of 1000 or fewer persons could be located on floors 1 through 4 but not on floor 5. In some cases (where a # symbol in Table 12.1.6 or a § symbol in Table 13.1.6 appears beside an entry), automatic sprinkler protection is required on certain floors of the building. The extent of the required sprinkler protection is illustrated in Exhibit 12/13.3 for new construction and Exhibit 12/13.4 for an existing assembly occupancy building.

In Exhibit 12/13.3, in the building on the left,

a new assembly occupancy with an occupant load greater than 300 persons is located on the fifth floor of an 8-story, Type II(222) building. Automatic sprinkler protection is required on the fifth story assembly occupancy floor and all floors below, including those below grade level. In the building on the right in Exhibit 12/13.3, the assembly occupancy is located in the subbasement, two levels below the level of exit discharge of an 8-story, Type II(222) building. Automatic sprinkler protection is required on the subbasement assembly occupancy floor, the basement level

Table 13.1.6 Construction Type Limitations

Type of Construction	Below LED	LED	Number of Levels above LED			
			1	2	3	≥4
I(443)†‡ I(332)†‡ II(222)†‡	Any assembly§	Any assembly	Any assembly	Any assembly	Any assembly	Any assembly; If OL > 1000§

II(000)	Assembly with OL ≤ 1000§ Limited to 1 level below LED	Any assembly; If OL > 1000§	Assembly with OL ≤ 300§	NP	NP	NP
III(200) V(000)	Assembly with OL ≤ 1000§ Limited to 1 level below LED	Any assembly; If OL > 1000§	Assembly with OL ≤ 300§	NP	NP	NP

NP: Not permitted.

LED: Level of exit discharge.

OL: Occupant load.

Note: For the purpose of this table, a mezzanine is not counted as a level.

†Where every part of the structural framework of roofs in Type I or Type II construction is 6100 mm (240 in.) or more above the floor immediately below, omission of all fire protection of the structural members shall be permitted, including protection of trusses, roof framing, decking, and portions of columns above 6100 mm (240 in.).

‡In open-air fixed seating facilities, including stadia, omission of fire protection of structural members exposed to the outside atmosphere shall be permitted where substantiated by an approved engineering analysis.

§Permitted if all the following are protected throughout by an approved automatic sprinkler system in accordance with Section 9.7:

- (1) The level of the assembly occupancy
- (2) Any level intervening between the level of the assembly occupancy and the level of exit discharge
- (3) The level of the exit discharge if there are any openings between the level of exit discharge and the exits serving the assembly occupancy

between the subbasement and the level of exit discharge, and the level of exit discharge.

In Exhibit 12/13.4, in the building on the left, an existing assembly occupancy with an occupant load greater than 1000 persons is located on the fifth floor of an 8-story, Type II(222) building. Automatic sprinkler protection is required on the fifth story assembly occupancy floor and all floors intervening between the fifth story and the level of exit discharge, including the level of exit discharge if any openings exist between the level of exit discharge and the enclosed

exit stairs serving the assembly occupancy. In the building on the right in Exhibit 12/13.4, the assembly occupancy is located in the subbasement, two levels below the level of exit discharge of an 8-story, Type II(222) building. Automatic sprinkler protection is required on the subbasement assembly occupancy floor, the basement level between the subbasement and the level of exit discharge, and the level of exit discharge if any openings exist between the level of exit discharge and the enclosed exit stairs serving the assembly occupancy.

Exhibit 12/13.2 Beverly Hills Supper Club following 1977 fire.

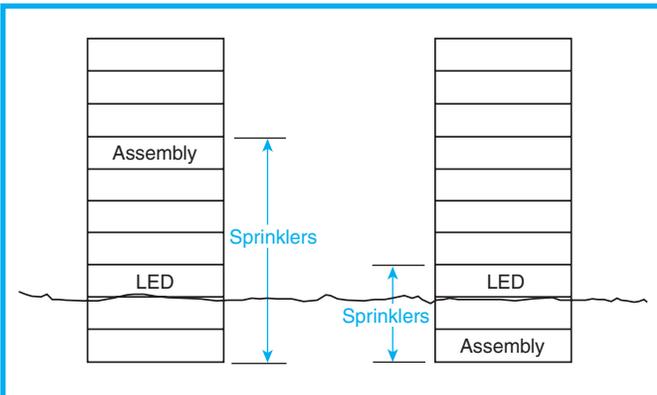

Exhibit 12/13.3 New assembly occupancy building—extent of required sprinkler protection.

The two primary subsections that address automatic sprinkler protection that might be required in assembly occupancies are 12/13.1.6 and 12/13.3.5. Each of these subsections is to be applied independently of the other to determine whether automatic sprinkler protection is required. For example, the provisions of 12/13.3.5.2 might exempt sprinklers,

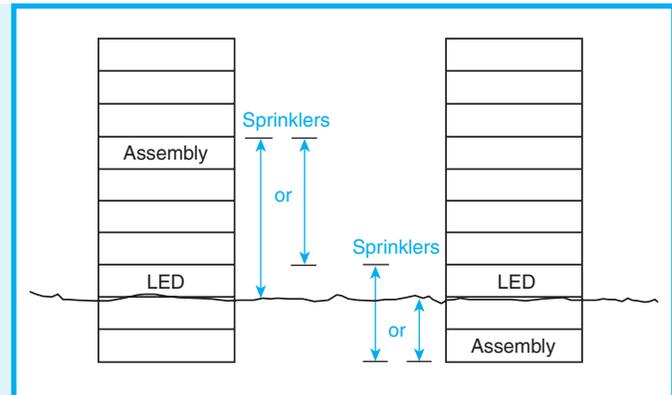

Exhibit 12/13.4 Existing assembly occupancy building—extent of required sprinkler protection.

while the provisions of 12/13.1.6 might require sprinklers for an assembly occupancy with a given occupant load based on building construction type and location within the building. If one subsection requires sprinklers while the other does not, sprinklers are required to be provided.

CHAPTER 12 • New

12.1.7 Occupant Load.

12.1.7.1* General. The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

A.12.1.7.1 The increase in occupant load above that calculated using occupant load factors from Table 7.3.1.2 is permitted if the provisions of 12.1.7.1 are followed. The owner or operator has the right to submit plans and to be permitted an increase in occupant load if the plans comply with the *Code*. The authority having jurisdiction is permitted to reject the plan for increase in occupant load if the plan is unrealistic, inaccurate, or otherwise does not properly reflect compliance with other *Code* requirements. It is not the intent of the provisions of 12.1.7.1 to prohibit an increase in occupant load solely on the basis of exceeding the limits calculated using occupant load factors from Table 7.3.1.2.

To assist in preventing serious overcrowding incidents in sports arenas, stadia, and similar occupancies, spectator standing room should not be permitted between the seating areas and the playing areas, except in horse race and dog track facilities.

Where a capacity or near-capacity audience is anticipated, all seating should be assigned with tickets showing the section, row, and seat number.

Where standing room is permitted, the capacity of the standing area should meet the following criteria:

- (1) It should be determined on the basis of 0.46 m² (5 ft²) per person.
- (2) It should have its capacity added to the seating capacity in determining egress requirements.
- (3) It should be located to the rear of the seating area.
- (4) It should be assigned standing-room-only tickets according to the area designated for the purpose.

The number of tickets sold or otherwise distributed should not exceed the aggregate number of seats plus the approved standing room numbers.

12.1.7.1.1 In areas not in excess of 930 m² (10,000 ft²), the occupant load shall not exceed one person in 0.46 m² (5 ft²).

CHAPTER 13 • Existing

13.1.7 Occupant Load.

13.1.7.1* General. The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

A.13.1.7.1 The increase in occupant load above that calculated using occupant load factors from Table 7.3.1.2 is permitted, if the provisions of 13.1.7.1 are followed. The owner or operator has the right to submit plans and to be permitted an increase in occupant load if the plans comply with the *Code*. The authority having jurisdiction is permitted to reject the plan for increase in occupant load if the plan is unrealistic, inaccurate, or otherwise does not properly reflect compliance with other *Code* requirements. It is not the intent of the provisions of 13.1.7.1 to prohibit an increase in occupant load solely on the basis of exceeding the limits calculated using occupant load factors from Table 7.3.1.2.

Existing auditorium and arena structures might not be designed for the added occupant load beyond the fixed seating. The authority having jurisdiction should consider exit access and aisles before permitting additional occupant load in areas using seating such as festival seating or movable seating on the auditorium or arena floor area.

To assist in preventing serious overcrowding incidents in sports arenas, stadia, and similar occupancies, spectator standing room should not be permitted between the seating areas and the playing areas, except in horse race and dog track facilities.

Where a capacity or near-capacity audience is anticipated, all seating should be assigned with tickets showing the section, row, and seat number.

Where standing room is permitted, the capacity of the standing area should meet the following criteria:

- (1) It should be determined on the basis of 0.46 m² (5 ft²) per person.
- (2) It should have its capacity added to the seating capacity in determining egress requirements.
- (3) It should be located to the rear of the seating area.
- (4) It should be assigned standing-room-only tickets according to the area designated for the purpose.

The number of tickets sold or otherwise distributed should not exceed the aggregate number of seats plus the approved standing room numbers.

13.1.7.1.1 In areas not in excess of 930 m² (10,000 ft²), the occupant load shall not exceed one person in 0.46 m² (5 ft²).

CHAPTER 12 • New

12.1.7.1.2 In areas in excess of 930 m² (10,000 ft²), the occupant load shall not exceed one person in 0.65 m² (7 ft²).

12.1.7.2 Waiting Spaces. In theaters and other assembly occupancies where persons are admitted to the building at times when seats are not available, or when the permitted occupant load has been reached based on 12.1.7.1 and persons are allowed to wait in a lobby or similar space until seats or space is available, the following requirements shall apply:

- (1) Such use of a lobby or similar space shall not encroach upon the required clear width of exits.
- (2) The waiting spaces shall be restricted to areas other than the required means of egress.
- (3) Exits shall be provided for the waiting spaces on the basis of one person for each 0.28 m² (3 ft²) of waiting space area.
- (4) Exits for waiting spaces shall be in addition to the exits specified for the main auditorium area and shall conform in construction and arrangement to the general rules for exits given in this chapter.

12.1.7.3 Life Safety Evaluation. Where the occupant load of an assembly occupancy exceeds 6000, a life safety evaluation shall be performed in accordance with 12.4.1.

12.1.7.4 Outdoor Facilities. In outdoor facilities, where approved by the authority having jurisdiction, the number of occupants who are each provided with not less than 1.4 m² (15 ft²) of lawn surface shall be permitted to be excluded from the maximum occupant load of 6000 of 12.1.7.3 in determining the need for a life safety evaluation.

Occupant load factors appear in Table 7.3.1.2. Note that occupant load factors are provided in Chapter 7, a core chapter, because occupant load is based on the use of the space, not on the occupancy classification. For example, a small conference room for approximately 30 persons located in a business occupancy doesn't have the requisite 50 persons to constitute an assembly occupancy. The occupancy classification is business, but the occupant load of the conference room is calculated using an occupant load factor from Table 7.3.1.2 for an assembly use, not

CHAPTER 13 • Existing

13.1.7.1.2 In areas in excess of 930 m² (10,000 ft²), the occupant load shall not exceed one person in 0.65 m² (7 ft²).

13.1.7.1.3 The authority having jurisdiction shall be permitted to establish the occupant load as the number of persons for which the existing means of egress is adequate, provided that measures are established to prevent occupancy by a greater number of persons.

13.1.7.2 Waiting Spaces. In theaters and other assembly occupancies where persons are admitted to the building at times when seats are not available, or when the permitted occupant load has been reached based on 13.1.7.1 and persons are allowed to wait in a lobby or similar space until seats or space is available, the following requirements shall apply:

- (1) Such use of a lobby or similar space shall not encroach upon the required clear width of exits.
- (2) The waiting spaces shall be restricted to areas other than the required means of egress.
- (3) Exits shall be provided for the waiting spaces on the basis of one person for each 0.28 m² (3 ft²) of waiting space area.
- (4) Exits for waiting spaces shall be in addition to the exits specified for the main auditorium area and shall conform in construction and arrangement to the general rules for exits given in this chapter.

13.1.7.3 Life Safety Evaluation. Where the occupant load of an assembly occupancy exceeds 6000, a life safety evaluation shall be performed in accordance with 13.4.1.

13.1.7.4 Outdoor Facilities. In outdoor facilities, where approved by the authority having jurisdiction the number of occupants who are each provided with not less than 1.4 m² (15 ft²) of lawn surface shall be permitted to be excluded from the maximum occupant load of 6000 of 13.1.7.3 in determining the need for a life safety evaluation.

a business use. Thus, the occupant load factors belong in Chapter 7 so that they can be employed based on the use of the space, regardless of the occupancy classification.

Note that 13.1.7.1.3, applicable to existing assembly occupancies, has no counterpart in Chapter 12 for new assembly occupancies. Paragraph 13.1.7.1.3 permits the authority having jurisdiction to ignore the calculated occupant load and establish the occupant load of an existing assembly occupancy as the number of persons for which the existing means of egress

CHAPTER 12 • New

is adequate. In other words, rather than forcing an existing assembly occupancy to unnecessarily upgrade its egress system, the existing system is permitted to serve, provided that the maximum number of persons present can be effectively regulated. The occupant load is to be posted and staff is to strictly enforce the posted occupant load. For example, the calculated occupant load—derived by dividing the available floor area by the occupant load factors that represent the uses—might be 1110 persons. Yet, the existing egress system [for example, three door openings that are each 1625 mm (64 in.) wide] might accommodate only 960 persons. If the authority having jurisdiction believes that the existing assembly occupancy itself can enforce an occupant load of not more than 960, then an occupant load of 960 can be established. Thus, a fourth exit with capacity for at least 150 persons does not have to be added. This is the only provision in the *Code* that permits the established occupant load to be less than the calculated occupant load. The exemption was written to recognize that the occupant load factors characteristic of assembly uses are small—such as 0.65 m² or 1.4 m² (7 ft² or 15 ft²) compared to those characteristic of business and residential uses—such as 9.3 m² or 18.6 m² (100 ft² or 200 ft²). These small occupant load factors result in large occupant loads for even modestly sized areas.

Numerous occupant load factors for assembly uses are presented in Table 7.3.1.2. The occupant load factors characteristic of assembly uses reflect the data developed from surveys of typical assembly occupancies. The following commentary explains some of these factors.

One of the assembly use occupant load factors is for concentrated use at 0.65 net m² (7 net ft²) per person. The terminology *one person per 0.65 net m² (7 net ft²)* means that one person is assumed to be present for each 0.65 m² (7 ft²) that is available to be used by occupants after deducting space occupied by such items as permanently fixed counters, partitions, and columns.

The 0.65-m² (7-ft²) occupant load factor is based on open floor space with people standing comfortably. This factor also can be used to estimate occupant load in a multipurpose room where portable chairs are placed in rows for meetings, film viewing, or lectures.

The terminology *one person per 1.4 net m² (15 net ft²)* means that one person is assumed to be present

CHAPTER 13 • Existing

for each 1.4 m² (15 ft²) that is available for use by occupants.

The 1.4-m² (15-ft²) occupant load factor is based on a use where a certain amount of space is occupied by furniture. An example is a space furnished with tables and chairs, as in restaurants or conference rooms.

The occupant load factor for kitchens has particular application to assembly uses, which are often characterized by food service and an associated kitchen. This factor helps to clarify the method of calculating the total occupant load in restaurants and cafeterias where a portion of the building is used as a kitchen, whether it is a separate room or divided from the dining area by a serving counter. Note that the occupant load of the kitchen is calculated by using gross area. The 9.3 gross m² (100 gross ft²) factor takes into consideration the stoves, sinks, counters, and culinary machinery found in a kitchen.

The 9.3 gross m² (100 gross ft²) associated with the occupant load factor for library stack areas takes into consideration the existence of bookshelves and permanent aisles. Because reading rooms typically have large magazine racks, chairs, tables, couches, and other furnishings that can require considerable space, an occupant load factor of 4.6 net m² (50 net ft²) is specified for such areas. Exhibit 12/13.5 illustrates a typical library reading room.

Swimming pools, pool decks, exercise rooms, skating rinks, and casino or gaming rooms are often

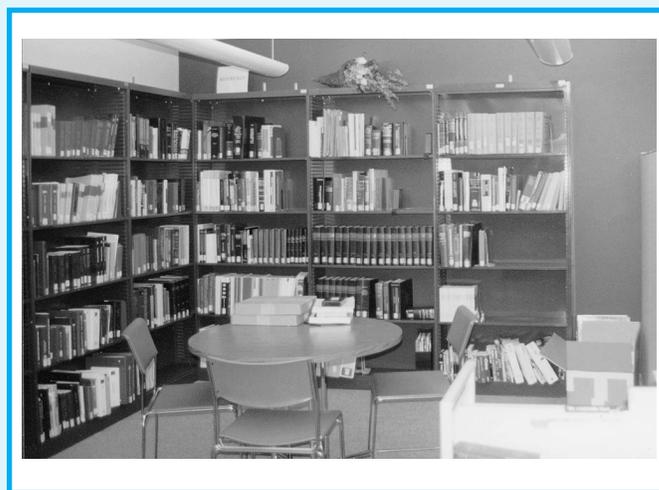

Exhibit 12/13.5 Library reading room for which *Code* specifies an occupant load factor of 4.6 net m² (50 net ft²).

CHAPTER 12 • New

parts of assembly occupancies. The occupant load factors for such areas are presented in Table 7.3.1.2 to help piece together a realistic occupant load for the entire assembly space.

The occupant load factor for stages is provided because it is necessary to include the occupant load of a stage in the total occupant load. The occupant load factor allows for the occupant load of a stage to be calculated with consistency.

Consideration needs to be given to the actual use of a room or space. A multi-use room might have several occupant loads, with each load applicable to a specific arrangement and use. This situation is especially common in multipurpose rooms in schools and hotels.

Exhibit 12/13.6 illustrates a net 232-m² (net 2500-ft²) room with two 1170-mm (46-in.) clear width doors. If the room were to be used as a banquet room with tables and chairs, its occupant load would be based on the 1.4-m² (15-ft²) per person factor. The occupant load calculation would divide 232 net m² (2500 net ft²) by 1.4 m² (15 ft²) per person for an occupant load of 167 persons. However, if the room were to be used for a stand-up cocktail party with essentially no furniture, the occupant load would be based on the 0.65-m² (7-ft²) per person factor. The occupant load calculation would divide 232 net m² (2500 net ft²) by 0.65 m² (7 ft²) per person, for an occupant load of 357 persons. Thus, based on the two planned forms of assembly use, the room has two occupant loads.

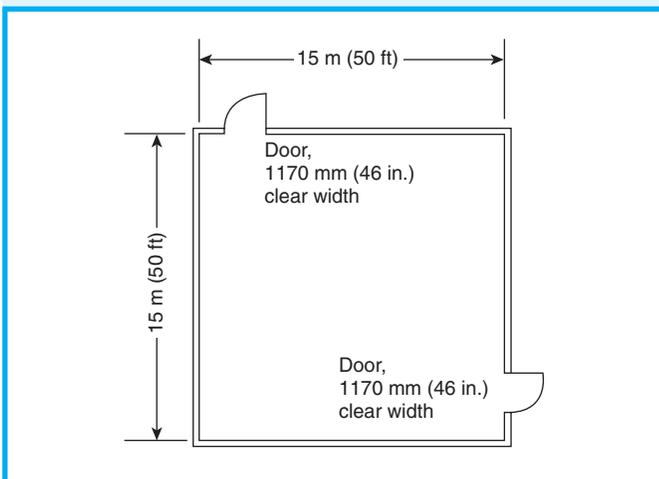

Exhibit 12/13.6 Acceptable scenario where calculated occupant load is less than number of persons means of egress can safely accommodate.

CHAPTER 13 • Existing

The egress capacity from the room is limited by the width available from the two 1170-mm (46-in.) clear width doors. The egress capacity is calculated by dividing the 1170-mm (46-in.) clear width by the 5 mm (0.2 in.) per person capacity factor for level travel, and then multiplying by 2 (because of the two identical doors). The calculation shows the room has an egress capacity of 460 occupants. Because each of the occupant loads calculated is less than the egress capacity, the situation is satisfactory.

As noted in the previous two paragraphs, both egress capacity and occupant load must be considered in establishing the permissible occupant load for a room or area. Exhibit 12/13.7 illustrates a net 334-m² (net 3600-ft²) room with two 915-mm (36-in.) clear width doors. The egress capacity of the room is calculated by dividing the 915-mm (36-in.) clear width of the doors by the 5 mm (0.2 in.) per person capacity factor for level travel, and then multiplying by 2. The calculation produces an egress capacity of 360 occupants. However, an occupant load for the same room, calculated based on 0.65 m² (7 ft²) per person, results in an occupant load of 514 persons. Section 7.3 requires that egress capacity be provided for the occupant load determined by application of the occupant load factor. Therefore, for new assembly occupancies, the egress capacity must be increased to accommodate at least 514 persons. For existing assembly occupancies, either the egress capacity must be increased to accommodate at least 514 persons or the occupant

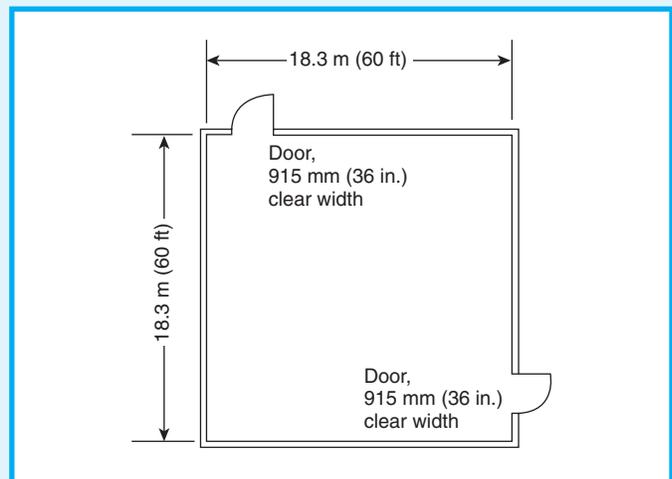

Exhibit 12/13.7 Unacceptable scenario where calculated occupant load is larger than egress capacity.

CHAPTER 12 • New

load can be set at 360 occupants—the number of persons for which the existing means of egress is adequate—in accordance with 13.1.7.1.3. The latter requires specific approval by the authority having jurisdiction after it has been assured that measures are in place to prevent occupancy by more than 360 persons. See the introductory commentary on the occupant load provisions of 12/13.1.7.

Often a controversy exists regarding where to use an occupant load factor of 0.65 m^2 (7 ft^2) versus 1.4 m^2 (15 ft^2). These factors are based on concentrated versus less concentrated use, and the selection of one over the other is based strictly on judgment. Because the occupant load is used in determining the required egress capacity and the construction, alarm, and sprinkler requirements, it is usually safer to provide features for the larger occupant load than to try to enforce, usually with great difficulty, a smaller occupant load limit.

Accessibility of a room's exit access doors is as important as the egress capacity of that room. Therefore, where an increase in occupant load is permitted over that established by 12/13.1.7.1, it must be demonstrated that adequate aisle accessways and aisles leading to the room exit access doors are provided. Where tables abut an aisle, the spacing must allow for chairs and aisles. Consideration should be given to the likelihood that, when occupants leave during an emergency, they might not take time to move chairs out of the aisles. See 12/13.2.5.7.3 and 12/13.2.5.8.3.

Dining and drinking areas make the most frequent use of the provisions of 7.3.1.3 for occupant load increases. There have been large banquet layouts where the occupant load was successfully increased to reflect an occupant load factor of 1 m^2 (11 ft^2) per person instead of the 1.4 m^2 (15 ft^2) per person specified by Table 7.3.1.2. In all cases where an increase in the occupant load is permitted, the authority having jurisdiction should insist on diagrams showing fixture and furniture layouts and should strictly enforce adherence to approved layouts. As noted previously, one room might have several approved occupant loads, depending on the various layouts.

Paragraphs 12/13.1.7.1, 12/13.1.7.1.1, and 12/13.1.7.1.2 limit the permitted increase in occupant load to avoid overcrowding, which affects the movement characteristics of the occupants.

Research by the National Research Council in Canada and by the London Transport Board has

CHAPTER 13 • Existing

shown that if people are crowded into a space so that each person occupies less than 0.65 m^2 (7 ft^2), movement approaches a shuffle; where each person occupies less than 0.28 m^2 (3 ft^2), “jam point” is approached, and all movement by occupants comes to a virtual stop.

Although 12/13.1.7.1.1 limits occupant density to one person for each available 0.46 m^2 (5 ft^2), 12/13.1.7.2(3) allows a density of one person per 0.28 m^2 (3 ft^2) for specially designated waiting spaces. The waiting space cannot be located in, or interfere with, the egress routes from the rest of the assembly occupancy. As shown in Exhibit 12/13.8, such waiting spaces might be associated with a theater where patrons wait for the audience seating chamber to clear of people attending a previous show before entering and taking their seats for the next performance. A similar waiting space might be established in an ante-room off the entrance foyer of a restaurant where diners await a table. Space at a bar where patrons gather to place a drink order does not qualify as a waiting space for purposes of the provisions of 12/13.1.7.2.

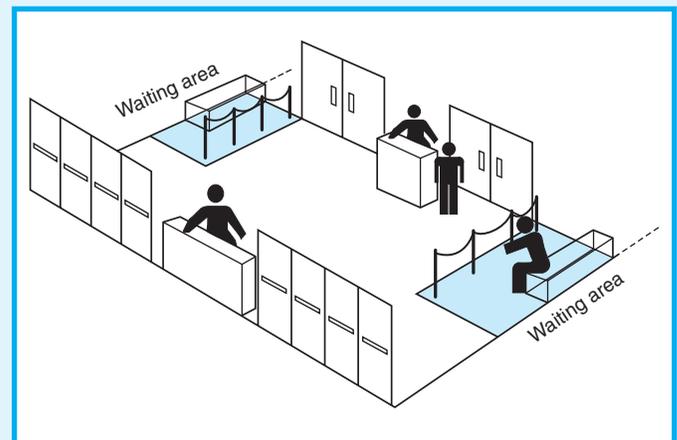

Exhibit 12/13.8 Designated waiting spaces.

The life safety evaluation required for large assembly occupancies by 12/13.1.7.3 recognizes that fixed protection and suppression systems alone do not ensure safe egress where large numbers of people are present. Expected crowd behavior is part of such an evaluation, as is consideration of techniques to manage any behavioral problems. See 12/13.4.1 and, in particular, A.12/13.4.1.3.

CHAPTER 12 • New

Section 12.2 Means of Egress Requirements

12.2.1 General.

All means of egress shall be in accordance with Chapter 7 and this chapter.

12.2.2 Means of Egress Components.

12.2.2.1 Components of means of egress shall be limited to the types described in 12.2.2.2 through 12.2.2.12.

Paragraph 12/13.2.2.1 limits components within the required means of egress to those detailed in 12/13.2.2.2 through 12/13.2.2.12. Note that it is not required that each component addressed in these paragraphs be used; rather, if a component is used, the provisions of Chapter 7 that apply to the component, as modified by Chapters 12 and 13, must be followed.

The provisions of 12/13.2.2 do not recognize elevators as part of the means of egress. Elevators are not suited for rapid evacuation of the large numbers of people found in these occupancies. Furthermore, elevators introduce other risk factors if used during a fire (see Section 9.4). Although escalators are per-

12.2.2.2 Doors.

12.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

12.2.2.2.2 Assembly occupancies with occupant loads of 300 or less in malls (*see* 36.4.4.2.2) shall be permitted to have horizontal or vertical security grilles or doors complying with 7.2.1.4.1.4 on the main entrance/exits.

12.2.2.2.3 Any door in a required means of egress from an area having an occupant load of 100 or more persons shall be permitted to be provided with a latch or lock only if the latch or lock is panic hardware or fire exit hardware complying with 7.2.1.7, unless otherwise permitted by the following:

- (1) This requirement shall not apply to delayed-egress locks as permitted in 12.2.2.2.5.
- (2) This requirement shall not apply to access-controlled egress doors as permitted in 12.2.2.2.6.

12.2.2.2.4 Locking devices complying with 7.2.1.5.4 shall be permitted to be used on a single door or a single pair of doors if both of the following conditions apply:

CHAPTER 13 • Existing

Section 13.2 Means of Egress Requirements

13.2.1 General.

All means of egress shall be in accordance with Chapter 7 and this chapter.

13.2.2 Means of Egress Components.

13.2.2.1 Components of means of egress shall be limited to the types described in 13.2.2.2 through 13.2.2.12.

mitted to be part of a means of egress in existing occupancies (see 13.2.28), they are not recognized as such in new construction. Note that Chapter 7 does not credit escalators that serve within the required means of egress in new construction. These devices can be (and often are) installed in assembly occupancies, but they cannot obstruct or interfere with the required means of egress. However, where a new assembly occupancy is located more than 9140 mm (360 in.) below the level of exit discharge, 12.4.3.3.2 requires a mechanical means of moving people vertically to the level of exit discharge. This requirement can be satisfied via an escalator or an elevator.

13.2.2.2 Doors.

13.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

13.2.2.2.2 Assembly occupancies with occupant loads of 300 or less in malls (*see* 37.4.4.2.2) shall be permitted to have horizontal or vertical security grilles or doors complying with 7.2.1.4.1.4 on the main entrance/exits.

13.2.2.2.3 Any door in a required means of egress from an area having an occupant load of 100 or more persons shall be permitted to be provided with a latch or lock only if the latch or lock is panic hardware or fire exit hardware complying with 7.2.1.7, unless otherwise permitted by the following:

- (1) This requirement shall not apply to delayed-egress locks as permitted in 13.2.2.2.5.
- (2) This requirement shall not apply to access-controlled egress doors as permitted in 13.2.2.2.6.

13.2.2.2.4 Locking devices complying with 7.2.1.5.4 shall be permitted to be used on a single door or a single pair of doors if both of the following conditions apply:

CHAPTER 12 • New

- (1) The door or pair of doors serve as the main exit and the assembly occupancy has an occupant load not greater than 500.
- (2) Any latching devices on such a door(s) from an assembly occupancy having an occupant load of 100 or more are released by panic hardware or fire exit hardware.

12.2.2.2.5 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted on doors other than main entrance/exit doors.

12.2.2.2.6 Doors in the means of egress shall be permitted to be equipped with an approved access control system complying with 7.2.1.6.2, and such doors shall not be locked from the egress side when the assembly occupancy is occupied. (See 7.2.1.1.3.)

12.2.2.2.7 Revolving doors complying with the requirements of 7.2.1.10 shall be permitted.

12.2.2.2.8 The provisions of 7.2.1.11.1.1 to allow turnstiles where revolving doors are permitted shall not apply.

12.2.2.2.9 No turnstiles or other devices that restrict the movement of persons shall be installed in any assembly occupancy in such a manner as to interfere with required means of egress facilities.

The provision of 12/13.2.2.2.2 allows, for example, small restaurants in covered mall buildings to use the security grilles or doors addressed by 7.2.1.4.1.4.

Paragraph 12/13.2.2.2.4 recognizes the particular key-operated deadbolt lock described in 7.2.1.5.4. Using a key-operated deadbolt lock in an assembly occupancy is permitted where all the conditions of 7.2.1.5.4 and 12/13.2.2.2.4 are met. The assembly occupancy is limited to an occupant load of not more than 500 persons in new assembly occupancies; 600 for existing ones. Use is limited to the main exit based on the assumption that the lock will need to be released for the facility to operate. The main exit is limited to a single door or single pair of doors to ensure that the main exit will be unlocked whenever the building is occupied.

12.2.2.3 Stairs.

12.2.2.3.1 General. Stairs complying with 7.2.2 shall be permitted, unless one of the following criteria applies:

- (1)* Stairs serving seating that is designed to be repositioned shall not be required to comply with 7.2.2.3.1.

CHAPTER 13 • Existing

- (1) The door or pair of doors serve as the main exit from assembly occupancies having an occupant load not greater than 600.
- (2) Any latching devices on such a door(s) from an assembly occupancy having an occupant load of 100 or more are released by panic hardware or fire exit hardware.

13.2.2.2.5 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted on doors other than main entrance/exit doors.

13.2.2.2.6 Doors in the means of egress shall be permitted to be equipped with an approved access control system complying with 7.2.1.6.2, and such doors shall not be locked from the egress side when the assembly occupancy is occupied. (See 7.2.1.1.3.)

13.2.2.2.7 Revolving doors complying with the requirements of 7.2.1.10 for new construction shall be permitted.

13.2.2.2.8 The provisions of 7.2.1.11.1.1 to allow turnstiles where revolving doors are permitted shall not apply.

13.2.2.2.9 No turnstiles or other devices that restrict the movement of persons shall be installed in any assembly occupancy in such a manner as to interfere with required means of egress facilities.

Although delayed-egress locks are addressed by 12/13.2.2.2.3(1) as an exemption to the requirement to provide panic hardware for doors that latch or lock, 12/13.2.2.2.5 further describes the allowance for delayed-egress locks. It allows delayed-egress hardware meeting the requirements of 7.2.1.6.1 to be used on all but the main exit. In addition to other requirements, 7.2.1.6.1 requires that the building be protected throughout by either an approved, supervised automatic sprinkler system or an approved, supervised automatic fire detection system.

Although access-controlled egress doors are permitted by 12/13.2.2.2.3(2) to omit panic hardware for doors that latch or lock, 12/13.2.2.2.6 further describes the allowance for access-control door locking systems complying with 7.2.1.6.2.

13.2.2.3 Stairs.

13.2.2.3.1 General. Stairs complying with 7.2.2 shall be permitted, unless one of the following criteria applies:

- (1)* Stairs serving seating that is designed to be repositioned shall not be required to comply with 7.2.2.3.1.

CHAPTER 12 • New

A.12.2.2.3.1(1) The seating plan and the means of egress should be reviewed each time the seating is substantially rearranged.

- (2) This requirement shall not apply to stages and platforms as permitted by 12.4.5.

12.2.2.3.2 Catwalk, Gallery, and Gridiron Stairs.

12.2.2.3.2.1 Noncombustible grated stair treads and landing floors shall be permitted in means of egress from lighting and access catwalks, galleries, and gridirons.

12.2.2.3.2.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted in means of egress from lighting and access catwalks, galleries, and gridirons.

Paragraph 7.2.2.3.1.1 requires that stairs within required means of egress be of permanent fixed construction, unless they serve seating that is designed to be repositioned, and so are exempted by 12/13.2.2.3.1(1). In some theaters, for example, entire

12.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

12.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

12.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted, and the following alternatives shall also apply:

- (1) Ramps not part of an accessible means of egress and serving only stages or nonpublic areas shall be permitted to have a slope not steeper than 1 in 8.
- (2) Ramped aisles not part of an accessible means of egress shall be permitted to have a slope not steeper than 1 in 8.

12.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

12.2.2.8 Reserved.

12.2.2.9 Reserved.

12.2.2.10 Fire Escape Ladders.

12.2.2.10.1 Fire escape ladders complying with 7.2.9 shall be permitted.

CHAPTER 13 • Existing

A.13.2.2.3.1(1) The seating plan and the means of egress should be reviewed each time the seating is substantially rearranged.

- (2) This requirement shall not apply to stages and platforms as permitted by 13.4.5.

13.2.2.3.2 Catwalk, Gallery, and Gridiron Stairs.

13.2.2.3.2.1 Noncombustible grated stair treads and landing floors shall be permitted in means of egress from lighting and access catwalks, galleries, and gridirons.

13.2.2.3.2.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted in means of egress from lighting and access catwalks, galleries, and gridirons.

seating sections are moved to accommodate the performance area requirements for a particular presentation. The stairs serving these movable seating sections cannot easily be of fixed permanent construction.

13.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

13.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

13.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

13.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

13.2.2.8 Escalators and Moving Walks. Escalators and moving walks complying with 7.2.7 shall be permitted.

13.2.2.9 Fire Escape Stairs. Fire escape stairs complying with 7.2.8 shall be permitted.

13.2.2.10 Fire Escape Ladders.

13.2.2.10.1 Fire escape ladders complying with 7.2.9 shall be permitted.

CHAPTER 12 • New

12.2.2.10.2 For ladders serving catwalks, the three-person limitation in 7.2.9.1(3) shall be permitted to be increased to ten persons.

12.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

12.2.2.12 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

12.2.3 Capacity of Means of Egress.

12.2.3.1 The capacity of means of egress shall be in accordance with one of the following:

- (1) Section 7.3 for other than theater-type seating or smoke-protected assembly seating
- (2) 12.2.3.2 for rooms with theater-type seating or similar seating arranged in rows
- (3) 12.4.2 for smoke-protected assembly seating.

12.2.3.2* Minimum clear widths of aisles and other means of egress serving theater-type seating, or similar seating arranged in rows, shall be in accordance with Table 12.2.3.2.

Table 12.2.3.2 Capacity Factors

Number of Seats	Clear Width per Seat Served			
	Stairs		Passageways, Ramps, and Doorways	
	mm	in.	mm	in.
Unlimited	7.6 AB	0.3 AB	5.6 C	0.22 C

A.12.2.3.2 The provisions of 12.2.3.2 should be applied within the audience seating chamber and to the room doors. The capacity of means of egress components encountered after leaving the audience seating chamber, such as concourses, lobbies, exit stair enclosures, and the exit discharge, should be calculated in accordance with Section 7.3.

12.2.3.3 The minimum clear widths shown in Table 12.2.3.2 shall be modified in accordance with all of the following:

- (1) If risers exceed 178 mm in height, the stair width in Table 12.2.3.2 shall be multiplied by factor A, where A equals the following:

$$A = 1 + \frac{\text{riser height} - 178}{125}$$

CHAPTER 13 • Existing

13.2.2.10.2 For ladders serving catwalks, the three-person limitation in 7.2.9.1(3) shall be permitted to be increased to ten persons.

13.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

13.2.2.12 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

13.2.3 Capacity of Means of Egress.

13.2.3.1 The capacity of means of egress shall be in accordance with one of the following:

- (1) Section 7.3 for other than theater-type seating or smoke-protected assembly seating
- (2) 13.2.3.2 for rooms with theater-type seating or similar seating arranged in rows
- (3) 13.4.2 for smoke-protected assembly seating

13.2.3.2* Minimum clear widths of aisles and other means of egress serving theater-type seating, or similar seating arranged in rows, shall be in accordance with Table 13.2.3.2.

Table 13.2.3.2 Capacity Factors

Number of Seats	Clear Width per Seat Served			
	Stairs		Passageways, Ramps, and Doorways	
	mm	in.	mm	in.
Unlimited	7.6 AB	0.3 AB	5.6 C	0.22 C

A.13.2.3.2 The provisions of 13.2.3.2 should be applied within the audience seating chamber and to the room doors. The capacity of means of egress components encountered after leaving the audience seating chamber, such as concourses, lobbies, exit stair enclosures, and the exit discharge, should be calculated in accordance with Section 7.3.

13.2.3.3 The minimum clear widths shown in Table 13.2.3.2 shall be modified in accordance with all of the following:

- (1) If risers exceed 178 mm in height, the stair width in Table 13.2.3.2 shall be multiplied by factor A, where A equals the following:

$$A = 1 + \frac{\text{riser height} - 178}{125}$$

CHAPTER 12 • New

- (2) If risers exceed 7 in. in height, the stair width in Table 12.2.3.2 shall be multiplied by factor A , where A equals the following:

$$A = 1 + \frac{\text{riser height} - 7}{5}$$

- (3) Stairs not having a handrail within a 760-mm (30-in.) horizontal distance shall be 25 percent wider than otherwise calculated; that is, their width shall be multiplied by factor B , where B equals the following:

$$B = 1.25$$

- (4) Ramps steeper than 1 in 10 slope where used in ascent shall have their width increased by 10 percent; that is, their width shall be multiplied by factor C , where C equals the following:

$$C = 1.10$$

12.2.3.4 Lighting and Access Catwalks. The requirements of 12.2.3.2 and 12.2.3.3 shall not apply to lighting and access catwalks as permitted by 12.4.5.9.

12.2.3.5 Reserved.

Paragraph 12/13.2.3.2 applies to egress serving theater-type seating or similar seating arranged in rows in assembly occupancies that are not smoke protected. See 12/13.2.3.1(2). If the assembly occupancy provides smoke-protected seating, the provisions of 12/13.4.2 and the capacity factors of Table 12/13.4.2.3 apply.

In using Table 12/13.2.3.2, the capacity factors might need to be adjusted using factors A , B , and C . Stair capacity is calculated at 7.6 mm (0.3 in.) per person only if the stair geometry and handrail details comply fully with the requirements of Chapter 7. If the stair riser height exceeds 178 mm (7 in.), the 7.6 mm (0.3 in.) per person factor must be multiplied by factor A , which is calculated using the formula in 12/13.2.3.3(1). If the stair does not have a handrail within a 760-mm (30-in.) horizontal distance, the 7.6 mm (0.3 in.) per person factor must be multiplied by factor B , which equals 1.25. If both the riser geometry and handrail deviations occur, the 7.6 mm (0.3 in.) per person factor must be multiplied by both a factor A that is greater than 1.0 and a factor B of 1.25.

CHAPTER 13 • Existing

- (2) If risers exceed 7 in. in height, the stair width in Table 13.2.3.2 shall be multiplied by factor A , where A equals the following:

$$A = 1 + \frac{\text{riser height} - 7}{5}$$

- (3) Stairs not having a handrail within a 760-mm (30-in.) horizontal distance shall be 25 percent wider than otherwise calculated; that is, their width shall be multiplied by factor B , where B equals the following:

$$B = 1.25$$

- (4) Ramps steeper than 1 in 10 slope where used in ascent shall have their width increased by 10 percent; that is, their width shall be multiplied by factor C , where C equals the following:

$$C = 1.10$$

13.2.3.4 Lighting and Access Catwalks. The requirements of 13.2.3.2 and 13.2.3.3 shall not apply to lighting and access catwalks as permitted by 13.4.5.9.

13.2.3.5 Bleachers Aisles. In seating composed entirely of bleachers for which the row-to-row dimension is 71 cm (28 in.) or less, and from which front egress is not limited, aisles shall not be required to exceed 1675 mm (66 in.) in width.

If the stair riser height does not exceed 178 mm (7 in.), factor A is still used but is to equal 1.0. Similarly, if the stair does have a handrail within a 760-mm (30-in.) horizontal distance, factor B is still used but is to equal 1.0.

For most occupancies, egress capacity involving horizontal travel is calculated at 5 mm (0.2 in.) per person. In Table 12/13.2.3.2, egress capacity within the audience seating chamber is penalized by 10 percent to 5.6 mm (0.22 in.) per person. Further, the presence of factor C indicates that additional modification of the capacity factor is necessary if the travel involves ascending a ramp with a slope steeper than 1 in 10. In such cases, the 5.6 mm (0.22 in.) per person capacity factor must be multiplied by a factor C of 1.10.

If the travel does not involve ascending a ramp with a slope steeper than 1 in 10, factor C is still used but is to equal 1.0.

Capacity Factor Modification

The following comparative examples demonstrate modification of the capacity factors of 12/13.2.3.2.

CHAPTER 12 • New

Example 1

SI Units. An auditorium has 5000 seats. It is not smoke protected. One stair is 1780 mm wide; riser height is 178 mm; handrails are positioned at each side; an additional handrail runs along the center of the aisle. One ramp is 1120 mm wide and rises with a slope of 1 in 12 to the rear exit access door.

The capacity of the stair is determined using the 7.6 AB formula from Table 12/13.2.3.2. Because the riser height does not exceed 178 mm, factor $A = 1.0$. Because there is a handrail within a 760-mm horizontal distance, factor $B = 1.0$. Substituting gives

$$\begin{aligned}\text{Stair capacity} &= \frac{1780 \text{ mm}}{(7.6) (1.0) (1.0) \text{ mm per person}} \\ &= 234 \text{ persons}\end{aligned}$$

The capacity of the ramp is determined using the 5.6 C formula from Table 12/13.2.3.2. Because the slope does not exceed 1 in 10, factor $C = 1.0$. Substituting gives

$$\begin{aligned}\text{Ramp capacity} &= \frac{1120 \text{ mm}}{(5.6) (1.0) \text{ mm per person}} \\ &= 200 \text{ persons}\end{aligned}$$

Inch/pound Units. An auditorium has 5000 seats. It is not smoke protected. One stair is 70 in. wide; riser height is 7 in.; handrails are positioned at each side; an additional handrail runs along the center of the aisle. One ramp is 44 in. wide and rises with a slope of 1 in 12 to the rear exit access door.

The capacity of the stair is determined using the 0.3 AB formula from Table 12/13.2.3.2. Because the riser height does not exceed 7 in., factor $A = 1.0$. Because there is a handrail within a 30-in. horizontal distance, factor $B = 1.0$. Substituting gives

$$\begin{aligned}\text{Stair capacity} &= \frac{70 \text{ in.}}{(0.300) (1.0) (1.0) \text{ in. per person}} \\ &= 233 \text{ persons}\end{aligned}$$

The capacity of the ramp is determined using the 0.22 C formula from Table 12/13.2.3.2. Because the slope does not exceed 1 in 10, factor $C = 1.0$. Substituting gives

$$\begin{aligned}\text{Ramp capacity} &= \frac{44 \text{ in.}}{(0.22) (1.0) \text{ in. per person}} \\ &= 200 \text{ persons}\end{aligned}$$

CHAPTER 13 • Existing

Example 2

SI Units. An auditorium has 5000 seats. It is not smoke protected. One stair is 1780 mm wide; riser height is 190 mm; handrails are positioned at each side; there is no handrail along the center of the aisle. One ramp is 1120 mm wide and rises with a slope of 1 in 9 to the rear exit access door.

The capacity of the stair is determined using the 7.6 AB formula from Table 12/13.2.3.2. Because the riser height exceeds 178 mm, factor A must be calculated using the formula in 12/13.2.3.3(1):

$$A = 1 + \frac{190 - 178}{125} = 1.1$$

Because there is not a handrail within a 760 mm horizontal distance, factor $B = 1.25$. Substituting,

$$\begin{aligned}\text{Stair capacity} &= \frac{1780 \text{ mm}}{(7.6) (1.1) (1.25) \text{ mm per person}} \\ &= 170 \text{ persons}\end{aligned}$$

The capacity of the ramp is determined using the 5.6 C formula from Table 12/13.2.3.2. Because the ramp is used in ascent for egress and the slope exceeds 1 in 10, factor $C = 1.10$. Substituting,

$$\begin{aligned}\text{Ramp capacity} &= \frac{1120 \text{ mm}}{(5.6) (1.10) \text{ mm per person}} \\ &= 182 \text{ persons}\end{aligned}$$

Inch/pound Units. An auditorium has 5000 seats. It is not smoke protected. One stair is 70 in. wide; riser height is 7.5 in.; handrails are positioned at each side; there is no handrail along the center of the aisle. One ramp is 44 in. wide and rises with a slope of 1 in 9 to the rear exit access door.

The capacity of the stair is determined using the 0.3 AB formula from Table 12/13.2.3.2. Because the riser height exceeds 7 in., factor A must be calculated using the formula in 12/13.2.3.3(2):

$$A = 1 + \frac{7.5 - 7.0}{5} = 1.1$$

Because there is not a handrail within a 30-in. horizontal distance, factor $B = 1.25$. Substituting,

$$\begin{aligned}\text{Stair capacity} &= \frac{70 \text{ in.}}{(0.3) (1.1) (1.25) \text{ in. per person}} \\ &= 170 \text{ persons}\end{aligned}$$

CHAPTER 12 • New

The capacity of the ramp is determined using the 0.22 C formula from Table 12/13.2.3.2. Because the ramp is used in ascent for egress and the slope exceeds 1 in 10, factor C = 1.10. Substituting,

12.2.3.6 Main Entrance/Exit. Every assembly occupancy shall be provided with a main entrance/exit.

12.2.3.6.1 The main entrance/exit shall be of a width that accommodates one-half of the total occupant load and shall be at the level of exit discharge or shall connect to a stairway or ramp leading to a street.

12.2.3.6.2 Each level of an assembly occupancy shall have access to the main entrance/exit, and such access shall have the capacity to accommodate 50 percent of the occupant load of such levels.

12.2.3.6.3 Where the main entrance/exit from an assembly occupancy is through a lobby or foyer, the aggregate capacity of all exits from the lobby or foyer shall be permitted to provide the required capacity of the main entrance/exit, regardless of whether all such exits serve as entrances to the building.

12.2.3.6.4 A bowling establishment shall have a main entrance/exit of a capacity that accommodates 50 percent of the total occupant load without regard to the number of aisles that it serves.

12.2.3.6.5* In assembly occupancies where there is no well-defined main entrance/exit, exits shall be permitted to be distributed around the perimeter of the building, provided that the total exit width furnishes not less than 100 percent of the width needed to accommodate the permitted occupant load.

A.12.2.3.6.5 The original *Code* wording exempted sports arenas and railway stations. If an assembly occupancy was not similar to a sports arena or railway station, it was often judged ineligible to use the provision of 12.2.3.6.5. A list of exempted assembly venues also raises the question as to why other occupancies are not included and necessitates additions to the list. For example, an exhibit hall of very large size might have several main entrances/exits. A theater extending the width of a block cannot really have a main entrance/exit in one confined location. A restaurant might have a main entrance serving the parking lot and another main entrance for those entering from the street. The authority having jurisdiction needs to determine where such arrangements are acceptable.

CHAPTER 13 • Existing

$$\begin{aligned} \text{Ramp capacity} &= \frac{44 \text{ in.}}{(0.22) (1.10) \text{ in. per person}} \\ &= 182 \text{ persons} \end{aligned}$$

13.2.3.6 Main Entrance/Exit. Every assembly occupancy shall be provided with a main entrance/exit.

13.2.3.6.1 The main entrance/exit shall be of a width that accommodates one-half of the total occupant load and shall be at the level of exit discharge or shall connect to a stairway or ramp leading to a street.

13.2.3.6.2 Reserved.

13.2.3.6.3 Where the main entrance/exit from an assembly occupancy is through a lobby or foyer, the aggregate capacity of all exits from the lobby or foyer shall be permitted to provide the required capacity of the main entrance/exit, regardless of whether all such exits serve as entrances to the building.

13.2.3.6.4 A bowling establishment shall have a main entrance/exit of a capacity that accommodates 50 percent of the total occupant load without regard to the number of aisles that it serves.

13.2.3.6.5* In assembly occupancies where there is no well-defined main entrance/exit, exits shall be permitted to be distributed around the perimeter of the building, provided that the total exit width furnishes not less than 100 percent of the width needed to accommodate the permitted occupant load.

A.13.2.3.6.5 The original *Code* wording exempted sports arenas and railway stations. If an assembly occupancy was not similar to a sports arena or railway station, it was often judged ineligible to use the provision of 13.2.3.6.5. A list of exempted assembly venues also raises the question as to why other occupancies are not included and necessitates additions to the list. For example, an exhibit hall of very large size might have several main entrances/exits. A theater extending the width of a block cannot really have a main entrance/exit in one confined location. A restaurant might have a main entrance serving the parking lot and another main entrance for those entering from the street. The authority having jurisdiction needs to determine where such arrangements are acceptable.

CHAPTER 12 • New

12.2.3.7 Other Exits. Each level of an assembly occupancy shall have access to the main entrance/exit and shall be provided with additional exits of a width to accommodate not less than one-half of the total occupant load served by that level.

12.2.3.7.1 Additional exits shall discharge in accordance with 12.2.7.

12.2.3.7.2 Additional exits shall be located as far apart as practicable and as far from the main entrance/exit as practicable.

12.2.3.7.3 Additional exits shall be accessible from a cross aisle or a side aisle.

12.2.3.7.4 In assembly occupancies where there is no well-defined main entrance/exit, exits shall be permitted to be distributed around the perimeter of the building, provided that the total exit width furnishes not less than 100 percent of the width required to accommodate the permitted occupant load.

12.2.3.8 The width of any exit access corridor serving 50 or more persons shall be not less than 1120 mm (44 in.).

The intent of 12/13.2.3.6 is to require that 50 percent of the occupants are able to egress through the same door(s) they used to enter the building. The door through which an occupant enters a building is generally the door most familiar to the occupant. The occupant can be expected to attempt to use that door for emergency egress. The term *main entrance/exit* clarifies that the *Code* intends the main entrance to a public assembly occupancy to be designated as the main exit.

Where the main entrance is through a lobby, a majority of the occupants can be expected to return to the lobby area during emergency egress. If the lobby has additional doors that are not used as entrance doors (for example, doors A and B in Exhibit 12/13.9), the occupants are likely to use these doors, because they have reached the lobby with which they are familiar. Thus, the *Code* permits all the lobby doors to serve collectively as the required main exit. See Exhibit 12/13.9.

Paragraph 12/13.2.3.6.4, which addresses bowling establishments, is no longer applicable and should be deleted when the *Code* is revised. It had been relevant in earlier *Code* editions, which required the main exit to be at least as wide as the aggregate width

CHAPTER 13 • Existing

13.2.3.7 Other Exits. Each level of an assembly occupancy shall have access to the main entrance/exit and shall be provided with additional exits of a width to accommodate not less than one-half of the total occupant load served by that level.

13.2.3.7.1 Additional exits shall discharge in accordance with 13.2.7.

13.2.3.7.2 Additional exits shall be located as far apart as practicable and as far from the main entrance/exit as practicable.

13.2.3.7.3 Additional exits shall be accessible from a cross aisle or a side aisle.

13.2.3.7.4 In assembly occupancies where there is no well-defined main entrance/exit, exits shall be permitted to be distributed around the perimeter of the building, provided that the total exit width furnishes not less than 100 percent of the width required to accommodate the permitted occupant load.

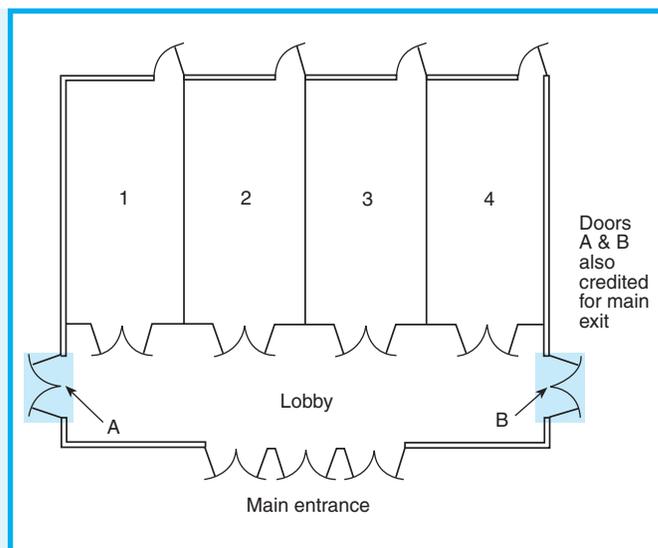

Exhibit 12/13.9 Main entrance/exit.

of all required aisles leading to the main exit. Bowling alleys have an unusually large number of aisles for functional purposes. The exemption previously modified an excessive main exit width that was required

CHAPTER 12 • New

to accommodate the sum of the required aisle widths served by the exit.

Paragraph 12/13.2.3.6.5 acknowledges that some assembly occupancy buildings have no well-defined main entrance exit. Occupants enter the building by doors in multiple walls. Under emergency egress conditions, all occupants will not attempt to use the same doors, because some occupants are familiar with certain doors while others are familiar with other doors. In such cases, it is the intent that egress width be distributed among the various exits without any one exit being required to provide 50 percent of the egress capacity. See also 12/13.2.3.7.4.

A major change occurred in the 1991 edition of the *Code* with the deletion of a requirement that exits other than the main exit had to accommodate two-thirds of the occupant load, which resulted in a 16% percent overdesign.

12.2.4* Number of Exits.

A.12.2.4 It is not the intent to require four means of egress from each level of an assembly occupancy building having a total occupant load of more than 1000 where, individually, the floors have occupant loads of less than 1000.

12.2.4.1 The number of exits shall be in accordance with Section 7.4, other than exits for fenced outdoor assembly occupancies in accordance with 12.2.4.4.

12.2.4.2 Reserved.

12.2.4.3 Reserved.

12.2.4.4 A fenced outdoor assembly occupancy shall have not less than two widely separated means of egress from the enclosure, unless otherwise required by one of the following:

- (1) If more than 6000 persons are to be served by such means of egress, there shall be not less than three means of egress.
- (2) If more than 9000 persons are to be served by such means of egress, there shall be not less than four means of egress.

12.2.4.5 Balconies or mezzanines having an occupant load not exceeding 50 shall be permitted to be served by a single means of egress, and such means of egress shall be permitted to lead to the floor below.

CHAPTER 13 • Existing

As an example of the requirements of 12/13.2.3.7, if an assembly occupancy has an occupant load of 900 persons, the main exit would have to accommodate 450 persons (50 percent). If, for compliance with 12/13.2.4 and Section 7.4, two additional exits were provided, together they would have to accommodate the remaining 450 persons.

The minimum 1120-mm (44-in.) width for exit access corridors serving 50 or more persons in new assembly occupancies—required by 12.2.3.8—allows more than one file of persons to travel along the corridor simultaneously. The minimum width also permits persons capable of traveling at normal speed to pass persons who are slower, rather than queuing behind them.

13.2.4* Number of Exits.

A.13.2.4 It is not the intent to require four means of egress from each level of an assembly occupancy building having a total occupant load of more than 1000 where, individually, the floors have occupant loads of less than 1000.

13.2.4.1 The number of exits shall be in accordance with Section 7.4, other than fenced outdoor assembly occupancies in accordance with 13.2.4.4, unless otherwise permitted by 13.2.4.2 or 13.2.4.3.

13.2.4.2 Assembly occupancies with occupant loads of 600 or fewer shall have two separate means of egress.

13.2.4.3 Assembly occupancies with occupant loads greater than 600 but fewer than 1000 shall have three separate means of egress.

13.2.4.4 A fenced outdoor assembly occupancy shall have not less than two widely separated means of egress from the enclosure, unless otherwise required by one of the following:

- (1) If more than 6000 persons are to be served by such means of egress, there shall be not less than three means of egress.
- (2) If more than 9000 persons are to be served by such means of egress, there shall be not less than four means of egress.

13.2.4.5 Balconies or mezzanines having an occupant load not exceeding 50 shall be permitted to be served by a single means of egress, and such means of egress shall be permitted to lead to the floor below.

CHAPTER 12 • New

12.2.4.6 Balconies or mezzanines having an occupant load exceeding 50 but not exceeding 100 shall have not less than two remote means of egress, but both such means of egress shall be permitted to lead to the floor below.

12.2.4.7 Balconies or mezzanines having an occupant load exceeding 100 shall have means of egress as described in 7.4.1.

12.2.4.8 A second means of egress shall not be required from lighting and access catwalks, galleries, and gridirons where a means of escape to a floor or a roof is provided. Ladders, alternating tread devices, or spiral stairs shall be permitted in such means of escape.

As the concentration or number of people in an assembly occupancy increases, the need for simultaneous egressing by a sizable group of occupants increases. Therefore, to reduce jamming at doorways (which might lead to panic and disorder), in accordance with the provisions of Section 7.4, more than two exits are needed for large occupant loads.

By permitting a single means of egress from a small balcony, 12/13.2.4.5 provides for balconies and mezzanines that do not accommodate more than 50 people, such as choir lofts. See also 12.2.5.1.2 and 13.2.5.1.1, which increase the permitted common path of travel to 23 m (75 ft) from an area with not more than 50 occupants.

12.2.5 Arrangement of Means of Egress.

12.2.5.1 General.

12.2.5.1.1 Means of egress shall be arranged in accordance with Section 7.5.

12.2.5.1.2 A common path of travel shall be permitted for the first 6100 mm (240 in.) from any point where the common path serves any number of occupants, and for the first 23 m (75 ft) from any point where the common path serves not more than 50 occupants.

12.2.5.1.3 Dead-end corridors shall not exceed 6100 mm (240 in.).

12.2.5.2 Access Through Hazardous Areas. Means of egress from a room or space for assembly purposes shall not be permitted through kitchens, storerooms, restrooms, closets, legitimate stages, projection rooms, or hazardous areas as described in 12.3.2.

CHAPTER 13 • Existing

13.2.4.6 Balconies or mezzanines having an occupant load exceeding 50 but not exceeding 100 shall have not less than two remote means of egress, but both such means of egress shall be permitted to lead to the floor below.

13.2.4.7 Balconies or mezzanines having an occupant load exceeding 100 shall have means of egress as described in 7.4.1.

13.2.4.8 A second means of egress shall not be required from lighting and access catwalks, galleries, and gridirons where a means of escape to a floor or a roof is provided. Ladders, alternating tread devices, or spiral stairs shall be permitted in such means of escape.

The balconies addressed by 12/13.2.4.6 might typically be found in restaurants or small theaters. The provisions explain that it is important to have two remote means of egress, but, because the total number of occupants does not exceed 100, it is reasonable to allow occupants to egress onto the floor below.

Any balcony or mezzanine that can accommodate more than 100 people, as addressed by 12/13.2.4.7, should be treated as a separate floor with regard to the number of means of egress. Such treatment avoids overloading the means of egress on the floor below and provides mezzanine occupants with independent travel paths in case of fire on the floor below.

13.2.5 Arrangement of Means of Egress.

13.2.5.1 General. Means of egress shall be arranged in accordance with Section 7.5.

13.2.5.1.1 The common paths of travel shall be permitted for the first 6100 mm (240 in.) from any point where the common path serves any number of occupants, and for the first 23 m (75 ft) from any point where the common path serves not more than 50 occupants.

13.2.5.1.2 Dead-end corridors shall not exceed 6100 mm (240 in.).

13.2.5.2 Access Through Hazardous Areas. Means of egress shall not be permitted through kitchens, storerooms, restrooms, closets, or hazardous areas as described in 13.3.2.

CHAPTER 12 • New

12.2.5.3 Auditorium and Area Floors. Where the floor area of auditoriums and arenas is used for assembly occupancy activities/events, not less than 50 percent of the occupant load shall have means of egress provided without passing through adjacent fixed seating areas.

Remoteness of exits is an important concept addressed by Chapter 7. Exits that are located too close to each other can quickly become unusable during the same fire. The fundamental principles of the *Code*, as expressed in Section 4.5, require remoteness of exits to the point that a single fire will not simultaneously block the required exits. This same concept of remoteness applies to exit access doors. The remoteness requirements of Section 7.5 must be met.

Revolving rooftop assembly occupancies require special consideration; as the structure revolves, exit signs are often lost from view. To provide an unobstructed panoramic view, the exterior ring-shaped floor area revolves around a small stationary interior core where the exits are often located. In many cases, the two exits are too close to each other to meet remoteness criteria. Usually, at least one stairway from the building core involves a horizontal passage on the floor below to transfer occupants from that stairway to the normal, remotely located exit stairways. This transfer, because it is a continuation of the stairway within the core, must be made via an exit passageway with a fire resistance rating equal to that required for the stair enclosure.

Although exit placement must meet the remoteness criteria of Section 7.5, it is not practical to require immediate access to two exits from every point in a building. Rather, occupants are permitted to be forced to travel in only one direction for a limited distance before reaching a point where travel in more

12.2.5.4 General Requirements for Access and Egress Routes Within Assembly Areas.

12.2.5.4.1 Festival seating, as defined in 3.3.188.1, shall be prohibited within a building, unless otherwise permitted by the following:

- (1) Festival seating shall be permitted in assembly occupancies having occupant loads of 1000 or less.
- (2) Festival seating shall be permitted in assembly occupancies where occupant loads exceed 1000 and where an approved life safety evaluation has been performed. (*See 12.4.1.*)

CHAPTER 13 • Existing

13.2.5.3 Reserved.

than one direction becomes possible. This limited travel in one direction is called *common path of travel* (see definition in 3.3.34). See the commentary associated with 7.5.1.6.

Paragraphs 12.2.5.1.2 and 13.2.5.1.1 establish two allowable common path of travel limitations as follows:

- (1) 6100 mm (240 in.) regardless of occupant load
- (2) 23 m (75 ft) where serving not more than 50 persons

Additionally, 12/13.2.5.5.5 permits a 9140-mm (360-in.) common path of travel between a point within an aisle accessway and the aisle serving a seating row. Paragraph 12/13.4.2.6 permits a 15-m (50-ft) common path of travel in seating areas in smoke-protected assembly seating. Thus, the common path of travel limitations are numerous for assembly occupancies.

The requirement of 12/13.2.5.2 clarifies that exit access travel is not permitted to pass through areas subject to locking or areas presenting a hazard level higher than that normally associated with an assembly occupancy.

The provision of 12.2.5.3, which applies only to new assembly occupancies, is intended to reduce the amount of merging and sharing of means of egress by persons in fixed seating areas and those who are forced to travel from the arena floor up into the seating sections to egress the building.

13.2.5.4 General Requirements for Access and Egress Routes Within Assembly Areas.

13.2.5.4.1 Festival seating, as defined in 3.3.188.1, shall be prohibited within a building, unless otherwise permitted by the following:

- (1) Festival seating shall be permitted in assembly occupancies having occupant loads of 1000 or less.
- (2) Festival seating shall be permitted in assembly occupancies where occupant loads exceed 1000 and where an approved life safety evaluation has been performed. (*See 13.4.1.*)

Tentative Interim Amendment
NFPA 101®
Life Safety Code®
2003 Edition

Reference: 12.2.5.4.1 and 13.2.5.4.1
 TIA 03-1 (NFPA 101)
 (SC 03-7-15/Log No. 737R)

Pursuant to Section 5 of the NFPA Regulations Governing Committee Projects, the National Fire Protection Association has issued the following Tentative Interim Amendment to NFPA 101®, *Life Safety Code®*, 2003 edition. The TIA was processed by the Safety to Life Committee, and was issued by the Standards Council on July 25, 2003, with an effective date of August 14, 2003.

A Tentative Interim Amendment is tentative because it has not been processed through the entire standards-making procedures. It is interim because it is effective only between editions of the standard. A TIA automatically becomes a proposal of the proponent for the next edition of the standard; as such, it then is subject to all of the procedures of the standards-making process.

Revise 12.2.5.4.1 and 13.2.5.4.1 to prohibit festival seating in assembly occupancies with occupant load more than 250 without a life safety evaluation as follows:

12.2.5.4.1 Festival seating, as defined in 3.3.188.1, shall be prohibited within a building, unless otherwise permitted by the following:

- (1) Festival seating shall be permitted in assembly occupancies having occupant loads of 250 ~~1000~~ or less.
- (2) Festival seating shall be permitted in assembly occupancies where occupant loads exceed 250 ~~1000~~ and ~~where~~ an approved life safety evaluation has been performed. (See 12.4.1.)

13.2.5.4.1 Festival seating, as defined in 3.3.188.1, shall be prohibited within a building, unless otherwise permitted by the following:

- (1) Festival seating shall be permitted in assembly occupancies having occupant loads of 250 ~~1000~~ or less.
- (2) Festival seating shall be permitted in assembly occupancies where occupant loads exceed 250 ~~1000~~ and ~~where~~ an approved life safety evaluation has been performed. (See 13.4.1.)

12.2.5.4.2* Access and egress routes shall be maintained so that any individual is able to move without undue hindrance, on personal initiative and at any time, from an occupied position to the exits.

A.12.2.5.4.2 This requirement and the associated requirement of 12.2.5.4.3 have the effect of prohibiting festival seating unless it truly is a form of seating, such as lawn seating, where generous spaces are commonly maintained between individuals and small groups so that people can circulate freely at any time. Such lawn seating will be characterized by densities of about one person per 1.4 m² (15 ft²). Both requirements prohibit uncontrolled crowd situations, such as in front of stages at rock music concerts where the number and density of people is uncontrolled by architectural or management features.

13.2.5.4.2* Access and egress routes shall be maintained so that any individual is able to move without undue hindrance, on personal initiative and at any time, from an occupied position to the exits.

A.13.2.5.4.2 This requirement and the associated requirement of 13.2.5.4.3 have the effect of prohibiting festival seating unless it truly is a form of seating, such as lawn seating, where generous spaces are commonly maintained between individuals and small groups so that people can circulate freely at any time. Such lawn seating will be characterized by densities of about one person per 1.4 m² (15 ft²). Both requirements prohibit uncontrolled crowd situations, such as in front of stages at rock music concerts where the number and density of people is uncontrolled by architectural or management features.

CHAPTER 12 • New

12.2.5.4.3* Access and egress routes shall be maintained so that crowd management, security, and emergency medical personnel are able to reach any individual at any time, without undue hindrance.

A.12.2.5.4.3 This requirement is intended to facilitate rapid emergency access to individuals who are experiencing a medical emergency, especially in the case of cardiopulmonary difficulties, where there is a need for rapid medical attention from trained personnel. The requirement also addresses the need for security and law enforcement personnel to reach individuals whose behavior is endangering themselves and others.

12.2.5.4.4* The width of aisle accessways and aisles shall provide sufficient egress capacity for the number of persons accommodated by the catchment area served by the aisle accessway or aisle in accordance with 12.2.3.2, or for smoke-protected assembly seating in accordance with 12.4.2.

A.12.2.5.4.4 The catchment area served by an aisle accessway or aisle is the portion of the total space that is naturally served by the aisle accessway or aisle. Hence, the requirement for combining the required capacity where paths converge is, in effect, a restatement of the idea of a catchment area. The establishment of catchment areas should be based on a balanced use of all means of egress, with the number of persons in proportion to egress capacity.

12.2.5.4.5 Where aisle accessways or aisles converge to form a single path of egress travel, the required egress capacity of that path shall not be less than the combined required capacity of the converging aisle accessways and aisles.

12.2.5.4.6 Those portions of aisle accessways and aisles where egress is possible in either of two directions shall be uniform in required width unless otherwise permitted by 12.2.5.4.7.

12.2.5.4.7 The requirement of 12.2.5.4.6 shall not apply to those portions of aisle accessways where the required width, not including the seat space described by 12.2.5.7.3, does not exceed 305 mm (12 in.).

12.2.5.4.8 In the case of side boundaries for aisle accessways or aisles, other than those for nonfixed seating at tables, the clear width shall be measured to boundary elements such as walls, guardrails, handrails, edges of seating, tables, and side edges of treads, and said measurement shall be made horizontally to the vertical projection of the elements, resulting in the smallest width measured perpendicularly to the line of travel.

CHAPTER 13 • Existing

13.2.5.4.3* Access and egress routes shall be maintained so that crowd management, security, and emergency medical personnel are able to reach any individual at any time, without undue hindrance.

A.13.2.5.4.3 This requirement is intended to facilitate rapid emergency access to individuals who are experiencing a medical emergency, especially in the case of cardiopulmonary difficulties, where there is a need for rapid medical attention from trained personnel. The requirement also addresses the need for security and law enforcement personnel to reach individuals whose behavior is endangering themselves and others.

13.2.5.4.4* The width of aisle accessways and aisles shall provide sufficient egress capacity for the number of persons accommodated by the catchment area served by the aisle accessway or aisle in accordance with 13.2.3.2, or for smoke-protected assembly seating in accordance with 13.4.2.

A.13.2.5.4.4 The catchment area served by an aisle accessway or aisle is the portion of the total space that is naturally served by the aisle accessway or aisle. Hence, the requirement for combining the required capacity where paths converge is, in effect, a restatement of the idea of a catchment area. The establishment of catchment areas should be based on a balanced use of all means of egress, with the number of persons in proportion to egress capacity.

13.2.5.4.5 Where aisle accessways or aisles converge to form a single path of egress travel, the required egress capacity of that path shall not be less than the combined required capacity of the converging aisle accessways and aisles.

13.2.5.4.6 Those portions of aisle accessways and aisles where egress is possible in either of two directions shall be uniform in required width unless otherwise permitted by 13.2.5.4.7.

13.2.5.4.7 The requirement of 13.2.5.4.6 shall not apply to those portions of aisle accessways where the required width, not including the seat space described by 13.2.5.7.3, does not exceed 305 mm (12 in.).

13.2.5.4.8 In the case of side boundaries for aisle accessways or aisles, other than those for nonfixed seating at tables, the clear width shall be measured to boundary elements such as walls, guardrails, handrails, edges of seating, tables, and side edges of treads, and said measurement shall be made horizontally to the vertical projection of the elements, resulting in the smallest width measured perpendicularly to the line of travel.

CHAPTER 12 • New

CHAPTER 13 • Existing

Festival seating, as addressed in 12/13.2.5.4.1, is illustrated in Exhibit 12/13.10. This low-density arrangement of people, which provides them with the ability to sit directly on the ground or floor and to move relatively easily through and out of the area, likely evolved from outdoor festivals held in open areas. Festival seating has been abused—at both indoor and outdoor events—where the assembled spectators are not controllable in terms of their numbers, location, or behavior. A rock music concert is an example of an event where the festival seating concept might become decidedly unfestive when unmanageable crowds of standing (not seated) people form in front of the stage area and circulation routes through the assembled crowd are completely lost. Injuries caused by bodies crushing against bodies or portions of the structure are likely when this situation occurs.

A description of a typical crowd crush is found in a report titled “Observations of Crowd Conditions at Rock Concert in Exhibition Stadium, Toronto, 16 July 1980,” by J. L. Pauls⁴. Because the number and arrangement of people in this instance were not controlled throughout the event, there were eventually some 30,000 to 40,000 people distributed unevenly in an area of about 10,600 m² (125,000 ft²). The result was an average density of about 1 person per 0.33 m² (3.5 ft²). However, due to localized crowding at the stage area, several thousand people were at crushing densities of about 1 person per 0.19 m² (2 ft²). Both

Exhibit 12/13.10 Outdoor festival seating at a rock music concert held in a stadium. (Photograph courtesy of Jake Pauls.)

normal access and emergency access into this congested area were all but impossible, and management efforts to instruct people to move back toward less densely occupied areas proved futile. Incidents such as this led to the requirements of 12/13.2.5.4.1, which prohibits indoor festival seating for more than 1000 persons unless an approved life safety evaluation is utilized.

In performance-oriented language, 12/13.2.5.4.2 prohibits overcrowding and the blocking of aisles and other portions of the exit access. See the explanation in A.12/A.13.2.5.4.2.

In addition to providing life safety under fire conditions, the requirements of 12/13.2.5.4.3 address the emergency and nonemergency movement of people. Because of the potential for ingress and egress paths to become blocked by the large crowds characteristic of many assembly occupancies, it is important that crowd management, security, and emergency medical personnel are able to move to any individual without undue hindrance at any time. The ability to deal effectively with an emergency while the problem is small often precludes having to deal with a larger emergency later.

The width referenced in 12/13.2.5.4.4 refers to the egress capacity-driven width requirements of 12/13.2.3. The capacity-related width requirements must be considered along with the other minimum width requirements detailed in 12/13.2.5.6.3. The applicable minimum width requirement is the larger of the widths established by the two sets of requirements.

Exhibit 12/13.11 illustrates how catchment areas would be allotted in the case of a theater with four egress doors having approximately equal egress capacity. Note that catchment area apportionment for normal, nonemergency uses often will make use of only some of the available exit access paths and exits, particularly those provided by the main entrance/exit. This arrangement might be quite different from a catchment area apportionment based on a balanced distribution of people in proportion to the egress capacity of individual exits. Facility management procedures must allow for the difficulties of informing people of and directing them to all the available means of egress, especially when normally used, familiar routes become blocked in an emergency.

Note that the term *required egress capacity* is used in 12/13.2.5.4.5 to clarify that the combined required width of the egress routes might be smaller than their

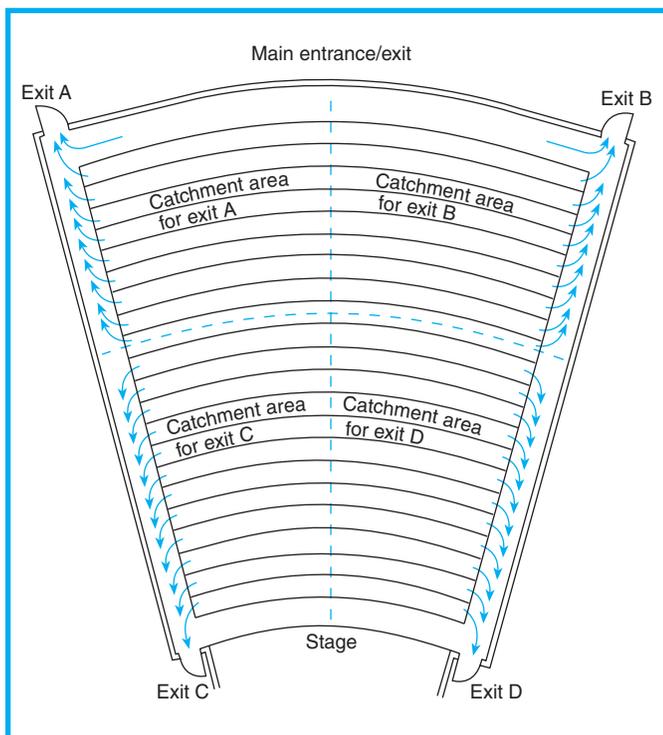

Exhibit 12/13.11 Catchment areas based on balanced use of all means of egress in proportion to egress capacity.

combined actual widths. Widths that exceed *Code* minimums might be provided voluntarily to facilitate day-to-day operations.

Per 12/13.2.5.4.6 if egress travel is possible in two directions, all portions of the aisle or aisle accessway must meet or exceed the minimum width required for any other portion of the aisle or aisle accessway. Generally, this prohibits aisles and aisle accessways from being hourglass shaped, allowing them to accommodate efficient egress travel that might have to reverse direction because of blockage at one end of the aisle or aisle accessway.

12.2.5.5* Aisle Accessways Serving Seating Not at Tables.

A.12.2.5.5 For purposes of the means of egress requirements of this *Code*, tablet-arm chair seating is not considered seating at tables. Dinner theater-style configurations are required to comply with the aisle accessway provisions applying to seating at tables and the aisle requirements of 12.2.5.6, if the aisles contain steps or are ramped. Generally, if aisles contain steps or are ramped, all of this *Code*'s requirements for aisles, stairs, and ramps are required to be met. (Also see 7.1.7 and A.7.1.7.2.)

12.2.5.5.1* The required clear width of aisle accessways between rows of seating shall be determined as follows:

- (1) Horizontal measurements shall be made, between vertical planes, from the back of one seat to the front of the most forward projection of the seat immediately behind it.
- (2) Where the entire row consists of automatic or self-rising seats that comply with ASTM F 851, *Test Method for Self-Rising Seat Mechanisms*, the measurement shall be permitted to be made with the seats in the up position.

13.2.5.5* Aisle Accessways Serving Seating Not at Tables.

A.13.2.5.5 For purposes of the means of egress requirements of this *Code*, tablet-arm chair seating is not considered seating at tables. Dinner theater-style configurations are required to comply with the aisle accessway provisions applying to seating at tables and the aisle requirements of 13.2.5.6, if the aisles contain steps or are ramped. Generally, if aisles contain steps or are ramped, all of this *Code*'s requirements for aisles, stairs, and ramps are required to be met. (Also see 7.1.7 and A.7.1.7.2.)

13.2.5.5.1* The required clear width of aisle accesses between rows of seating shall be determined as follows:

- (1) Horizontal measurements shall be made, between vertical planes, from the back of one seat to the front of the most forward projection of the seat immediately behind it.
- (2) Where the entire row consists of automatic or self-rising seats that comply with ASTM F 851, *Test Method for Self-Rising Seat Mechanisms*, the measurement shall be permitted to be made with the seats in the up position.

CHAPTER 12 • New

A.12.2.5.5.1 Seats having reclining backs are assumed to be in their most upright position when unoccupied.

12.2.5.5.2 The aisle accessway between rows of seating shall have a clear width of not less than 305 mm (12 in.), and this minimum shall be increased as a function of row length in accordance with 12.2.5.5.4 and 12.2.5.5.5.

12.2.5.5.3 If used by not more than four persons, no minimum clear width shall be required for the portion of an aisle accessway having a length not exceeding 1830 mm (72 in.), measured from the center of the seat farthest from the aisle.

Aisle accessway is defined in 3.3.8 as the initial portion of an exit access that leads to an aisle. Exhibit 12/13.12 illustrates the aisle accessways formed by rows of chairs. The space between each row of chairs (indicated by the arrows) is an aisle accessway.

The method for measuring the width of an aisle accessway formed by rows of chairs is illustrated in Exhibit 12/13.13. In illustration (a) in Exhibit 12/13.12, the seats are not self-rising. In illustration (b), the seats are self-rising.

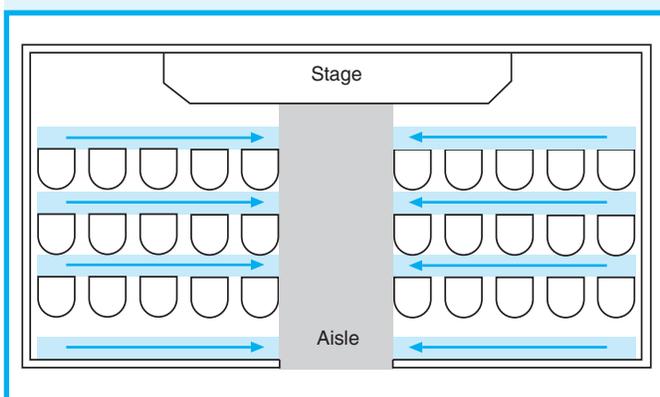

Exhibit 12/13.12 Aisle accessways.

12.2.5.5.4* Rows of seating served by aisles or doorways at both ends shall not exceed 100 seats per row.

A.12.2.5.5.4 The system known as *continental seating* has one pair of egress doors provided for every five rows that is located close to the ends of the rows. In previous editions of the *Code*, such egress doors were required to provide a clear width of not less than 1675 mm (66 in.) discharging into a foyer, into a lobby, or to the exterior of the building. This continental seating arrangement can result in egress

CHAPTER 13 • Existing

A.13.2.5.5.1 Seats having reclining backs are assumed to be in their most upright position when unoccupied.

13.2.5.5.2 The aisle accessway between rows of seating shall have a clear width of not less than 305 mm (12 in.), and this minimum shall be increased as a function of row length in accordance with 13.2.5.5.4 and 13.2.5.5.5.

13.2.5.5.3 If used by not more than four persons, no minimum clear width shall be required for the portion of an aisle accessway having a length not exceeding 1830 mm (72 in.), measured from the center of the seat farthest from the aisle.

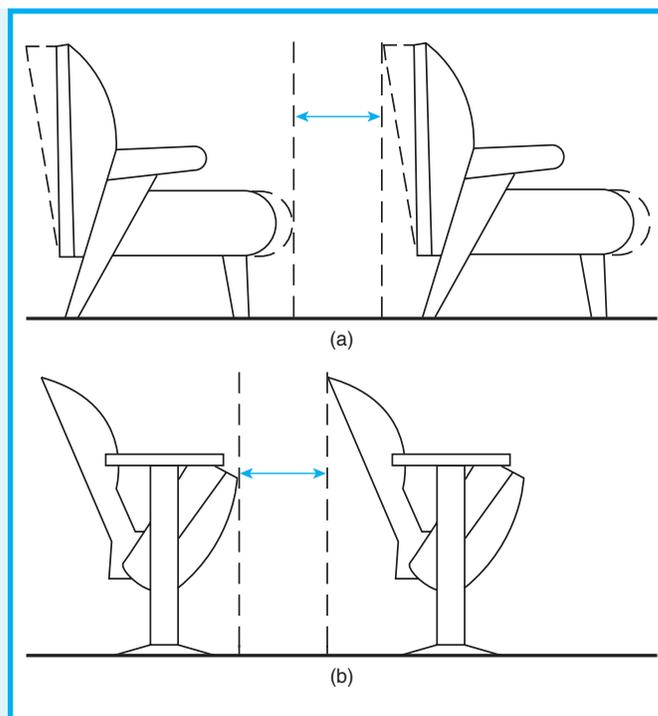

Exhibit 12/13.13 Measurement of width of aisle accessway formed by rows of chairs.

13.2.5.5.4* Rows of seating served by aisles or doorways at both ends shall not exceed 100 seats per row.

A.13.2.5.5.4 The system known as *continental seating* has one pair of egress doors provided for every five rows that is located close to the ends of the rows. In previous editions of the *Code*, such egress doors were required to provide a clear width of not less than 1675 mm (66 in.) discharging into a foyer, into a lobby, or to the exterior of the building. This continental seating arrangement can result in egress

CHAPTER 12 • New

flow times (that is, with nominal flow times of approximately 100 seconds, rather than 200 seconds) that are approximately one-half as long as those resulting where side aisles lead to more remote doors. Such superior egress flow time performance is desirable in some situations; however, special attention should be given either to a comparably good egress capacity for other parts of the egress system or to sufficient space to accommodate queuing outside the seating space.

12.2.5.5.4.1 The 305-mm (12-in.) minimum clear width of aisle accessway between such rows shall be increased by 7.6 mm (0.3 in.) for every seat over a total of 14 but shall not be required to exceed 560 mm (22 in.).

12.2.5.5.4.2 The requirement of 12.2.5.5.4.1 shall not apply to smoke-protected assembly seating as permitted by 12.4.2.4.

12.2.5.5.5 Rows of seating served by an aisle or doorway at one end only shall have a path of travel not exceeding 9140 mm (360 in.) in length from any seat to an aisle.

12.2.5.5.5.1 The 305-mm (12-in.) minimum clear width of aisle accessway between rows of seating as specified in 12.2.5.5.5 shall be increased by 15 mm (0.6 in.) for every seat over a total of seven.

12.2.5.5.5.2 The requirements of 12.2.5.5.5 and 12.2.5.5.5.1 shall not apply to smoke-protected assembly seating as permitted by 12.4.2.5 and 12.4.2.6.

12.2.5.5.6 Rows of seating using tablet-arm chairs shall be permitted only if the clear width of aisle accessways complies with the requirements of 12.2.5.5 when measured under one of the following conditions:

- (1) The clear width is measured with the tablet arm in the usable position.
- (2) The clear width is measured with the tablet arm in the stored position where the tablet arm automatically returns to the stored position when raised manually to a vertical position in one motion and falls to the stored position by force of gravity.

12.2.5.5.7 The depth of seat boards shall not be less than 230 mm (9 in.) where the same level is not used for both seat boards and footboards.

12.2.5.5.8 Footboards, independent of seats, shall be provided so that there is no horizontal opening that allows the passage of a 13-mm (½-in.) diameter sphere.

CHAPTER 13 • Existing

flow times (that is, with nominal flow times of approximately 100 seconds rather than 200 seconds) that are approximately one-half as long as those resulting where side aisles lead to more remote doors. Such superior egress flow time performance is desirable in some situations; however, special attention should be given either to a comparably good egress capacity for other parts of the egress system or to sufficient space to accommodate queuing outside the seating space.

13.2.5.5.4.1 The 305-mm (12-in.) minimum clear width of aisle accessway between such rows shall be increased by 7.6 mm (0.3 in.) for every seat over a total of 14 but shall not be required to exceed 560 mm (22 in.).

13.2.5.5.4.2 The requirement of 13.2.5.5.4.1 shall not apply to smoke-protected assembly seating as permitted by 13.4.2.4.

13.2.5.5.5 Rows of seating served by an aisle or doorway at one end only shall have a path of travel not exceeding 9140 mm (360 in.) in length from any seat to an aisle.

13.2.5.5.5.1 The 305-mm (12-in.) minimum clear width of aisle accessway between rows of seating as specified in 13.2.5.5.5 shall be increased by 15 mm (0.6 in.) for every seat over a total of seven.

13.2.5.5.5.2 The requirements of 13.2.5.5.5 and 13.2.5.5.5.1 shall not apply to smoke-protected assembly seating as permitted by 13.4.2.5 and 13.4.2.6.

13.2.5.5.6 Rows of seating using tablet-arm chairs shall be permitted only if the clear width of aisle accessways complies with the requirements of 13.2.5.5 when measured under one of the following conditions:

- (1) The clear width is measured with the tablet arm in the usable position.
- (2) The clear width is measured with the tablet arm in the stored position where the tablet arm automatically returns to the stored position when raised manually to a vertical position in one motion and falls to the stored position by force of gravity.

13.2.5.5.7 The depth of seat boards shall not be less than 230 mm (9 in.) where the same level is not used for both seat boards and footboards.

13.2.5.5.8 Footboards, independent of seats, shall be provided so that there is no horizontal opening that allows the passage of a 13-mm (½-in.) diameter sphere.

CHAPTER 12 • New

The annex to 12/13.2.5.5.4 relates the expected egress flow time performance of continental seating, as addressed by the *Code* prior to 1988, to the egress flow time performance of the more flexible requirements for egress width related to capacity. See Exhibit 12/13.14 for an example of continental seating. In earlier editions of the *Code*, this arrangement was required where there were more than 14 seats in a row. A maximum of 100 seats was permitted for one row.

Currently, the *Code* permits design flexibility, based on the continental seating principle of variable minimum spacing for rows of seats and row length, using the provisions of 12/13.2.5.5.4.1. As reference points for each end of the spacing range, the newer requirement uses the previous 305 mm (12 in.) of clearance for rows up to 14 seats in length and 560 mm (22 in.) for rows over 47 seats in length. For example, rows with 47 seats require a clearance of 555 mm (21.9 in.). This clearance is calculated by subtracting 14 from 47 and multiplying the result, 33, by 7.6 mm (0.3 in.) to obtain 250 mm (9.9 in.), which is added to the 305-mm (12-in.) minimum aisle accessway width

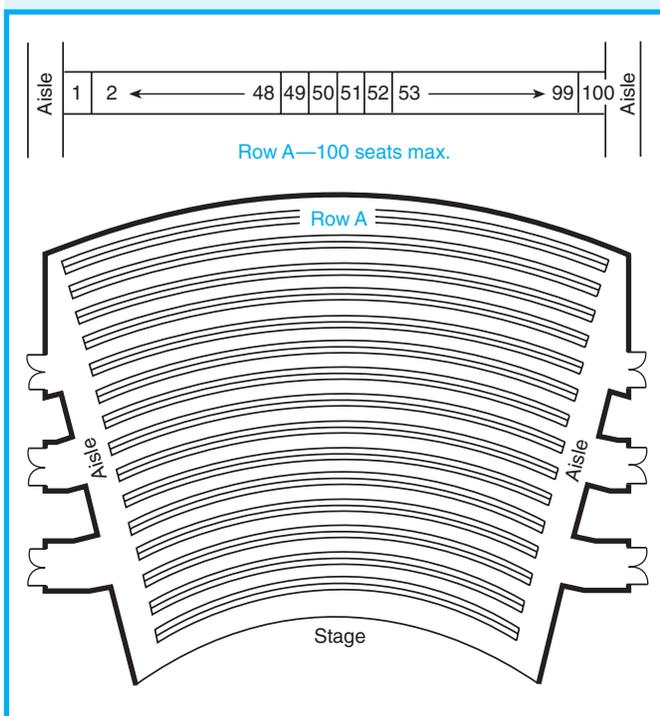

Exhibit 12/13.14 Arrangement of seats and aisles with continental seating.

CHAPTER 13 • Existing

to obtain the total required clear aisle accessway width of 555 mm (21.9 in.). Because the aisle accessway width is not required to exceed 560 mm (22 in.), rows with 48 to 100 seats require 560 mm (22 in.) of clear aisle accessway width.

The current flexibility, which applies to all seating arranged in rows, is based on the assumption that the egress time required for a seating arrangement will be influenced more by the capacity of routes downstream from the rows of seating than by the rows' clear widths. Subsection 12/13.2.3 provides a standardized method for calculating the widths of those routes serving the space containing the seating. The combination of 12/13.2.3 and 12/13.2.5.5 offers designers of theaters, in particular, a great deal of flexibility in laying out blocks of seating while still requiring a standard of egress flow time performance that is based on traditionally accepted egress performance. Traditional performance, nominally about 200 seconds of flow time, is achieved through the application of specific requirements on aisle and cross aisle design. For example, rows longer than 14 seats are permitted, and egress door locations can be more flexibly determined than permitted under the continental seating rules contained in previous *Code* editions.

Exhibit 12/13.15 illustrates the seating layout for a theater with 630 seats in one unbroken area, with 21 rows ranging uniformly in length from 20 seats at row 1 to 40 seats at row 21. The required minimum aisle accessway clear width between the front row (with 20 seats) and the row behind it (with 21 seats) is 360 mm (14.1 in.). The required minimum aisle accessway clear width between the back row (with 40 seats) and the row in front of it (with 39 seats) is 505 mm (19.8 in.). The designer has the option of making the clear widths of all aisle accessways uniform and at least 505 mm (19.8 in.) wide or progressively increasing them from front to back.

For the theater shown in Exhibit 12/13.15, the option of a traditional layout can be used. The traditional arrangement is a maximum of 14 seats per row for rows served by aisles at both ends and a maximum of 7 seats per row where the row is served by an aisle at only one end and abuts the wall at the other end. This layout would require that more space be devoted to aisles and cross aisles, but this lost space might be partly offset by the minimum 305-mm (12-in.) aisle accessway clear width permitted of such rows of seating.

CHAPTER 12 • New

CHAPTER 13 • Existing

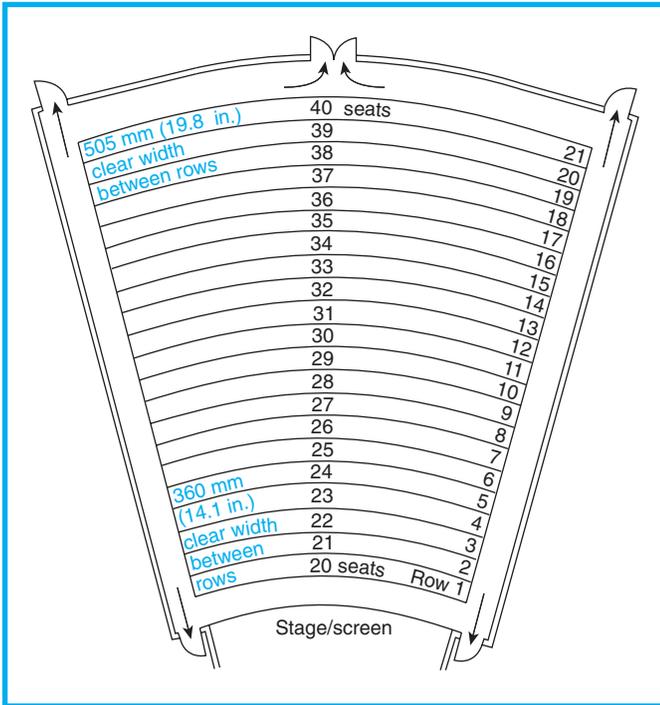

Exhibit 12/13.15 Minimum aisle accessway clear widths.

In a seating row served by an aisle at one end only, the occupant of the seat farthest from the aisle must be able to reach the aisle with not more than 9140 mm (360 in.) of aisle accessway travel in accordance with 12/13.2.5.5.5. Exhibit 12/13.16 illustrates a seating

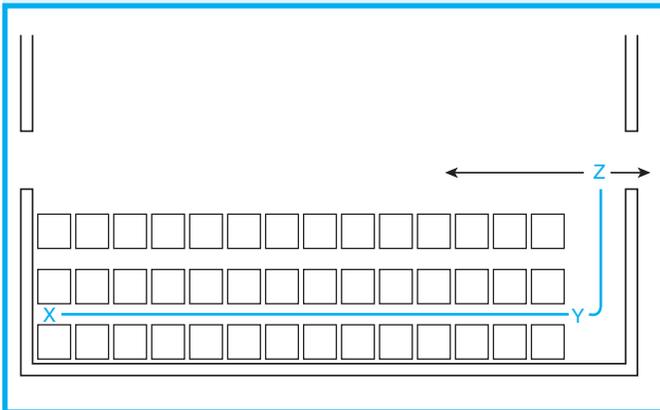

Exhibit 12/13.16 Maximum 9140-mm (360-in.) aisle accessway length (point X to point Y) for seating row served by aisle at one end only.

row served by an aisle at one end only where, upon reaching the aisle, it is not immediately possible to move in either of two egress directions because of the obstruction to egress created by the rear wall of the room. The aisle accessway (point X to point Y) cannot exceed 9140 mm (360 in.). However, upon reaching the aisle, the common path of travel measurement does not end; it continues to point Z, which is the first point at which travel in two independent directions becomes possible. Per 12.2.5.1.2 and 13.2.5.1.1, the common path of travel (point X to point Z) is permitted to be 23 m (75 ft), because the area served does not exceed 50 persons (in this case, 42 occupants, based on three rows of seats with 14 seats per row).

In rows of tablet-arm chairs on which the tablet arms are fixed in the in-use position, the chairs must be arranged to meet the row spacing requirements of 12/13.2.5.5. Exhibit 12/13.17 illustrates this provision. Although the clear space between the back of a seat and the leading edge of the tablet arm of a chair located behind that seat varies, depending on row length, in accordance with the requirements of 12/13.2.5.5, the clear space cannot be less than 305 mm (12 in.). Paragraph 12/13.2.5.5.6 addresses tablet-arm chairs with self-storing tablet arms, which present little threat to life safety.

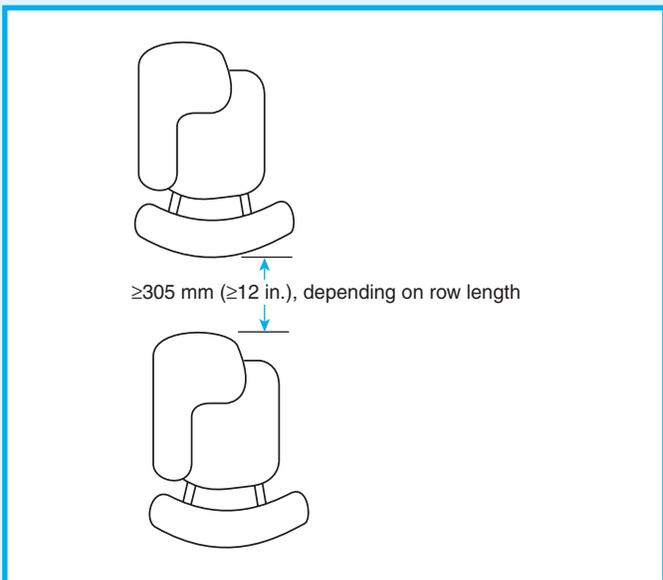

Exhibit 12/13.17 Minimum spacing between rows of seats with fixed tablet arms.

CHAPTER 12 • New

12.2.5.6 Aisles Serving Seating Not at Tables.

12.2.5.6.1 General. Aisles shall be provided so that the number of seats served by the nearest aisle is in accordance with 12.2.5.5.2 through 12.2.5.5.5, unless otherwise permitted by the following:

- (1) Aisles shall not be required in bleachers, provided that all of the following conditions are met:
 - (a) Egress from the front row shall not be obstructed by a rail, a guard, or other obstruction.
 - (b) The row spacing shall be 710 mm (28 in.) or less.
 - (c) The rise per row, including the first row, shall be 150 mm (6 in.) or less.
 - (d) The number of rows shall not exceed 16.
 - (e) The seat spaces shall not be physically defined.
 - (f) Seat boards that are also used as stepping surfaces for descent shall provide a walking surface with a width not less than 305 mm (12 in.), and, where a depressed footboard exists, the gap between seat boards of adjacent rows shall not exceed 305 mm (12 in.), measured horizontally.
 - (g) The leading edges of seat boards used as stepping surfaces shall be provided with a contrasting marking stripe so that the location of the leading edge is readily apparent, particularly where viewed in descent and the following shall also apply:
 - i. The marking stripe shall be not less than 25 mm (1 in.) wide and shall not exceed 51 mm (2 in.) in width.
 - ii. The marking stripe shall not be required where bleacher surfaces and environmental conditions, under all conditions of use, are such that the location of each leading edge is readily apparent, particularly when viewed in descent.

12.2.5.6.2 Dead-End Aisles. Dead-end aisles shall not exceed 6100 mm (240 in.) in length, unless otherwise permitted by the following:

- (1) A dead-end aisle shall be permitted to exceed 6100 mm (240 in.) in length where seats served by the dead-end aisle are not more than 24 seats from another aisle, measured along a row of seats having a clear width of not less than 305 mm (12 in.) plus 15 mm (0.6 in.) for each additional seat over a total of 7 in the row.
- (2) A 16-row, dead-end aisle shall be permitted in folding and telescopic seating and grandstands.
- (3) Aisle termination in accordance with 12.4.2.7 for smoke-protected assembly seating shall be permitted.

CHAPTER 13 • Existing

13.2.5.6 Aisles Serving Seating Not at Tables.

13.2.5.6.1 General. Aisles shall be provided so that the number of seats served by the nearest aisle is in accordance with 13.2.5.5.2 through 13.2.5.5.4, unless otherwise permitted by the following:

- (1) Aisles shall not be required in bleachers, provided that all of the following conditions are met:
 - (a) Egress from the front row shall not be obstructed by a rail, a guard, or other obstruction.
 - (b) The row spacing shall be 710 mm (28 in.) or less.
 - (c) The rise per row, including the first row, shall be 150 mm (6 in.) or less.
 - (d) The number of rows shall not exceed 16.
 - (e) The seat spaces shall not be physically defined.
 - (f) Seat boards that are also used as stepping surfaces for descent shall provide a walking surface with a width of not less than 305 mm (12 in.), and, where a depressed footboard exists, the gap between seat boards of adjacent rows shall not exceed 305 mm (12 in.), measured horizontally.
 - (g) The leading edges of seat boards used as stepping surfaces shall be provided with a contrasting marking stripe so that the location of the leading edge is readily apparent, particularly where viewed in descent and the following shall also apply:
 - i. The marking stripe shall be not less than 25 mm (1 in.) wide and shall not exceed 51 mm (2 in.) in width.
 - ii. The marking stripe shall not be required where bleacher surfaces and environmental conditions, under all conditions of use, are such that the location of each leading edge is readily apparent, particularly when viewed in descent.

13.2.5.6.2 Dead-End Aisles. Dead-end aisles shall not exceed 6100 mm (240 in.) in length, unless otherwise permitted by the following:

- (1) A dead-end aisle shall be permitted to exceed 6100 mm (240 in.) in length where seats served by the dead-end aisle are not more than 24 seats from another aisle, measured along a row of seats having a clear width of not less than 305 mm (12 in.) plus 15 mm (0.6 in.) for each additional seat over a total of 7 in the row.
- (2) A 16-row, dead-end aisle shall be permitted in folding and telescopic seating and grandstands.
- (3) Aisle termination in accordance with 13.4.2.7 for smoke-protected assembly seating shall be permitted.
- (4) Bleacher aisles in accordance with 13.2.3.5 shall not be considered as dead-end aisles.

CHAPTER 12 • New

Bleacher seating, as addressed in 12/13.2.5.6.1(1), does not have seat backs. Provided the row-to-row dimension does not exceed 710 mm (28 in.) and egress is not restricted from the front of the bleacher, occupants can effectively walk on the seating surfaces and not rely on aisles.

Paragraph 12/13.2.5.6.2(1) formally recognizes the inherent redundancy that exists where a block of seating rows is served by more than one aisle, so that the problem created by the blockage of any one aisle can be mitigated by greater movement along rows to reach a more distant aisle. The exemption recognizes that movement along rows (even with the constricted

12.2.5.6.3* Minimum Aisle Width. The minimum clear width of aisles shall be sufficient to provide egress capacity in accordance with 12.2.3.2 but shall be not less than the following:

- (1) 1220 mm (48 in.) for stairs having seating on each side, or 915 mm (36 in.) where aisle does not serve more than 50 seats
- (2) 915 mm (36 in.) for stairs having seating on only one side
- (3) 585 mm (23 in.) between a handrail and seating, or between a guardrail and seating where the aisle is subdivided by a handrail
- (4) 1065 mm (42 in.) for level or ramped aisles having seating on both sides, or 915 mm (36 in.) where aisle does not serve more than 50 seats
- (5) 915 mm (36 in.) for level or ramped aisles having seating on only one side
- (6) 585 mm (23 in.) between a handrail or guardrail and seating where the aisle does not serve more than five rows on one side

CHAPTER 13 • Existing

row widths) provides many routes that permit faster movement to alternative aisles than would be possible with a dedicated cross aisle. It is useful in arenas and theaters where it is not easy to provide a cross aisle or a door at the end of an aisle but where it is relatively easy to reach a remote aisle and its associated exit by moving along the aisle accessways created by the seating rows. Note that 12/13.2.5.6.2(1) requires increased aisle accessway clear width to facilitate travel along the seating rows to reach alternative aisles. At the row length limit of 24 seats, the required aisle accessway clear width for use of this exemption is 565 mm (22.2 in.).

13.2.5.6.3* Minimum Aisle Width. The minimum clear width of aisles shall be sufficient to provide egress capacity in accordance with 13.2.3.2 but shall be not less than the following:

- (1) 1065 mm (42 in.) for stairs having seating on each side, unless otherwise permitted by the following:
 - (a) The minimum clear width required by 13.2.5.6.3(1) shall be permitted to be not less than 760 mm (30 in.) for catchment areas having not more than 60 seats.
 - (b) The minimum clear width required by 13.2.5.6.3(1) shall be permitted to be not less than 915 mm (36 in.) where an aisle does not serve more than 50 seats.
- (2) 915 mm (36 in.) for stairs having seating on only one side, or 760 mm (30 in.) for catchment areas having not more than 60 seats
- (3) 510 mm (20 in.) between a handrail and seating or between a guardrail and seating where the aisle is subdivided by a handrail
- (4) 1065 mm (42 in.) for level or ramped aisles having seating on both sides, unless otherwise permitted by the following:
 - (a) The minimum clear width required by 13.2.5.6.3(4) shall be not less than 760 mm (30 in.) for catchment areas having not more than 60 seats.
 - (b) The minimum clear width required by 13.2.5.6.3(4) shall be not less than 915 mm (36 in.) where an aisle does not serve more than 50 seats.
- (5) 915 mm (36 in.) for level or ramped aisles having seating on only one side, or 760 mm (30 in.) for catchment areas having not more than 60 seats
- (6) 580 mm (23 in.) between a handrail or guardrail and seating where aisle does not serve more than five rows on one side

CHAPTER 12 • New

A.12.2.5.6.3 It is the intent to permit handrails to project not more than 90 mm (3½ in.) into the clear width of aisles required by 12.2.5.6.3.

Where the minimum aisle width specified by 12/13.2.5.6.3 is wider than that calculated for a required egress capacity, as is often the case, the width specified by 12/13.2.5.6.3 is the minimum required width. The requirements of 12/13.2.5.6.3 take into account the width needed by individuals moving alone or with others, overtaking others, and moving in counterflow past others on aisles. Differing movement behavior and the need for handrails on different walking surfaces, such as stepped aisles versus level aisles, are considered. Exhibits 12/13.18 and 12/13.19 illustrate how intensively a 1220-mm (48-in.) aisle stair subdivided by a center handrail can be used. Exhibit 12/13.20 shows an overhead view of a large male walking down a similar aisle stair. Chair seating is shown adjoining the aisle in these photographs.

Paragraph 12/13.2.5.6.3(6) is based on the requirement for handrails in aisle stairs. It specifically addresses the allowance for extending such handrails down the center of aisles for as many as five rows, leaving only about 585 mm (23 in.) of nominal width clear to the side of the handrail. This width is readily used by individuals moving in single or staggered file and can be used with tolerable inconvenience

Exhibit 12/13.18 Intensive use of stadium aisle stair, 1220 mm (48 in.) wide with central handrail. (Photograph courtesy of Jake Pauls.)

CHAPTER 13 • Existing

A.13.2.5.6.3 It is the intent to permit handrails to project not more than 90 mm (3½ in.) into the clear width of aisles required by 13.2.5.6.3.

Exhibit 12/13.19 Intensive use of stadium handrail, approximately 865 mm (34 in.) high, at center of 1220-mm- (48-in.-) wide aisle stair. (Photograph courtesy of Jake Pauls.)

where people must pass each other on the same side of the handrail. This provision of the *Code* might be useful in cases where a short stub aisle is needed to serve rows of seating immediately beside a vomitory.

Generally, the effective width of aisles is often somewhat wider than is necessary for egress stairs or corridors that are bounded on both sides by wall construction. One important exception to this generalization occurs where many people are attempting to sit on undivided benches or bleachers served by an aisle. The 455-mm (18-in.) spacing usually provided for each person is often too small, and there is a natural tendency for people to extend their legs,

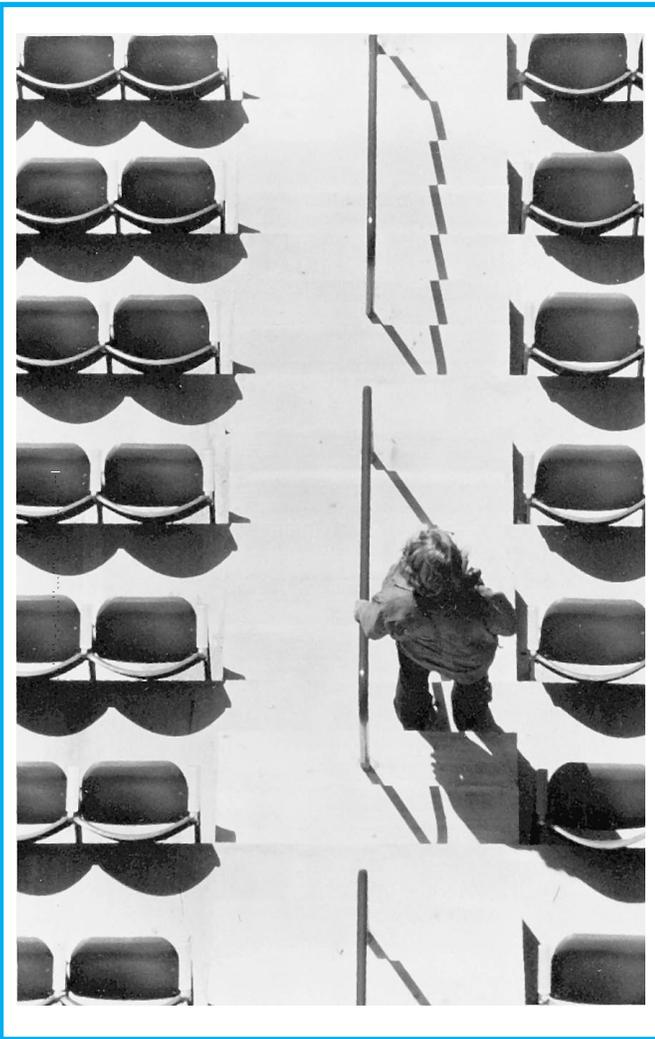

Exhibit 12/13.20 Overhead view of 1220-mm- (48-in.-) wide aisle stair with center handrail. (Photograph courtesy of Jake Pauls.)

hips, and shoulders into a significant part of the aisle width. Therefore, it is prudent when designing for crowded, nonchair seating to increase either the width of the seat per person or the minimum aisle widths to facilitate normal circulation in the aisles.

12.2.5.6.4* Aisle Stairs and Ramps. The following shall apply to aisle stairs and ramps:

- (1) Aisles having a gradient steeper than 1 in 20, but not steeper than 1 in 8, shall consist of a ramp.
- (2) Aisles having a gradient steeper than 1 in 8 shall consist of an aisle stair.
- (3) The marking stripe exemption of 12.2.5.6.8.3 shall not be permitted for aisle stairs.
- (4) Aisles in folding and telescopic seating shall be permitted to be stepped aisles.
- (5) The limitation on height between landings in Table 7.2.2.2.1(a) and Table 7.2.2.2.1(b) shall not apply to aisle stairs.

13.2.5.6.4* Aisle Stairs and Ramps. The following shall apply to aisle stairs and ramps:

- (1) Aisles having a gradient steeper than 1 in 20, but not steeper than 1 in 8, shall consist of a ramp.
- (2) Aisles having a gradient steeper than 1 in 8 shall consist of an aisle stair.
- (3) The marking stripe exemption of 13.2.5.6.8.3 shall not be permitted for aisle stairs.
- (4) Aisles in folding and telescopic seating shall be permitted to be stepped aisles.
- (5) The limitation on height between landings in Table 7.2.2.2.1(a) and Table 7.2.2.2.1(b) shall not apply to aisle stairs.

CHAPTER 12 • New

A.12.2.5.6.4 Technical information about the convenience and safety of ramps and stairs having gradients in the region of 1 in 8 clearly suggests that the goal should be slopes for ramps that are less steep and combinations of stair risers and treads that are, for example, superior to 100-mm (4-in.) risers and 865-mm (32-in.) treads. This goal should be kept in mind by designers in establishing the gradient of seating areas to be served by aisles.

12.2.5.6.5 Aisle Stair Treads. Aisle stair treads shall meet the following criteria:

- (1) There shall be no variation in the depth of adjacent treads that exceeds 4.8 mm ($\frac{3}{16}$ in.).

CHAPTER 13 • Existing

A.13.2.5.6.4 Technical information about the convenience and safety of ramps and stairs having gradients in the region of 1 in 8 clearly suggests that the goal should be slopes for ramps that are less steep and combinations of stair risers and treads that are, for example, superior to 100-mm (4-in.) risers and 865-mm (32-in.) treads. This goal should be kept in mind by designers in establishing the gradient of seating areas to be served by aisles.

13.2.5.6.5 Aisle Stair Treads. Aisle stair treads shall meet the following criteria:

- (1) There shall be no variation in the depth of adjacent treads that exceeds 4.8 mm ($\frac{3}{16}$ in.), unless otherwise permitted by the following:
 - (a)* In aisle stairs where a single intermediate tread is provided halfway between seating platforms, such intermediate treads shall be permitted to be of a relatively smaller but uniform depth but shall be not less than 330 mm (13 in.).

A.13.2.5.6.5(1)(a) Completely uniform tread dimensions are preferred over aisle stair designs where tread depths alternate between relatively small intermediate treads between seating platforms and relatively large treads at seating platforms. A larger tread that is level with the seating platform is not needed to facilitate easy access to and egress from a row of seating. If this arrangement is used, it is important to provide a tread depth that is better than minimum for the intermediate tread; hence, 330 mm (13 in.) is specified. Where nonuniformities exist due to construction tolerance, they should not exceed 4.8 mm ($\frac{3}{16}$ in.) between adjacent treads.

- (b) The following shall apply to grandstands, bleachers, and folding and telescopic seating:
 - i. Steps shall not be required to be provided in aisles to overcome differences in level unless the gradient exceeds 1 unit of rise in 10 units of run.
 - ii. Where the rise of the seating platform exceeds 280 mm (11 in.), an intermediate step shall be provided for the full width of the aisle and shall be proportioned to provide two steps of equal rise per platform.
 - iii. Where the rise of the seating platform exceeds 455 mm (18 in.), two intermediate steps for the full width of the aisle shall be provided and proportioned to provide three steps of equal rise per platform that are uniform and not less than 230 mm (9 in.).
 - iv. The full length of the nose of each step in the aisle required by 13.2.5.6.5(1)(b)iii shall be conspicuously marked.

CHAPTER 12 • New

(2)* Treads shall be not less than 280 mm (11 in.).

A.12.2.5.6.5(2) Tread depth is more important to stair safety than is riser height. Therefore, in cases where the seating area gradient is less than 5 in 11, it is recommended that the tread dimension be increased beyond 280 mm (11 in.) rather than reducing the riser height. Where the seating area gradient exceeds 8 in 11, it is recommended that the riser height be increased while maintaining a tread depth of not less than 280 mm (11 in.).

(3) All treads shall extend the full width of the aisle.

The requirements of 12/13.2.5.6.4 address the need to design aisle stairs, for example, with all the attention and care required for stairs in general, plus additional care due to the unique design and use conditions encountered with aisles serving seating arranged in rows. Extra attention is especially necessary where large elevation differences exist between the rows of seating. Paragraph 12/13.2.5.6.4(1) addresses aisles in terms of steepness. Ideally, designing aisles with a gradient of approximately 1 in 8 is to be avoided; however, sight lines might dictate the use of such slopes in some situations. These ramps are relatively steep and problematic for people with walking difficulties. Stairs with a very small rise and long treads also present problems, notably trips and missteps, because the presence of low-height risers might not be evident, especially when a crowd is present. Generally, people using aisles are also distracted because of the unusual aisle length, the presence of other people in the aisles, and the presence of those entering the aisles from adjoining seating rows. Therefore, aisles of any slope must be designed with considerable care and attention to human factors.

Allowing unequal-sized treads within aisle stairs, a practice previously believed to be useful in facilitating access to seat rows, is not permitted by the *Code* for new assembly occupancies. Even with the increased minimum tread size requirement of older editions of the *Code*, the end result (larger treads at the seat row entry level and smaller intermediate treads between seat row levels) was not as beneficial in terms of stair safety as that provided by consistently sized treads. The desirability of uniformly sized treads holds even for treads as large as 510 mm (20 in.) in depth (assuming a relatively low riser height).

CHAPTER 13 • Existing

(2)* Treads shall be not less than 280 mm (11 in.).

A.13.2.5.6.5(2) Tread depth is more important to stair safety than is riser height. Therefore, in cases where the seating area gradient is less than 5 in 11, it is recommended that the tread dimension be increased beyond 280 mm (11 in.) rather than reducing the riser height. Where the seating area gradient exceeds 8 in 11, it is recommended that the riser height be increased while maintaining a tread depth of not less than 280 mm (11 in.).

(3) All treads shall extend the full width of the aisle.

Handrails (required by 12/13.2.5.6.7) help to compensate for the stretched but consistent stride length that might be needed in such long-tread aisle stairs. It is preferable to keep treads uniform so that the risk of misstepping, particularly the risk of overstepping on relatively smaller treads, is reduced.

For existing aisle stairs, 13.2.5.6.5(1)(a) continues to recognize an intermediate tread between seating platforms but requires that the intermediate treads be uniform in depth and at least 330 mm (13 in.) deep. This exaggerated depth makes the intermediate tread more obvious and provides a deep surface on which to place one's feet.

Special attention must be given to careful design detailing and construction practice in relation to the placement of treads in aisle stairs. Careful site supervision is recommended to avoid serious problems both in cast-in-place concrete construction and in precast concrete construction of aisle stairs. Field research studies of situations where aisle step dimensions are not consistent indicate that the incidence of missteps rises significantly where tolerances of tread uniformity exceed those specified by 12/13.2.5.6.5.

Exhibit 12/13.21 shows a side view of an aisle stair with 280-mm (11-in.) treads used by a person with footwear measuring 305 mm (12 in.) in length. This situation is experienced by 5 percent of adults generally, and it might occur more often in those assembly situations attracting a higher proportion of male adults.

With respect to 12/13.2.5.6.5(1), which requires tread depth to be uniform, apparently no difficulty is experienced in entering or leaving the aisles or in entering or leaving the seat row where three 280-mm (11-in.) treads at each seat row are provided, as shown in Exhibit 12/13.21.

Exhibit 12/13.21 Side view of aisle stair with uniform tread depth of 280 mm (11 in.). (Photograph courtesy of Jake Pauls.)

If treads do not extend the full width of the aisle, a pocket (or drop-off) might occur between the side edge of the tread and the side edge of the seat nearest the aisle. The requirement of 12/13.2.5.6.5(3), that treads extend the full width of the aisle, is intended to avoid such drop-offs and prevent missteps and falls.

12.2.5.6.6 Aisle Stair Risers. Aisle stair risers shall meet the following criteria:

- (1) Riser heights shall be not less than 100 mm (4 in.) but shall not exceed 205 mm (8 in.), unless otherwise permitted by the following:
 - (a) The riser height of aisle stairs in folding and telescopic seating shall be permitted to be not less than 90 mm (3½ in.) but shall not exceed 280 mm (11 in.).
 - (b) Where the gradient of an aisle is steeper than 205 mm (8 in.) in rise in 280 mm (11 in.) of run for the purpose of maintaining necessary sight lines in the adjoining seating area, the riser height shall be permitted to exceed 205 mm (8 in.) but shall not exceed 230 mm (9 in.).
- (2) Riser heights shall not exceed 205 mm (8 in.), unless otherwise permitted by 12.2.5.6.6(3).
- (3) The riser height of aisle stairs in folding and telescopic seating shall be permitted to be not more than 280 mm (11 in.).
- (4) Riser heights shall be designed to be uniform in each aisle, and the construction-caused nonuniformities shall not exceed 4.8 mm (¾ in.) between adjacent risers, unless the following conditions apply:
 - (a) Riser height shall be permitted to be nonuniform only for the purpose of accommodating changes in gradient necessary to maintain sight lines within a

13.2.5.6.6 Aisle Stair Risers. Aisle stair risers shall meet the following criteria:

- (1) Riser heights shall be not less than 100 mm (4 in.) unless otherwise permitted by the following:
 - (a) The riser height of aisle stairs in folding and telescopic seating shall be permitted to be not less than 90 mm (3½ in.).
 - (b) Where the gradient of an aisle is steeper than 205 mm (8 in.) in rise in 280 mm (11 in.) of run for the purpose of maintaining necessary sight lines in the adjoining seating area, the riser height shall be permitted to exceed 205 mm (8 in.) but shall not exceed 280 mm (11 in.).
- (2) Riser heights shall not exceed 205 mm (8 in.) unless otherwise permitted by 13.2.5.6.6(3).
- (3) The riser height of aisle stairs in folding and telescopic seating shall be permitted to be not more than 280 mm (11 in.).
- (4) Riser heights shall be designed to be uniform in each aisle, and the construction-caused nonuniformities shall not exceed 4.8 mm (¾ in.) between adjacent risers, unless the following conditions apply:
 - (a) Riser height shall be permitted to be nonuniform only for the purpose of accommodating changes in gradient necessary to maintain sight lines within a

CHAPTER 12 • New

- seating area, in which case the riser height shall be permitted to exceed 4.8 mm ($\frac{3}{16}$ in.) in any flight.
- (b) Where nonuniformities permitted by 12.2.5.6.6(4)(a) exceed 4.8 mm ($\frac{3}{16}$ in.) between adjacent risers, the exact location of such nonuniformities shall be indicated by a distinctive marking stripe on each tread at the nosing or leading edge adjacent to the nonuniform risers.

At the minimum slope for which the *Code* requires aisle stairs (that is, slopes steeper than 1 in 8), there is a riser height of 100 mm (4 in.) for which the seat platform is 810 mm (32 in.) deep. At such low riser heights, which present a tripping hazard if the risers are not detected by people, the tread nosing marking requirement in 12/13.2.5.6.8 is especially significant.

Editions of the *Code* prior to 1988 permitted new aisle stairs to have a maximum riser height of 280 mm (11 in.). Current editions of the *Code* limit the maximum riser height for new aisle stairs to 230 mm (9 in.). In addition to reducing movement safety, the unusually high risers of some aisle stairs reduce the speed and efficiency of movement, especially in the descending direction. This is taken into account in 12/13.2.3.3 where, for each additional 25 mm (1 in.) of riser height above 178 mm (7 in.), an additional 20 percent must be added to the required capacity-related width of the aisle to satisfy *Code* requirements

12.2.5.6.7* Aisle Handrails.

A.12.2.5.6.7 Failure to provide a handrail within a 760-mm (30-in.) horizontal distance of all required portions of the aisle stair width means that the egress capacity calculation is required to be modified as specified by 12.2.3.3(3). This modification might lead to an increase in the aisle width. Although this increase will compensate for reduced egress efficiency, it does not help individuals walking on such portions of stairs to recover from missteps other than by possibly reducing marginally the crowding that might exacerbate the problem of falls. (*See also* 7.2.2.4.)

12.2.5.6.7.1 Ramped aisles having a gradient exceeding 1 in 20 and aisle stairs shall be provided with handrails at one side or along the centerline and in accordance with 7.2.2.4.4.1, 7.2.2.4.4.5, and 7.2.2.4.4.6.

12.2.5.6.7.2 Where seating exists on both sides of the aisle, the handrails shall be noncontinuous with gaps or breaks at intervals not exceeding five rows to facilitate access to seat-

CHAPTER 13 • Existing

- seating area, in which case the riser height shall be permitted to exceed 4.8 mm ($\frac{3}{16}$ in.) in any flight.
- (b) Where nonuniformities permitted by 13.2.5.6.6(4)(a) exceed 4.8 mm ($\frac{3}{16}$ in.) between adjacent risers, the exact location of such nonuniformities shall be indicated by a distinctive marking stripe on each tread at the nosing or leading edge adjacent to the nonuniform risers.

and achieve an acceptable egress flow time performance.

A special case is made for severely nonuniform riser heights [those beyond the usual 4.8-mm ($\frac{3}{16}$ -in.) tolerance] only in situations where there is a break in the slope of a seating deck to maintain adequate sight lines. The seating deck slope might change incrementally at each row or, more commonly, a large change might occur at one or more locations. At such locations, there is often a change in the row-to-row elevation that greatly exceeds the 4.8-mm ($\frac{3}{16}$ -in.) tolerance. Aisle step riser heights will, as a consequence, change radically at this point. It is the duty of the designer and owner to alert people using the aisle of this unusual change in the riser dimensions. Such an alert might constitute more than the usual marking of all step nosings required by 12/13.2.5.6.8; additional warning techniques might be needed to reduce the risk of stumbles and falls.

13.2.5.6.7* Aisle Handrails.

A.13.2.5.6.7 Failure to provide a handrail within a 760-mm (30-in.) horizontal distance of all required portions of the aisle stair width means that the egress capacity calculation is required to be modified as specified by 13.2.3.3(3). This modification might lead to an increase in the aisle width. Although this increase will compensate for reduced egress efficiency, it does not help individuals walking on such portions of stairs to recover from missteps other than by possibly reducing marginally the crowding that might exacerbate the problem of falls. (*See also* 7.2.2.4.)

13.2.5.6.7.1 Ramped aisles having a gradient exceeding 1 in 12 and aisle stairs shall be provided with handrails at one side or along the centerline and in accordance with 7.2.2.4.4.1, 7.2.2.4.4.5, and 7.2.2.4.4.6.

13.2.5.6.7.2 Where seating exists on both sides of the aisle, the handrails shall be noncontinuous with gaps or breaks at intervals not exceeding five rows to facilitate access to seat-

CHAPTER 12 • New

ing and to allow crossing from one side of the aisle to the other.

12.2.5.6.7.3 The gaps or breaks permitted by 12.2.5.6.7.2 shall have a clear width of not less than 560 mm (22 in.) and shall not exceed 915 mm (36 in.), measured horizontally, and the handrail shall have rounded terminations or bends.

12.2.5.6.7.4 Where handrails are provided in the middle of aisle stairs, an additional intermediate rail shall be located approximately 305 mm (12 in.) below the main handrail.

12.2.5.6.7.5 Handrails shall not be required where otherwise permitted by the following:

- (1) Handrails shall not be required for ramped aisles having a gradient not steeper than 1 in 8 and having seating on both sides where the aisle does not serve as an accessible route.
- (2) The requirement for a handrail shall be satisfied by the use of a guard provided with a rail that complies with the graspability requirements for handrails and located at a consistent height between 865 mm and 1065 mm (34 in. and 42 in.), measured using one of the following methods:
 - (a) Vertically from the top of the rail to the leading edge (nosing) of stair treads
 - (b) Vertically from the top of the rail to the adjacent walking surface in the case of a ramp

The *Code* requires handrails on aisle stairs in new construction even where riser heights are less than 180 mm (7 in.). This requirement is a result of increased experience with the provision and use of aisle handrails, as well as a general realization that aisles pose unique challenges to users that might go beyond those encountered on other stairs. Exhibits 12/13.19 and 12/13.20 illustrate the variety of use conditions in aisles and the extensive use of handrails. Field research studies show that aisle stair handrails have been used about twice as often as handrails provided to meet *Code* requirements for non-aisle stairs. This high level of use is not surprising, given the unusual lengths, varied step geometries, and very complex use conditions of aisles. Aside from their value in increasing the safety and comfort of people using the aisles, handrails also help to improve egress efficiency. This benefit is taken into account in calculation of egress capacity. See 12/13.2.3.3(3).

CHAPTER 13 • Existing

ing and to allow crossing from one side of the aisle to the other.

13.2.5.6.7.3 The gaps or breaks permitted by 13.2.5.6.7.2 shall have a clear width of not less than 560 mm (22 in.) and shall not exceed 915 mm (36 in.), measured horizontally, and the handrail shall have rounded terminations or bends.

13.2.5.6.7.4 Where handrails are provided in the middle of aisle stairs, an additional intermediate rail shall be located approximately 305 mm (12 in.) below the main handrail.

13.2.5.6.7.5 Handrails shall not be required where otherwise permitted by the following:

- (1) Handrails shall not be required for ramped aisles having a gradient not steeper than 1 in 8 and having seating on both sides.
- (2) The requirement for a handrail shall be satisfied by the use of a guard provided with a rail that complies with the graspability requirements for handrails and located at a consistent height between 865 mm (34 in.) and 1065 mm (42 in.), measured using one of the following methods:
 - (a) Vertically from the top of the rail to the leading edge (nosing) of stair treads
 - (b) Vertically from the top of the rail to the adjacent walking surface in the case of a ramp
- (3) Handrails shall not be required where risers do not exceed 180 mm (7 in.) in height.

The required gaps between sections of center-aisle handrails are illustrated in Exhibit 12/13.20. Spacing such gaps as frequently as every three rows is recommended where there is extensive use of aisles during events. A spacing of up to five rows between gaps might be acceptable where there is little use of the aisles during events and little counterflow at any time. Gap size should be kept at the lower end of the permitted range of 560 mm to 915 mm (22 in. to 36 in.) where the aisles are unusually steep, and handrail use is especially valuable in reducing the risk of falls.

Paragraph 12/13.2.5.6.7.5(2) takes into account the proven utility of handrails that are higher than those permitted, even with the increased handrail height range introduced with the 1988 edition of the *Code*. A guardrail that is 1065 mm (42 in.) high (such as at the side of an aisle where there is a vomitory) can be considered a usable handrail if it offers graspability as required for handrails. See 7.2.2.4.4.

CHAPTER 12 • New

12.2.5.6.8* Aisle Marking.

A.12.2.5.6.8 Certain tread cover materials such as plush carpets, which are often used in theaters, produce an inherently well-marked tread nosing under most lighting conditions. On the other hand, concrete treads have nosings with a sharp edge and, especially under outdoor lighting conditions, are difficult to discriminate. Therefore, concrete treads require an applied marking stripe. The slip resistance of such marking stripes should be similar to the rest of the treads, and no tripping hazard should be created; luminescent, self-luminous, and electroluminescent tread markings have the advantage of being apparent in reduced light or in the absence of light.

12.2.5.6.8.1 A contrasting marking stripe shall be provided on each tread at the nosing or leading edge so that the location of such tread is readily apparent, particularly when viewed in descent.

12.2.5.6.8.2 The marking stripe shall be not less than 25 mm (1 in.) wide and shall not exceed 51 mm (2 in.) in width.

12.2.5.6.8.3 The marking stripe shall not be required where tread surfaces and environmental conditions, under all conditions of use, are such that the location of each tread is readily apparent, particularly when viewed in descent.

Exhibit 12/13.22 illustrates some of the step visibility difficulties that are commonly encountered in outdoor facilities with concrete stair treads. Without the shadows from the handrail posts, there would be little indication of the exact location of each tread nosing. This situation requires the applied nosing markings referred to in 12/13.2.5.6.8. The distractions of the playing field and the unusually long aisle further justify making the steps as obvious as possible. Each situation needs to be carefully evaluated, with mock-ups at the design stage and inspection of actual conditions during use, to determine whether any improvements are warranted in marking and lighting such aisles.

CHAPTER 13 • Existing

13.2.5.6.8* Aisle Marking.

A.13.2.5.6.8 Certain tread cover materials such as plush carpets, which are often used in theaters, produce an inherently well-marked tread nosing under most lighting conditions. On the other hand, concrete treads have nosings with a sharp edge and, especially under outdoor lighting conditions, are difficult to discriminate. Therefore, concrete treads require an applied marking stripe. The slip resistance of such marking stripes should be similar to the rest of the treads, and no tripping hazard should be created; luminescent, self-luminous, and electroluminescent tread markings have the advantage of being apparent in reduced light or in the absence of light.

13.2.5.6.8.1 A contrasting marking stripe shall be provided on each tread at the nosing or leading edge so that the location of such tread is readily apparent, particularly when viewed in descent.

13.2.5.6.8.2 The marking stripe shall be not less than 25 mm (1 in.) wide and shall not exceed 51 mm (2 in.) in width.

13.2.5.6.8.3 The marking stripe shall not be required where tread surfaces and environmental conditions, under all conditions of use, are such that the location of each tread is readily apparent, particularly when viewed in descent.

CHAPTER 12 • New

12.2.5.7* Aisle Accessways Serving Seating at Tables.

A.12.2.5.7 For purposes of the means of egress requirements of this *Code*, seating at counters or at other furnishings is considered to be the same as seating at tables.

12.2.5.7.1 The required clear width of an aisle accessway shall be not less than 305 mm (12 in.) where measured in accordance with 12.2.5.7.3 and shall be increased as a function of length in accordance with 12.2.5.7.4, unless otherwise permitted by 12.2.5.7.2.

12.2.5.7.2* If used by not more than four persons, no minimum clear width shall be required for the portion of an aisle accessway having a length not exceeding 1830 mm (72 in.) and located farthest from an aisle.

A.12.2.5.7.2 Effectively, where the aisle accessway is bounded by movable seating, the 305-mm (12-in.) minimum width might be increased by about 380 mm to 760 mm (15 in. to 30 in.) as seating is pushed in toward tables. Moreover, it is such movement of chairs during normal and emergency egress situations that makes the zero-clearance allowance workable. The allowance also applies to booth seating where people sitting closest to the aisle normally move out ahead of people farthest from the aisle.

12.2.5.7.3* Where nonfixed seating is located between a table and an aisle accessway or aisle, the measurement of required clear width of the aisle accessway or aisle shall be made to a line 485 mm (19 in.), measured perpendicularly to the edge of the table, away from the edge of said table.

A.12.2.5.7.3 See A.12.2.5.8.3.

12.2.5.7.4* The minimum required clear width of an aisle accessway, measured in accordance with 12.2.5.4.8 and 12.2.5.7.3, shall be increased beyond the 305-mm (12-in.) requirement of 12.2.5.7.1 by 13 mm ($\frac{1}{2}$ in.) for each additional 305 mm (12 in.) or fraction thereof beyond 3660 mm (144 in.) of aisle accessway length, where measured from the center of the seat farthest from an aisle.

A.12.2.5.7.4 The minimum width requirement as a function of accessway length is as follows:

- (1) 0 mm (0 in.) for the first 1830 mm (72 in.) of length toward the exit
- (2) 305 mm (12 in.) for the next 1830 mm (72 in.), that is, up to 3660 mm (144 in.) of length
- (3) 305 mm to 610 mm (12 in. to 24 in.) for lengths from 3660 mm to 10,900 mm (144 in. to 432 in.), the maxi-

CHAPTER 13 • Existing

13.2.5.7* Aisle Accessways Serving Seating at Tables.

A.13.2.5.7 For purposes of the means of egress requirements of this *Code*, seating at counters or at other furnishings is considered to be the same as seating at tables.

13.2.5.7.1 The required clear width of an aisle accessway shall be not less than 305 mm (12 in.) where measured in accordance with 13.2.5.7.3 and shall be increased as a function of length in accordance with 13.2.5.7.4, unless otherwise permitted by 13.2.5.7.2.

13.2.5.7.2* If used by not more than four persons, no minimum clear width shall be required for the portion of an aisle accessway having a length not exceeding 1830 mm (72 in.) and located farthest from an aisle.

A.13.2.5.7.2 Effectively, where the aisle accessway is bounded by movable seating, the 305-mm (12-in.) minimum width might be increased by about 380 mm to 760 mm (15 in. to 30 in.) as seating is pushed in toward tables. Moreover, it is such movement of chairs during normal and emergency egress situations that makes the zero-clearance exception workable. The exception also applies to booth seating where people sitting closest to the aisle normally move out ahead of people farthest from the aisle.

13.2.5.7.3* Where nonfixed seating is located between a table and an aisle accessway or aisle, the measurement of required clear width of the aisle accessway or aisle shall be made to a line 485 mm (19 in.), measured perpendicularly to the edge of the table, away from the edge of said table.

A.13.2.5.7.3 See A.13.2.5.8.3.

13.2.5.7.4* The minimum required clear width of an aisle accessway, measured in accordance with 13.2.5.4.8 and 13.2.5.7.3, shall be increased beyond the 305-mm (12-in.) requirement of 13.2.5.7.1 by 13 mm ($\frac{1}{2}$ in.) for each additional 305 mm (12 in.) or fraction thereof beyond 3660 mm (144 in.) of aisle accessway length, where measured from the center of the seat farthest from an aisle.

A.13.2.5.7.4 The minimum width requirement as a function of accessway length is as follows:

- (1) 0 mm (0 in.) for the first 1830 mm (72 in.) of length toward the exit
- (2) 305 mm (12 in.) for the next 1830 mm (72 in.), that is, up to 3660 mm (144 in.) of length
- (3) 305 mm to 610 mm (12 in. to 24 in.) for lengths from 3660 mm to 10,900 mm (144 in. to 432 in.), the maxi-

CHAPTER 12 • New

imum length to the closest aisle or egress doorway permitted by 12.2.5.7.4

Any additional width needed for seating is to be added to these widths, as described in 12.2.5.8.3.

12.2.5.7.5 The path of travel along the aisle accessway shall not exceed 11 m (36 ft) from any seat to the closest aisle or egress doorway.

Paragraph 12/13.2.5.7.2 exempts a portion of the aisle accessway from the minimum width requirement under the specific conditions illustrated in Exhibit 12/13.23. The groupings of four chairs within the first 1830 mm (72 in.) of the aisle accessway are unregulated with respect to spacing. From the 1830-mm (72-in.) point away from the wall to the point where the aisle accessway reaches the aisle, the minimum width requirement of 12/13.2.5.7.1 applies.

Figure A.12/13.2.5.8.3 illustrates the provisions of 12/13.2.5.7.3 and 12/13.2.5.8.3. These requirements provide guidance on how aisle accessways and aisles with movable chairs are to be measured.

Exhibit 12/13.24 illustrates the maximum length of aisle accessway at tables permitted with the minimum 305-mm (12-in.) clear width. The aisle accessway width is greater than or equal to 305 mm

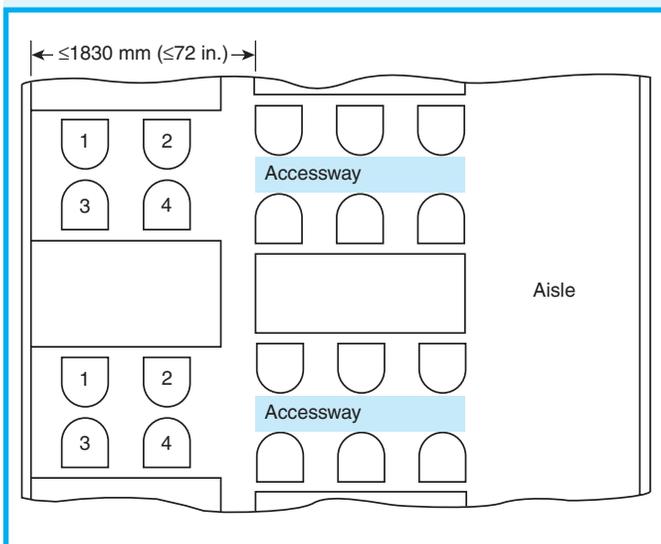

Exhibit 12/13.23 First 1830 mm (72 in.) of aisle accessway serving four or fewer persons exempted from minimum aisle accessway width.

CHAPTER 13 • Existing

imum length to the closest aisle or egress doorway permitted by 13.2.5.7.4

Any additional width needed for seating is to be added to these widths, as described in 13.2.5.8.3.

13.2.5.7.5 The path of travel along the aisle accessway shall not exceed 11 m (36 ft) from any seat to the closest aisle or egress doorway.

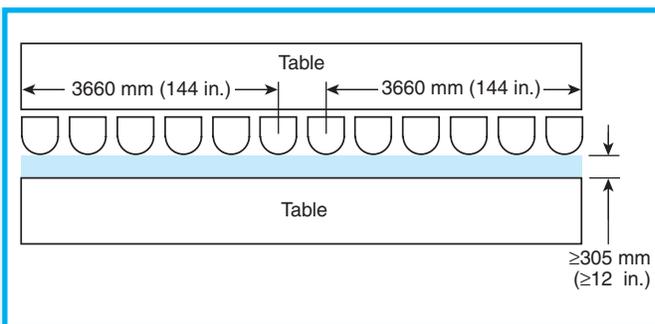

Exhibit 12/13.24 Minimum aisle accessway at tables.

(12 in.), with increased spacing of 13 mm (0.5 in.) for each additional 305 mm (12 in.) of aisle accessway beyond the initial 3660 mm (12 ft) from the center of the seat farthest from an aisle. In accordance with 12/13.2.5.7.3, the presence of chairs at one side of the aisle accessway increases the table-to-table spacing by 485 mm (19 in.).

Exhibit 12/13.25 illustrates the maximum length permitted for an aisle accessway serving seating at tables. The total length of the table is slightly more than 22 m (72 ft). Seating at longer tables requires a 915-mm (36-in.) aisle in accordance with the minimum width requirements of 12/13.2.5.8.2 instead of an aisle accessway. For the arrangement shown in Exhibit 12/13.25, the aisle accessway clear width, X,

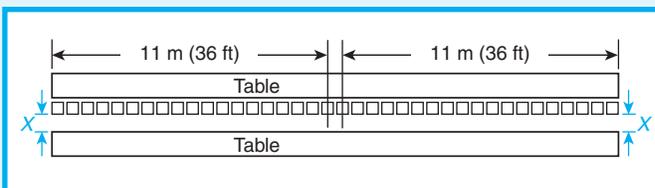

Exhibit 12/13.25 Maximum 11 m (36 ft) permitted for an aisle accessway serving seating at tables.

CHAPTER 12 • New

is 305 mm (12 in.) plus 13 mm (0.5 in.) for each additional 305 mm (12 in.) of aisle accessway beyond the initial 3660 mm (12 ft) from the center seat farthest from an aisle. The aisle accessway clear width is calculated as follows:

$$\begin{aligned} 13 \text{ mm} / 305 \text{ mm} &= 42.6 \text{ mm/m} \\ X &= 305 \text{ mm} + [42.6 \text{ mm/m} (11 \text{ m} - 3.7 \text{ m})] \\ &= 305 \text{ mm} + 310 \text{ mm} \\ &= 615 \text{ mm} \end{aligned}$$

12.2.5.8 Aisles Serving Seating at Tables.

12.2.5.8.1* Aisles that contain steps or that are ramped, such as aisles serving dinner theater-style configurations, shall comply with the requirements of 12.2.5.6.

A.12.2.5.8.1 See 7.1.7 and A.7.1.7.2 for special circulation safety precautions applicable where small elevation differences occur.

12.2.5.8.2* The width of aisles serving seating at tables shall be not less than 1120 mm (44 in.) where serving an occupant load exceeding 50, and 915 mm (36 in.) where serving an occupant load of 50 or fewer.

A.12.2.5.8.2 It is important to make facilities accessible to people using wheelchairs. See ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, which provides guidance on appropriate aisle widths.

12.2.5.8.3* Where nonfixed seating is located between a table and an aisle, the measurement of required clear width of the aisle shall be made to a line 485 mm (19 in.), measured perpendicularly to the edge of the table, away from the edge of said table.

A.12.2.5.8.3 Figure A.12.2.5.8.3 shows typical measurements involving seating and tables abutting an aisle. For purposes of the means of egress requirements of this *Code*, seating at counters or other furnishings is considered to be the same as seating at tables.

12.2.5.9 Approval of Layouts.

12.2.5.9.1 Where required by the authority having jurisdiction, plans drawn to scale showing the arrangement of furnishings or equipment shall be submitted to the authority by the building owner, manager, or authorized agent to substantiate conformance with the provisions of 12.2.5.

CHAPTER 13 • Existing

For inch/pound units,

$$\begin{aligned} X &= 12 \text{ in.} + [0.5 \text{ in./ft} (36 \text{ ft} - 12 \text{ ft})] \\ &= 12 \text{ in.} + 12 \text{ in.} \\ &= 24 \text{ in.} \end{aligned}$$

With the 485-mm (19-in.) space required for the chairs, the table-to-table spacing must be ≥ 1090 mm (43 in.).

13.2.5.8 Aisles Serving Seating at Tables.

13.2.5.8.1* Aisles that contain steps or that are ramped, such as aisles serving dinner theater-style configurations, shall comply with the requirements of 13.2.5.6.

A.13.2.5.8.1 See 7.1.7 and A.7.1.7.2 for special circulation safety precautions applicable where small elevation differences occur.

13.2.5.8.2* The width of aisles serving seating at tables shall be not less than 1120 mm (44 in.) where serving an occupant load exceeding 50, and 915 mm (36 in.) where serving an occupant load of 50 or fewer.

A.13.2.5.8.2 It is important to make facilities accessible to people using wheelchairs. See ICC/ANSI A117.1 *American National Standard for Accessible and Usable Buildings and Facilities*, which provides guidance on appropriate aisle widths.

13.2.5.8.3* Where nonfixed seating is located between a table and an aisle, the measurement of required clear width of the aisle shall be made to a line 485 mm (19 in.), measured perpendicularly to the edge of the table, away from the edge of said table.

A.13.2.5.8.3 Figure A.13.2.5.8.3 shows typical measurements involving seating and tables abutting an aisle. Note that, for purposes of the means of egress requirements of this *Code*, seating at counters or other furnishings is considered to be the same as seating at tables.

13.2.5.9 Approval of Layouts.

13.2.5.9.1 Where required by the authority having jurisdiction, plans drawn to scale showing the arrangement of furnishings or equipment shall be submitted to the authority by the building owner, manager, or authorized agent to substantiate conformance with the provisions of 13.2.5.

CHAPTER 12 • New

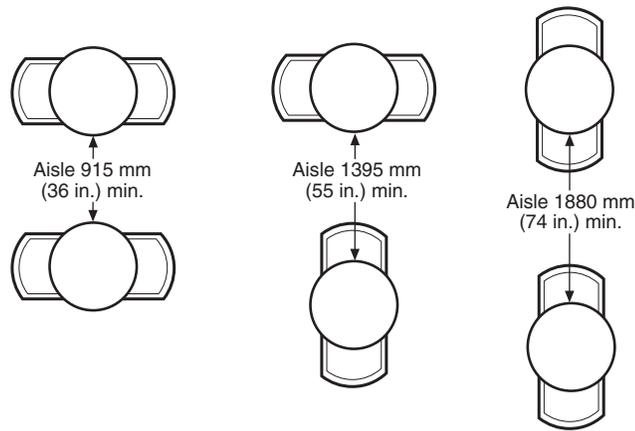

FIGURE A.12.2.5.8.3 Seating at Tables Abutting an Aisle.

12.2.5.9.2 The layout plans shall constitute the only acceptable arrangement, unless one of the following criteria is met:

- (1) The plans are revised.
- (2) Additional plans are submitted and approved.
- (3) Temporary deviations from the specifications of the approved plans are used, provided that the occupant load is not increased and the intent of 12.2.5.9 is maintained.

12.2.6 Travel Distance to Exits.

Exits shall be arranged so that the total length of travel from any point to reach an exit shall not exceed 61 m (200 ft) in any assembly occupancy, unless otherwise permitted by the following:

- (1) The travel distance shall not exceed 76 m (250 ft) in assembly occupancies protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) The travel distance requirement shall not apply to smoke-protected assembly seating as permitted by 12.4.2.8, 12.4.2.9, and 12.4.2.10.

Travel distance to exits from balconies or galleries that are served by unenclosed stairways must be measured to include the distance on the slope of the stair

CHAPTER 13 • Existing

13.2.5.9.2 The layout plans shall constitute the only acceptable arrangement, unless one of the following criteria is met:

- (1) The plans are revised
- (2) Additional plans are submitted and approved.
- (3) Temporary deviations from the specifications of the approved plans are used, provided that the occupant load is not increased and the intent of 13.2.5.9 is maintained.

13.2.6 Travel Distance to Exits.

Exits shall be arranged so that the total length of travel from any point to reach an exit shall not exceed 61 m (200 ft) in any assembly occupancy, unless otherwise permitted by the following:

- (1) The travel distance shall not exceed 76 m (250 ft) in assembly occupancies protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.
- (2) The travel distance requirement shall not apply to smoke-protected assembly seating as permitted by 13.4.2.8, 13.4.2.9, and 13.4.2.10.

in the plane of the nosings and the distance from the bottom of the stair to the exterior exit door at the level of discharge, as illustrated in Exhibit 12/13.26.

CHAPTER 12 • New

CHAPTER 13 • Existing

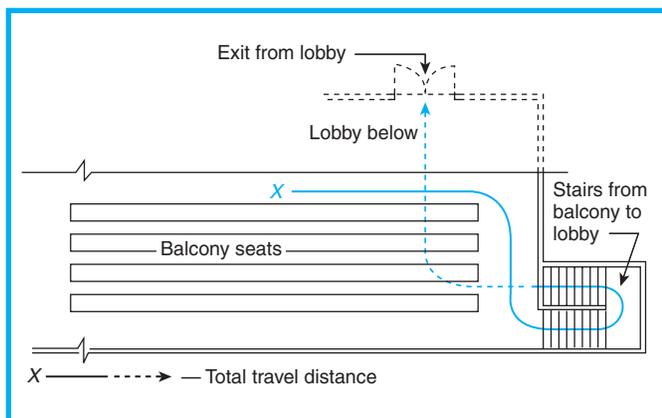

Exhibit 12/13.26 Measurement of travel distance from balcony with egress by unenclosed stairs.

12.2.7 Discharge from Exits.

12.2.7.1 Exit discharge shall comply with Section 7.7.

12.2.7.2 The level of exit discharge shall be measured at the point of principal entrance to the building.

12.2.7.3 Where the principal entrance to an assembly occupancy is via a terrace, either raised or depressed, such terrace shall be permitted to be considered to be the level of exit discharge for the purposes of Table 12.1.6 where the following criteria are met:

- (1) The terrace is at least as long, measured parallel to the building, as the total width of the exit(s) it serves but not less than 1525 mm (60 in.) long.
- (2) The terrace is at least as wide, measured perpendicularly to the building, as the exit(s) it serves but not less than 3050 mm (120 in.) wide.
- (3) Required stairs leading from the terrace to grade are protected in accordance with 7.2.2.6.3 or are not less than 3050 mm (120 in.) from the building.

The *Code* specifies that 3050 mm (120 in.) is the minimum terrace depth necessary to allow people to exit the building into a depressed or raised area without causing a jamming effect at the exit. The same result was intended in requiring stairs to be at least 3050 mm (120 in.) from the face of the building, unless they are protected as provided in Chapter 7. The requirements of 12/13.2.7.3 are illustrated in Exhibit 12/13.27. Assuming that stair D serves exit B plus one-half of entrance A and that stair E serves exit C

13.2.7 Discharge from Exits.

13.2.7.1 Exit discharge shall comply with Section 7.7.

13.2.7.2 The level of exit discharge shall be measured at the point of principal entrance to the building.

13.2.7.3 Where the principal entrance to an assembly occupancy is via a terrace, either raised or depressed, such terrace shall be permitted to be considered to be the level of exit discharge for the purposes of Table 13.1.6 where the following criteria are met:

- (1) The terrace is at least as long, measured parallel to the building, as the total width of the exit(s) it serves but not less than 1525 mm (60 in.) long.
- (2) The terrace is at least as wide, measured perpendicularly to the building, as the exit(s) it serves but not less than 1525 mm (60 in.) wide.
- (3) Required stairs leading from the terrace to grade are protected in accordance with 7.2.2.6.3 or are not less than 3050 mm (120 in.) from the building.

plus one-half of entrance A, then X must be equal to or greater than the largest one of the following:

- (1) 3050 mm (120 in.) per 12/13.2.7.3(2)
- (2) 1525 mm (60 in.) + $\frac{1}{2}$ of 4270 mm (168 in.) = 3660 mm (144 in.)
- (3) 1830 mm (72 in.) + $\frac{1}{2}$ of 4270 mm (168 in.) = 3960 mm (156 in.)

Therefore, $X \geq 3960$ mm (156 in.).

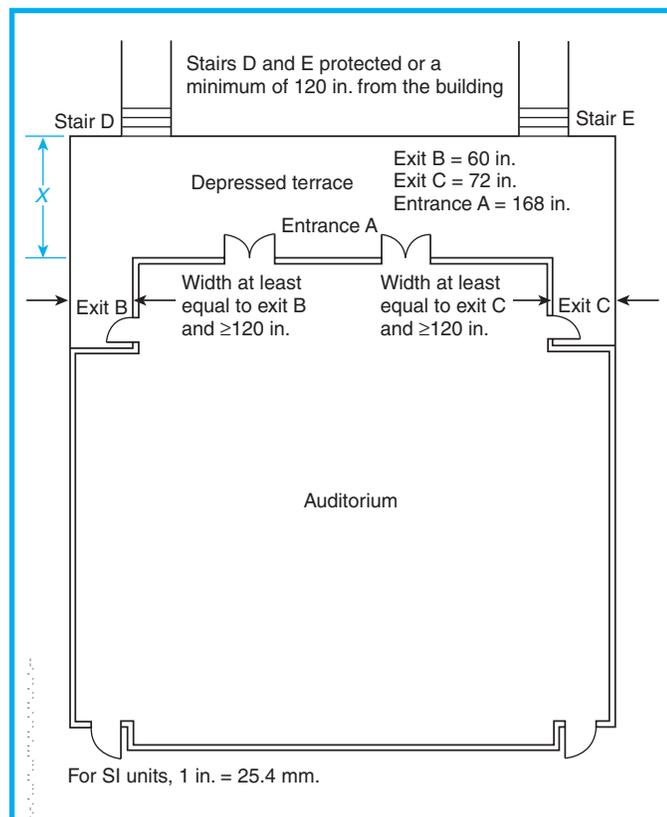

Exhibit 12/13.27 Assembly occupancy with depressed terrace as principal entrance.

12.2.8 Illumination of Means of Egress.

Means of egress, other than for private party tents not exceeding 112 m² (1200 ft²), shall be illuminated in accordance with Section 7.8.

12.2.9 Emergency Lighting.

12.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9.

12.2.9.2 Private party tents not exceeding 112 m² (1200 ft²) shall not be required to have emergency lighting.

12.2.10 Marking of Means of Egress.

12.2.10.1 Means of egress shall be provided with signs in accordance with Section 7.10.

13.2.8 Illumination of Means of Egress.

Means of egress, other than for private party tents not exceeding 112 m² (1200 ft²), shall be illuminated in accordance with Section 7.8.

13.2.9 Emergency Lighting.

13.2.9.1 Emergency lighting, other than that permitted by 13.2.9.3, shall be provided in accordance with Section 7.9.

13.2.9.2 Private party tents not exceeding 112 m² (1200 ft²) shall not be required to have emergency lighting.

13.2.9.3 Assembly occupancies with an occupant load not exceeding 300 and used exclusively for a place of worship shall not be required to have emergency lighting.

13.2.10 Marking of Means of Egress.

13.2.10.1 Means of egress shall be provided with signs in accordance with Section 7.10.

CHAPTER 12 • New

12.2.10.2 Exit markings shall not be required on the seating side of vomitories from seating areas where exit marking is provided in the concourse and where such marking is readily apparent from the vomitories.

12.2.11 Special Means of Egress Features.

12.2.11.1 Guards and Railings.

12.2.11.1.1* Sightline-Constrained Rail Heights. Unless subject to the requirements of 12.2.11.1.2, a fascia or railing system complying with the guard requirements of 7.2.2.4 and having a height of not less than 660 mm (26 in.) shall be provided where the floor or footboard elevation is more than 760 mm (30 in.) above the floor or grade below and where the fascia or railing system would otherwise interfere with the sightlines of immediately adjacent seating.

A.12.2.11.1.1 This requirement includes provisions of guards and rails at the front of boxes, galleries, and balconies, and at aisle accessways adjacent to vomitories and orchestra pits.

12.2.11.1.2 At Foot of Aisles.

12.2.11.1.2.1 A fascia or railing system complying with the guard requirements of 7.2.2.4 shall be provided for the full width of the aisle where the foot of the aisle is more than 760 mm (30 in.) above the floor or grade below.

12.2.11.1.2.2 The fascia or railing shall be not less than 915 mm (36 in.) high and shall provide not less than 1065 mm (42 in.), measured diagonally, between the top of the rail and the nosing of the nearest tread.

12.2.11.1.3 At Cross Aisles. Guards and railings at cross aisles shall meet the following criteria:

- (1) Cross aisles located behind seating rows shall be provided with railings not less than 660 mm (26 in.) above the adjacent floor of the aisle.
- (2) The requirement of 12.2.11.1.3(1) shall not apply where the backs of seats located at the front of the aisle project 610 mm (24 in.) or more above the adjacent floor of the aisle.
- (3) Where cross aisles exceed 760 mm (30 in.) above the floor or grade below, guards shall be provided in accordance with 7.2.2.4.

12.2.11.1.4 At Side and Back of Seating Areas. Guards complying with the guard requirements of 7.2.2.4 shall be provided with a height not less than 1065 mm (42 in.) above the aisle, aisle accessway, or footboard where the floor elevation exceeds 760 mm (30 in.) above the floor or grade to the side or back of seating.

CHAPTER 13 • Existing

13.2.10.2 Exit markings shall not be required on the seating side of vomitories from seating areas where exit marking is provided in the concourse and where such marking is readily apparent from the vomitories.

13.2.11 Special Means of Egress Features.

13.2.11.1 Guards and Railings: Boxes, Balconies, and Galleries. Boxes, balconies, and galleries shall meet the following criteria:

- (1) The fascia of boxes, balconies, and galleries shall rise not less than 660 mm (26 in.) above the adjacent floor or shall have substantial railings not less than 660 mm (26 in.) above the adjacent floor.
- (2) The height of the rail above footrests on the adjacent floor immediately in front of a row of seats shall be not less than 660 mm (26 in.), and the following also shall apply:
 - (a) Railings at the ends of aisles shall be not less than 915 mm (36 in.) high for the full width of the aisle.
 - (b) Railings at the end of aisles shall be not less than 1065 mm (42 in.) high for the width of the aisle where steps occur.
 - (c) Existing railings 915 mm (36 in.) high at the ends of aisles where steps occur shall be permitted to be continued to be used.
- (3) Aisle accessways adjacent to orchestra pits and vomitories, and all cross aisles, shall be provided with railings not less than 660 mm (26 in.) above the adjacent floor.
- (4) The requirement of 13.2.11.1(3) shall not apply where the backs of seats located at the front of the aisle project 610 mm (24 in.) or more above the adjacent floor of the aisle.
- (5) Guardrails shall not be required on the audience side of stages, raised platforms, and other raised floor areas such as runways, ramps, and side stages used for entertainment or presentations.
- (6) Permanent guardrails shall not be required at vertical openings in the performance area of stages.
- (7) Guardrails shall not be required where the side of an elevated walking surface is required to be open for the normal functioning of special lighting or for access and use of other special equipment.

CHAPTER 12 • New

12.2.11.1.5 Below Seating. Openings between footboards and seat boards shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

12.2.11.1.6 Locations Not Requiring Guards. Guards shall not be required in the following locations:

- (1) Guards shall not be required on the audience side of stages, of raised platforms, and of other raised floor areas such as runways, ramps, and side stages used for entertainment or presentations.
- (2) Permanent guards shall not be required at vertical openings in the performance area of stages.
- (3) Guards shall not be required where the side of an elevated walking surface is required to be open for the normal functioning of special lighting or for access and use of other special equipment.

The requirements for guards and handrails for new assembly seating areas were revised for the 1997 edition of the *Code*. The requirements for guards and handrails for existing assembly seating areas remained without revision. The provisions for new construction are, thus, different from those applicable to existing facilities. The following commentary addresses new installations first and existing arrangements second.

Paragraphs 12.2.11.1.1 and 12.2.11.1.2 clarify that new assembly seating area guards, where the floor is more than 760 mm (30 in.) above the floor or grade below, must comply with the guard requirements of 7.2.2.4. This requirement includes the provision for intermediate rails or balusters to meet the 100-mm-(4-in.-) diameter sphere requirement of 7.2.2.4.5.3, which is illustrated in Exhibit 12/13.28.

Paragraph 12.2.11.1.1 permits a guard height of 660 mm (26 in.) at the front of seating but not at the foot of aisles. Further, the 660-mm (26-in.) height allowance applies only if a 915-mm (36-in.) height rail [as permitted by 12.2.11.1.2.2 in lieu of the typical 1065-mm (42-in.) height guard detailed in 7.2.2.4.5] would otherwise interfere with sight lines of immediately adjacent seating. Note that the heading for paragraph 12.2.11.1.1 is “Sightline-Constrained Rail Heights.” The minimum 660-mm (26-in.) height is illustrated in Exhibit 12/13.28.

Paragraph 12.2.11.1.2.1 requires that a guard be provided at the foot of an aisle if there is more than a 760-mm (30-in.) vertical distance to fall. Again, such

CHAPTER 13 • Existing

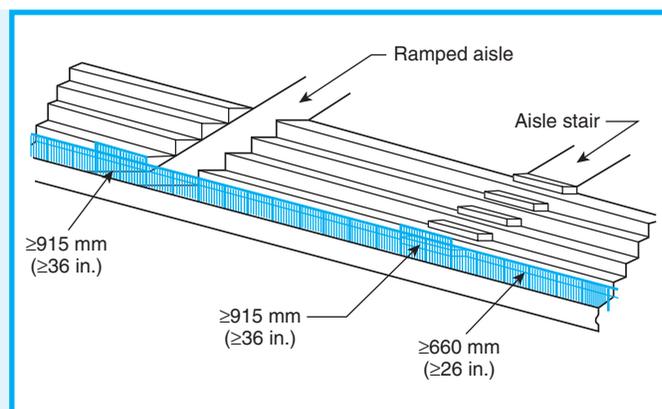

Exhibit 12/13.28 New assembly occupancy building with railings installed in accordance with 12.2.11.1.1 and 12.2.11.1.2.

guards must meet the guard requirements of 7.2.2.4.5 and must be at least 915 mm (36 in.) in height. See Exhibit 12/13.28. Where previous editions of the *Code* required a 1065-mm (42-in.) guard at the foot of a stepped aisle, the current requirement of 12.2.11.1.2.2 is for a minimum 915-mm (36-in.) height and a minimum 1065 mm (42 in.), measured diagonally between the top of the guardrail and the nosing of the nearest step tread. This requirement is illustrated in Exhibit 12/13.29.

Where there is a stepped aisle, the requirement of 12.2.11.1.2.2 to provide a minimum of 1065 mm (42 in.), measured diagonally between the top of the

CHAPTER 12 • New

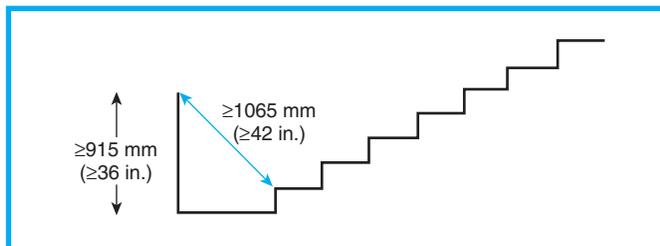

Exhibit 12/13.29 New assembly occupancy building with railings installed at foot of stepped aisle in accordance with 12.2.11.1.2.2.

guardrail and the nosing of the nearest step tread, will force the guardrail height to be greater than 915 mm (36 in.) if the first riser is positioned too close, horizontally, to the guard. For example, if the first riser is positioned 710 mm (28 in.) horizontally from the guard and a 205-mm (8-in.) riser height is used, the minimum 1065-mm (42-in.) diagonal distance requirement will force the guardrail height to be a minimum of 990 mm (39 in.). For the same riser height of 205 mm (8 in.), a 915-mm- (36-in.-) high guardrail at the foot of the stepped aisle would require that the first step riser be positioned at least 785 mm (31 in.), horizontally, from the guardrail.

Paragraph 13.2.11.1 addresses guards and railings in existing assembly occupancies.

Exhibit 12/13.30 illustrates the requirements of 13.2.11.1(1) and 13.2.11.1(2). Rail height at the fascia end of a sloping aisle must not be less than 915 mm (36 in.). However, where the aisle has steps, the rail height must be at least 1065 mm (42 in.). There is greater danger of people tripping on steps than on a ramped surface with a maximum gradient of 1 unit of rise to 8 units of run.

It is not the intent of the *Code* to reduce the height of guards where sightlines are not a problem, such as with cross aisles at the rear or top of seating areas or where cross aisles are sufficiently below seating that a proper height guard will not interfere with sightlines.

Note that, for existing assembly occupancies, the railings described by 13.2.11.1(1) and 13.2.11.1(2) are, in fact, railings and not the guards required by 7.2.2.4.5. As depicted in Exhibit 12/13.30, there is no requirement for intermediate rails or balusters—the assembly seating rails are not required to meet the 100-mm (4-in.) diameter sphere requirement of

CHAPTER 13 • Existing

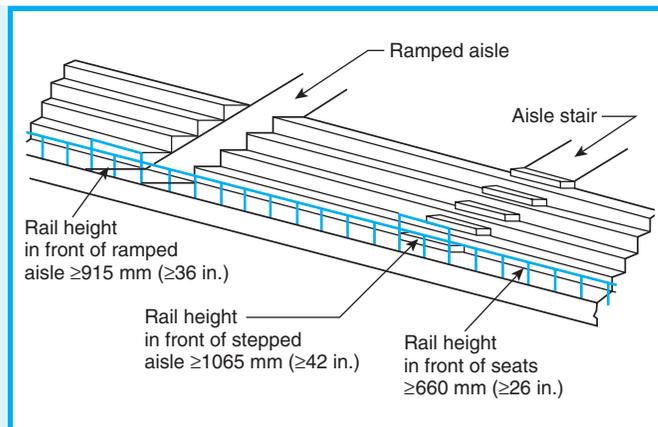

Exhibit 12/13.30 Existing assembly occupancy building with railings installed in accordance with 13.2.11.1(1) and 13.2.11.1(2).

7.2.2.4.5.3. This provision is more lenient than the requirements applicable to new assembly occupancies, where 12.2.11.1 requires a railing system to comply with the guard requirements of 7.2.2.4 [see Exhibit 12/13.28].

The *Code* requires a barrier along the downhill side of a cross aisle for both new construction and existing buildings. The barrier might consist of a rail or the backs of the seats that abut the downhill side of the aisle where the backs project 610 mm (24 in.) or more above the cross aisle. The difference between the 610-mm (24-in.) back height and the required 660-mm (26-in.) railing is not sufficient to require the railing. See Exhibit 12/13.31.

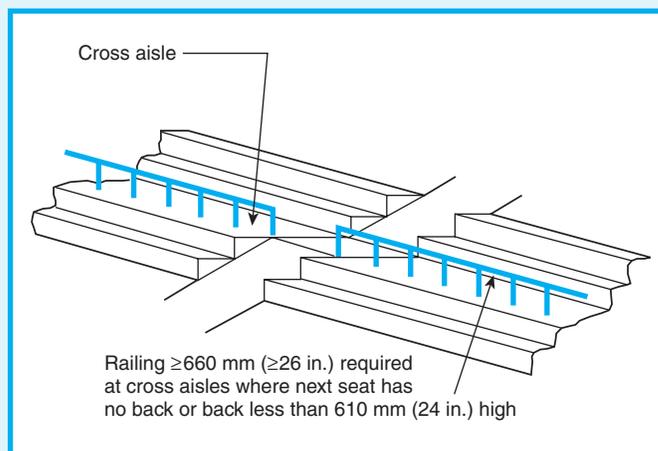

Exhibit 12/13.31 Barrier for cross aisles.

CHAPTER 12 • New

Section 12.3 Protection**12.3.1 Protection of Vertical Openings.**

Any vertical opening shall be enclosed or protected in accordance with 8.6, unless otherwise permitted by the following:

- (1)* Stairs or ramps shall be permitted to be unenclosed between balconies or mezzanines and main assembly areas located below, provided that the balcony or mezzanine is open to the main assembly area.

A.12.3.1(1) The allowance for unenclosed stairs or ramps presumes the balcony or mezzanine complies with the other provisions of the *Code*, such as travel distance to exits in accordance with 12.2.6 and numbers of exits in accordance with 12.2.4. For the purposes of this exception, a balcony with glazing that provides a visual awareness of the main assembly area is considered open.

- (2) Exit access stairs from lighting and access catwalks, galleries, and gridirons shall not be required to be enclosed.
- (3) Assembly occupancies protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7 shall be permitted to have unprotected vertical openings in accordance with 8.6.8.2.

12.3.2 Protection from Hazards.**12.3.2.1 Service Equipment, Hazardous Operations or Processes, and Storage Facilities.**

12.3.2.1.1 Rooms containing high-pressure boilers, refrigerating machinery of other than the domestic refrigerator type, large transformers, or other service equipment subject to explosion shall meet the following requirements.

- (1) Such rooms shall not be located directly under or abutting required exits.
- (2) Such rooms shall be separated from other parts of the building by fire barriers in accordance with Section 8.3 that have a fire resistance rating of not less than 1 hour

CHAPTER 13 • Existing

Section 13.3 Protection**13.3.1 Protection of Vertical Openings.**

Any vertical opening shall be enclosed or protected in accordance with 8.6, unless otherwise permitted by the following:

- (1)* Stairs or ramps shall be permitted to be unenclosed between balconies or mezzanines and main assembly areas located below, provided that the balcony or mezzanine is open to the main assembly area.

A.13.3.1(1) The allowance for unenclosed stairs or ramps presumes the balcony or mezzanine complies with the other provisions of the *Code*, such as travel distance to exits in accordance with 13.2.6 and numbers of exits in accordance with 13.2.4. For the purposes of this exception, a balcony with glazing that provides a visual awareness of the main assembly area is considered open.

- (2) Exit access stairs from lighting and access catwalks, galleries, and gridirons shall not be required to be enclosed.
- (3) Assembly occupancies protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7 shall be permitted to have unprotected vertical openings in accordance with 8.6.8.2.
- (4) Use of the following alternative materials shall be permitted where assemblies constructed of such materials are in good repair and free of any condition that would diminish their original fire resistance characteristics:
 - (a) Existing wood lath and plaster
 - (b) Existing 13-mm (½-in.) gypsum wallboard
 - (c) Existing installations of 6.3-mm (¼ in.) thick wired glass that are, or are rendered, inoperative and fixed in the closed position
 - (d) Other existing materials having similar fire resistance capabilities

13.3.2 Protection from Hazards.**13.3.2.1 Service Equipment, Hazardous Operations or Processes, and Storage Facilities.**

13.3.2.1.1 Rooms containing high-pressure boilers, refrigerating machinery of other than the domestic refrigerator type, large transformers, or other service equipment subject to explosion shall meet the following requirements:

- (1) Such rooms shall not be located directly under or abutting required exits.
- (2) Such rooms shall be separated from other parts of the building by fire barriers in accordance with Section 8.3 that have a fire resistance rating of not less than 1 hour

CHAPTER 12 • New

or shall be protected by automatic extinguishing systems in accordance with Section 8.7.

12.3.2.1.2 Rooms or spaces for the storage, processing, or use of materials specified in 12.3.2.1.2(1) through 12.3.2.1.2(3) shall be protected in accordance with the following:

- (1) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour or protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
 - (a) Boiler and furnace rooms, unless otherwise permitted by the following:
 - i. The requirement of 12.3.2.1.2(1)(a) shall not apply to rooms enclosing furnaces, heating and air-handling equipment, or compressor equipment with a total aggregate input rating less than 211 MJ (200,000 Btu), provided that such rooms are not used for storage.
 - ii. The requirements of 12.3.2.1.2(1)(a) shall not apply to attic locations of the rooms addressed in 12.3.2.1.2(1)(a)i provided such rooms comply with the draft stopping requirements of 8.6.10.
 - (b) Rooms or spaces used for the storage of combustible supplies in quantities deemed hazardous by the authority having jurisdiction
 - (c) Rooms or spaces used for the storage of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
- (2) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour and protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
 - (a) Laundries
 - (b) Maintenance shops, including woodworking and painting areas
 - (c) Rooms or spaces used for processing or use of combustible supplies deemed hazardous by the authority having jurisdiction
 - (d) Rooms or spaces used for processing or use of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
- (3) Where automatic extinguishing is used to meet the requirements of 12.3.2, the protection shall be permitted to be in accordance with 9.7.1.2.

CHAPTER 13 • Existing

or shall be protected by automatic extinguishing systems in accordance with Section 8.7.

13.3.2.1.2 Rooms or spaces for the storage, processing, or use of materials specified in 13.3.2.1.2(1) through 13.3.2.1.2(3) shall be protected in accordance with the following:

- (1) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour or protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
 - (a) Boiler and furnace rooms, unless otherwise protected by the following:
 - i. The requirement of 13.3.2.1.2(1)(a) shall not apply to rooms enclosing furnaces, heating and air-handling equipment, or compressor equipment with a total aggregate input rating less than 211 MJ (200,000 Btu), provided that such rooms are not used for storage.
 - ii. The requirement of 13.3.2.1.2(1)(a) shall not apply to attic locations of the rooms addressed in 13.3.2.1.2(1)(a)i provided such rooms comply with the draftstopping requirements of 8.6.10.
 - (b) Rooms or spaces used for the storage of combustible supplies in quantities deemed hazardous by the authority having jurisdiction.
 - (c) Rooms or spaces used for the storage of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
- (2) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour and protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
 - (a) Laundries
 - (b) Maintenance shops, including woodworking and painting areas
 - (c) Rooms or spaces used for processing or use of combustible supplies deemed hazardous by the authority having jurisdiction
 - (d) Rooms or spaces used for processing or use of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
- (3) Where automatic extinguishing is used to meet the requirements of 13.3.2, the protection shall be permitted to be in accordance with 9.7.1.2.

CHAPTER 12 • New

CHAPTER 13 • Existing

The intent of 12/13.3.2.1.2 is to specify the degree of protection necessary for certain hazardous areas. The requirements are separated into three subdivisions: 12/13.3.2.1.2(1) and 12/13.3.2.1.2(2), which are based on the degree of hazard, and 12/13.3.2.1.2(3), which addresses the use of the domestic water supply for sprinklers used to protect the hazardous area. The hazards noted in 12/13.3.2.1.2(1) are required to be enclosed in 1-hour construction *or* protected by sprinklers. If the sprinkler option is chosen, an enclosure is still required; however, the enclosure need not be fire rated but is required to form a membrane against the passage of smoke.

The hazards noted in 12/13.3.2.1.2(2) must be enclosed in 1-hour construction *and* protected by automatic sprinklers.

Exhibits 12/13.32 through 12/13.34 illustrate the three methods of protection specified by 12/13.3.2.1.2. Exhibits 12/13.32 and 12/13.33 illustrate the two options for complying with 12/13.3.2.1.2(1), that is, separation via fire-rated barriers or protection by automatic sprinklers. Exhibit 12/13.34 illustrates the requirement of 12/13.3.2.1.2(2) that both fire resistance-rated separation and automatic sprinkler protection be provided.

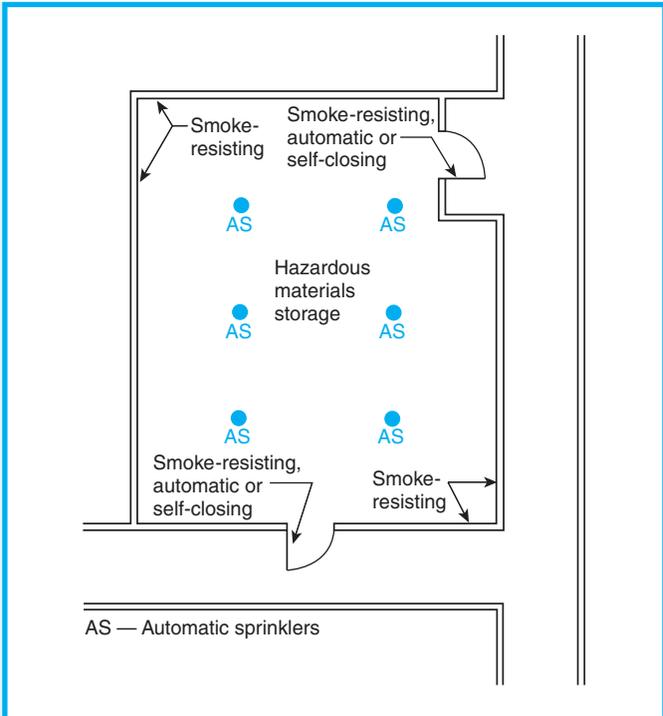

Exhibit 12/13.33 Protection of hazardous areas using automatic sprinklers.

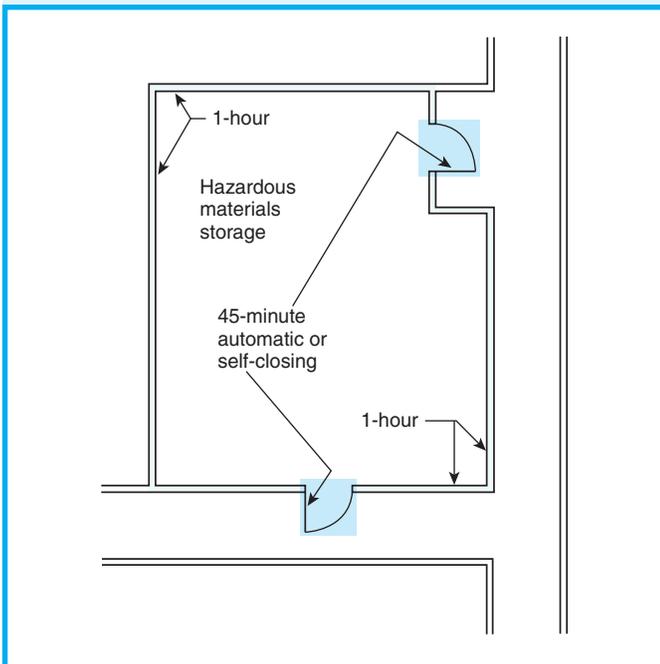

Exhibit 12/13.32 Protection of hazardous areas using fire-rated enclosure.

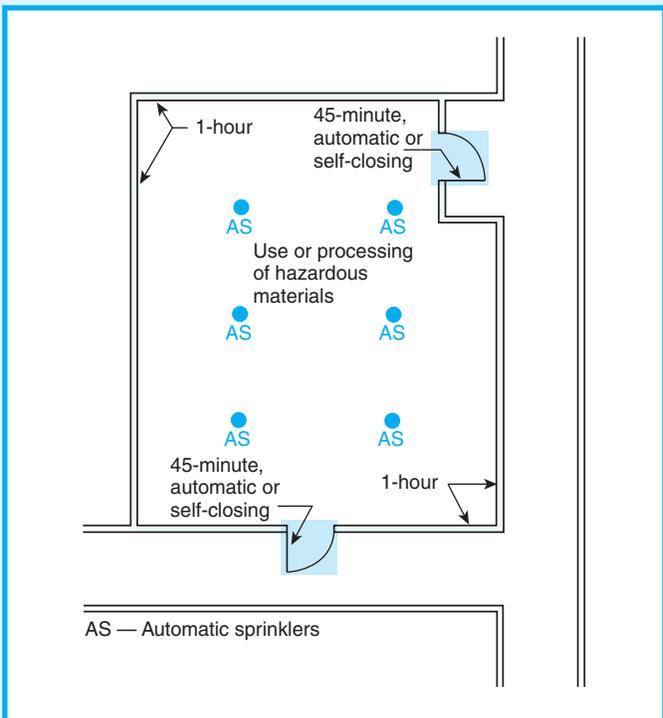

Exhibit 12/13.34 Protection of hazardous areas using both fire-rated enclosure and automatic sprinklers.

CHAPTER 12 • New

12.3.2.2 Cooking Equipment. Cooking equipment shall be protected in accordance with 9.2.3 unless the cooking equipment meets one of the following:

- (1) Outdoor equipment
- (2) Portable equipment not flue connected
- (3) Equipment used only for food warming

12.3.3 Interior Finish.

12.3.3.1 Interior finish shall be in accordance with Section 10.2.

12.3.3.2 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in all corridors and lobbies and shall be Class A in enclosed stairways.

12.3.3.3 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in general assembly areas having occupant loads of more than 300 and shall be Class A, Class B, or Class C in assembly areas having occupant loads of 300 or fewer.

12.3.3.4 Screens on which pictures are projected shall comply with requirements of Class A or Class B interior finish in accordance with Section 10.2.

Evaluation of existing interior finish is sometimes difficult. Where flame spread characteristics cannot be readily determined, the questionable material should be removed or treated with approved flame

12.3.3.5 Interior Floor Finish.

12.3.3.5.1 Interior floor finish shall comply with Section 10.2.

12.3.3.5.2 Interior floor finish in exit enclosures and exit access corridors and in spaces not separated from them by walls complying with 12.3.6 shall be not less than Class II.

12.3.3.5.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2, as applicable.

12.3.4 Detection, Alarm, and Communications Systems.

12.3.4.1 General. Assembly occupancies with occupant loads of more than 300 and all theaters with more than one audience-viewing room shall be provided with an approved fire alarm system in accordance with 9.6.1 and 12.3.4, unless otherwise permitted by the following:

CHAPTER 13 • Existing

13.3.2.2 Cooking Equipment. Cooking equipment shall be protected in accordance with 9.2.3 unless the cooking equipment meets one of the following:

- (1) Outdoor equipment
- (2) Portable equipment not flue connected
- (3) Equipment used only for food warming

13.3.3 Interior Finish.

13.3.3.1 Interior finish shall be in accordance with Section 10.2.

13.3.3.2 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in all corridors and lobbies and shall be Class A in enclosed stairways.

13.3.3.3 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in general assembly areas having occupant loads of more than 300, and shall be Class A, Class B, or Class C in assembly areas having occupant loads of 300 or fewer.

13.3.3.4 Screens on which pictures are projected shall comply with requirements of Class A or Class B interior finish in accordance with Section 10.2.

retardants. Where treatment cannot reduce flame spread to the required limits, automatic sprinklers might be provided to help compensate for the deficiency.

13.3.3.5 Interior Floor Finish. (No requirements.)

13.3.4 Detection, Alarm, and Communications Systems.

13.3.4.1 General. Assembly occupancies with occupant loads of more than 300 and all theaters with more than one audience-viewing room shall be provided with an approved fire alarm system in accordance with 9.6.1 and 13.3.4, unless otherwise permitted by the following:

CHAPTER 12 • New

- (1) Assembly occupancies that are a part of a multiple occupancy protected as a mixed occupancy (*see 6.1.14*) shall be permitted to be served by a common fire alarm system, provided that the individual requirements of each occupancy are met.
- (2) Voice communication or public address systems complying with 12.3.4.3.3 shall not be required to comply with 9.6.1.

12.3.4.2 Initiation.

12.3.4.2.1 Initiation of the required fire alarm system shall be by manual means in accordance with 9.6.2.1(1), and the system shall be provided with an emergency power source, unless otherwise permitted by the following:

- (1) This requirement shall not apply to fire alarm systems initiated by means of an approved automatic fire detection system in accordance with 9.6.2.1(2) that provides fire detection throughout the building.
- (2) This requirement shall not apply to fire alarm systems initiated by means of an approved automatic sprinkler system in accordance with 9.6.2.1(3) that provides fire detection and protection throughout the building.

12.3.4.2.2 The initiating device shall be capable of transmitting an alarm to a receiving station, located within the building, that is constantly attended when the assembly occupancy is occupied.

12.3.4.2.3* In assembly occupancies with occupant loads of more than 300, automatic detection shall be provided in all hazardous areas that are not normally occupied, unless such areas are protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

A.12.3.4.2.3 The intent is to require detectors only in nonsprinklered hazardous areas that are unoccupied. When the building is occupied, the detectors in the unoccupied, unsprinklered hazardous areas will initiate occupant notification. If the building is unoccupied, the fire in the nonsprinklered hazardous area is not a life safety issue, and the detectors, upon activation, are not required to notify anyone. The signal from a detector is permitted to be sent to a control panel in an area that is occupied when the building is occupied, but that is unoccupied when the building is unoccupied, without the need for central station monitoring or the equivalent.

CHAPTER 13 • Existing

- (1) Assembly occupancies that are a part of a multiple occupancy protected as a mixed occupancy (*see 6.1.14*) shall be permitted to be served by a common fire alarm system, provided that the individual requirements of each occupancy are met.
- (2) Voice communication or public address systems complying with 13.3.4.3.3 shall not be required to comply with 9.6.1.
- (3) This requirement shall not apply to assembly occupancies where, in the judgment of the authority having jurisdiction, adequate alternative provisions exist or are provided for the discovery of a fire and for alerting the occupants promptly.

13.3.4.2 Initiation.

13.3.4.2.1 Initiation of the required fire alarm system shall be by manual means in accordance with 9.6.2.1(1), and the system shall be provided with an emergency power source, unless otherwise permitted by the following:

- (1) This requirement shall not apply to fire alarm systems initiated by means of an approved automatic fire detection system in accordance with 9.6.2.1(2) that provides fire detection throughout the building.
- (2) This requirement shall not apply to fire alarm systems initiated by means of an approved automatic sprinkler system in accordance with 9.6.2.1(3) that provides fire detection and protection throughout the building.

13.3.4.2.2 The initiating device shall be capable of transmitting an alarm to a receiving station, located within the building, that is constantly attended when the assembly occupancy is occupied.

13.3.4.2.3* In assembly occupancies with occupant loads of more than 300, automatic detection shall be provided in all hazardous areas that are not normally occupied, unless such areas are protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

A.13.3.4.2.3 The intent is to require detectors only in nonsprinklered hazardous areas that are unoccupied. Where the building is occupied, the detectors in the unoccupied, unsprinklered hazardous areas will initiate occupant notification. If the building is unoccupied, the fire in the nonsprinklered hazardous area is not a life safety issue, and the detectors, upon activation, are not required to notify anyone. The signal from a detector is permitted to be sent to a control panel in an area that is occupied when the building is occupied, but that is unoccupied when the building is unoccupied, without the need for central station monitoring or the equivalent.

CHAPTER 12 • New

12.3.4.3 Notification. The required fire alarm system shall sound an audible alarm in a constantly attended receiving station within the building when occupied for purposes of initiating emergency action.

12.3.4.3.1 Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.

12.3.4.3.2 Reserved.

12.3.4.3.3 Occupant notification shall be by means of visible signals and voice announcements, either live or prerecorded, initiated by the person in the constantly attended location.

12.3.4.3.4 The announcement shall be made via an approved voice communication or public address system, provided with an emergency power source, that is audible above the ambient noise level of the assembly occupancy.

12.3.4.3.5 Where the authority having jurisdiction determines that a constantly attended location is impractical, a fire alarm system in accordance with Section 9.6 shall be used that meets the following criteria:

- (1) It shall be initiated by manual fire alarm boxes in accordance with 9.6.2.1(1) or other approved means.
- (2) It shall automatically provide prerecorded evacuation instructions in accordance with 9.6.3.10.

Paragraph 12/13.3.4.1(1) clarifies that a common alarm system can be used within a building housing occupancies in addition to an assembly occupancy, provided that system meets the alarm requirements applicable to each of those occupancies. This provision allows an assembly occupancy in a school, hotel, hospital, mall, or other building to be served by the same fire alarm as the predominant occupancy, provided that it also meets the requirements applicable to alarm systems in an assembly occupancy.

Paragraph 12/13.3.4.1(2) allows a voice communication system or public address system installed to comply with 12/13.3.4.3.3 to be exempt from the installation requirements of *NFPA 72, National Fire Alarm Code*⁵, including electrical supervision. The daily use of this system should provide adequate self-supervision.

Paragraph 13.3.4.1(3), which applies only to existing assembly occupancies, specifically allows the authority having jurisdiction to permit the continued

CHAPTER 13 • Existing

13.3.4.3 Notification. The required fire alarm system shall sound an audible alarm in a constantly attended receiving station within the building when occupied for purposes of initiating emergency action.

13.3.4.3.1 Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.

13.3.4.3.2 A presignal system in accordance with 9.6.3.3 shall be permitted.

13.3.4.3.3 Occupant notification shall be by means of voice announcements, either live or prerecorded, initiated by the person in the constantly attended location.

13.3.4.3.4 The announcement shall be made via an approved voice communication or public address system that is audible above the ambient noise level of the assembly occupancy.

13.3.4.3.5 Where the authority having jurisdiction determines that a constantly attended location is impractical, a fire alarm system in accordance with Section 9.6 shall be used that meets the following criteria:

- (1) It shall be initiated by manual fire alarm boxes in accordance with 9.6.2.1(1) or other approved means.
- (2) It shall automatically provide prerecorded evacuation instructions in accordance with 9.6.3.10.

use of existing alternative means for discovering fire and alerting occupants—even if such means do not meet the myriad requirements of *NFPA 72*.

The provisions of 12/13.3.4.2.3 recognize that a fire developing in an unoccupied, nonsprinklered, hazardous area while the assembly area is in use could go undiscovered. Although separated by 1-hour fire resistance-rated barriers, these hazardous areas can present a significant hazard to occupants. Because a fire alarm system is already required, the additional requirement for either heat or smoke detection, as appropriate, is not a significant burden. Where sprinkler protection is provided, the fire is expected to be controlled, permitting early detection to be exempted.

The intent of 12/13.3.4.3 is to provide an alarm system that will not elicit a panic reaction from occupants. The panic reaction is avoided by providing a system that will permit activation by pull stations as required by 9.6.2 but that will not sound an audible

CHAPTER 12 • New

alarm in the seating or audience areas of the assembly occupancy. In lieu of the audible alarm throughout the assembly occupancy, the system must sound an alarm in a constantly attended location. *Constantly attended*, in this case, means that the alarm panel must be attended while the assembly occupancy is in use. From that constantly attended location, voice messages that instruct the occupants can be issued via a public address system. This method allows for the

12.3.5 Extinguishment Requirements.

12.3.5.1 Buildings containing assembly occupancies with occupant loads of more than 300 shall be protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7 as follows (*see also 12.1.6, 12.2.6, 12.3.2, and 12.3.6*):

- (1) Throughout the story containing the assembly occupancy
- (2) Throughout all stories below the story containing the assembly occupancy
- (3) In the case of an assembly occupancy located below the level of exit discharge, throughout all stories intervening between that story and the level of exit discharge, including the level of exit discharge

(SC 03-7-18/Log No. 741R)

Pursuant to Section 5 of the NFPA Regulations Governing Committee Projects, the National Fire Protection Association has issued the following Tentative Interim Amendment to NFPA 101®, *Life Safety Code®*, 2003 edition. The TIA was processed by the Safety to Life Committee, and was issued by the Standards Council on July 25, 2003, with an effective date of August 14, 2003.

A Tentative Interim Amendment is tentative because it has not been processed through the entire standards-making procedures. It is interim because it is effective only between editions of the standard. A TIA automat-

CHAPTER 13 • Existing

orderly evacuation of the occupants and permits the issuance of proper evacuation instructions rather than simply sounding an evacuation alarm that might produce panic. The *Code* permits the use of pre-recorded or electronically synthesized evacuation instructions that will automatically be played upon initiation of the system. With the approval of the authority having jurisdiction, this arrangement is permitted to be used in lieu of the attended station.

13.3.5 Extinguishment Requirements.

See also 13.1.6, 13.2.6, and 13.3.2.

13.3.5.1 Any assembly occupancy used or capable of being used for exhibition or display purposes shall be protected throughout by an approved automatic sprinkler system in accordance with Section 9.7 where the exhibition or display area exceeds 1400 m² (15,000 ft²).

TIA 03-3 (NFPA 101)
(SC 03-7-17/Log No. 739R)

Pursuant to Section 5 of the NFPA Regulations Governing Committee Projects, the National Fire Protection Association has issued the following Tentative Interim Amendment to NFPA 101®, *Life Safety Code®*, 2003 edition. The TIA was processed by the Safety to Life Committee, and was issued by the Standards Council on July 25, 2003, with an effective date of August 14, 2003.

A Tentative Interim Amendment is tentative because it has not been processed through the entire standards-making procedures. It is interim because it is effective only between editions of the standard. A TIA automat-

CHAPTER 12 • New

ically becomes a proposal of the proponent for the next edition of the standard; as such, it then is subject to all of the procedures of the standards-making process.

Insert a new 12.3.5.1 (and renumber existing 12.3.5.1 through 12.3.5.3) to require sprinklers in new nightclubs and similar assembly occupancies as follows:

12.3.5.1 The following assembly occupancies shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7:

- (1) Bars
- (2) Dance Halls
- (3) Discotheques
- (4) Nightclubs
- (5) Assembly occupancies with festival seating

Copyright © 2003 All Rights Reserved
NATIONAL FIRE PROTECTION ASSOCIATION

12.3.5.2 The requirements of 12.3.5.1 shall not apply to the following:

- (1) Assembly occupancies used primarily for worship with fixed seating that are not part of a multiple occupancy protected as a mixed occupancy (*see 6.1.14*)
- (2)* Assembly occupancies consisting of a single multipurpose room of less than 1115 m² (12,000 ft²) that are not used for exhibition or display and are not part of a mixed occupancy

A.12.3.5.2(2) It is the intent to permit a single multipurpose room of less than 1115 m² (12,000 ft²) to have certain small rooms as part of the single room. These rooms could be a kitchen, office, equipment room, and the like. It is also the intent that an addition could be made to an existing building without requiring that the existing building be sprinklered, where both the new and existing buildings have independent means of egress and a fire-rated separation is provided to isolate one building from the other.

A school gymnasium with egress independent of, and separated from, the school would be included in this exception, as would a function hall attached to a church with a similar egress arrangement.

- (3) Gymnasiums, skating rinks, and swimming pools used exclusively for participant sports with no audience facilities for more than 300 persons
- (4) In the following locations in stadia and arenas:
 - (a) Over the floor area used for contest, performance, or entertainment

CHAPTER 13 • Existing

ically becomes a proposal of the proponent for the next edition of the standard; as such, it then is subject to all of the procedures of the standards-making process.

Insert a new 13.3.5.1 (and renumber existing 13.3.5.1 through 13.3.5.3) to require sprinklers in existing nightclubs and similar assembly occupancies with occupant load exceeding 100 as follows:

13.3.5.1 Where occupant load exceeds 100, the following assembly occupancies shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7:

- (1) Bars
- (2) Dance Halls
- (3) Discotheques
- (4) Nightclubs
- (5) Assembly occupancies with festival seating

Copyright © 2003 All Rights Reserved
NATIONAL FIRE PROTECTION ASSOCIATION

13.3.5.2 The sprinklers specified by 13.3.5.1 shall not be required where otherwise permitted by the following:

- (1) In stadia and arenas:
 - (a) Over the floor area used for contest, performance, or entertainment
 - (b) Over the seating areas
 - (c) Over open-air concourses where an approved engineering analysis substantiates the ineffectiveness of the sprinkler protection due to building height and combustible loading
- (2) In the following areas in unenclosed stadia and arenas:
 - (a) Press boxes less than 93 m² (1000 ft²)
 - (b) Storage facilities less than 1000 ft² (93 m²) if enclosed with not less than 1-hour fire resistance-rated construction
 - (c) Enclosed areas underneath grandstands that comply with 13.4.8.5

CHAPTER 12 • New

- (b) Over the seating areas
 - (c) Over open-air concourses where an approved engineering analysis substantiates the ineffectiveness of the sprinkler protection due to building height and combustible loading
- (5) In the following areas in unenclosed stadia and arenas:
- (a) In press boxes less than 93 m² (1000 ft²)
 - (b) In storage facilities less than 93 m² (1000 ft²) if enclosed with not less than 1-hour fire resistance-rated construction
 - (c) In enclosed areas underneath grandstands that comply with 12.4.8.5

12.3.5.3 Where another provision of this chapter requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with 9.7.1.1(1).

Subsection 12/13.3.5 is one of the two primary locations within the chapter where automatic sprinkler protection might be required. The other is 12/13.1.6, which applies to minimum construction requirements. Each of these subsections is to be applied independently to determine whether automatic sprinkler protection is required. For example, if 12/13.1.6 does not require sprinklers for a particular assembly occupancy on the basis of building construction type and location within the building, 12.3.5 might require automatic sprinklers for that assembly occupancy based on occupant load, or 13.3.5 might require automatic sprinklers based on the floor area that is capable of being used for exhibition purposes. If one subsection requires sprinklers and the other does not, sprinklers must be provided.

The requirement for automatic sprinkler protection for new assembly occupancies with an occupant load in excess of 300 persons was prompted by the occurrence of fires involving assembly occupancies, most notably the Beverly Hills Supper Club fire in 1977⁶ and the MGM Grand Hotel fire in 1980⁷. The exemptions to the general requirement, as contained in 12.3.5.2, are important in that they limit the areas or buildings requiring sprinkler protection.

The concepts used in the # symbol note of Table 12.1.6 and the § symbol note of Table 13.1.6 are also used with regard to which areas must be sprinklered. If a five-story building has an assembly occupancy on the first floor, the floors above the assembly occupancy are not required to be sprinklered by the assembly occupancy provisions; however, sprinklering of those floors might be required by the applicable

CHAPTER 13 • Existing

13.3.5.3 Where another provision of this chapter requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with 9.7.1.1(1).

occupancy chapter. If the assembly occupancy is on the fifth floor, then the fifth floor and all floors below it would be required to be sprinklered.

Paragraph 12.3.5.2(1) exempts new places of worship with fixed seating from the sprinkler requirement of 12.3.5.1. The life safety record is reasonably good in these occupancies.

Paragraph 12.3.5.2(2) exempts multipurpose assembly occupancies that are contained in one room, have an area of less than 1100 m² (12,000 ft²), and are not used as an exhibition hall or for a display room. Exhibit and display halls have been shown to be fire and life safety problems because of their high fuel load and potential for rapid fire spread.

The text of A.12.3.5.2(2) clarifies that it is not the intent to prohibit the presence of normal ancillary spaces. However, a number of assembly rooms or a mixed occupancy would not be permitted to use this exception.

Paragraph 12.3.5.2(3) exempts gymnasiums, skating rinks (including ice and roller rinks), and swimming pools where there is an audience or spectator gallery with an occupant load of 300 or fewer persons. If the skating rink or swimming pool can be floored over and used for other purposes, then the multipurpose room requirements contained in 12.3.5.2(2) might apply. If the spectator gallery has an occupant load greater than 300, then an automatic sprinkler system is required. In effect, 12.3.5.2(3) exempts the participants on the gym floor, skating rink, or swimming pool from being counted as part of the 300-person threshold at which the provisions of 12.3.5.1 apply.

CHAPTER 12 • New

Two major questions that arise with regard to 12.3.5 deal with multiple occupancies (especially assembly/educational) and multiple assembly occupancies (especially religious halls with multipurpose rooms).

With regard to multiple occupancies, 6.1.14.3 states that, if mixed occupancies provisions are to be used to protect a multiple occupancy, the most stringent requirements applicable to any of the involved occupancies must be provided for all occupancies. Therefore, schools with assembly occupancies need to be fully sprinklered, unless the multiple occupancy is treated as separated occupancies in accordance with 6.1.14.4, which would normally require independent egress systems and substantial fire-rated separating construction. If separated occupancies can be established, only the assembly occupancy would need to be sprinklered. Also, many school multipurpose rooms could potentially use 12.3.5.2(2) for exemption from the sprinkler requirement. Paragraph 12.3.5.2(2) emphasizes that the assembly occupancy is essentially a single room and, thus, cannot be part of a multiple occupancy.

12.3.6 Corridors.

Interior corridors and lobbies shall be constructed in accordance with 7.1.3.1 and Section 8.3, unless otherwise permitted by the following:

- (1) Corridor and lobby protection shall not be required where assembly rooms served by the corridor or lobby have at least 50 percent of their exit capacity discharging directly to the outside, independent of corridors and lobbies.
- (2) Corridor and lobby protection shall not be required in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (3) Lobbies serving only one assembly area that meet the requirements for intervening rooms (*see 7.5.1.6*) shall not be required to have a fire resistance rating.
- (4) Where the corridor ceiling is an assembly having a 1-hour fire resistance rating where tested as a wall, the corridor walls shall be permitted to terminate at the corridor ceiling.
- (5) Corridor and lobby protection shall not be required in buildings protected throughout by an approved, total (complete) coverage smoke detection system, providing occupant notification and installed in accordance with Section 9.6.

CHAPTER 13 • Existing

Paragraph 12.3.5.2(2) was originally intended for a typical fellowship hall, such as a VFW, American Legion, or Grange hall. Some ancillary rooms, such as kitchens, restrooms, storage rooms, or minor offices, will exist, and it is not the intent that these ancillary spaces disqualify a facility from using this exception; however, it is the intent that the facility consist essentially of only one major room. Often a church or similar facility would like to apply 12.3.5.2(1) and 12.3.5.2(2). Both exemptions would apply only if each area of the facility were treated separately. In other words, the egress systems of each area would have to be independent of each other, and appropriate fire separation would need to be provided.

The provisions of 13.3.5—which apply to existing assembly occupancies used or capable of being used for exhibition or display purposes—are not as stringent as those for new assembly occupancies. This requirement would apply to many facilities over 1400 m² (15,000 ft²), unless fixed seating or similar permanent obstruction to exhibition use is provided.

13.3.6 Corridors.

(No requirements.)

CHAPTER 12 • New

The corridor provisions apply only to new assembly occupancies.

Paragraph 12.3.6(1) allows for corridor protection to be eliminated but requires 50 percent of the egress capacity of each assembly room to be direct to the outside, independent of corridors or lobbies. This requirement allows theaters, for example, to use non-rated doors between the audience seating chamber and the lobby. Nonrated doors are not required to latch. Absence of the latch helps to avoid the disruptive noise associated with unlatching the door any time an occupant enters or leaves the room.

Paragraph 12.3.6(2) recognizes the excellent record of automatic sprinkler systems. However, this exemption requires the entire building, not only the assembly area, to be sprinklered.

CHAPTER 13 • Existing

Paragraph 12.3.6(3) recognizes the situation where the lobby serves only one assembly space and where, from a fire “safety” perspective, it can be considered part of that assembly space.

Paragraph 12.3.6(4) does not exempt the facility from providing fire-rated corridor walls. It permits the rated fire barrier to terminate tight against a ceiling that is constructed to be equivalent to a 1-hour wall.

Paragraph 12.3.6(5) recognizes the excellent record of automatic smoke detection systems in providing early warning. However, this exemption requires the entire building, not only the assembly area, to be equipped with smoke detectors.

Section 12.4 Special Provisions

12.4.1 Life Safety Evaluation.

12.4.1.1* Where a life safety evaluation is required by other provisions of the *Code*, it shall comply with the following:

- (1) The life safety evaluation shall be performed by persons acceptable to the authority having jurisdiction.
- (2) The life safety evaluation shall include a written assessment of safety measures for conditions listed in 12.4.1.2.
- (3) The life safety evaluation shall be approved annually by the authority having jurisdiction and shall be updated for special or unusual conditions.

A.12.4.1.1 Life safety evaluations are examples of performance-based approaches to life safety. In this respect, significant guidance in the form and process of life safety evaluations is provided by Chapter 5, keeping in mind the firesafety emphasis in Chapter 5. The general approach to performance criteria, scenarios, evaluation, safety factors, documentation, maintenance, and periodic assessment (including a warrant of fitness) all apply to the broader considerations in a life safety evaluation. A life safety evaluation deals not only with fire but also with fire, storm, collapse, crowd behavior, and other related safety considerations for which a checklist is provided in A.12.4.1.3. Chapter 5 provides guidance, based on fire safety requirements, for establishing a documented case showing that products of combustion in all conceivable fire scenarios will not significantly endanger occupants using means of egress in the facility (for example, because of fire detection, automatic suppression, smoke control, large-volume space, or manage-

13.4 Special Provisions.

13.4.1 Life Safety Evaluation.

13.4.1.1* Where a life safety evaluation is required by other provisions of the *Code*, it shall comply with the following:

- (1) The life safety evaluation shall be performed by persons acceptable to the authority having jurisdiction.
- (2) The life safety evaluation shall include a written assessment of safety measures for conditions listed in 13.4.1.2.
- (3) The life safety evaluation shall be approved annually by the authority having jurisdiction and shall be updated for special or unusual conditions.

A.13.4.1.1 Life safety evaluations are examples of performance-based approaches to life safety. In this respect, significant guidance in the form and process of life safety evaluations is provided by Chapter 5, keeping in mind the firesafety emphasis in Chapter 5. The general approach to performance criteria, scenarios, evaluation, safety factors, documentation, maintenance, and periodic assessment (including a warrant of fitness) all apply to the broader considerations in a life safety evaluation. A life safety evaluation deals not only with fire but also with fire, storm, collapse, crowd behavior, and other related safety considerations for which a checklist is provided in A.13.4.1.3. Chapter 5 provides guidance, based on fire safety requirements, for establishing a documented case showing that products of combustion in all conceivable fire scenarios will not significantly endanger occupants using means of egress in the facility (for example, because of fire detection, automatic suppression, smoke control, large-volume space, or manage-

CHAPTER 12 • New

ment procedures). Moreover, means of egress facilities plus facility management capabilities should be adequate to cope with scenarios where certain egress routes are blocked for some reason.

In addition to making realistic assumptions about the capabilities of persons in the facility (for example, an assembled crowd including many disabled persons or persons unfamiliar with the facility), the life safety evaluation should include a factor of safety of not less than 2.0 in all calculations relating to hazard development time and required egress time (the combination of flow time and other time needed to detect and assess an emergency condition, initiate egress, and move along the egress routes). The factor of safety takes into account the possibility that half of the egress routes might not be used (or be usable) in certain situations.

Regarding crowd behavior, the potential hazards created by larger masses of people and greater crowd densities (which can be problematic during ingress, occupancy, and egress) demand that technology be used by designers, managers, and authorities responsible for buildings to compensate for the relaxed egress capacity provisions of Table 12.4.2.3. In very large buildings for assembly use, the hazard of crowd crushes can exceed that of fire or structural failure. Therefore, the building designers, managers, event planners, security personnel, police authorities, and fire authorities, as well as the building construction authorities, should understand the potential problems and solutions, including coordination of their activities. For crowd behavior, this understanding includes factors of space, energy, time, and information, as well as specific crowd management techniques such as metering. Published guidance on these factors and techniques is found in the *SFPE Handbook of Fire Protection Engineering*, Section 3, Chapter 13, pp. 3-263–3-285 (Pauls, J., “Movement of People”), and the publications referenced therein.

Table 12.2.3.2 and Table 12.4.2.3 are based on a linear relationship between number of seats and nominal flow time, with not less than 200 seconds (3.3 minutes) for 2000 seats plus 1 second for every additional 50 seats up to 25,000. Beyond 25,000 total seats, the nominal flow time is limited to 660 seconds (11 minutes). Nominal flow time refers to the flow time for the most able group of patrons; some groups less familiar with the premises or less able groups might take longer to pass a point in the egress system. Although three or more digits are noted in the tables, the resulting calculations should be assumed to provide only two significant figures of precision.

12.4.1.2 Life safety evaluations shall include an assessment of the following conditions and related appropriate safety measures:

CHAPTER 13 • Existing

ment procedures). Moreover, means of egress facilities plus facility management capabilities should be adequate to cope with scenarios where certain egress routes are blocked for some reason.

In addition to making realistic assumptions about the capabilities of persons in the facility (for example, an assembled crowd including many disabled persons or persons unfamiliar with the facility), the life safety evaluation should include a factor of safety of not less than 2.0 in all calculations relating to hazard development time and required egress time (the combination of flow time and other time needed to detect and assess an emergency condition, initiate egress, and move along the egress routes). This factor of safety takes into account the possibility that half of the egress routes might not be used (or be usable) in certain situations.

Regarding crowd behavior, the potential hazards created by larger masses of people and greater crowd densities (which can be problematic during ingress, occupancy, and egress) demand that technology be used by designers, managers, and authorities responsible for buildings to compensate for the relaxed egress capacity provisions of Table 13.4.2.3. In very large buildings for assembly use, the hazard of crowd crushes can exceed that of fire or structural failure. Therefore, the building designers, managers, event planners, security personnel, police authorities, and fire authorities, as well as the building construction authorities, should understand the potential problems and solutions, including coordination of their activities. For crowd behavior, this understanding includes factors of space, energy, time, and information, as well as specific crowd management techniques such as metering. Published guidance on these factors and techniques is found in the *SFPE Handbook of Fire Protection Engineering*, Section 3, Chapter 13, pp. 3-263–3-285 (Pauls, J., “Movement of People”) and the publications referenced therein.

Table 13.2.3.2 and Table 13.4.2.3 are based on a linear relationship between number of seats and nominal flow time, with not less than 200 seconds (3.3 minutes) for 2000 seats plus 1 second for every additional 50 seats up to 25,000. Beyond 25,000 total seats, the nominal flow time is limited to 660 seconds (11 minutes). Nominal flow time refers to the flow time for the most able group of patrons; some groups less familiar with the premises or less able groups might take longer to pass a point in the egress system. Although three or more digits are noted in the tables, the resulting calculations should be assumed to provide only two significant figures of precision.

13.4.1.2 Life safety evaluations shall include an assessment of the following conditions and the related appropriate safety measures:

CHAPTER 12 • New

- (1) Nature of the events and the participants and attendees
- (2) Access and egress movement, including crowd density problems
- (3) Medical emergencies
- (4) Fire hazards
- (5) Permanent and temporary structural systems
- (6) Severe weather conditions
- (7) Earthquakes
- (8) Civil or other disturbances
- (9) Hazardous materials incidents within and near the facility
- (10) Relationships among facility management, event participants, emergency response agencies, and others having a role in the events accommodated in the facility

12.4.1.3* Life safety evaluations shall include assessments of both building systems and management features upon which reliance is placed for the safety of facility occupants, and such assessments shall consider scenarios appropriate to the facility.

A.12.4.1.3 Factors to be considered in a Life Safety Evaluation include the following.

- (1) Nature of the Events Being Accommodated
 - (a) Ingress, intra-event movement, and egress patterns
 - (b) Ticketing and seating policies/practices
 - (c) Event purpose (e.g., sports contest, religious meeting)
 - (d) Emotional qualities (e.g., competitiveness) of event
 - (e) Time of day when event held
 - (f) Time duration of single event
 - (g) Time duration of attendees' occupancy of the building
- (2) Occupant Characteristics and Behavior
 - (a) Homogeneity
 - (b) Cohesiveness
 - (c) Familiarity with building
 - (d) Familiarity with similar events
 - (e) Capability (as influenced by factors such as age, physical abilities)
 - (f) Socioeconomic factors
 - (g) Small minority involved with recreational violence
 - (h) Emotional involvement with the event and other occupants
 - (i) Use of alcohol or drugs
 - (j) Food consumption
 - (k) Washroom utilization

CHAPTER 13 • Existing

- (1) Nature of the events and the participants and attendees
- (2) Access and egress movement, including crowd density problems
- (3) Medical emergencies
- (4) Fire hazards
- (5) Permanent and temporary structural systems
- (6) Severe weather conditions
- (7) Earthquakes
- (8) Civil or other disturbances
- (9) Hazardous materials incidents within and near the facility
- (10) Relationships among facility management, event participants, emergency response agencies, and others having a role in the events accommodated in the facility

13.4.1.3* Life safety evaluations shall include assessments of both building systems and management features upon which reliance is placed for the safety of facility occupants, and such assessments shall consider scenarios appropriate to the facility.

A.13.4.1.3 Factors to be considered in a life safety evaluation might include the following.

- (1) Nature of the Events Being Accommodated
 - (a) Ingress, intra-event movement, and egress patterns
 - (b) Ticketing and seating policies/practices
 - (c) Event purpose (e.g., sports contest, religious meeting)
 - (d) Emotional qualities (e.g., competitiveness) of event
 - (e) Time of day when event held
 - (f) Time duration of single event
 - (g) Time duration of attendees' occupancy of the building
- (2) Occupant Characteristics and Behavior
 - (a) Homogeneity
 - (b) Cohesiveness
 - (c) Familiarity with building
 - (d) Familiarity with similar events
 - (e) Capability (as influenced by factors such as age, physical abilities)
 - (f) Socioeconomic factors
 - (g) Small minority involved with recreational violence
 - (h) Emotional involvement with the event and other occupants
 - (i) Use of alcohol or drugs
 - (j) Food consumption
 - (k) Washroom utilization

CHAPTER 12 • New

- (3) Management
- (a) Clear, contractual arrangements for facility operation/use as follows:
 - i. Between facility owner and operator
 - ii. Between facility operator and event promoter
 - iii. Between event promoter and performer
 - iv. Between event promoter and attendee
 - v. With police forces
 - vi. With private security services
 - vii. With ushering services
 - (b) Experience with the building
 - (c) Experience with similar events and attendees
 - (d) Thorough, up-to-date operations manual
 - (e) Training of personnel
 - (f) Supervision of personnel
 - (g) Communications systems and utilization
 - (h) Ratios of management and other personnel to attendees
 - (i) Location/distribution of personnel
 - (j) Central command location
 - (k) Rapport between personnel and attendees
 - (l) Personnel supportive of attendee goals
 - (m) Attendees respect for personnel due to the following:
 - i. Dress (uniform) standards
 - ii. Age and perceived experience
 - iii. Personnel behavior, including interaction
 - iv. Distinction between crowd management and control
 - v. Management's concern for facility quality (e.g., cleanliness)
 - vi. Management's concern for entire event experience of attendees (i.e., not just during the occupancy of the building)
- (4) Emergency Management Preparedness
- (a) Complete range of emergencies addressed in operations manual
 - (b) Power loss
 - (c) Fire
 - (d) Severe weather
 - (e) Earthquake
 - (f) Crowd incident
 - (g) Terrorism
 - (h) Hazardous materials
 - (i) Transportation accident (e.g., road, rail, air)
 - (j) Communications systems available
 - (k) Personnel and emergency forces ready to respond
 - (l) Attendees clearly informed of situation and proper behavior

CHAPTER 12 • New

- (qq) Services
- (rr) Washroom provision and distribution
- (ss) Concessions
- (tt) First aid and EMS facilities
- (uu) General attendee services

A scenario-based approach to performance-based fire safety is addressed in Chapter 5. In addition to using such scenarios and, more generally, the attention to performance criteria, evaluation, safety factors, documentation, maintenance, and periodic assessment required when the Chapter 5 option is used, life safety evaluations should consider scenarios based on characteristics important in assembly occupancies. These characteristics include the following:

- (1) Whether there is a local or mass awareness of an incident, event, or condition that might provoke egress
- (2) Whether the incident, event, or condition stays localized or spreads
- (3) Whether or not egress is designed by facility occupants
- (4) Whether there is a localized start to any egress or mass start to egress
- (5) Whether exits are available or not available

Examples of scenarios and sets of characteristics that might occur in a facility include the following.

Scenario 1. Characteristics: Mass start, egress desired (by management and attendees), exits not available, local awareness.

Normal egress at the end of an event occurs just as a severe weather condition induces evacuees at the exterior doors to retard or stop their egress. The backup that occurs in the egress system is not known to most evacuees, who continue to press forward (potentially resulting in a crowd crush).

Scenario 2. Characteristics: Mass start, egress not desired (by management), exits possibly not available, mass awareness.

An earthquake occurs during an event. The attendees are relatively safe in the seating area. The means of egress outside the seating areas are relatively unsafe and vulnerable to aftershock damage. Facility management discourages mass egress until the means of egress can be checked and cleared for use.

Scenario 3. Characteristics: Local start, incident stays local, egress desired (by attendees and management), exits available, mass awareness.

A localized civil disturbance (for example, firearms violence) provokes localized egress, which is seen by attendees, generally, who then decide to leave also.

Scenario 4. Characteristics: Mass start, egress desired, incident spreads, exits not available, mass awareness.

CHAPTER 13 • Existing

- (qq) Services
- (rr) Washroom provision and distribution
- (ss) Concessions
- (tt) First aid and EMS facilities
- (uu) General attendee services

A scenario-based approach to performance-based fire safety is addressed in Chapter 5. In addition to utilizing such scenarios and, more generally, the attention to performance criteria, evaluation, safety factors, documentation, maintenance, and periodic assessment required when the Chapter 5 option is used, life safety evaluations should consider scenarios based on characteristics important in assembly occupancies. These characteristics include the following:

- (1) Whether there is a local or mass awareness of an incident, event, or condition that might provoke egress
- (2) Whether the incident, event, or condition stays localized or spreads
- (3) Whether or not egress is designed by facility occupants
- (4) Whether there is a localized start to any egress or mass start to egress
- (5) Whether exits are available or not available

Examples of scenarios and sets of characteristics that might occur in a facility include the following.

Scenario 1. Characteristics: Mass start, egress desired (by management and attendees), exits not available, local awareness.

Normal egress at the end of an event occurs just as a severe weather condition induces evacuees at the exterior doors to retard or stop their egress. The backup that occurs in the egress system is not known to most evacuees, who continue to press forward potentially resulting in a crowd crush.

Scenario 2. Characteristics: Mass start, egress not desired (by management), exits possibly not available, mass awareness.

An earthquake occurs during an event. The attendees are relatively safe in the seating area. The means of egress outside the seating areas are relatively unsafe and vulnerable to aftershock damage. Facility management discourages mass egress until the means of egress can be checked and cleared for use.

Scenario 3. Characteristics: Local start, incident stays local, egress desired (by attendees and management), exits available, mass awareness.

A localized civil disturbance (for example, firearms violence) provokes localized egress, which is seen by attendees, generally, who then decide to leave also.

Scenario 4. Characteristics: Mass start, egress desired, incident spreads, exits not available, mass awareness.

CHAPTER 12 • New

In an open-air facility unprotected from wind, precipitation, and lightning, sudden severe weather prompts egress to shelter but not from the facility. The means of egress congest and block quickly as people in front stop once they are under shelter while people behind them continue to press forward (potentially resulting in a crowd crush).

These scenarios illustrate some of the broader factors to be taken into account when assessing the capability of both building systems and management features on which reliance is placed in a range of situations, not just fire emergencies. Some scenarios also illustrate the conflicting motivations of management and attendees based on differing perceptions of danger and differing knowledge of hazards, countermeasures, and capabilities. Mass egress might not be the most appropriate life safety strategy in some scenarios, such as Scenario 2.

Table A.12.4.1.3 summarizes the characteristics in the scenarios and provides a framework for developing other characteristics and scenarios that might be important for a particular facility, hazard, occupant type, event, or management.

CHAPTER 13 • Existing

4		X		X			X			X		X	

The preparation of life safety evaluations will become more common as assembly occupancy designers request approval, from authorities having jurisdiction, of designs using the various Code provisions that conditionally require the life safety evaluation. For exam-

ple, to be considered smoke protected and thus be permitted to use the reduced egress capacity criteria of Table 12/13.4.2.3, a building must be sprinklered, be provided with features that prevent smoke-logging, and—most important—be assessed using a

CHAPTER 12 • New

life safety evaluation conducted in accordance with 12/13.4.1.

The expansive material contained in A.12/A.13.4.1.3 helps stress that conducting a life safety evaluation is a complex process that should not be attempted by most *Code* practitioners. Such an evaluation must demonstrate that all life safety hazards have been considered and that control measures have been provided to ensure that occupants evacuating the building will not be endangered by conditions developing faster than the time required to clear the

12.4.2* Smoke-Protected Assembly Seating.

A.12.4.2 Outdoor facilities are not accepted as inherently smoke-protected but must meet the requirements of smoke-protected assembly seating in order to utilize the special requirements for means of egress.

12.4.2.1 To be considered smoke protected, an assembly seating facility shall comply with the following:

- (1) All enclosed areas with walls and ceilings in buildings or structures containing smoke-protected assembly seating shall be protected with an approved, supervised automatic sprinkler system in accordance with Section 9.7, unless otherwise permitted by the following:
 - (a) The requirement of 12.4.2.1(1) shall not apply to the floor area used for the contest, performance, or entertainment, provided that the roof construction is more than 15 m (50 ft) above the floor level and use is restricted to low fire hazard uses.
 - (b)* Sprinklers shall not be required to be located over the floor area used for contest, performance, or entertainment and over the seating areas where an approved engineering analysis substantiates the ineffectiveness of the sprinkler protection due to building height and combustible loading.

A.12.4.2.1(1)(b) The engineering analysis should be part of the life safety evaluation required by 12.4.1.

- (2) All means of egress serving a smoke-protected assembly seating area shall be provided with smoke-actuated ventilation facilities or natural ventilation designed to maintain the level of smoke at not less than 1830 mm (72 in.) above the floor of the means of egress.

12.4.2.2 To use the provisions of smoke-protected assembly seating, a facility shall be subject to a life safety evaluation in accordance with 12.4.1.

CHAPTER 13 • Existing

means of egress. The authority having jurisdiction needs to realize that, if an evaluation doesn't cover nearly all of the subjects addressed in A.12/A.13.4.1.3, it should not be approved. A reduced egress capacity system in accordance with 12/13.4.2.3, but for which the life safety evaluation is inadequate, is itself an inadequate egress system. The reduced capacity factors of Table 12/13.4.2.3 are not to be used as a matter of right; rather, their use needs to be earned by providing a comprehensive life safety evaluation.

13.4.2* Smoke-Protected Assembly Seating.

A.13.4.2 Outdoor facilities are not accepted as inherently smoke-protected but must meet the requirements of smoke-protected assembly seating in order to use the special requirements for means of egress.

13.4.2.1 To be considered smoke protected, an assembly seating facility shall comply with the following:

- (1) All enclosed areas with walls and ceilings in buildings or structures containing smoke-protected assembly seating shall be protected with an approved automatic sprinkler system in accordance with Section 9.7, unless otherwise permitted by the following:
 - (a) The requirement of 13.4.2.1(1) shall not apply to the floor area used for the contest, performance, or entertainment, provided that the roof construction is more than 15 m (50 ft) above the floor level and use is restricted to low fire hazard uses.
 - (b)* Sprinklers shall not be required to be located over the floor area used for contest, performance, or entertainment and over the seating areas where an approved engineering analysis substantiates the ineffectiveness of the sprinkler protection due to building height and combustible loading.

A.13.4.2.1(1)(b) The engineering analysis should be part of the life safety evaluation required by 13.4.1.

- (2) All means of egress serving a smoke-protected assembly seating area shall be provided with smoke-actuated ventilation facilities or natural ventilation designed to maintain the level of smoke at not less than 1830 mm (72 in.) above the floor of the means of egress.

13.4.2.2 To use the provisions of smoke-protected assembly seating, a facility shall be subject to a life safety evaluation in accordance with 13.4.1.

CHAPTER 12 • New

12.4.2.3 Where using Table 12.4.2.3, the number of seats specified shall be within a single assembly space, and interpolation shall be permitted between the specific values shown. A single seating space shall be permitted to have multiple levels, floors or mezzanines. The minimum clear widths shown shall be modified in accordance with all of the following:

- (1) If risers exceed 178 mm in height, the stair width in Table 12.4.2.3 shall be multiplied by factor *A*, where *A* equals the following:

$$A = 1 + \frac{\text{riser height} - 178}{125}$$

Table 12.4.2.3 Capacity Factors for Smoke-Protected Assembly Seating

- (4) Ramps steeper than 1 in 10 slope used in ascent shall have their width increased by 10 percent; that is, their width shall be multiplied by factor *C*, where *C* equals the following:

$$C = 1.10$$

CHAPTER 12 • New

The *Code* requires that extra caution be taken before a facility is permitted to use the less stringent egress capacity factors contained in Table 12/13.4.2.3 (versus those in Table 12/13.2.3.2). The authority having jurisdiction must approve a life safety evaluation, which should not be undertaken lightly or without special competence in a wide range of life safety issues including, but not limited to, fire safety. See 12/13.4.1.

When conducting the life safety evaluation, the capabilities of the potential occupants must be taken into account (for example, will the facilities be used by groups of occupants who are unfamiliar with the facility, or who are unable to move quickly and in dense groups?). The need to consider the capabilities of occupants in relation to circulation facility geometry has led to the application of several correction factors for use with the values for clear width in Tables 12/13.2.3.2 and 12/13.4.2.3. Maintaining the best possible geometries should be a priority that is heavily emphasized in new facilities. Therefore, the correction factors in the tables, *A*, *B*, and *C*, will usually be 1.0. It might not be possible to achieve this level of safety in existing facilities. However, handrails can be retrofitted on aisles and other means of egress to significantly improve occupant safety and comfort. These factors are taken into account here and in other *Code* requirements for means of egress.

The reduction in required egress capacity factors provided by Table 12/13.4.2.3 must be used with caution. The proper balance must be maintained among the relative egress capacities of each part of the means of egress system that occupants encounter as they leave the facility. Otherwise, queuing or waiting at some points other than the point of origin may result.

Attention should be given to the occupants' acceptance of the queue or the wait at their seats before

12.4.2.4 Where smoke-protected assembly seating conforms to the requirements of 12.4.2, for rows of seats served by aisles or doorways at both ends, the number of seats per row shall not exceed 100, and the clear width of not less than 305 mm (12 in.) for aisle accessways shall be increased by 7.6 mm (0.3 in.) for every additional seat beyond the number stipulated in Table 12.4.2.4; however, the minimum clear width shall not be required to exceed 560 mm (22 in.).

12.4.2.5 Where smoke-protected assembly seating conforms to the requirements of 12.4.2, for rows of seats served by an aisle or doorway at one end only, the aisle accessway

CHAPTER 13 • Existing

proceeding out of the building; however, if a "downstream" component of the means of egress system is expected to slow the occupant movement, even greater attention should be given to the actual and perceived conditions faced by occupants.

Exhibit 12/13.35 shows egress from a large stadium. The egress performance provided is perceived to be acceptable in terms of time and other factors. Occupants' acceptance of the longer egress flow times, permitted by the *Code* for larger assembly facilities, should be taken into account when performing a life safety evaluation for the building.

Exhibit 12/13.35 Crowd egress from a large assembly facility that might be eligible for egress capacity factor reductions of Table 12/13.4.2.3. (Photograph courtesy of Jake Pauls.)

13.4.2.4 Where smoke-protected assembly seating conforms to the requirements of 13.4.2, for rows of seats served by aisles or doorways at both ends, the number of seats per row shall not exceed 100, and the clear width of not less than 305 mm (12 in.) for aisle accessways shall be increased by 7.6 mm (0.3 in.) for every additional seat beyond the number stipulated in Table 13.4.2.4; however, the minimum clear width shall not be required to exceed 560 mm (22 in.).

13.4.2.5 Where smoke-protected assembly seating conforms with the requirements of 13.4.2, for rows of seats served by an aisle or doorway at one end only, the aisle accessway clear

CHAPTER 12 • New

clear width of not less than 305 mm (12 in.) shall be increased by 15 mm (0.6 in.) for every additional seat beyond the number stipulated in Table 12.4.2.4; however, the minimum clear width shall not be required to exceed 560 mm (22 in.).

Table 12.4.2.4 Smoke-Protected Assembly Seating Aisle Accessways

10,000–12,999	17	8
13,000–15,999	18	9
16,000–18,999	19	9
19,000–21,999	20	10
≥22,000	21	11

12.4.2.6 Smoke-protected assembly seating conforming with the requirements of 12.4.2 shall be permitted to have a common path of travel of 15 m (50 ft) from any seat to a point where a person has a choice of two directions of egress travel.

12.4.2.7 Where smoke-protected assembly seating conforms to the requirements of 12.4.2, the dead ends in aisle stairs shall not exceed a distance of 21 rows, unless both of the following criteria are met:

- (1) The seats served by the dead-end aisle are not more than 40 seats from another aisle
- (2) The 40-seat distance is measured along a row of seats having an aisle accessway with a clear width of not less than 305 mm (12 in.) plus 7.6 mm (0.3 in.) for each additional seat above 7 in the row

12.4.2.8 Where smoke-protected assembly seating conforms to the requirements of 12.4.2, the travel distance from each seat to the nearest entrance to an egress vomitory portal or egress concourse shall not exceed 122 m (400 ft).

12.4.2.9 Where smoke-protected assembly seating conforms to the requirements of 12.4.2, the travel distance from the entrance to the vomitory portal or from the egress concourse to an approved egress stair, ramp, or walk at the building exterior shall not exceed 61 m (200 ft).

CHAPTER 13 • Existing

width of not less than 305 mm (12 in.) shall be increased by 15 mm (0.6 in.) for every additional seat beyond the number stipulated in Table 13.4.2.4; however, the minimum clear width shall not be required to exceed 560 mm (22 in.).

Table 13.4.2.4 Smoke-Protected Assembly Seating Aisle Accessways

Total Number of Seats in the Space	Number of Seats per Row Permitted to Have a Clear Width Aisle Accessway of Not Less than 305 mm (12 in.)	
	Aisle or Doorway at Both Ends of Row	Aisle or Doorway at One End of Row
	<4,000	14
4,000–6,999	15	7
7,000–9,999	16	8
10,000–12,999	17	8
13,000–15,999	18	9
16,000–18,999	19	9
19,000–21,999	20	10
≥22,000	21	11

13.4.2.6 Smoke-protected assembly seating conforming with the requirements of 13.4.2 shall be permitted to have a common path of travel of 15 m (50 ft) from any seat to a point where a person has a choice of two directions of egress travel.

13.4.2.7 Where smoke-protected assembly seating conforms to the requirements of 13.4.2, the dead ends in aisle stairs shall not exceed a distance of 21 rows, unless both of the following criteria are met:

- (1) The seats served by the dead-end aisle are not more than 40 seats from another aisle.
- (2) The 40-seat distance is measured along a row of seats having an aisle accessway with a clear width of not less than 305 mm (12 in.) plus 7.6 mm (0.3 in.) for each additional seat above 7 in the row.

13.4.2.8 Where smoke-protected assembly seating conforms to the requirements of 13.4.2, the travel distance from each seat to the nearest entrance to an egress vomitory portal or egress concourse shall not exceed 122 m (400 ft).

13.4.2.9 Where smoke-protected assembly seating conforms to the requirements of 13.4.2, the travel distance from the entrance to the vomitory portal or from the egress concourse to an approved egress stair, ramp, or walk at the building exterior shall not exceed 61 m (200 ft).

CHAPTER 12 • New

12.4.2.10 The travel distance requirements of 12.4.2.8 and 12.4.2.9 shall not apply to outdoor assembly seating facilities of Type I or Type II construction, where all portions of the means of egress are essentially open to the outside.

12.4.3 Limited Access or Underground Buildings.

12.4.3.1 Limited access or underground buildings shall comply with 12.4.3 and Section 11.7.

12.4.3.2 Underground buildings or portions of buildings having a floor level more than 9140 mm (360 in.) below the level of exit discharge shall comply with the requirements of 12.4.3.3 through 12.4.3.5, unless otherwise permitted by the following:

- (1) This requirement shall not apply to areas within buildings used only for service to the building, such as boiler/heater rooms, cable vaults, and dead storage.
- (2) This requirement shall not apply to auditoriums without intervening occupiable levels.

12.4.3.3 Each level more than 9140 mm (360 in.) below the level of exit discharge shall be divided into not less than two smoke compartments by a smoke barrier complying with Section 8.5 and shall have a 1-hour fire resistance rating.

12.4.3.3.1 Smoke compartments shall comply with the following:

- (1) Each smoke compartment shall have access to not less than one exit without passing through the other required compartment.
- (2) Any doors connecting required compartments shall be tight-fitting, minimum 1-hour rated fire door assemblies designed and installed to minimize smoke leakage and to close and latch automatically upon detection of smoke.

12.4.3.3.2 Each smoke compartment shall be provided with a mechanical means of moving people vertically, such as an elevator or escalator.

12.4.3.3.3 Each smoke compartment shall have an independent air supply and exhaust system capable of smoke control or smoke exhaust functions that provide a smoke exhaust rate of not less than six air changes per hour.

12.4.3.3.4 Throughout each smoke compartment shall be provided an automatic smoke detection system designed such that the activation of any two detectors causes the smoke control system to operate and the building voice alarm to sound.

12.4.3.4 Any required smoke control or exhaust system shall be provided with a standby power system complying with Article 701 of NFPA 70, *National Electrical Code*®.

CHAPTER 13 • Existing

13.4.2.10 The travel distance requirements of 13.4.2.8 and 13.4.2.9 shall not apply to outdoor assembly seating facilities of Type I or Type II construction, where all portions of the means of egress are essentially open to the outside.

13.4.3 Limited Access or Underground Buildings.

Limited access or underground buildings shall comply with Section 11.7.

CHAPTER 12 • New

12.4.3.5 The building shall be provided with an approved, supervised voice alarm system, in accordance with Section 9.6, that complies with 9.6.3.10 and provides a prerecorded evacuation message.

Recognizing the potential hazard that limited access and underground buildings pose, the *Code* requires compliance with Section 11.7. In addition, new assembly occupancies must comply with the provisions of 12.4.3.3 through 12.4.3.5 if the assembly occupancy is more than 9140 mm (360 in.) below the level of exit discharge.

Exemptions are provided for areas used only for service functions (such as boiler rooms or heater rooms) and for assembly occupancies where there is no occupiable intervening level between the assembly occupancy and the level of exit discharge.

The provisions for underground buildings or portions of assembly buildings with an occupiable floor more than 9140 mm (360 in.) below the level of exit discharge are designed to provide protected areas on the subterranean level. This protection, coupled with a smoke control or smoke exhaust system, will pro-

12.4.4 High-Rise Buildings.

High-rise assembly occupancy buildings and high-rise mixed occupancy buildings that house assembly occupancies in the high-rise portions of the building shall comply with Section 11.8.

A high-rise assembly occupancy has the same inherent life safety dangers that are found in other high-rise buildings. Therefore, the protection provided for high-rise buildings in general should be appropriate and applicable to high-rise assembly occupancies

12.4.5 Stages and Platforms.

(See 3.3.210 and 3.3.166.)

12.4.5.1 Materials and Design. Materials used in the construction of platforms and stages shall conform to the applicable requirements of the local building code.

12.4.5.2 Platform Construction.

12.4.5.2.1 Temporary platforms shall be permitted to be constructed of any materials.

CHAPTER 13 • Existing

vide sufficient time to egress the building. Elevators or escalators are required in each compartment to help rapidly evacuate the area (see Exhibit 9.4). It is believed that elevators or escalators will not, themselves, create a life safety threat because of the other requirements of 12.4.3, including separate smoke compartments and smoke control or exhaust systems. The elevator or escalator is not being considered the required means of egress; normal exits are still required.

To provide redundancy in the life safety provisions, standby power as defined in Article 701 of NFPA 70, *National Electrical Code*[®], is required by 12.4.3.4 for the smoke control or exhaust system.

To facilitate orderly evacuation and reduce the possibility of panic, 12.4.3.5 requires the use of a supervised voice alarm system that will sound a prerecorded evacuation message.

13.4.4 High-Rise Buildings.

Existing high-rise buildings that house assembly occupancies in high-rise portions of the building shall have the highest level of the assembly occupancy and all levels below protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7. (See also 13.1.6.)

and portions of high-rise buildings that are used for assembly occupancy. Note that the sprinkler requirement applies even to existing assembly occupancies located in the high-rise portion of a building.

13.4.5 Stages and Platforms.

See 3.3.210 and 3.3.166.

13.4.5.1 Materials and Design. (Reserved)

13.4.5.2 Platform Construction. (Reserved)

CHAPTER 12 • New

CHAPTER 13 • Existing

12.4.5.2.2 The space between the floor and the temporary platform above shall not be used for any purpose other than the electrical wiring to platform equipment.

12.4.5.2.3 Permanent platforms shall be of the materials required for the type of building construction in which the permanent platform is located, except that the finish floor shall be permitted to be of wood in all types of construction.

12.4.5.2.4 Where the space beneath the permanent platform is used for storage or any purpose other than equipment wiring or plumbing, the floor construction shall not be less than 1-hour fire resistive.

12.4.5.3 Stage Construction.

12.4.5.3.1 Regular stages shall be of the materials required for the type of building construction in which they are located. In all cases, the finish floor shall be permitted to be of wood.

12.4.5.3.2 Legitimate stages shall be constructed of materials required for Type I buildings, except that the area extending from the proscenium opening to the back wall of the stage, and for a distance of 1830 mm (72 in.) beyond the proscenium opening on each side, shall be permitted to be constructed of steel or heavy timber covered with a wood floor not less than 38 mm (1½ in.) in actual thickness.

12.4.5.3.3 Openings through stage floors shall be equipped with tight-fitting traps with approved safety locks, and such traps shall comply with one of the following:

- (1) The traps shall be of wood having an actual thickness of not less than 38 mm (1½ in.).
- (2) The traps shall be of a material that provides fire and heat resistance at least equivalent to that provided by wood traps having an actual thickness of not less than 38 mm (1½ in.).

12.4.5.4 Accessory Rooms.

12.4.5.4.1 Workshops, storerooms, permanent dressing rooms, and other accessory spaces contiguous to stages shall be separated from each other and other building areas by 1-hour fire resistance-rated construction and protected openings.

12.4.5.4.2 The separation requirements of 12.4.5.4.1 shall not apply to be required for stages having a floor area not exceeding 93 m² (1000 ft²).

12.4.5.5 Ventilators. Regular stages in excess of 93 m² (1000 ft²) and legitimate stages shall be provided with emergency ventilation to provide a means of removing smoke

13.4.5.3 Stage Construction. (Reserved)

13.4.5.4 Accessory Rooms. (Reserved)

13.4.5.5 Ventilators. Regular stages in excess of 93 m² (1000 ft²) and legitimate stages shall be provided with emergency ventilation to provide a means of removing smoke

CHAPTER 12 • New

and combustion gases directly to the outside in the event of a fire and shall be achieved by one or a combination of the methods specified in 12.4.5.5.1 through 12.4.5.5.3.

12.4.5.5.1 Smoke Control.

12.4.5.5.1.1 A means complying with Section 9.3 shall be provided to maintain the smoke level at not less than 1830 mm (72 in.) above the highest level of assembly seating or above the top of the proscenium opening where a proscenium wall and opening protection are provided.

12.4.5.5.1.2 The system shall be activated independently by each of the following:

- (1) Activation of the sprinkler system in the stage area
- (2) Activation of smoke detectors over the stage area
- (3) Activation by manually operated switch at an approved location

12.4.5.5.1.3 The emergency ventilation system shall be supplied by both normal and standby power.

12.4.5.5.1.4 The fan(s) power wiring and ducts shall be located and properly protected to ensure not less than 20 minutes of operation in the event of activation.

12.4.5.5.2 Roof Vents.

12.4.5.5.2.1 Two or more vents shall be located near the center of and above the highest part of the stage area.

12.4.5.5.2.2 The vents shall be raised above the roof and shall provide a net-free vent area equal to 5 percent of the stage area.

12.4.5.5.2.3 Vents shall be constructed to open automatically by approved heat-activated devices, and supplemental means shall be provided for manual operation and periodic testing of the ventilator from the stage floor.

12.4.5.5.2.4 Vents shall be labeled.

CHAPTER 13 • Existing

and combustion gases directly to the outside in the event of a fire and shall be achieved by one or a combination of the methods specified in 13.4.5.5.1 through 13.4.5.5.3.

13.4.5.5.1 Smoke Control.

13.4.5.5.1.1 A means complying with Section 9.3 shall be provided to maintain the smoke level at not less than 1830 mm (72 in.) above the highest level of assembly seating or above the top of the proscenium opening where a proscenium wall and opening protection are provided.

13.4.5.5.1.2 The system shall be activated independently by each of the following:

- (1) Activation of the sprinkler system in the stage area
- (2) Activation of smoke detectors over the stage area
- (3) Activation by manually operated switch at an approved location

13.4.5.5.1.3 The emergency ventilation system shall be supplied by both normal and standby power.

13.4.5.5.1.4 The fan(s) power wiring and ducts shall be located and properly protected to ensure not less than 20 minutes of operation in the event of activation.

13.4.5.5.2 Roof Vents.

13.4.5.5.2.1 Two or more vents shall be located near the center of and above the highest part of the stage area.

13.4.5.5.2.2 The vents shall be raised above the roof and shall provide a net-free vent area equal to 5 percent of the stage area.

13.4.5.5.2.3 Vents shall be constructed to open automatically by approved heat-activated devices, and supplemental means shall be provided for manual operation and periodic testing of the ventilator from the stage floor.

13.4.5.5.2.4 Vents shall be labeled.

13.4.5.5.2.5 Existing roof vents that are not labeled shall be permitted where they conform to the following requirements.

- (1) Vents shall open by spring action or force of gravity sufficient to overcome the effects of neglect, rust, dirt, frost, snow, or expansion by heat or warping of the framework, and the following requirements also shall apply:
 - (a) Glass, if used in vents, shall be protected against falling onto the stage.
 - (b) A wire screen, if used under the glass, shall be placed so that if clogged, it does not reduce the required venting area, interfere with the operating

12.4.5.5.3 Other Means.

12.4.5.5.3.1 Approved, alternate means of removing smoke and combustion gases shall be permitted.

12.4.5.6 Proscenium Walls. Legitimate stages shall be completely separated from the seating area by a proscenium wall of not less than 2-hour fire-resistive, noncombustible construction.

12.4.5.6.1 The proscenium wall shall extend not less than 1220 mm (48 in.) above the roof of the auditorium in combustible construction.

12.4.5.6.2 All openings in the proscenium wall of a legitimate stage shall be protected by a fire assembly having a 1½-hour fire protection rating.

12.4.5.6.3 The main proscenium opening used for viewing performances shall be provided with an automatic-closing fire-resistive curtain as described in 12.4.5.7.

mechanism, or obstruct the distribution of water from an automatic sprinkler.

- (c) Vents shall be arranged to open automatically by the use of fusible links.
- (d) The fusible links and operating cable shall hold each door closed against a minimum 133-N (30-lb) counterforce that shall be exerted on each door through its entire arc of travel and for not less than 115 degrees.
- (e) Vents shall be provided with manual control.
- (f) Springs, where employed to actuate vent doors, shall be capable of maintaining full required tension.
- (g) Springs shall not be stressed more than 50 percent of their rated capacity and shall not be located directly in the airstream nor exposed to the outside.
- (h) A fusible link shall be placed in the cable control system on the underside of the vent at or above the roofline, or as approved by the building official.
- (i) The fusible link shall be located so as not to be affected by the operation of an automatic sprinkler system.
- (j) Remote, manual, or electric controls shall provide for both opening and closing of the vent doors for periodic testing and shall be located at a point on stage designated by the authority having jurisdiction.
- (k) Where remote control vents are electrical, power failure shall not affect instant operation of the vent in the event of fire.
- (l) Hand winches shall be permitted to be employed to facilitate operation of manually controlled vents.

13.4.5.5.3 Other Means. Approved, alternate means of removing smoke and combustion gases shall be permitted.

13.4.5.6 Proscenium Walls. (Reserved)

CHAPTER 12 • New

12.4.5.6.4 Proscenium walls shall not be required in smoke-protected assembly seating facilities constructed and operated in accordance with 12.4.2.

12.4.5.7* Proscenium Opening Protection. Where required by 12.4.5.6, the proscenium opening shall be protected by a fire curtain or an approved water curtain complying with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

A.12.4.5.7 Proscenium openings may be protected by one of three means:

- (1) A listed, minimum 20-minute opening protective assembly that might be a door or a curtain
- (2) A fire curtain in accordance with 12.4.5.7.2(A) through 12.4.5.7.2(G) with the fabric tested for 30 minutes
- (3) A water curtain in accordance with NFPA 13

12.4.5.7.1 The fire curtain or water curtain shall be designed to activate upon automatic detection of a fire and upon manual activation.

12.4.5.7.2 The fire curtain shall be a listed minimum 20-minute opening protective assembly or shall be constructed as required in 12.4.5.7.2(A) through 12.4.5.7.2(G).

(A) Fabrics. Curtains shall be made of one or more thicknesses of a noncombustible fabric or a fabric with a noncombustible base material and shall comply with the following:

- (1) The fabric shall be permitted to be given a coating, provided that the modified fabric meets the criteria detailed in 12.4.5.7.
- (2) Curtain fabrics shall have a weight of not less than 1.3 kg/m² (2 ³/₈ lb/yd²).

(B) Tensile Strength Requirements. Curtain fabric shall have tensile strength requirements of not less than 540 N/m (400 lbf/in.) in both the warp and fill directions.

(C) Wire-Insertion Reinforcement Requirements. The fabric shall be reinforced with noncorrosive wire intertwined with the base fiber at a rate of not less than one wire per yarn. Wire shall not be required, and fabric weight shall be permitted to be less than 1.3 kg/m² (2 ³/₈ lb/yd²) if it can be substantiated by approved tests that it is equivalent in strength and durability.

(D) Fire Test. A sample curtain with not less than two vertical seams shall be subjected to the standard fire test specified in NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*, as applicable to nonbearing walls and partitions for a period of 30 minutes, as follows:

CHAPTER 13 • Existing

13.4.5.7 Proscenium Curtain.

13.4.5.7.1 The proscenium opening of every legitimate stage shall be provided with a curtain constructed and mounted so as to intercept hot gases, flames, and smoke and to prevent flame from a fire on the stage from becoming visible from the auditorium side for a 5-minute period where the curtain is of asbestos.

13.4.5.7.2 Materials other than asbestos shall be permitted if they have passed a 30-minute fire test in a small-scale 915 mm × 915 mm (36 in. × 36 in.) furnace with the sample mounted in the horizontal plane at the top of the furnace and subjected to the standard time-temperature curve.

13.4.5.7.3 The curtain shall be automatic-closing without the use of applied power.

13.4.5.7.4 All proscenium curtains shall be in the closed position, except during performances, rehearsals, or similar activities.

13.4.5.7.5 In lieu of the protection required by 13.4.5.7 through 13.4.5.7.4, all the following shall be provided:

- (1) A noncombustible opaque fabric curtain shall be arranged so that it closes automatically.
- (2) An automatic, fixed waterspray deluge system shall be located on the auditorium side of the proscenium opening and shall be arranged so that the entire face of the curtain will be wetted, and the following requirements also shall apply:
 - (a) The system shall be activated by combination of rate-of-rise and fixed-temperature detectors located on the ceiling of the stage.
 - (b) Detectors shall be spaced in accordance with their listing.
 - (c) The water supply shall be controlled by a deluge valve and shall be sufficient to keep the curtain completely wet for 30 minutes or until the valve is closed by fire department personnel.
- (3) The curtain shall be automatically operated in case of fire by a combination of rate-of-rise and fixed-temperature detectors that also activates the deluge spray system.
- (4) Stage sprinklers and vents shall be automatically operated by fusible elements in case of fire.
- (5) Operation of the stage sprinkler system or spray deluge valve shall automatically activate the emergency ventilating system and close the curtain.

CHAPTER 12 • New

- (1) The curtain shall overlap the furnace edges by a length that is appropriate to seal the top and sides.
- (2) The curtain shall have a bottom pocket containing not less than 5 kg/linear m (4 lb/linear ft) of batten.
- (3) The unexposed surface of the curtain shall not glow, and neither flame nor smoke shall penetrate the curtain during the test period.
- (4) Unexposed surface temperature and hose stream test requirements shall not be applicable to this proscenium fire safety curtain test.

(E) Smoke Test. Curtain fabrics shall have a smoke density not to exceed 25 where tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, and the curtain fabric shall be tested in the condition in which it is to be used.

(F) Curtain Operation. The complete installation of every proscenium curtain shall be subjected to operating tests, as follows:

- (1) Any theater in which a proscenium curtain is placed shall not be open to public performance until after the proscenium curtain has been accepted and approved by the authority having jurisdiction.
- (2) The curtain shall be automatic-closing without the use of applied power.
- (3) The curtain also shall be capable of manual operation.

(G) Curtain Position. All proscenium curtains shall be in the closed position, except during performances, rehearsals, or similar activities.

12.4.5.8 Gridiron, Fly Galleries, and Pinrails.

12.4.5.8.1 Structural framing designed only for the attachment of portable or fixed theater equipment, gridirons, galleries, and catwalks shall be constructed of materials consistent with the building type of construction, and a fire resistance rating shall not be required.

12.4.5.8.2 Combustible materials shall be permitted to be used for the floors of galleries and catwalks of all types of construction.

12.4.5.9 Catwalks. The clear width of lighting and access catwalks and the means of egress from galleries and gridirons shall be not less than 560 mm (22 in.).

12.4.5.10 Fire Protection. Every stage shall be protected by an approved, supervised automatic sprinkler system in compliance with Section 9.7.

12.4.5.10.1 Protection shall be provided throughout the stage and in storerooms, workshops, permanent dressing rooms, and other accessory spaces contiguous to such stages.

CHAPTER 13 • Existing

- (6) The curtain, vents, and spray deluge system valve shall also be capable of manual operation.

13.4.5.7.6 This requirement shall not apply to proscenium fire curtains or water curtains complying with 12.4.5.7.

13.4.5.8 Gridirons, Fly Galleries, and Pinrails.

(Reserved)

13.4.5.9 Catwalks. The clear width of lighting and access catwalks and the means of egress from galleries and gridirons shall be not less than 560 mm (22 in.).

13.4.5.10 Fire Protection. Every stage shall be protected by an approved automatic sprinkler system in compliance with Section 9.7.

13.4.5.10.1 Protection shall be provided throughout the stage and in storerooms, workshops, permanent dressing rooms, and other accessory spaces contiguous to such stages.

CHAPTER 12 • New

12.4.5.10.2 Sprinklers shall not be required for stages 93 m² (1000 ft²) or less in area and 15 m (50 ft) or less in height where the following criteria are met:

- (1) Curtains, scenery, or other combustible hangings are not retractable vertically.
- (2) Combustible hangings are limited to borders, legs, a single main curtain, and a single backdrop.

12.4.5.10.3 Sprinklers shall not be required under stage areas less than 1220 mm (48 in.) in clear height that are used exclusively for chair or table storage and lined on the inside with 16-mm (⁵/₈-in.) Type X gypsum wallboard or the approved equivalent.

12.4.5.11 Flame-Retardant Requirements.

12.4.5.11.1 Combustible scenery of cloth, film, vegetation (dry), and similar materials shall meet the requirements of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*.

12.4.5.11.2 Foamed plastics (*see definition of cellular or foamed plastic in 3.3.30*) shall be permitted to be used only by specific approval of the authority having jurisdiction.

12.4.5.11.3 Scenery and stage properties not separated from the audience by proscenium opening protection shall be of either noncombustible or limited-combustible materials.

12.4.5.11.4 In theaters, motion picture theaters, and television stage settings, with or without horizontal projections, and in simulated caves and caverns of foamed plastic, any single fuel package shall have a heat release rate not to exceed 100 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*.

12.4.5.12* Standpipes.

A.12.4.5.12 Prior editions of the *Code* required stages to be protected by a Class III standpipe system in accordance with NFPA 14, *Standard for the Installation of Standpipe, Private Hydrant, and Hose Systems*. NFPA 14 requires that Class II and Class III standpipes be automatic—not manual—because they are intended to be used by building occupants. Automatic standpipe systems are required to provide not less than 1890 L/min (500 gpm) at 689 kN (100 psi). This requirement often can be met only if a fire pump is installed. Installation of a fire pump presents an unreasonable burden for the system supplying the two hose outlets at the side of the stage. The revised wording of 12.4.5.12 offers some relief by permitting the hose outlets to be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

CHAPTER 13 • Existing

13.4.5.10.2 Sprinklers shall not be required for stages 93 m² (1000 ft²) or less in area where the following criteria are met:

- (1) Curtains, scenery, or other combustible hangings are not retractable vertically.
- (2) Combustible hangings are limited to borders, legs, a single main curtain, and a single backdrop.

13.4.5.10.3 Sprinklers shall not be required under stage areas less than 1220 mm (48 in.) in clear height that are used exclusively for chair or table storage and lined on the inside with 16-mm (⁵/₈-in.) Type X gypsum wallboard or the approved equivalent.

13.4.5.11 Flame-Retardant Requirements.

13.4.5.11.1 Combustible scenery of cloth, film, vegetation (dry), and similar materials shall meet the requirements of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*.

13.4.5.11.2 Foamed plastics (*see definition of cellular or foamed plastic in 3.3.30*) shall be permitted to be used only by specific approval of the authority having jurisdiction.

13.4.5.11.3 Scenery and stage properties on thrust stages shall be of either noncombustible or limited-combustible materials.

13.4.5.12* Standpipes.

A.13.4.5.12 Prior editions of the *Code* required stages to be protected by a Class III standpipe system in accordance with NFPA 14, *Standard for the Installation of Standpipe, Private Hydrant, and Hose Systems*. NFPA 14 requires that Class II and Class III standpipes be automatic—not manual—because they are intended to be used by building occupants. Automatic standpipe systems are required to provide not less than 1890 L/min (500 gpm) at 689 kN/m² (100 psi). This requirement often can be met only if a fire pump is installed. Installation of a fire pump presents an unreasonable burden for the system supplying the two hose outlets at the side of the stage. The revised wording of 13.4.5.12 offers some relief by permitting the hose outlets to be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

CHAPTER 12 • New

12.4.5.12.1 Regular stages over 93 m² (1000 ft²) in area and all legitimate stages shall be equipped with 38-mm (1½-in.) hose lines for first aid fire fighting at each side of the stage.

12.4.5.12.2 Hose connections shall be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, unless Class II or Class III standpipes in accordance with NFPA 14, *Standard for the Installation of Standpipe, Private Hydrant, and Hose Systems*, are used.

Modern stages pose problems that did not exist in the past. Scenery might be shifted horizontally, vertically, or both ways. The use of thrust stages and arena stages creates other problems.

The classic stage of the past rose high above the proscenium opening to accommodate the rigid asbestos curtain. The high void was a natural place to house combustible scenery for a performance, along with the rigging necessary for handling scene changes. This vertical storage area represented both a high fuel load and a space difficult to reach in case of fire. Many new theaters use a flexible, noncombustible curtain that does not require much height to accommodate it. Scenery on these stages is moved horizontally, thus reducing the distance necessary for storage between the top of the proscenium opening and the stage ceiling. Most combustible scenery is now stored in areas adjacent to the stage. All rigging and lighting is condensed in less vertical space.

Ventilators are addressed in 12/13.4.5.5. The venting requirements of 12/13.4.5.5 apply to regular stages larger than 93 m² (1000 ft²) and to all legitimate stages. Smaller stages, such as those commonly seen in small schools, do not pose the same fire potential as larger stages. See the definitions of *stage* in 3.3.210 and *platform* in 3.3.166.

Paragraph 12/13.4.5.5.1 uses performance-oriented language to specify the intended function of smoke control, if smoke control is the method used to provide the required ventilation. The performance criterion is to maintain the smoke level not less than 1830 mm (72 in.) above the highest level of the assembly seating or above the top of a proscenium opening where a proscenium wall and opening protection are provided. The methods detailed in NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*⁹, might be used in designing the smoke control system.

In lieu of a smoke control system, 12/13.4.5.5 permits roof vents as prescribed by 12/13.4.5.5.2 to pro-

CHAPTER 13 • Existing

13.4.5.12.1 Stages over 93 m² (1000 ft²) in area shall be equipped with 38-mm (1½-in.) hose lines for first aid fire fighting at each side of the stage.

13.4.5.12.2 Hose connections shall be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, unless Class II or Class III standpipes in accordance with NFPA 14, *Standard for the Installation of Standpipe, Private Hydrant, and Hose Systems*, are used.

vide the required ventilation. For existing vents that are not listed, 13.4.5.5.2.5 provides prescriptive criteria that help to ensure that the vent will operate as reliably as a vent that is listed.

Paragraph 12/13.4.5.5.3 allows for other approved means of removing smoke and combustion gases to fulfill the ventilation requirement of 12/13.4.5.5.

Proscenium opening protection is addressed in 12/13.4.5.7. The protection is to be provided by either a fire curtain or an approved water curtain. If a fire curtain is used, it is permitted to be a curtain complying with the criteria of 12.4.5.7.2(A) through (G), or it can be a listed opening protective assembly. The option to use a listed opening protective assembly includes use of a fire door. The horizontal sliding door detailed in 7.2.1.14 might be appropriate for such use.

For existing assembly occupancies, if, instead of the fire-resistant curtain specified in 13.4.5.7, a flexible proscenium curtain is used, the *Code* requires an automatic water spray system with nozzles on the auditorium side of the curtain. This system must be capable of completely wetting the curtain and of maintaining waterflow for at least 30 minutes or until the deluge valve is closed by the fire department.

Paragraph 13.4.5.7.2 permits the new fire curtains or water curtains mandated in Chapter 12 to serve in lieu of the curtains detailed in 13.4.5.7.

A proscenium curtain must be subjected to operating tests and be approved before its first use in a public performance. The curtain must be kept in the closed position after each performance is completed to help ensure its proper operation in an emergency. The 1903 Iroquois Theater fire in Chicago demonstrated that a proscenium curtain might fail to close fully if it is not operated on a regular basis, if it is obstructed temporarily by scenery or props, or if it is obstructed permanently by alterations to the building.

Another benefit of keeping the curtain closed

CHAPTER 12 • New

after performances is the prevention of property damage if a fire occurs after hours.

Regardless of whether a stage has automatic sprinkler protection, standpipes are required on each

12.4.6 Projection Rooms.

12.4.6.1 Projection rooms shall comply with 12.4.6.2 through 12.4.6.10.

12.4.6.2 Where cellulose nitrate film is used, the projection room shall comply with NFPA 40, *Standard for the Storage and Handling of Cellulose Nitrate Motion Picture Film*.

12.4.6.3 Film or video projectors or spotlights utilizing light sources that produce particulate matter, or toxic gases or light sources that produce hazardous radiation, without protective shielding, shall be located within a projection room complying with 12.3.2.1.2.

12.4.6.4 Every projection room shall be of permanent construction consistent with the construction requirements for the type of building in which the projection room is located and shall comply with the following:

- (1) Openings shall not be required to be protected.
- (2) The room shall have a floor area of not less than 7.4 m² (80 ft²) for a single machine and not less than 3.7 m² (40 ft²) for each additional machine.
- (3) Each motion picture projector, floodlight, spotlight, or similar piece of equipment shall have a clear working space of not less than 760 mm (30 in.) on each side and at its rear, but only one such space shall be required between adjacent projectors.

12.4.6.5 The projection room and the rooms appurtenant to it shall have a ceiling height of not less than 2285 mm (90 in.).

12.4.6.6 Each projection room for safety film shall have not less than one out-swinging, self-closing door not less than 760 mm (30 in.) wide and 2030 mm (80 in.) high.

12.4.6.7 The aggregate of ports and openings for projection equipment shall not exceed 25 percent of the area of the wall between the projection room and the auditorium, and all openings shall be provided with glass or other approved material so as to completely close the opening.

12.4.6.8 Projection room ventilation shall comply with 12.4.6.8.1 and 12.4.6.8.2.

CHAPTER 13 • Existing

side of the stage to provide stagehands and the responding fire department with manual fire-fighting capability in the area of a theater where a fire is most likely to occur.

13.4.6 Projection Rooms.

13.4.6.1 Projection rooms shall comply with 13.4.6.2 through 13.4.6.10.

13.4.6.2 Where cellulose nitrate film is used, the projection room shall comply with NFPA 40, *Standard for the Storage and Handling of Cellulose Nitrate Film*.

13.4.6.3 Film or video projectors or spotlights utilizing light sources that produce particulate matter, or toxic gases or light sources that produce hazardous radiation without protective shielding, shall be located within a projection room complying with 13.3.2.1.2.

13.4.6.4 Every projection room shall be of permanent construction consistent with the construction requirements for the type of building in which the projection room is located and shall comply with the following:

- (1) Openings shall not be required to be protected.
- (2) The room shall have a floor area of not less than 7.4 m² (80 ft²) for a single machine and not less than 3.7 m² (40 ft²) for each additional machine.
- (3) Each motion picture projector, floodlight, spotlight, or similar piece of equipment shall have a clear working space of not less than 760 mm (30 in.) on each side and at its rear, but only one such space shall be required between adjacent projectors.

13.4.6.5 The projection room and the rooms appurtenant to it shall have a ceiling height of not less than 2285 mm (90 in.).

13.4.6.6 Each projection room for safety film shall have not less than one out-swinging, self-closing door not less than 760 mm (30 in.) wide and 2030 mm (80 in.) high.

13.4.6.7 The aggregate of ports and openings for projection equipment shall not exceed 25 percent of the area of the wall between the projection room and the auditorium, and all openings shall be provided with glass or other approved material so as to completely close the opening.

13.4.6.8 Projection room ventilation shall comply with 13.4.6.8.1 and 13.4.6.8.2.

CHAPTER 12 • New

12.4.6.8.1 Supply Air.

12.4.6.8.1.1 Each projection room shall be provided with adequate air supply inlets arranged to provide well-distributed air throughout the room.

12.4.6.8.1.2 Air inlet ducts shall provide an amount of air equivalent to the amount of air being exhausted by projection equipment.

12.4.6.8.1.3 Air shall be permitted to be taken from the outside; from adjacent spaces within the building, provided that the volume and infiltration rate is sufficient; or from the building air conditioning system, provided that it is arranged to supply sufficient air whether or not other systems are in operation.

12.4.6.8.2 Exhaust Air.

12.4.6.8.2.1 Projection booths shall be permitted to be exhausted through the lamp exhaust system.

12.4.6.8.2.2 The lamp exhaust system shall be positively interconnected with the lamp so that the lamp cannot operate unless there is sufficient airflow required for the lamp.

12.4.6.8.2.3 Exhaust air ducts shall terminate at the exterior of the building in such a location that the exhaust air cannot be readily recirculated into any air supply system.

12.4.6.8.2.4 The projection room ventilation system shall be permitted also to serve appurtenant rooms, such as the generator room and the rewind room.

12.4.6.9 Each projection machine shall be provided with an exhaust duct that draws air from each lamp and exhausts it directly to the outside of the building.

12.4.6.9.1 The lamp exhaust shall be permitted to exhaust air from the projection room to provide room air circulation.

12.4.6.9.2 Such ducts shall be of rigid materials, except for a flexible connector approved for the purpose.

12.4.6.9.3 The projection lamp and projection room exhaust systems shall be permitted to be combined but shall not be interconnected with any other exhaust system or return-air system within the buildings.

12.4.6.9.4 Specifications for electric arc and xenon projection equipment shall comply with 12.4.6.9.4(A) and 12.4.6.9.4(B).

(A) Electric Arc Projection Equipment. The exhaust capacity shall be 0.09 m³/s (200 ft³/min) for each lamp con-

CHAPTER 13 • Existing

13.4.6.8.1 Supply Air.

13.4.6.8.1.1 Each projection room shall be provided with adequate air supply inlets arranged to provide well-distributed air throughout the room.

13.4.6.8.1.2 Air inlet ducts shall provide an amount of air equivalent to the amount of air being exhausted by projection equipment.

13.4.6.8.1.3 Air shall be permitted to be taken from the outside; from adjacent spaces within the building, provided that the volume and infiltration rate is sufficient; or from the building air conditioning system, provided that it is arranged to supply sufficient air whether or not other systems are in operation.

13.4.6.8.2 Exhaust Air.

13.4.6.8.2.1 Projection booths shall be permitted to be exhausted through the lamp exhaust system.

13.4.6.8.2.2 The lamp exhaust system shall be positively interconnected with the lamp so that the lamp cannot operate unless there is sufficient airflow required for the lamp.

13.4.6.8.2.3 Exhaust air ducts shall terminate at the exterior of the building in such a location that the exhaust air cannot be readily recirculated into any air supply system.

13.4.6.8.2.4 The projection room ventilation system shall be permitted also to serve appurtenant rooms, such as the generator room and the rewind room.

13.4.6.9 Each projection machine shall be provided with an exhaust duct that draws air from each lamp and exhausts it directly to the outside of the building.

13.4.6.9.1 The lamp exhaust shall be permitted to exhaust air from the projection room to provide room air circulation.

13.4.6.9.2 Such ducts shall be of rigid materials, except for a flexible connector approved for the purpose.

13.4.6.9.3 The projection lamp and projection room exhaust systems shall be permitted to be combined but shall not be interconnected with any other exhaust system or return-air system within the buildings.

13.4.6.9.4 Specifications for electric arc and xenon projection equipment shall comply with 13.4.6.9.4(A) and 13.4.6.9.4(B).

(A) Electric Arc Projection Equipment. The exhaust capacity shall be 0.09 m³/s (200 ft³/min) for each lamp con-

CHAPTER 12 • New

nected to the lamp exhaust system, or as recommended by the equipment manufacturer, and auxiliary air shall be permitted to be introduced into the system through a screened opening to stabilize the arc.

(B) Xenon Projection Equipment. The lamp exhaust system shall exhaust not less than 0.14 m³/s (300 ft³/min) per lamp, or not less than the exhaust volume required or recommended by the equipment manufacturer, whichever is greater.

12.4.6.10 Miscellaneous equipment and storage shall be protected as follows:

- (1) Each projection room shall be provided with rewind and film storage facilities.
- (2) Flammable liquids containers shall be permitted in projection rooms, provided that the following criteria are met:
 - (a) There are not more than four containers per projection room.
 - (b) No container has capacity exceeding 0.5 L (16 oz).
 - (c) Containers are of a nonbreakable type.
- (3) Appurtenant electrical equipment, such as rheostats, transformers, and generators, shall be permitted to be located within the booth or in a separate room of equivalent construction.

The requirements for projection booths were developed jointly with those of NFPA 40, *Standard for the Storage and Handling of Cellulose Nitrate Film*¹⁰, and the motion picture industry when cellulose nitrate film was still being used. Although only safety film is now used (except at film festivals or revivals) and the risk level has been reduced, the primary function of the requirements of 12/13.4.6.3 is to enclose the projection booth, eliminating it as an exposure threat to the theater audience.

The intent of 12/13.4.6.3 is to protect the audience from the dangers associated with light sources, such as electric arc or xenon. Where incandescent light is used, projection booths are not required in assembly occupancies. Note that the booth is required based on the light source, not on the use of film.

The provisions of 12/13.4.6.4 apply only to projection booths for the use of cellulose acetate or other safety film. Although openings in the booth do not need to be protected, they must be provided with glass or other approved material that will completely close the opening and prevent gas, dust, or radiation from contaminating the audience seating area.

CHAPTER 13 • Existing

nected to the lamp exhaust system or as recommended by the equipment manufacturer, and auxiliary air shall be permitted to be introduced into the system through a screened opening to stabilize the arc.

(B) Xenon Projection Equipment. The lamp exhaust system shall exhaust not less than 0.14 m³/s (300 ft³/min) per lamp, or not less than the exhaust volume required or recommended by the equipment manufacturer, whichever is greater.

13.4.6.10 Miscellaneous equipment and storage shall be protected as follows:

- (1) Each projection room shall be provided with rewind and film storage facilities.
- (2) Flammable liquids containers shall be permitted in projection rooms, provided that the following criteria are met:
 - (a) There are not more than four containers per projection room.
 - (b) No container has capacity exceeding 0.5 L (16 oz).
 - (c) Containers are of a nonbreakable type.
- (3) Appurtenant electrical equipment, such as rheostats, transformers, and generators, shall be permitted to be located within the booth or in a separate room of equivalent construction.

New projection equipment in new theaters has a console that draws air in at the floor and up through the projection machine, thus eliminating the need to provide ducts near the floor.

The requirements of 12/13.4.6.8 for the ventilation of a projection booth are designed to isolate the booth from the theater so that any products of combustion created by a fire in a projection booth are not circulated into the theater. This isolation is achieved by providing an independent exhaust system for the booth, making certain that the exhaust outlet on the exterior of the building is located at a point where the air intake for the theater cannot recirculate the exhausted air.

If fresh air for the projection booth's ventilation system is supplied from the general system of the building, it is essential that the combined system be arranged to ensure the required air changes in the booth even when no air is supplied to the general system of the building.

In 12/13.4.6.9.4, the *Code* specifies the minimum capacity for the exhaust system of a projection machine; however, a greater capacity must be provided

CHAPTER 12 • New

where recommended by the manufacturer of the projection equipment. The system must be independent of any other ventilation system in the building housing the theater, but it can be combined with projection room ventilation.

The requirement of 12/13.4.6.10 for the storage and rewinding of film is intended to prevent these

12.4.7* Special Amusement Buildings.

A.12.4.7 Where a special amusement building is installed inside another building, such as within an exhibit hall, the special amusement building requirements apply only to the special amusement building. For example, the smoke detectors required by 12.4.7.4 are not required to be connected to the building's system. Where installed in an exhibit hall, such smoke detectors are also required to comply with the provisions applicable to an exhibit.

12.4.7.1* General. Special amusement buildings, regardless of occupant load, shall meet the requirements for assembly occupancies in addition to the requirements of 12.4.7, unless the special amusement building is a multilevel play structure that is not more than 3050 mm (120 in.) in height and has aggregate horizontal projections not exceeding 15 m² (160 ft²).

A.12.4.7.1 The aggregate horizontal projections of a multilevel play structure are indicative of the number of children who might be within the structure and at risk from a fire or similar emergency. The word “aggregate” is used in recognition that the platforms and tubes that make up the multilevel play structure run above each other at various levels. In calculating the area of the projections, it is important to account for all areas that might be expected to be occupied within, on top, or beneath the components of the structure when the structure is used for its intended function.

12.4.7.2* Automatic Sprinklers. Every special amusement building, other than buildings or structures not exceeding 3050 mm (120 in.) in height and not exceeding 15 m² (160 ft²) in aggregate horizontal projection, shall be protected throughout by an approved, supervised automatic sprinkler system installed and maintained in accordance with Section 9.7.

A.12.4.7.2 See A.12.4.7.1.

12.4.7.3 Temporary Water Supply. Where the special amusement building required to be sprinklered by 12.4.7.2 is movable or portable, the sprinkler water supply shall be permitted to be provided by an approved, temporary means.

CHAPTER 13 • Existing

operations from taking place outside the projection booth at some less protected location where, if a fire occurred, the exposure to the theater would be significantly greater. All operations that relate to projection activities must be kept within the protected enclosure afforded by the projection booth.

13.4.7* Special Amusement Buildings.

A.13.4.7 Where a special amusement building is installed inside another building, such as within an exhibit hall, the special amusement building requirements apply only to the special amusement building. For example, the smoke detectors required by 13.4.7.4 are not required to be connected to the building's system. Where installed in an exhibit hall, such smoke detectors are also required to comply with the provisions applicable to an exhibit.

13.4.7.1* General. Special amusement buildings, regardless of occupant load, shall meet the requirements for assembly occupancies in addition to the requirements of 13.4.7, unless the special amusement building is a multilevel play structure that is not more than 3050 mm (120 in.) in height and has aggregate horizontal projections not exceeding 15 m² (160 ft²).

A.13.4.7.1 The aggregate horizontal projections of a multilevel play structure are indicative of the number of children who might be within the structure and at risk from a fire or similar emergency. The word “aggregate” is used in recognition that the platforms and tubes that make up the multilevel play structure run above each other at various levels. In calculating the area of the projections, it is important to account for all areas that might be expected to be occupied within, on top, or beneath the components of the structure when the structure is used for its intended function.

13.4.7.2* Automatic Sprinklers. Every special amusement building, other than buildings or structures not exceeding 3050 mm (120 in.) in height and not exceeding 15 m² (160 ft²) in aggregate horizontal projection, shall be protected throughout by an approved, supervised automatic sprinkler system installed and maintained in accordance with Section 9.7.

A.13.4.7.2 See A.13.4.7.1.

13.4.7.3 Temporary Water Supply. Where the special amusement building required to be sprinklered by 13.4.7.2 is movable or portable, the sprinkler water supply shall be permitted to be provided by an approved, temporary means.

CHAPTER 12 • New

12.4.7.4 Smoke Detection. Where the nature of the special amusement building is such that it operates in reduced lighting levels, the building shall be protected throughout by an approved automatic smoke detection system in accordance with Section 9.6.

12.4.7.5 Alarm Initiation. Actuation of any smoke detection system device shall sound an alarm at a constantly attended location on the premises.

12.4.7.6 Illumination. Actuation of the automatic sprinkler system, or any other suppression system, or actuation of a smoke detection system having an approved verification or cross-zoning operation capability shall provide the following:

- (1) Cause illumination in the means of egress to increase to that required by Section 7.8
- (2) Stop any conflicting or confusing sounds and visuals

12.4.7.7 Exit Marking.

12.4.7.7.1 Exit marking shall be in accordance with Section 7.10.

12.4.7.7.2 Floor proximity exit signs shall be provided in accordance with 7.10.1.6.

12.4.7.7.3* In special amusement buildings where mazes, mirrors, or other designs are used to confound the egress path, approved directional exit marking that becomes apparent in an emergency shall be provided.

A.12.4.7.7.3 Consideration should be given to the provision of directional exit marking on or adjacent to the floor.

12.4.7.8 Interior Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A throughout.

Any special amusement building is considered an assembly occupancy, even if the occupant load is not more than 50 persons. However, special amusement buildings do not include theaters, movie houses, and other similar types of assembly occupancies.

Quick-response automatic sprinklers will be appropriate in most cases. However, competent automatic sprinkler designers and the authority having jurisdiction should review the design.

Paragraph 12/13.4.7.6 addresses the importance of the exits and means of egress being well lighted

CHAPTER 13 • Existing

13.4.7.4 Smoke Detection. Where the nature of the special amusement building is such that it operates in reduced lighting levels, the building shall be protected throughout by an approved automatic smoke detection system in accordance with Section 9.6.

13.4.7.5 Alarm Initiation. Actuation of any smoke detection system device shall sound an alarm at a constantly attended location on the premises.

13.4.7.6 Illumination. Actuation of the automatic sprinkler system, or any other suppression system, or actuation of a smoke detection system having an approved verification or cross-zoning operation capability shall provide the following:

- (1) Cause illumination in the means of egress to increase to that required by Section 7.8
- (2) Stop any conflicting or confusing sounds and visuals

13.4.7.7 Exit Marking.

13.4.7.7.1 Exit marking shall be in accordance with Section 7.10.

13.4.7.7.2 Floor proximity exit signs shall be provided in accordance with 7.10.1.6.

13.4.7.7.3* In special amusement buildings where mazes, mirrors, or other designs are used to confound the egress path, approved directional exit marking that becomes apparent in an emergency shall be provided.

A.13.4.7.7.3 Consideration should be given to the provision of directional exit marking on or adjacent to the floor.

13.4.7.8 Interior Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A throughout in accordance with Section 10.2.

upon the activation of a smoke detector or suppression system. It is also important that any conflicting or confusing sounds or visuals be stopped and that, where a person's relative position to an exit is changed, additional exit signs be provided.

In special amusement buildings, the provision of directions to an exit is particularly important. Floor proximity exit signs, as required by 12/13.4.7.2, should provide patrons an additional tool to assist them in finding their way out under emergency conditions.

CHAPTER 12 • New

CHAPTER 13 • Existing

12.4.8 Grandstands.

The *Life Safety Code* means of egress provisions concerning bleacher or grandstand seating and folding or telescopic seating were taken from NFPA 102, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*¹¹.

12.4.8.1 General. Grandstands shall comply with the provisions of this chapter as modified by 12.4.8.

12.4.8.2 Seating.

12.4.8.2.1 Where grandstand seating without backs is used indoors, rows of seats shall be spaced not less than 560 mm (22 in.) back-to-back.

12.4.8.2.2 The depth of footboards and seat boards in grandstands shall be not less than 230 mm (9 in.); where the same level is not used for both seat foundations and footrests, footrests independent of seats shall be provided.

12.4.8.2.3 Seats and footrests of grandstands shall be supported securely and fastened in such a manner that they cannot be displaced inadvertently.

12.4.8.2.4 Individual seats or chairs shall be permitted only if secured in rows in an approved manner, unless seats do not exceed 16 in number and are located on level floors and within railed-in enclosures, such as boxes.

12.4.8.2.5 The maximum number of seats permitted between the farthest seat in an aisle in grandstands and bleachers shall not exceed that shown in Table 12.4.8.2.5.

Table 12.4.8.2.5 Maximum Number of Seats Between Farthest Seat and an Aisle

Application	Outdoors	Indoors
Grandstands	11	6
Bleachers [(see 12.2.5.6.1(1))]	20	9

12.4.8.3 Special Requirements—Wood Grandstands.

12.4.8.3.1 The distance between an outdoor wood grandstand and a building shall be not less than two-thirds of the grandstand height and in no case less than 3050 mm (120 in.) of a building, unless otherwise permitted by the following:

13.4.8 Grandstands.

13.4.8.1 General.

13.4.8.1.1 Grandstands shall comply with the provisions of this chapter as modified by 13.4.8.

13.4.8.1.2 Approved existing grandstands shall be permitted to be continued to be used.

13.4.8.2 Seating.

13.4.8.2.1 Where grandstand seating without backs is used indoors, rows of seats shall be spaced not less than 560 mm (22 in.) back-to-back.

13.4.8.2.2 The depth of footboards and seat boards in grandstands shall be not less than 230 mm (9 in.), where the same level is not used for both seat foundations and footrests, footrests independent of seats shall be provided.

13.4.8.2.3 Seats and footrests of grandstands shall be supported securely and fastened in such a manner that they cannot be displaced inadvertently.

13.4.8.2.4 Individual seats or chairs shall be permitted only if secured firmly in rows in an approved manner, unless seats do not exceed 16 in number and are located on level floors and within railed-in enclosures, such as boxes.

13.4.8.2.5 The maximum number of seats permitted between the farthest seat in an aisle in grandstands and bleachers shall not exceed that shown in Table 13.4.8.2.5.

Table 13.4.8.2.5 Maximum Number of Seats Between Farthest Seat and an Aisle

Application	Outdoors	Indoors
Grandstands	11	6
Bleachers [(see 13.2.5.6.1(1))]	20	9

13.4.8.3 Special Requirements — Wood Grandstands.

13.4.8.3.1 The distance between an outdoor wood grandstand and a building shall be not less than two-thirds of the grandstand height and in no case less than 3050 mm (120 in.) of a building, unless otherwise permitted by the following:

CHAPTER 12 • New

- (1) The distance requirement shall not apply to buildings of not less than 1-hour fire resistance-rated construction with openings protected against the fire exposure hazard created by the grandstand.
- (2) The distance requirement shall not apply where a wall of not less than 1-hour fire resistance-rated construction separates the grandstand from the building.

12.4.8.3.2 An outdoor wood grandstand unit shall not exceed 929 m² (10,000 ft²) in ground area or 61 m (200 ft) in length, and the following requirements also shall apply:

- (1) Grandstand units of the maximum size shall be placed not less than 6100 mm (240 in.) apart or shall be separated by walls of 1-hour fire resistance rating.
- (2) The number of grandstand units erected in any one group shall not exceed three.
- (3) Each group of grandstand units shall be separated from any other group by a wall of 2-hour fire resistance-rated construction extending 610 mm (24 in.) above the seat platforms or by an open space of not less than 15 m (50 ft).

12.4.8.3.3 The ground area or length required by 12.4.8.3.2 shall be permitted to be doubled where one of the following criteria is met:

- (1) Where the grandstand is constructed entirely of labeled fire-retardant-treated wood that has passed the standard rain test, ASTM D 2898, *Test Method for Accelerated Weathering of Fire-Retardant-Treated Wood for Fire Testing*
- (2) Where the grandstand is constructed of members conforming to dimensions for heavy timber construction (Type IV (2HH))

12.4.8.3.4 The highest level of seat platforms above the ground or the surface at the front of any wood grandstand shall not exceed 6100 mm (240 in.).

12.4.8.3.5 The highest level of seat platforms above the ground, or the surface at the front of a portable grandstand within a tent or membrane structure, shall not exceed 3660 mm (144 in.).

12.4.8.3.6 The height requirements specified in 12.4.8.3.4 and 12.4.8.3.5 shall be permitted to be doubled where constructed entirely of labeled fire-retardant-treated wood that has passed the standard rain test, ASTM D 2898, *Test Method for Accelerated Weathering of Fire-Retardant-Treated Wood for Fire Testing*, or where constructed of members conforming to dimensions for heavy timber construction (Type IV (2HH)).

CHAPTER 13 • Existing

- (1) The distance requirement shall not apply to buildings of not less than 1-hour fire resistance-rated construction with openings protected against the fire exposure hazard created by the grandstand.
- (2) The distance requirement shall not apply where a wall of not less than 1-hour fire resistance-rated construction separates the grandstand from the building.

13.4.8.3.2 An outdoor wood grandstand unit shall not exceed 929 m² (10,000 ft²) in ground area or 61 m (200 ft.) in length, and the following requirements also shall apply:

- (1) Grandstand units of the maximum size shall be placed not less than 6100 mm (240 in.) apart or shall be separated by walls of 1-hour fire resistance rating.
- (2) The number of grandstand units erected in any one group shall not exceed three.
- (3) Each group of grandstand units shall be separated from any other group by a wall of 2-hour fire resistance-rated construction extending 610 mm (24 in.) above the seat platforms or by an open space of not less than 15 m (50 ft).

13.4.8.3.3 The ground area or length required by 13.4.8.3.2 shall be permitted to be doubled where one of the following criteria is met:

- (1) Where the grandstand is constructed entirely of labeled fire-retardant-treated wood that has passed the standard rain test, ASTM D 2898, *Test Method for Accelerated Weathering of Fire-Retardant-Treated Wood for Fire Testing*
- (2) Where the grandstand is constructed of members conforming to dimensions for heavy timber construction (Type IV (2HH))

13.4.8.3.4 The highest level of seat platforms above the ground or the surface at the front of any wood grandstand shall not exceed 6100 mm (240 in.).

13.4.8.3.5 The highest level of seat platforms above the ground, or the surface at the front of a portable grandstand within a tent or membrane structure, shall not exceed 3660 mm (144 in.).

13.4.8.3.6 The height requirements specified in 13.4.8.3.4 and 13.4.8.3.5 shall be permitted to be doubled where the grandstand is constructed entirely of labeled fire-retardant-treated wood that has passed the standard rain test, ASTM D 2898, *Test Method for Accelerated Weathering of Fire-Retardant-Treated Wood for Fire Testing*, or where constructed of members conforming to dimensions for heavy timber construction (Type IV (2HH)).

CHAPTER 12 • New

12.4.8.4 Special Requirements—Portable Grandstands.

12.4.8.4.1 Portable grandstands shall conform to the requirements of 12.4.8 for grandstands and the requirements of 12.4.8.4.2 through 12.4.8.4.7.

12.4.8.4.2 Portable grandstands shall be self-contained and shall have within them all necessary parts to withstand and restrain all forces that might be developed during human occupancy.

12.4.8.4.3 Portable grandstands shall be designed and manufactured so that, if any structural members essential to the strength and stability of the structure have been omitted during erection, the presence of unused connection fittings shall make the omissions self-evident.

12.4.8.4.4 Portable grandstand construction shall be skillfully accomplished to produce the strength required by the design.

12.4.8.4.5 Portable grandstands shall be provided with base plates, sills, floor runners, or sleepers of such area that the permitted bearing capacity of the supporting material is not exceeded.

12.4.8.4.6 Where portable grandstands rest directly on a base of such character that it is incapable of supporting the load without appreciable settlement, mud sills of suitable material, having sufficient area to prevent undue or dangerous settlement, shall be installed under base plates, runners, or sleepers.

12.4.8.4.7 All bearing surfaces of portable grandstands shall be in contact with each other.

12.4.8.5 Spaces Underneath Grandstands. Spaces underneath a grandstand shall be kept free of flammable or combustible materials, unless protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7, unless otherwise permitted by the following:

- (1) This requirement shall not apply to accessory uses of 28 m² (300 ft²) or less, such as ticket booths, toilet facilities, or concession booths where constructed of noncombustible or fire-resistive construction in otherwise nonsprinklered facilities.
- (2) This requirement shall not apply to rooms that are enclosed in not less than 1-hour fire resistance-rated construction and are less than 93 m² (1000 ft²) in otherwise nonsprinklered facilities.

12.4.8.6 Guards and Railings.

12.4.8.6.1 Railings or guards not less than 1065 mm (42 in.) above the aisle surface or footrest or not less than 915 mm

CHAPTER 13 • Existing

13.4.8.4 Special Requirements—Portable Grandstands.

13.4.8.4.1 Portable grandstands shall conform to the requirements of 13.4.8 for grandstands and the requirements of 13.4.8.4.2 through 13.4.8.4.7.

13.4.8.4.2 Portable grandstands shall be self-contained and shall have within them all necessary parts to withstand and restrain all forces that might be developed during human occupancy.

13.4.8.4.3 Portable grandstands shall be designed and manufactured so that if any structural members essential to the strength and stability of the structure have been omitted during erection, the presence of unused connection fittings shall make the omissions self-evident.

13.4.8.4.4 Portable grandstands construction shall be skillfully accomplished to produce the strength required by the design.

13.4.8.4.5 Portable grandstands shall be provided with base plates, sills, floor runners, or sleepers of such area that the permitted bearing capacity of the supporting material is not exceeded.

13.4.8.4.6 Where portable grandstands rest directly on a base of such character that it is incapable of supporting the load without appreciable settlement, mud sills of suitable material, having sufficient area to prevent undue or dangerous settlement, shall be installed under base plates, runners, or sleepers.

13.4.8.4.7 All bearing surfaces shall be in contact with each other.

13.4.8.5 Spaces Underneath Grandstands. Spaces underneath a grandstand shall be kept free of flammable or combustible materials, unless protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7 or unless otherwise permitted by the following:

- (1) This requirement shall not apply to accessory uses of 28 m² (300 ft²) or less such as ticket booths, toilet facilities, or concession booths, where constructed of noncombustible or fire-resistive construction, in materials otherwise nonsprinklered facilities.
- (2) This requirement shall not apply to rooms that are enclosed in not less than 1-hour fire resistance-rated construction and are less than 93 m² (1000 ft²) in otherwise nonsprinklered facilities.

13.4.8.6 Guards and Railings.

13.4.8.6.1 Railings or guards not less than 1065 mm (42 in.) above the aisle surface or footrest or not less than 915 mm

CHAPTER 12 • New

(36 in.) vertically above the center of the seat or seat board surface, whichever is adjacent, shall be provided along those portions of the backs and ends of all grandstands where the seats are more than 1220 mm (48 in.) above the floor or ground.

12.4.8.6.2 The requirement of 12.4.8.6.1 shall not apply where an adjacent wall or fence affords equivalent safeguard.

12.4.8.6.3 Where the front footrest of any grandstand is more than 610 mm (24 in.) above the floor, railings or guards not less than 825 mm (33 in.) above such footrests shall be provided.

12.4.8.6.4 The railings required by 12.4.8.6.3 shall be permitted to be not less than 660 mm (26 in.) high in grandstands or where the front row of seats includes backrests.

12.4.8.6.5 Cross aisles located within the seating area shall be provided with rails not less than 660 mm (26 in.) high along the front edge of the cross aisle.

12.4.8.6.6 The railings specified by 12.4.8.6.5 shall not be required where the backs of the seats in front of the cross aisle project 610 mm (24 in.) or more above the surface of the cross aisle.

12.4.8.6.7 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

12.4.8.6.8 An opening between the seat board and footboard located more than 760 mm (30 in.) above grade shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

12.4.9 Folding and Telescopic Seating.

12.4.9.1 General. Folding and telescopic seating shall comply with the provisions of this chapter as modified by 12.4.9.

12.4.9.2 Seating.

12.4.9.2.1 The horizontal distance of seats, measured back-to-back, shall be not less than 560 mm (22 in.) for seats without backs, and the following requirements shall also apply:

- (1) There shall be a space of not less than 305 mm (12 in.) between the back of each seat and the front of each seat immediately behind it.

CHAPTER 13 • Existing

(36 in.) vertically above the center of the seat or seat board surface, whichever is adjacent, shall be provided along those portions of the backs and ends of all grandstands where the seats are in excess of 1220 mm (48 in.) above the floor or ground.

13.4.8.6.2 The requirement of 13.4.8.6.1 shall not apply where an adjacent wall or fence affords equivalent safeguard.

13.4.8.6.3 Where the front footrest of any grandstand is more than 610 mm (24 in.) above the floor, railings or guards not less than 825 mm (33 in.) above such footrests shall be provided.

13.4.8.6.4 The railings required by 13.4.8.6.3 shall be permitted to be not less than 660 mm (26 in.) high in grandstands or where the front row of seats includes backrests.

13.4.8.6.5 Cross aisles located within the seating area shall be provided with rails not less than 660 mm (26 in.) high along the front edge of the cross aisle.

13.4.8.6.6 The railings specified by 13.4.8.6.5 shall not be required where the backs of the seats in front of the cross aisle project 610 mm (24 in.) or more above the surface of the cross aisle.

13.4.8.6.7 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

13.4.8.6.8 An opening between the seat board and footboard located more than 760 mm (30 in.) above grade shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

13.4.9 Folding and Telescopic Seating.

13.4.9.1 General.

13.4.9.1.1 Folding and telescopic seating shall comply with the provisions of this chapter as modified by 13.4.9.

13.4.9.1.2 Approved existing folding and telescopic seating shall be permitted to be continued to be used.

13.4.9.2 Seating.

13.4.9.2.1 The horizontal distance of seats, measured back-to-back, shall be not less than 560 mm (22 in.) for seats without backs, and the following requirements shall also apply:

- (1) There shall be a space of not less than 305 mm (12 in.) between the back of each seat and the front of each seat immediately behind it.

CHAPTER 12 • New

- (2) If seats are of the chair type, the 305-mm (12-in.) dimension shall be measured to the front edge of the rear seat in its normal unoccupied position.
- (3) All measurements shall be taken between plumb lines.

12.4.9.2.2 The depth of footboards (footrests) and seat boards in folding and telescopic seating shall be not less than 230 mm (9 in.).

12.4.9.2.3 Where the same level is not used for both seat foundations and footrests, footrests independent of seats shall be provided.

12.4.9.2.4 Individual chair-type seats shall be permitted in folding and telescopic seating only if firmly secured in groups of not less than three.

12.4.9.2.5 The maximum number of seats permitted between the farthest seat in an aisle in folding and telescopic seating shall not exceed that shown in Table 12.4.8.2.5.

12.4.9.3 Guards and Railings.

12.4.9.3.1 Railings or guards not less than 1065 mm (42 in.) above the aisle surface or footrest or not less than 915 mm (36 in.) vertically above the center of the seat or seat board surface, whichever is adjacent, shall be provided along those portions of the backs and ends of all folding and telescopic seating where the seats are more than 1220 mm (48 in.) above the floor or ground.

12.4.9.3.2 The requirement of 12.4.9.3.1 shall not apply where an adjacent wall or fence affords equivalent safeguard.

12.4.9.3.3 Where the front footrest of folding or telescopic seating is more than 610 mm (24 in.) above the floor, railings or guards not less than 825 mm (33 in.) above such footrests shall be provided.

12.4.9.3.4 The railings required by 12.4.9.3.3 shall be permitted to be not less than 660 mm (26 in.) high where the front row of seats includes backrests.

12.4.9.3.5 Cross aisles located within the seating area shall be provided with rails not less than 660 mm (26 in.) high along the front edge of the cross aisle.

12.4.9.3.6 The railings specified by 12.4.9.3.5 shall not be required where the backs of the seats in front of the cross aisle project 610 mm (24 in.) or more above the surface of the cross aisle.

12.4.9.3.7 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

CHAPTER 13 • Existing

- (2) If seats are of the chair type, the 305-mm (12-in.) dimension shall be measured to the front edge of the rear seat in its normal unoccupied position.
- (3) All measurements shall be taken between plumb lines.

13.4.9.2.2 The depth of footboards (footrests) and seat boards in folding and telescopic seating shall be not less than 230 mm (9 in.).

13.4.9.2.3 Where the same level is not used for both seat foundations and footrests, footrests independent of seats shall be provided.

13.4.9.2.4 Individual chair-type seats shall be permitted in folding and telescopic seating only if firmly secured in groups of not less than three.

13.4.9.2.5 The maximum number of seats permitted between the farthest seat in an aisle in folding and telescopic seating shall not exceed that shown in Table 13.4.8.2.5.

13.4.9.3 Guards and Railings.

13.4.9.3.1 Railings or guards not less than 1065 mm (42 in.) above the aisle surface or footrest or not less than 915 mm (36 in.) vertically above the center of the seat or seat board surface, whichever is adjacent, shall be provided along those portions of the backs and ends of all folding and telescopic seating where the seats are more than 1220 mm (48 in.) above the floor or ground.

13.4.9.3.2 The requirement of 13.4.9.3.1 shall not apply where an adjacent wall or fence affords equivalent safeguard.

13.4.9.3.3 Where the front footrest of folding or telescopic seating is more than 610 mm (24 in.) above the floor, railings or guards not less than 825 mm (33 in.) above such footrests shall be provided.

13.4.9.3.4 The railings required by 13.4.9.3.3 shall be permitted to be not less than 660 mm (26 in.) high where the front row of seats includes backrests.

13.4.9.3.5 Cross aisles located within the seating area shall be provided with rails not less than 660 mm (26 in.) high along the front edge of the cross aisle.

13.4.9.3.6 The railings specified by 13.4.9.3.5 shall not be required where the backs of the seats in front of the cross aisle project 610 mm (24 in.) or more above the surface of the cross aisle.

13.4.9.3.7 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

CHAPTER 12 • New

12.4.9.3.8 An opening between the seat board and footboard located more than 760 mm (30 in.) above grade shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

12.4.10 Airport Loading Walkways.

12.4.10.1 Airport loading walkways shall conform to NFPA 415, *Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways*, and the provisions of 12.4.10.2 and 12.4.10.3.

12.4.10.2 Doors in the egress path from the aircraft through the airport loading walkway into the airport terminal building shall meet the following criteria:

- (1) They shall swing in the direction of egress from the aircraft.
- (2)* They shall not be permitted to have delayed egress locks.

A.12.4.10.2(2) Delayed egress locks doors from the airport loading walkway into the airport terminal building might compromise life safety due to the limited period of time the airport loading walkway will provide protection for emergency egress. The requirement of 12.4.10.2(2) would not limit the use of access-controlled or delayed-egress hardware from the airport terminal building into the airport loading walkway.

12.4.10.3 Exit access shall be unimpeded from the airport loading walkway to the non-secured public areas of the airport terminal building.

Section 12.5 Building Services

12.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

12.5.2 Heating, Ventilating, and Air Conditioning Equipment.

Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

12.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

CHAPTER 13 • Existing

13.4.9.3.8 An opening between the seat board and footboard located more than 760 mm (30 in.) above grade shall be provided with intermediate construction so that a 100-mm (4-in.) diameter sphere cannot pass through the opening.

13.4.10 Airport Loading Walkways.

13.4.10.1 Airport loading walkways shall conform with NFPA 415, *Standard on Airport Terminal Buildings, Fueling Ramp Drainage, and Loading Walkways*, and the provisions of 13.4.10.2 and 13.4.10.3.

13.4.10.2 Doors in the egress path from the aircraft through the airport loading walkway into the airport terminal building shall meet the following criteria:

- (1) They shall swing in the direction of egress from the aircraft.
- (2)* They shall not be permitted to have delayed egress locks.

A.13.4.10.2(2) Delayed egress locks doors from the airport loading walkway into the airport terminal building might compromise life safety due to the limited period of time the airport loading walkway will provide protection for emergency egress. The requirement of 13.4.10.2(2) would not limit the use of access-controlled or delayed-egress hardware from the airport terminal building into the airport loading walkway.

13.4.10.3 Exit access shall be unimpeded from the airport loading walkway to the non-secured public areas of the airport terminal building.

Section 13.5 Building Services

13.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

13.5.2 Heating, Ventilating, and Air Conditioning Equipment.

Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

13.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

CHAPTER 12 • New

12.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 12.6 Reserved**Section 12.7 Operating Features****12.7.1 Special Provisions for Food Service Operations.**

12.7.1.1 All devices in connection with the preparation of food shall be installed and operated to avoid hazard to the safety of occupants.

CHAPTER 13 • Existing

13.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 13.6 Reserved**Section 13.7 Operating Features****13.7.1 Special Provisions for Food Service Operations.**

13.7.1.1 All devices in connection with the preparation of food shall be installed and operated to avoid hazard to the safety of occupants.

**Tentative Interim Amendment
NFPA 101®
Life Safety Code®
2003 Edition**

Reference: 12.7.1 and 13.7.1
TIA 03-5 (NFPA 101)
(SC 03-7-19/Log No. 742R)

Pursuant to Section 5 of the NFPA Regulations Governing Committee Projects, the National Fire Protection Association has issued the following Tentative Interim Amendment to NFPA 101®, *Life Safety Code*®, 2003 edition. The TIA was processed by the Safety to Life Committee, and was issued by the Standards Council on July 25, 2003, with an effective date of August 14, 2003.

A Tentative Interim Amendment is tentative because it has not been processed through the entire standards-making procedures. It is interim because it is effective only between editions of the standard. A TIA automatically becomes a proposal of the proponent for the next edition of the standard; as such, it then is subject to all of the procedures of the standards-making process.

Insert a new 12.7.1 and 13.7.1 (and renumber existing 12.7.1 through 12.7.11 and 13.7.1 through 13.7.11) to require means of egress inspections as follows:

12.7.1 Means of Egress Inspection.

12.7.1.1 The building owner or agent shall inspect the means of egress to ensure it is maintained free of obstructions, and correct any deficiencies found, prior to each opening of the building to the public.

12.7.1.2 The building owner or agent shall prepare and maintain records of the date and time of each inspection on approved forms, listing any deficiencies found and actions taken to correct them.

13.7.1 Means of Egress Inspection.

13.7.1.1 The building owner or agent shall inspect the means of egress to ensure it is maintained free of obstructions, and correct any deficiencies found, prior to each opening of the building to the public.

13.7.1.2 The building owner or agent shall prepare and maintain records of the date and time of each inspection on approved forms, listing any deficiencies found and actions taken to correct them.

CHAPTER 12 • New

12.7.1.2 All devices in connection with the preparation of food shall be of an approved type and shall be installed in an approved manner.

12.7.1.3 Food preparation facilities shall be protected in accordance with 9.2.3 and shall not be required to have openings protected between food preparation areas and dining areas.

12.7.1.4 Portable cooking equipment that is not flue-connected shall be permitted only as follows:

- (1) Equipment fueled by small heat sources that can be readily extinguished by water, such as candles or alcohol-burning equipment, including solid alcohol, shall be permitted to be used, provided that precautions satisfactory to the authority having jurisdiction are taken to prevent ignition of any combustible materials.
- (2) Candles shall be permitted to be used on tables used for food service where securely supported on substantial noncombustible bases located to avoid danger of ignition of combustible materials and only where approved by the authority having jurisdiction.
- (3) Candle flames shall be protected.
- (4) “Flaming sword” or other equipment involving open flames and flamed dishes, such as cherries jubilee or crêpe suzette, shall be permitted to be used, provided that precautions subject to the approval of the authority having jurisdiction are taken.
- (5)* Listed and approved LP-Gas commercial food service appliances shall be permitted to be used where in accordance with NFPA 58, *Liquefied Petroleum Gas Code*.

A.12.7.1.4(5) NFPA 58, *Liquefied Petroleum Gas Code*, permits portable butane-fueled appliances in restaurants and in attended commercial food catering operations where fueled by not more than two 0.3-L (10-oz) LP-Gas capacity, nonrefillable butane containers that have a water capacity not exceeding 0.5 kg (1.08 lb) per container. The containers are required to be directly connected to the appliance, and manifolding of containers is not permitted. Storage of cylinders is also limited to 24 containers, with an additional 24 permitted where protected by a 2-hour fire resistance-rated barrier.

An approved type of device, as required by 12/13.7.1.2, is one that, with regard to potential fire hazards, is acceptable to the authority having jurisdiction. An “approved manner” of installation means installation acceptable to the AHJ.

CHAPTER 13 • Existing

13.7.1.2 All devices in connection with the preparation of food shall be of an approved type and shall be installed in an approved manner.

13.7.1.3 Food preparation facilities shall be protected in accordance with 9.2.3 and shall not be required to have openings protected between food preparation areas and dining areas.

13.7.1.4 Portable cooking equipment that is not flue-connected shall be permitted only as follows:

- (1) Equipment fueled by small heat sources that can be readily extinguished by water, such as candles or alcohol-burning equipment, including solid alcohol, shall be permitted to be used, provided that precautions satisfactory to the authority having jurisdiction are taken to prevent ignition of any combustible materials.
- (2) Candles shall be permitted to be used on tables used for food service where securely supported on substantial noncombustible bases located to avoid danger of ignition of combustible materials and only where approved by the authority having jurisdiction.
- (3) Candle flames shall be protected.
- (4) “Flaming sword” or other equipment involving open flames and flamed dishes, such as cherries jubilee or crêpe suzette, shall be permitted to be used, provided that precautions subject to the approval of the authority having jurisdiction are taken.
- (5)* Listed and approved LP-Gas commercial food service appliances shall be permitted to be used where in accordance with NFPA 58, *Liquefied Petroleum Gas Code*.

A.13.7.1.4(5) NFPA 58, *Liquefied Petroleum Gas Code*, permits portable butane-fueled appliances in restaurants and in attended commercial food catering operations where fueled by not in excess of two 0.3-L (10-oz) LP-Gas capacity, nonrefillable butane containers that have a water capacity not exceeding 0.5 kg (1.08 lb) per container. The containers are required to be directly connected to the appliance, and manifolding of containers is not permitted. Storage of cylinders is also limited to 24 containers, with an additional 24 permitted where protected by a 2-hour fire resistance-rated barrier.

The *Code* depends on the automatic extinguishing system mandated by 9.2.3 to control any fire on the cooking surfaces and, thus, 12/13.7.1.3 does not require enclosure by rated construction.

The list of tragic fires in assembly occupancies

CHAPTER 12 • New

caused by “friendly” fire (for example, alcohol or solid alcohol fires in restaurants, flames used for dramatic effects in theaters) is well documented. The

12.7.2 Open Flame Devices and Pyrotechnics.

No open flame devices or pyrotechnic devices shall be used in any assembly occupancy, unless otherwise permitted by the following:

- (1) Pyrotechnic special effect devices shall be permitted to be used on stages before proximate audiences for ceremonial or religious purposes, as part of a demonstration in exhibits, or as part of a performance, provided that both of the following criteria are met:
 - (a) Precautions satisfactory to the authority having jurisdiction are taken to prevent ignition of any combustible material.
 - (b) Use of the pyrotechnic device complies with NFPA 1126, *Standard for the Use of Pyrotechnics before a Proximate Audience*.
- (2) Flame effects before an audience shall be permitted in accordance with NFPA 160, *Standard for Flame Effects Before an Audience*.
- (3) Open flame devices shall be permitted to be used in the following situations, provided that precautions satisfactory to the authority having jurisdiction are taken to prevent ignition of any combustible material or injury to occupants:
 - (a)* For ceremonial or religious purposes

A.12.7.2(3)(a) Securely supported altar candles in churches that are well separated from any combustible material are permitted. On the other hand, lighted candles carried by children wearing cotton robes present a hazard too great to be permitted. There are many other situations of intermediate hazard where the authority having jurisdiction will have to exercise judgment.

- (b) On stages and platforms where part of a performance
- (c) Where candles on tables are securely supported on substantial noncombustible bases and candle flame is protected
- (4) This requirement shall not apply to heat-producing equipment complying with 9.2.2.
- (5) This requirement shall not apply to food service operations in accordance with 12.7.1.

CHAPTER 13 • Existing

requirements of 12/13.7.1.4 and 12/13.7.2 attempt to prevent a fire by tightly controlling the use of open flame devices.

13.7.2 Open Flame Devices and Pyrotechnics.

No open flame devices or pyrotechnic devices shall be used in any assembly occupancy, unless otherwise permitted by the following:

- (1) Pyrotechnic special effect devices shall be permitted to be used on stages before proximate audiences for ceremonial or religious purposes, as part of a demonstration in exhibits, or as part of a performance, provided that both of the following are met:
 - (a) Precautions satisfactory to the authority having jurisdiction are taken to prevent ignition of any combustible material.
 - (b) Use of the pyrotechnic device complies with NFPA 1126, *Standard for the Use of Pyrotechnics before a Proximate Audience*.
- (2) Flame effects before an audience shall be permitted in accordance with NFPA 160, *Standard for Flame Effects Before an Audience*.
- (3) Open flame devices shall be permitted to be used in the following situations, provided that precautions satisfactory to the authority having jurisdiction are taken to prevent ignition of any combustible material or injury to occupants:
 - (a)* For ceremonial or religious purposes

A.13.7.2(3)(a) Securely supported altar candles in churches that are well separated from any combustible material, are permitted. On the other hand, lighted candles carried by children wearing cotton robes present a hazard too great to be permitted. There are many other situations of intermediate hazard where the authority having jurisdiction will have to exercise judgment.

- (b) On stages and platforms where part of a performance
- (c) Where candles on tables are securely supported on substantial noncombustible bases and candle flame is protected
- (4) This requirement shall not apply to heat-producing equipment complying with 9.2.2.
- (5) This requirement shall not apply to food service operations in accordance with 13.7.1.

CHAPTER 12 • New

- (6) Gas lights shall be permitted to be used, provided that precautions are taken, subject to the approval of the authority having jurisdiction, to prevent ignition of any combustible materials.

12.7.3 Furnishings, Decorations, and Scenery.

12.7.3.1 Fabrics and films used for decorative purposes, all draperies and curtains, and similar furnishings shall be in accordance with the provisions of 10.3.1.

12.7.3.2 The authority having jurisdiction shall impose controls on the quantity and arrangement of combustible contents in assembly occupancies to provide an adequate level of safety to life from fire.

12.7.3.3* Exposed foamed plastic materials and unprotected materials containing foamed plastic used for decorative purposes or stage scenery shall have a heat release rate not exceeding 100 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*.

A.12.7.3.3 The term *unprotected materials containing foamed plastic* is meant to include foamed plastic items covered by “thermally thin” combustible fabrics or paint. (See A.10.2.3.4.)

12.7.3.4 The requirement of 12.7.3.3 shall not apply to individual foamed plastic items and items containing foamed plastic where the foamed plastic does not exceed 0.45 kg (1 lb) in weight.

12.7.4 Special Provisions for Exposition Facilities.

12.7.4.1 General. No display or exhibit shall be installed or operated to interfere in any way with access to any required exit or with the visibility of any required exit or required exit sign; nor shall any display block access to fire-fighting equipment.

12.7.4.2 Materials Not On Display. A storage room having an enclosure consisting of a smoke barrier having a fire resistance rating of 1 hour and protected by an automatic extinguishing system shall be provided for combustible materials not on display, including combustible packing crates used to ship exhibitors’ supplies and products.

Exposition facilities have problems that differ from those of theaters, restaurants, or other assembly occupancies. They are generally large, multi-use facili-

CHAPTER 13 • Existing

- (6) Gas lights shall be permitted to be used, provided that precautions are taken, subject to the approval of authority having jurisdiction, to prevent ignition of any combustible materials.

13.7.3 Furnishings, Decorations, and Scenery.

13.7.3.1 Fabrics and films used for decorative purposes, all draperies and curtains, and similar furnishings shall be in accordance with the provisions of 10.3.1.

13.7.3.2 The authority having jurisdiction shall impose controls on the quantity and arrangement of combustible contents in assembly occupancies to provide an adequate level of safety to life from fire.

13.7.3.3* Exposed foamed plastic materials and unprotected materials containing foamed plastic used for decorative purposes or stage scenery shall have a heat release rate not exceeding 100 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*.

A.13.7.3.3 The term *unprotected materials containing foamed plastic* is meant to include foamed plastic items covered by “thermally-thin” combustible fabrics or paint. (See A.10.2.3.4.)

13.7.3.4 The requirement of 13.7.3.3 shall not apply to individual foamed plastic items and items containing foamed plastic where the foamed plastic does not exceed 0.45 kg (1 lb) in weight.

13.7.4 Special Provisions for Exposition Facilities.

13.7.4.1 General. No display or exhibit shall be installed or operated to interfere in any way with access to any required exit or with the visibility of any required exit or required exit sign; nor shall any display block access to fire-fighting equipment.

13.7.4.2 Materials Not on Display. A storage room having an enclosure consisting of a smoke barrier having a fire resistance rating of 1 hour and protected by an automatic extinguishing system shall be provided for combustible materials not on display, including combustible packing crates used to ship exhibitors’ supplies and products.

ties with high ceilings appropriate to their size. Combustible materials are frequently displayed, and the containers in which the exhibits are shipped con-

CHAPTER 12 • New

tribute to the fuel load. Due to the size of exhibition halls, most are required by 12/13.1.6 and 12/13.3.5.1 to be protected by automatic sprinklers.

The authority having jurisdiction at the local level is often working with organizations that exhibit on a national basis and that are unaware of the local fire safety regulations. It is the intent that this *Code* provide the more consistent and universal treatment needed in these occupancies and at the same time encourage more uniform enforcement practices.

Prior to the inclusion of 12/13.7.4, the trade show and exposition hall regulations used by many jurisdictions were very similar; however, there was no nationally recognized model code that could be referenced. This lack of a model code presented a hardship as well as confusion between the local AHJ and persons responsible for the various functions of the trade show or exposition.

To meet the intent of 12/13.7.4.1, it is advisable to have prepared plans or diagrams to show the arrangement of displays or exhibits, including any that are to be suspended from the ceiling or housed within an overhead structure. Displays or exhibits must not interfere with access to any required exit, and they must not conceal exit signs. See Exhibit 12/13.36. A display should not block access to fire-fighting equipment or interfere with the normal operation of automatic extinguishing equipment or devices for smoke evacuation.

Aisles serving rows of booths are exit accesses;

CHAPTER 13 • Existing

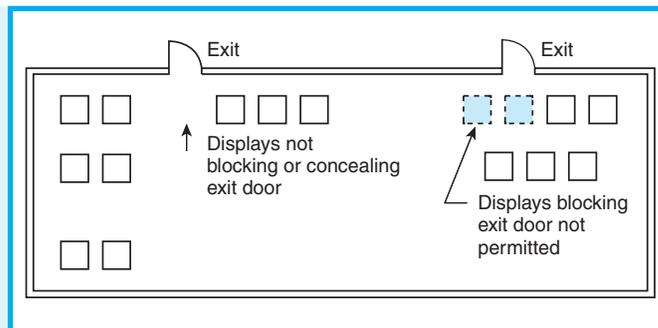

Exhibit 12/13.36 Arrangement of displays in an exhibition hall.

therefore, booths and other temporary construction should be of minimal combustible construction or should be protected to avoid undue hazard of fire that might endanger occupants before they can reach available exits.

Displays or exhibits of combustible material must be limited in quantity to reduce the fuel load to an acceptable level. In accordance with 12/13.7.4.2, excess combustible display material and all other combustible materials that are not in use should be kept in a separate storage room until needed. A separation with a fire resistance rating of 1 hour is required between such a storage room and all other parts of the building, and the room must be protected by an automatic sprinkler system.

12.7.4.3 Exhibits.

12.7.4.3.1 Exhibits shall comply with 12.7.4.3.2 through 12.7.4.3.11.

12.7.4.3.2 The travel distance within the exhibit booth or exhibit enclosure to an exit access aisle shall not exceed 15 m (50 ft).

12.7.4.3.3 The upper deck of multilevel exhibits exceeding 28 m² (300 ft²) shall have not less than two remote means of egress.

12.7.4.3.4 Exhibit booths shall be constructed of the following:

- (1) Noncombustible or limited-combustible materials
- (2) Wood exceeding 6.3 mm (1/4 in.) nominal thickness or wood not exceeding 6.3 mm (1/4 in.) nominal thickness

13.7.4.3 Exhibits.

13.7.4.3.1 Exhibits shall comply with 13.7.4.3.2 through 13.7.4.3.11.

13.7.4.3.2 The travel distance within the exhibit booth or exhibit enclosure to an exit access aisle shall not exceed 15 m (50 ft).

13.7.4.3.3 The upper deck of multilevel exhibits greater than 28 m² (300 ft²) shall have not less than two remote means of egress.

13.7.4.3.4 Exhibit booths shall be constructed of the following:

- (1) Noncombustible or limited-combustible materials
- (2) Wood exceeding 6.3 mm (1/4 in.) nominal thickness or wood not exceeding 6.3 mm (1/4 in.) nominal thickness

CHAPTER 12 • New

that is pressure-treated, fire-retardant wood meeting the requirements of NFPA 703, *Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*

- (3)* Flame-retardant materials complying with NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*

A.12.7.4.3.4(3) The authority having jurisdiction might use the field flame test contained in NFPA 705, *Recommended Practice for a Field Flame Test for Textiles and Films*, as one method of determining flame retardancy.

- (4) Textile wall coverings, such as carpeting and similar products used as wall or ceiling finishes, complying with the provisions of 10.2.2 and 10.2.4
- (5) Plastics limited to those that comply with 12.3.3 and Section 10.2
- (6) Foamed plastics and materials containing foamed plastics having a heat release rate for any single fuel package that does not exceed 100 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*
- (7) Cardboard, honeycombed paper, and other combustible materials having a heat release rate for any single fuel package that does not exceed 150 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*

12.7.4.3.5 Curtains, drapes, and decorations shall comply with the applicable portions of 10.3.1.

12.7.4.3.6 Acoustical and decorative material including, but not limited to, cotton, hay, paper, straw, moss, split bamboo, and wood chips shall be flame-retardant treated to the satisfaction of the authority having jurisdiction.

12.7.4.3.6.1 Materials that cannot be treated for flame retardancy shall not be used.

12.7.4.3.6.2 Foamed plastics and materials containing foamed plastics and used as decorative objects such as, but not limited to, mannequins, murals, and signs shall have a heat release rate for any single fuel package that does not exceed 150 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*.

12.7.4.3.6.3 Where the aggregate area of acoustical and decorative materials is less than 10 percent of the individual floor or wall area, such materials shall be permitted to be used subject to the approval of the authority having jurisdiction.

CHAPTER 13 • Existing

that is pressure-treated, fire-retardant wood meeting the requirements of NFPA 703, *Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*

- (3)* Flame-retardant materials complying with NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*

A.13.7.4.3.4(3) The authority having jurisdiction might use the field flame test contained in NFPA 705, *Recommended Practice for a Field Flame Test for Textiles and Films*, as one method of determining flame retardancy.

- (4) Textile wall coverings, such as carpeting and similar products used as wall or ceiling finishes, complying with the provisions of 10.2.2 and 10.2.4
- (5) Plastics limited to those that comply with 13.3.3 and Section 10.2
- (6) Foamed plastics and materials containing foamed plastics having a heat release rate for any single fuel package that does not exceed 100 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*
- (7) Cardboard, honeycombed paper, and other combustible materials having a heat release rate for any single fuel package that does not exceed 150 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*

13.7.4.3.5 Curtains, drapes, and decorations shall comply with the applicable portions of 10.3.1.

13.7.4.3.6 Acoustical and decorative material including, but not limited to, cotton, hay, paper, straw, moss, split bamboo, and wood chips shall be flame-retardant treated to the satisfaction of the authority having jurisdiction.

13.7.4.3.6.1 Materials that cannot be treated for flame retardancy shall not be used.

13.7.4.3.6.2 Foamed plastics and materials containing foamed plastics and used as decorative objects such as, but not limited to, mannequins, murals, and signs shall have a heat release rate for any single fuel package that does not exceed 150 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*.

13.7.4.3.6.3 Where the aggregate area of acoustical and decorative materials is less than 10 percent of the individual floor or wall area, such materials shall be permitted to be used subject to the approval of the authority having jurisdiction.

CHAPTER 12 • New

12.7.4.3.7 The following shall be protected by automatic extinguishing systems:

- (1) Single-level exhibit booths exceeding 28 m² (300 ft²) and covered with a ceiling
- (2) Each level of multilevel exhibit booths, including the uppermost level where the uppermost level is covered with a ceiling

12.7.4.3.7.1 The requirements of 12.7.4.3.7 shall not apply where otherwise permitted by the following:

- (1) Ceilings that are constructed of open grate design or listed dropout ceilings in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not be considered ceilings within the context of 12.7.4.3.7.
- (2) Vehicles, boats, and similar exhibited products having over 9.3 m² (100 ft²) of roofed area shall be provided with smoke detectors acceptable to the authority having jurisdiction.
- (3)* The requirement of 12.7.4.3.7(2) shall not apply where fire protection of multilevel exhibit booths is consistent with the criteria developed through a life safety evaluation of the exhibition hall in accordance with 12.4.1, subject to approval of the authority having jurisdiction.

A.12.7.4.3.7.1(3) See A.12.4.1.1.

12.7.4.3.7.2 A single exhibit or group of exhibits with ceilings that do not require sprinklers shall be separated by a distance of not less than 3050 mm (120 in.) where the aggregate ceiling exceeds 28 m² (300 ft²).

12.7.4.3.7.3 The water supply and piping for the sprinkler system shall be permitted to be of an approved, temporary means that is provided by a domestic water supply, a stand-pipe system, or a sprinkler system.

The requirement of 12/13.7.4.3.2 applies to a standard exhibit booth arrangement, whether constructed of pipe supports and cloth or paper drapes, or whether it is a large exhibit enclosure designed and built from other materials, which could include small booths, open displays, large board displays, or other arrangements. This requirement also includes exhibit enclosures that are created by the arrangement of products such as machinery or vehicles. The intent is that travel distance is not to be more than 15 m (50 ft) for occupants who are inside the enclosure, whether they are

CHAPTER 13 • Existing

13.7.4.3.7 The following shall be protected by automatic extinguishing systems:

- (1) Single-level exhibit booths exceeding 28 m² (300 ft²) and covered with a ceiling
- (2) Each level of multilevel exhibit booths, protected throughout, including the uppermost level where the uppermost level is covered with a ceiling

13.7.4.3.7.1 The requirements of 13.7.4.3.7 shall not apply where otherwise permitted by the following:

- (1) Ceilings of open grate design or listed dropout ceilings in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not be considered ceilings within the context of 13.7.4.3.7.
- (2) Vehicles, boats, and similar exhibited products having over 9.3 m² (100 ft²) of roofed area shall be provided with smoke detectors acceptable to the authority having jurisdiction.
- (3)* The requirement of 13.7.4.3.7(2) shall not apply where fire protection of multilevel exhibit booths is consistent with the criteria developed through a life safety evaluation of the exhibition hall in accordance with 13.4.1, subject to approval of the authority having jurisdiction.

A.13.7.4.3.7.1(3) See A.13.4.1.1.

13.7.4.3.7.2 A single exhibit or group of exhibits with ceilings that do not require sprinklers shall be separated by a distance not less than 3050 mm (120 in.) where the aggregate ceiling exceeds 28 m² (300 ft²).

13.7.4.3.7.3 The water supply and piping for the sprinkler system shall be permitted to be of approved, temporary means that is provided by a domestic water supply, a stand-pipe system, or a sprinkler system.

employees or patrons. Note that this is not travel distance to an exit, but only to an aisle.

The requirement of 12/13.7.4.3.3 ensures that larger exhibits with a second level will provide at least two means of egress to prevent entrapping occupants on the upper level.

Paragraph 12/13.7.4.3.4 is intended to provide direction to manufacturers of exhibit booths as well as decorators, exhibitors, and authorities having jurisdiction. This paragraph focuses on the construction components of the ceilings, walls, and floors of an

CHAPTER 12 • New

exhibit booth or display area in addition to the finish treatment. The intent is to regulate the materials used for large signs and display boards; small signs [approximately 610 mm × 915 mm (24 in. × 36 in.) or smaller] would not normally be considered part of the wall covering. Paragraph 12/13.7.4.3.4 does not apply to the goods or products that are being displayed.

Plastics are limited to Class A and Class B for wall and ceiling finishes. The intent of 12/13.7.4.3.4(6) is to prohibit the use of foamed plastics because of their inherent burning characteristics, unless they have been tested for heat-release rate in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastic Used for Decorative Purposes*¹², and meet the maximum 100-kW threshold. Foamed plastics are used in sign construction and display boards, and, in some cases, the entire booth is constructed of foamed plastics.

Large booths and multistory booths pose special life safety problems in exhibit halls. A fire in these booths could grow to proportions large enough to have a significant negative impact on the performance of the building's sprinkler system. The intent of 12/13.7.4.3.7 is to provide sprinkler protection in these booths by means of a temporary tap into the

12.7.4.3.8 Open flame devices within exhibit booths shall comply with 12.7.2.

12.7.4.3.9 Cooking and food-warming devices in exhibit booths shall comply with 12.7.1 and the following:

- (1) Gas-fired devices shall comply with the following:
 - (a) Natural gas-fired devices shall comply with 9.1.1.
 - (b) The requirement of 12.7.4.3.9(1)(a) shall not apply to compressed natural gas where permitted by the authority having jurisdiction.
 - (c) The use of LP-Gas cylinders shall be prohibited.
 - (d) Nonrefillable LP-Gas cylinders shall be approved for use where permitted by the authority having jurisdiction.
- (2) The devices shall be isolated from the public by not less than 1220 mm (48 in.) or by a barrier between the devices and the public.
- (3) Multi-well cooking equipment using combustible oils or solids shall comply with 9.2.3.
- (4) Single-well cooking equipment using combustible oils or solids shall meet the following criteria:
 - (a) They shall have lids available for immediate use.

CHAPTER 13 • Existing

existing sprinkler system. Sprinklers should provide the protection necessary to extinguish a fire in its incipient stage, thus reducing the life hazard to occupants.

Paragraph 12/13.7.4.3.7.1(1) is not really an exemption to 12/13.7.4.3.7, because the exemption of sprinklers below dropout ceilings is already permitted by the reference document, NFPA 13, *Standard for the Installation of Sprinkler Systems*.¹³ The exemption was added to emphasize that it is not the intent to prohibit this provision of the sprinkler installation standard from being applied.

Paragraph 12/13.7.4.3.7.1(2) exempts large vehicles (that is, boats, mobile homes, and recreational vehicles) from the sprinkler requirement but requires a smoke detector if the vehicle is larger than 9.3 m² (100 ft²) to provide early warning in the immediate area to allow for orderly evacuation. This provision could most probably be met by single-station, battery-operated smoke alarms.

Paragraph 12/13.7.4.3.7.1(3) allows exposition hall operators to work with the authority having jurisdiction to devise alternate methods of compliance via the life safety evaluation of 12/13.4.1.

13.7.4.3.8 Open flame devices within exhibit booths shall comply with 13.7.2.

13.7.4.3.9 Cooking and food-warming devices in exhibit booths shall comply with 13.7.1 and the following:

- (1) Gas-fired devices shall comply with the following:
 - (a) Natural gas-fired devices shall comply with 9.1.1.
 - (b) The requirement of 13.7.4.3.9(1)(a) shall not apply to compressed natural gas where permitted by the authority having jurisdiction.
 - (c) The use of LP-Gas cylinders shall be prohibited.
 - (d) Nonrefillable LP-Gas cylinders shall be permitted for use where approved by the authority having jurisdiction.
- (2) The devices shall be isolated from the public by not less than 1220 mm (48 in.) or by a barrier between the devices and the public.
- (3) Multi-well cooking equipment using combustible oils or solids shall comply with 9.2.3.
- (4) Single-well cooking equipment using combustible oils or solids shall meet the following criteria:
 - (a) They shall have lids available for immediate use.

CHAPTER 12 • New

- (b) They shall be limited to 0.2 m² (288 in.²) of cooking surface.
 - (c) They shall be placed on noncombustible surface materials.
 - (d) They shall be separated from each other by a horizontal distance of not less than 610 mm (24 in.).
 - (e) The requirement of 12.7.4.3.9(4)(d) shall not apply to multiple single-well cooking equipment where the aggregate cooking surface area does not exceed 0.2 m² (288 in.²).
 - (f) They shall be kept at a horizontal distance of not less than 610 mm (24 in.) from any combustible material.
- (5) A portable fire extinguisher in accordance with 9.7.4.1 shall be provided within the booth for each device, or an approved automatic extinguishing system shall be provided.

12.7.4.3.10 Combustible materials within exhibit booths shall be limited to a one-day supply. Storage of combustible materials behind the booth shall be prohibited. (See 12.7.3.2 and 12.7.4.2.)

12.7.4.3.11 Plans for the exposition, in an acceptable form, shall be submitted to the authority having jurisdiction for approval prior to setting up any exhibit.

12.7.4.3.11.1 The plan shall show all details of the proposed exposition.

12.7.4.3.11.2 No exposition shall occupy any exposition facility without approved plans.

Open flame devices, as noted in 12/13.7.4.3.8, need to comply with the provisions of 12/13.7.2. Any use of open flames requires the approval of the authority having jurisdiction.

The provisions of 12/13.7.4.3.9(2) require separation distance or a barrier between the public and the device. The purpose is to guard against the dangers of accidental spills of hot greases or foods and to minimize the potential for ignition of combustibles, especially clothing worn by patrons.

Paragraph 12/13.7.4.3.9(3) requires that multivolt cooking equipment comply with NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*¹⁴.

The intent of requiring the lid in 12/13.7.4.3.9(4)(a) is to provide the operator with a ready method of smothering the fire.

CHAPTER 13 • Existing

- (b) They shall be limited to 0.2 m² (288 in.²) of cooking surface.
 - (c) They shall be placed on noncombustible surface materials.
 - (d) They shall be separated from each other by a horizontal distance of not less than 610 mm (24 in.).
 - (e) The requirement of 13.7.4.3.9(4)(d) shall not apply to multiple single-well cooking equipment where the aggregate cooking surface area does not exceed 0.2 m² (288 in.²).
 - (f) They shall be kept at a horizontal distance of not less than 610 mm (24 in.) from any combustible material.
- (5) A portable fire extinguisher in accordance with 9.7.4.1 shall be provided within the booth for each device, or an approved automatic extinguishing system shall be provided.

13.7.4.3.10 Combustible materials within exhibit booths shall be limited to a one-day supply. Storage of combustible materials behind the booth shall be prohibited. (See 13.7.3.2 and 13.7.4.2.)

13.7.4.3.11 Plans for the exposition, in an acceptable form, shall be submitted to the authority having jurisdiction for approval prior to setting up any exhibit.

13.7.4.3.11.1 The plan shall show all details of the proposed exposition.

13.7.4.3.11.2 No exposition shall occupy any exposition facility without approved plans.

The provisions of 12/13.7.4.3.9(4)(c) are important because the bottom surface of many devices could be subject to heating to temperatures that could ignite combustible surfaces.

The minimum separation distances in 12/13.7.4.3.9(4)(d) are necessary to minimize the danger of a fire in one device extending into another device; the same principle applies to 12/13.7.4.3.9(4)(f), except that the exposure of concern is to combustible decorations or other products as opposed to another cooking device.

Paragraph 12/13.7.4.3.9(5) requires a portable extinguisher for each cooking device. The intent is to provide an extinguisher near each cooking device so the operator is able to access the extinguisher readily if a lid does not extinguish the fire or cannot be applied. It is not the intent to permit all extinguishers

CHAPTER 12 • New

to be located in one place. The reference to 9.7.4.1 leads the user to NFPA 10, *Standard for Portable Fire Extinguishers*¹⁵, which provides the necessary information with regard to type and size of the appropriate extinguisher.

The provisions of 12/13.7.4.3.9 recognize the inherent dangers in cooking and warming devices that are used in an exhibit hall subject to large, transient crowds.

Paragraph 12/13.7.4.3.10 limits the amount of literature, brochures, boxes, give-aways, and other products that are kept in the exhibit booth. The number of items necessary to constitute a one-day supply obviously varies. However, the authority having jurisdiction should be able to make a judgment after reviewing the activity anticipated by the exhibitor. Additional supplies and combustible crates (such as

12.7.4.4 Vehicles. Vehicles on display within an exposition facility shall comply with 12.7.4.4.1 through 12.7.4.4.5.

12.7.4.4.1 All fuel tank openings shall be locked and sealed in an approved manner to prevent the escape of vapors; fuel tanks shall not contain in excess of one-half their capacity or contain in excess of 38 L (10 gal) of fuel, whichever is less.

12.7.4.4.2 At least one battery cable shall be removed from the batteries used to start the vehicle engine, and the disconnected battery cable shall then be taped.

12.7.4.4.3 Batteries used to power auxiliary equipment shall be permitted to be kept in service.

12.7.4.4.4 Fueling or defueling of vehicles shall be prohibited.

12.7.4.4.5 Vehicles shall not be moved during exhibit hours.

Paragraph 12/13.7.4.4 on vehicles is intended to minimize the danger from both fuel and ignition sources.

In accordance with 12/13.7.4.4.1, it is important that fuel tank openings be locked to prevent tampering and accessibility to fuel. It is also important that the tank openings be taped to prevent the escape of flammable vapors. When these *Code* requirements were written, the issue of the quantity of fuel that is allowed in a tank was studied. Some jurisdictions preferred empty tanks to eliminate fuel, while others preferred full tanks to prevent vapors. It was deter-

CHAPTER 13 • Existing

those used for shipping) should be kept in a separate storage area having a fire resistance rating of 1 hour and protected by an automatic sprinkler system, as required by 12/13.7.4.2.

The intent of 12/13.7.4.3.11 is to provide the authority having jurisdiction with a set of plans that shows aisle widths, travel distances, exits, booth locations, display area configurations, types of displays (for example, cooking, machinery, drapery, arts and crafts), location of fire protection equipment (extinguishers, manual fire alarm boxes, hose cabinets), and lobby and registration area usage. This list is not complete, but it provides some guidance in determining the plans that should be submitted. The plan should also be drawn to scale. The scale used is not usually critical provided that it is indicated on the plan.

13.7.4.4 Vehicles. Vehicles on display within an exposition facility shall comply with 13.7.4.4.1 through 13.7.4.4.5.

13.7.4.4.1 All fuel tank openings shall be locked and sealed in an approved manner to prevent the escape of vapors; fuel tanks shall not contain in excess of one-half their capacity or contain in excess of 38 L (10 gal) of fuel, whichever is less.

13.7.4.4.2 At least one battery cable shall be removed from the batteries used to start the vehicle engine, and the disconnected battery cable shall then be taped.

13.7.4.4.3 Batteries used to power auxiliary equipment shall be permitted to be kept in service.

13.7.4.4.4 Fueling or defueling of vehicles shall be prohibited.

13.7.4.4.5 Vehicles shall not be moved during exhibit hours.

mined that most exhibitors were unaware of the local regulation until they arrived at the exhibit hall. After learning the specific rule (empty or full), exhibitors proceeded to make their adjustment in the adjacent parking area or some other unsuitable area. It is also difficult for the authority having jurisdiction to determine whether a tank is absolutely full or empty. Fueling and defueling by exhibitors outside the hall presented a greater danger than the level of fuel in the tanks, given that the tanks are locked and sealed and ignition sources are eliminated from the vehicle.

CHAPTER 12 • New

However, to avoid excessive quantities of fuel in the exhibition hall, the *Code* does limit the quantity of fuel in tanks.

In accordance with 12/13.7.4.4.2, it is important that at least one of the battery cables be removed from each battery. Many vehicles have more than one battery. The intent is to eliminate the possibility of a spark from the battery that might ignite fuel or surrounding combustibles. Battery cable connectors should be thoroughly taped after they have been removed.

The provision of 12/13.7.4.4.3 allows batteries that

12.7.4.5 Prohibited Materials.

12.7.4.5.1 The following items shall be prohibited within exhibit halls:

- (1) Compressed flammable gases
- (2) Flammable or combustible liquids
- (3) Hazardous chemicals or materials
- (4) Class II or greater lasers, blasting agents, and explosives

12.7.4.5.2 The authority having jurisdiction shall be permitted to allow the limited use of any items specified in 12.7.4.5.1 under special circumstances.

12.7.4.6 Alternatives. See Section 1.4.

Compressed gas containers, as addressed by 12/13.7.4.5.1, are subject to fire damage that could cause an explosion or create a serious threat to life safety. Flammable and combustible liquids compromise life safety by their inherent capability to contribute to rapid fire spread. Hazardous materials present a variety of hazards to life safety, from their flammability to their toxicity. Class II or greater lasers can cause tissue damage to humans, and blasting agents and explosives can cause a large loss of life or injury if handled improperly.

Exhibitors who wish to display explosives or pes-

12.7.5* Crowd Managers.

A.12.7.5 The training program in crowd management should develop a clear appreciation of factors of space, energy, time, and information, as well as specific crowd management techniques such as metering. Published guidelines on these factors and techniques are found in the *SFPE*

CHAPTER 13 • Existing

cannot be used to start the vehicle to remain in service. These batteries present no more of an ignition hazard than does providing house electrical power to the item on display.

Vehicle movement is addressed in 12/13.7.4.4.5. The movement of vehicles inside the exhibit hall potentially compromises the means of egress by blocking the exit access; vehicles should, therefore, be positioned before the hall is opened to the public. There is also a concern regarding the effects of carbon monoxide inside an exhibit hall that is occupied.

13.7.4.5 Prohibited Materials.

13.7.4.5.1 The following items shall be prohibited within exhibit halls:

- (1) Compressed flammable gases
- (2) Flammable or combustible liquids
- (3) Hazardous chemicals or materials
- (4) Class II or greater lasers, blasting agents, and explosives

13.7.4.5.2 The authority having jurisdiction shall be permitted to allow the limited use of any items specified in 13.7.4.5.1 under special circumstances.

13.7.4.6 Alternatives. See Section 1.4.

ticides or a type of compressed gas container, among other items, can effectively do so without bringing the actual product into the hall, by using empty containers instead.

Paragraph 12/13.7.4.5.2 gives the AHJ the discretion to permit small amounts of otherwise prohibited materials under special circumstances. For example, an exhibit or trade show for collectors of small arms ammunition or a highly supervised and closed (to the public) vocational trade show using such materials is permitted where special controls and professional supervision are provided.

13.7.5* Crowd Managers.

A.13.7.5 The training program in crowd management should develop a clear appreciation of factors of space, energy, time, and information, as well as specific crowd management techniques such as metering. Published guidelines on these factors and techniques are found in the *SFPE*

CHAPTER 12 • New

Handbook of Fire Protection Engineering, Section 3, Chapter 13.

12.7.5.1 In assembly occupancies having occupant loads exceeding 1000, trained crowd managers or crowd manager supervisors shall be provided at a ratio of 1 crowd manager/supervisor for every 250 occupants, unless otherwise permitted by the following:

- (1) This requirement shall not apply to assembly occupancies used exclusively for religious worship with an occupant load not exceeding 2000.
- (2) The ratio of trained crowd managers to occupants shall be permitted to be reduced where, in the opinion of the authority having jurisdiction, the existence of an approved, supervised automatic sprinkler system and the nature of the event warrant.

CHAPTER 13 • Existing

Handbook of Fire Protection Engineering, Section 3, Chapter 13.

13.7.5.1 In assembly occupancies having occupant loads exceeding 1000, trained crowd managers or crowd manager supervisors shall be provided at a ratio of 1 crowd manager/supervisor for every 250 occupants, unless otherwise permitted by the following:

- (1) This requirement shall not apply to assembly occupancies used exclusively for religious worship with an occupant load not exceeding 2000.
- (2) The ratio of trained crowd managers to occupants shall be permitted to be reduced where, in the opinion of the authority having jurisdiction, the existence of an approved, supervised automatic sprinkler system and the nature of the event warrant.

Tentative Interim Amendment

NFPA 101® *Life Safety Code*® 2003 Edition

Reference: 12.7.5 and 13.7.5
TIA 03-2 (NFPA 101)
(SC 03-7-16/Log No. 738)

Pursuant to Section 5 of the NFPA Regulations Governing Committee Projects, the National Fire Protection Association has issued the following Tentative Interim Amendment to NFPA 101®, *Life Safety Code*®, 2003 edition. The TIA was processed by the Safety to Life Committee, and was issued by the Standards Council on July 25, 2003, with an effective date of August 14, 2003.

A Tentative Interim Amendment is tentative because it has not been processed through the entire standards-making procedures. It is interim because it is effective only between editions of the standard. A TIA automatically becomes a proposal of the proponent for the next edition of the standard; as such, it then is subject to all of the procedures of the standards-making process.

Revise 12.7.5 and 13.7.5 to lower the threshold for crowd managers in assembly occupancies as follows:

12.7.5* Crowd Managers.

12.7.5.1 ~~In assembly occupancies having occupant loads exceeding 1000,~~ shall be provided with a minimum of one trained crowd manager or crowd manager supervisor. Where the occupant load exceeds 250, additional trained crowd managers or crowd manager supervisors shall be provided at a ratio of 1 crowd manager/supervisor for every 250 occupants unless otherwise permitted by the following:

- (1) This requirement shall not apply to assembly occupancies used exclusively for religious worship with an occupant load not exceeding 2000.
- (2) The ratio of trained crowd managers to occupants shall be permitted to be reduced where, in the opinion of the authority having jurisdiction, the existence of an approved, supervised automatic sprinkler system and the nature of the event warrant.

12.7.5.2 The crowd manager shall receive approved training in crowd management techniques.

13.7.5* Crowd Managers.

13.7.5.1 ~~In assembly~~ Assembly occupancies ~~having occupant loads exceeding 1000~~, shall be provided with a minimum of one trained crowd manager or crowd manager supervisor. Where the occupant load exceeds 250, additional trained crowd managers or crowd manager supervisors shall be provided at a ratio of 1 crowd manager/supervisor for every 250 occupants unless otherwise permitted by the following:

- (1) This requirement shall not apply to assembly occupancies used exclusively for religious worship with an occupant load not exceeding 2000.
- (2) The ratio of trained crowd managers to occupants shall be permitted to be reduced where, in the opinion of the authority having jurisdiction, the existence of an approved, supervised automatic sprinkler system and the nature of the event warrant.

13.7.5.2 The crowd manager shall receive approved training in crowd management techniques.

NATIONAL FIRE PROTECTION ASSOCIATION

12.7.5.2 The crowd manager shall receive approved training in crowd management techniques.

13.7.5.2 The crowd manager shall receive approved training in crowd management techniques.

The material in Section 3, Chapter 13, of the third edition of the *SFPE Handbook of Fire Protection Engineering*¹⁶, which is referenced in A.12/13.7.5, makes a distinction between the required crowd management and the more extreme, but nonmandatory, crowd control. Crowd management meshes the design fea-

tures of a facility, the established operating features of that facility, and an understanding of the occupants' expected natural behavior in that facility for a specific type of event. Crowd control, on the other hand, is often necessitated when crowd management fails.

12.7.6* Drills.

A.12.7.6 It is important that an adequate number of competent attendants are on duty at all times when the assembly occupancy is occupied.

12.7.6.1 The employees or attendants of assembly occupancies shall be trained and drilled in the duties they are to perform in case of fire, panic, or other emergency to effect orderly exiting.

12.7.6.2 Employees or attendants of assembly occupancies shall be instructed in the proper use of portable fire extinguishers and other manual fire suppression equipment where provided.

12.7.6.3* In the following assembly occupancies, an audible announcement shall be made, or a projected image shall be shown, prior to the start of each program that notifies occupants of the location of the exits to be used in case of a fire or other emergency:

- (1) Theaters
- (2) Motion picture theaters

13.7.6* Drills.

A.13.7.6 It is important that an adequate number of competent attendants are on duty at all times when the assembly occupancy is occupied.

13.7.6.1 The employees or attendants of assembly occupancies shall be trained and drilled in the duties they are to perform in case of fire, panic, or other emergency to effect orderly exiting.

13.7.6.2 Employees or attendants of assembly occupancies shall be instructed in the proper use of portable fire extinguishers and other manual fire suppression equipment where provided.

13.7.6.3* In the following assembly occupancies, an audible announcement shall be made, or a projected image shall be shown, prior to the start of each program that notifies occupants of the location of the exits to be used in case of a fire or other emergency:

- (1) Theaters
- (2) Motion picture theaters

CHAPTER 12 • New

- (3) Auditoriums
- (4) Other similar assembly occupancies with occupant loads exceeding 300 where there are noncontinuous programs

A.12.7.6.3 It is not the intent of this provision to require an announcement in bowling alleys, cocktail lounges, restaurants, or places of worship.

12.7.6.4 The requirement of 12.7.6.3 shall not apply to assembly occupancies in schools where used for nonpublic events.

The provisions of 12/13.7.6.2 do not require fire extinguishers for life safety in an assembly occupancy. It does specify, however, that if fire extinguishers are provided, the staff must be trained in their use to prevent a false sense of security and possible injury. The extent of this training, whether instruction only, or instruction and hands-on use, is determined by the authority having jurisdiction.

The relatively simple requirement of 12/13.7.6.3 for notifying occupants of the location of exits can make a significant difference during an emergency.

12.7.7 Smoking.

12.7.7.1 Smoking in assembly occupancies shall be regulated by the authority having jurisdiction.

12.7.7.2 In rooms or areas where smoking is prohibited, plainly visible signs shall be posted that read as follows:

NO SMOKING

12.7.7.3 No person shall smoke in prohibited areas that are so posted, unless permitted by the authority having jurisdiction under both of the following conditions:

- (1) Smoking shall be permitted on a stage only where it is a necessary and rehearsed part of a performance
- (2) Smoking shall be permitted only where the smoker is a regular performing member of the cast.

12.7.7.4 Where smoking is permitted, suitable ashtrays or receptacles shall be provided in convenient locations.

12.7.8 Seating.

12.7.8.1 Secured Seating.

12.7.8.1.1 Seats in assembly occupancies accommodating more than 200 persons shall be securely fastened to the floor, except where fastened together in groups of not less

CHAPTER 13 • Existing

- (3) Auditoriums
- (4) Other similar assembly occupancies with occupant loads exceeding 300 where there are noncontinuous programs

A.13.7.6.3 It is not the intent of this provision to require an announcement in bowling alleys, cocktail lounges, restaurants, or places of worship.

13.7.6.4 The requirement of 13.7.6.3 shall not apply to assembly occupancies in schools where used for nonpublic events.

Note that the requirement does not apply to assembly occupancies where the flow of people is constantly changing, such as in a restaurant. Movie theaters commonly meet the provisions of 12/13.7.6.3 through means of sound and screen projection that are presented prior to the main feature, during the same period that notifications of restroom, trash container, and snack bar locations are made and previews are shown. The same complete message is thereby delivered to each audience without the need for human intervention.

13.7.7 Smoking.

13.7.7.1 Smoking in assembly occupancies shall be regulated by the authority having jurisdiction.

13.7.7.2 In rooms or areas where smoking is prohibited, plainly visible signs shall be posted that read as follows:

NO SMOKING

13.7.7.3 No person shall smoke in prohibited areas that are so posted, unless permitted by the authority having jurisdiction under both of the following conditions:

- (1) Smoking shall be permitted on a stage only where it is a necessary and rehearsed part of a performance
- (2) Smoking shall be permitted only where the smoker is a regular performing member of the cast

13.7.7.4 Where smoking is permitted, suitable ashtrays or receptacles shall be provided in convenient locations.

13.7.8 Seating.

13.7.8.1 Secured Seating.

13.7.8.1.1 Seats in assembly occupancies accommodating more than 200 persons shall be securely fastened to the floor, except where fastened together in groups of not less

CHAPTER 12 • New

than three and not exceeding seven and as permitted by 12.7.8.2.

12.7.8.1.2 All seats in balconies and galleries shall be securely fastened to the floor, except in places of religious worship.

12.7.8.2 Unsecured Seating.

12.7.8.2.1 Seats not secured to the floor shall be permitted in restaurants, night clubs, and other occupancies where fastening seats to the floor might be impracticable.

12.7.8.2.2 Unsecured seats shall be permitted, provided that, in the area used for seating, excluding such areas as dance floors and stages, there is not more than one seat for each 1.4 m² (15 ft²) of net floor area, and adequate aisles to reach exits are maintained at all times.

12.7.8.2.3 Seating diagrams shall be submitted for approval by the authority having jurisdiction to permit an increase in occupant load per 7.3.1.3.

The function of 12/13.7.8.2 is to prevent the movement of seats so that aisles, rows, and access to the exits do not become blocked in an assembly occupancy

12.7.8.3 Occupant Load Posting.

12.7.8.3.1 Every room constituting an assembly occupancy and not having fixed seats shall have the occupant load of the room posted in a conspicuous place near the main exit from the room.

12.7.8.3.2 Approved signs shall be maintained in a legible manner by the owner or authorized agent.

12.7.8.3.3 Signs shall be durable and shall indicate the number of occupants permitted for each room use.

12.7.9 Maintenance of Outdoor Grandstands.

12.7.9.1 The owner shall provide for not less than annual inspection and required maintenance of each outdoor grandstand to ensure safe conditions.

12.7.9.2 At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer.

12.7.9.3 Where required by the authority having jurisdiction, the owner shall provide certification that such inspection has been performed.

CHAPTER 13 • Existing

than three and not exceeding seven and as permitted by 13.7.8.2.

13.7.8.1.2 All seats in balconies and galleries shall be securely fastened to the floor, except in places of religious worship.

13.7.8.2 Unsecured Seating.

13.7.8.2.1 Seats not secured to the floor shall be permitted in restaurants, night clubs, and other occupancies where fastening seats to the floor might be impracticable.

13.7.8.2.2 Unsecured seats shall be permitted, provided that, in the area used for seating, excluding such areas of dance floors and stages, there is not more than one seat for each 1.4 m² (15 ft²) of net floor area, and adequate aisles to reach exits are maintained at all times.

13.7.8.2.3 Seating diagrams shall be submitted for approval by the authority having jurisdiction to permit an increase in occupant load per 7.3.1.3.

during the jostling that occurs when people flee from a fire.

13.7.8.3 Occupant Load Posting.

13.7.8.3.1 Every room constituting an assembly occupancy and not having fixed seats shall have the occupant load of the room posted in a conspicuous place near the main exit from the room.

13.7.8.3.2 Approved signs shall be maintained in a legible manner by the owner or authorized agent.

13.7.8.3.3 Signs shall be durable and shall indicate the number of occupants permitted for each room use.

13.7.9 Maintenance of Outdoor Grandstands.

13.7.9.1 The owner shall provide for not less than annual inspection and required maintenance of each outdoor grandstand to ensure safe conditions.

13.7.9.2 At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer.

13.7.9.3 Where required by the authority having jurisdiction, the owner shall provide certification that such inspection has been performed.

CHAPTER 12 • New

12.7.10 Maintenance and Operation of Folding and Telescopic Seating.

12.7.10.1 Instructions in both maintenance and operation shall be transmitted to the owner by the manufacturer of the seating or his or her representative.

12.7.10.2 Maintenance and operation of folding and telescopic seating shall be the responsibility of the owner or his or her duly authorized representative and shall include the following:

- (1) During operation of the folding and telescopic seats, the opening and closing shall be supervised by responsible personnel who shall ensure that the operation is in accordance with the manufacturer's instructions.
- (2) Only attachments specifically approved by the manufacturer for the specific installation shall be attached to the seating.
- (3) An annual inspection and required maintenance of each grandstand shall be performed to ensure safe conditions. At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer.

12.7.11 Clothing.

Clothing and personal effects shall not be stored in corridors, unless otherwise permitted by the following:

- (1) This requirement shall not apply to corridors protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) This requirement shall not apply to corridor areas protected by a smoke detection system in accordance with Section 9.6.
- (3) This requirement shall not apply to storage in metal lockers, provided that the required egress width is maintained.

Clothing hung on hooks along corridor walls or on racks in lobbies greatly increases the combustible load and will generally allow flame to spread quickly. Each of the exemptions (control of fire by sprinklers, early warning of incipient stage fire via smoke detection, or isolating fuel packages by locating the clothing in metal lockers) helps to mitigate the chance that a clothing fire would render the exit access unusable.

CHAPTERS 14 and 15

New and Existing Educational Occupancies

Chapters 14 and 15 work to provide the life safety features necessary to protect students in an educational setting such as a school. These chapters apply to educational settings for students in kindergarten through the 12th grade; they do not apply to college classrooms. The range of student characteristics and self-preservation abilities found in the educational occupancies regulated by Chapters 14 and 15 requires that student fire safety needs be treated differently from those for adults occupying a college classroom.

Many of the life safety requirements applicable to educational occupancies are the result of lessons learned from fires involving schools in which a large loss of life occurred. Fortunately, such fires are now rare. Fatal fires have been extremely rare in educational occupancies for many years. Those fires that do occur tend to involve either employees in accidental fires (for example, fires caused by cleaning floors with flammable liquids) or, more often, firesetters trapped by their own fires. Children who died in school fires in recent years have been largely limited to juvenile firesetters, acting as individuals or groups, who are on school grounds after hours without permission.

The protection measures used for educational occupancy recognize the structured environment found in a school. For example, class times, time between classes, and activities during class time are rigidly structured. These factors make it possible to train students to respond to a fire by conducting emergency egress and relocation drills.

Smaller children who might be overwhelmed and pushed aside by older students during a fire emergency evacuation or relocation must be housed in classrooms on lower floor levels. Paragraphs 14/15.2.1.2 through 14/15.2.1.4 recognize this problem and establish criteria to control it. The minimum corridor width requirement (see 14/15.2.3.2) is based on expected student behavior. The wider corridor width accommodates students who are filing out of classrooms and forming parallel lines to proceed down the corridor.

Schools also have one of the more assertive schedules for conducting emergency egress and relocation drills (see 14/15.7.2). The drills not only provide a structured fire escape/relocation plan, they also help to instill fire-safe behavior for long-term use.

Section 14.1 General Requirements

14.1.1 Application.

14.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as educational occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, an educational occupancy (*see 4.6.7*)

Section 15.1 General Requirements

15.1.1 Application.

15.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as educational occupancies. (*See also 14.1.1.*)

CHAPTER 14 • New

- (3) Alterations, modernizations, or renovations of existing educational occupancies (*see 4.6.8*)
- (4) Existing buildings or portions thereof upon change of occupancy to an educational occupancy (*see 4.6.12*)

14.1.1.2 Educational facilities that do not meet the definition of an educational occupancy shall not be required to comply with this chapter but shall comply with the following requirements:

- (1) Instructional building—business occupancy
- (2) Classrooms under 50 persons—business occupancy
- (3) Classrooms, 50 persons and over—assembly occupancy
- (4) Laboratories, instructional—business occupancy
- (5) Laboratories, noninstructional—industrial

Paragraph 14.1.1.1 echoes the provision of 4.6.7 that additions must comply with the requirements for new construction. Alterations, modernizations, and renovations must meet the requirements for new construction to the extent practical. A change of occupancy to an educational occupancy requires compliance with the requirements applicable to new construction.

As defined in Chapter 6 and repeated in 14/15.1.4.1, educational occupancies include those buildings, or portions of buildings, used for educating stu-

14.1.2 Multiple Occupancies.

14.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

14.1.2.2 Assembly and Educational.

14.1.2.2.1 Spaces subject to assembly occupancy shall comply with Chapter 12, including 12.1.2, which provides that, where auditorium and gymnasium egress lead through corridors or stairways also serving as egress for other parts of the building, the egress capacity shall be sufficient to allow simultaneous egress from auditorium and classroom sections.

14.1.2.2.2 In the case of an assembly occupancy of a type suitable for use only by the school occupant load and therefore not subject to simultaneous occupancy, the same egress capacity shall be permitted to serve both sections.

14.1.2.3 Dormitory and Classrooms.

14.1.2.3.1 Any building used for both classroom and dormitory purposes shall comply with the applicable provisions of Chapter 28 in addition to complying with Chapter 14.

CHAPTER 15 • Existing

15.1.1.2 Educational facilities that do not meet the definition of an educational occupancy shall not be required to comply with this chapter but shall comply with the following requirements:

- (1) Instructional building—business occupancy
- (2) Classrooms under 50 persons—business occupancy
- (3) Classrooms, 50 persons and over—assembly occupancy
- (4) Laboratories, instructional—business occupancy
- (5) Laboratories, noninstructional—industrial

dents through the 12th grade. The provisions of 14/15.1.1.2 recognize that colleges, universities, and similar educational facilities that do not meet the definition of educational occupancies do not pose the same life safety concerns as elementary and high schools. Because of the maturity of their occupants, college buildings more closely resemble business occupancies. Paragraph 14/15.1.1.2 also identifies other educational uses that are not classified as educational occupancies and specifies how they should be addressed.

15.1.2 Multiple Occupancies.

15.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

15.1.2.2 Assembly and Educational.

15.1.2.2.1 Spaces subject to assembly occupancy shall comply with Chapter 13, including 13.1.2, which provides that, where auditorium and gymnasium egress lead through corridors or stairways also serving as egress for other parts of the building, the egress capacity shall be sufficient to allow simultaneous egress from auditorium and classroom sections.

15.1.2.2.2 In the case of an assembly occupancy of a type suitable for use only by the school occupant load and therefore not subject to simultaneous occupancy, the same egress capacity shall be permitted to serve both sections.

15.1.2.3 Dormitory and Classrooms.

15.1.2.3.1 Any building used for both classroom and dormitory purposes shall comply with the applicable provisions of Chapter 29 in addition to complying with Chapter 15.

CHAPTER 14 • New

14.1.2.3.2 Where classroom and dormitory sections are not subject to simultaneous occupancy, the same egress capacity shall be permitted to serve both sections.

Paragraph 14/15.1.2.1 refers to 6.1.14, which specifies that, where multiple occupancies are to be protected as mixed occupancies, the most stringent requirement applicable to any of the occupancies present is to be applied to all occupancies. For example, one of the occupancies present might have a travel distance limitation stricter than that of the other occupancies present; therefore, the stricter limitation is to be applied throughout the building. An occupancy that differs from the occupancy with the strictest travel distance limit might have the strictest requirements for protection of vertical openings, and these provisions also need to be implemented throughout the building. Similarly, for each subject addressed by the *Code*, a comparison must be made among the requirements applicable to each of the occupancies present and the strictest requirement must be provided throughout the building.

Paragraph 14/15.1.2.2 addresses multiple occupancies that are part assembly and part educational, in recognition of the fact that the occupancy that most typically appears within an educational occupancy building to create a mixed occupancy is an assembly occupancy. Because of the large numbers of occupants characteristic of both assembly and educational

14.1.3 Definitions.

A list of terms used in this chapter follows:

- (1) **Common Atmosphere.** See 3.3.20.1.
- (2) **Flexible Plan and Open Plan Educational or Day-Care Building.** See 3.3.27.6.
- (3) **Separate Atmosphere.** See 3.3.20.2.

14.1.4 Classification of Occupancy.

See 6.1.3.

14.1.4.1 Educational occupancies shall include all buildings used for educational purposes through the twelfth grade by six or more persons for 4 or more hours per day or more than 12 hours per week.

14.1.4.2 Educational occupancies shall include part-day preschools, kindergartens, and other schools whose purpose is primarily educational, even though the children who attend such schools are of preschool age.

CHAPTER 15 • Existing

15.1.2.3.2 Where classroom and dormitory sections are not subject to simultaneous occupancy, the same egress capacity shall be permitted to serve both sections.

occupancies, it is important that their combined occupant loads be used to size the means of egress system if they share common egress components such as corridors and exit stair enclosures. The requirement assumes that the classrooms and assembly areas are likely to be occupied simultaneously. For example, classrooms are often used during the evening for adult or remedial education while a school's gymnasium or auditorium is being used by another group. Where simultaneous occupancy does not occur, 14/15.1.2.2.2 permits the shared means of egress to be sized to handle the larger of the uses, either educational or assembly.

Chapters 12 and 13 contain several requirements applicable to assembly occupancies that could have a significant impact on an educational occupancy contained in a multiple use building if the building is not designed so the occupancies can be treated separately. For example, in new construction, if the mixed use creates a multiple occupancy that is to be protected as a mixed occupancy, the building will most likely have to be sprinklered throughout by applying the provisions of 12.3.5. The other option is to use the separated occupancies provisions of 6.1.14.4 so as to sprinkler only the assembly occupancy.

15.1.3 Definitions.

A list of terms used in this chapter follows:

- (1) **Common Atmosphere.** See 3.3.20.1.
- (2) **Flexible Plan and Open Plan Educational or Day-Care Building.** See 3.3.27.6.
- (3) **Separate Atmosphere.** See 3.3.20.2.

15.1.4 Classification of Occupancy.

See 6.1.3.

15.1.4.1 Educational occupancies shall include all buildings used for educational purposes through the twelfth grade by six or more persons for 4 or more hours per day or more than 12 hours per week.

15.1.4.2 Educational occupancies shall include part-day preschools, kindergartens, and other schools whose purpose is primarily educational, even though the children who attend such schools are of preschool age.

CHAPTER 14 • New

14.1.4.3 In cases where instruction is incidental to some other occupancy, the section of this *Code* governing such other occupancy shall apply.

14.1.4.4 Other occupancies associated with educational institutions shall be in accordance with the appropriate parts of this *Code*. (See Chapters 18, 20, 26, 28, 30, 40, and 42 and 6.1.14.)

Paragraph 14/15.1.4.1 has the effect of exempting the following three types of schools from the provisions of Chapters 14 and 15:

- (1) Schools with small numbers of students (fewer than six), such as facilities providing private tutoring or individual lessons
- (2) Schools with limited operating hours (less than 4 hours per day and not more than 12 hours per week), such as some sports schools or weekend religious instruction schools
- (3) Schools that educate people above the high school level, as in the case of universities or military training.

For purposes of determining occupant load, a classroom area—regardless of whether it is part of an educational occupancy—is still considered an educational use, and the occupant load factors provided for educational uses by Table 7.3.1.2 should be used to calculate a realistic occupant load.

Where instruction is incidental to other occupancies, the requirements for the occupancy in which the instruction takes place are applicable. Church schools used for instruction for a few hours once or twice a week are generally considered part of

14.1.5 Classification of Hazard of Contents.

The contents of educational occupancies shall be classified in accordance with the provisions of Section 6.2.

In general, educational occupancies contain ordinary hazard contents. Some laboratories and storage areas might contain high hazard contents. See Section 7.11

14.1.6 Minimum Construction Requirements.

(No requirements)

CHAPTER 15 • Existing

15.1.4.3 In cases where instruction is incidental to some other occupancy, the section of this *Code* governing such other occupancy shall apply.

15.1.4.4 Other occupancies associated with educational institutions shall be in accordance with the appropriate parts of this *Code*. (See Chapter 19, Chapter 21, Chapter 26, Chapter 29, Chapter 31, Chapter 40, Chapter 42, and 6.1.14.)

the assembly occupancy in which instruction takes place.

Paragraph 14/15.1.4.2 classifies part-time day-care facilities as educational occupancies if they primarily provide education in addition to care services. This classification parallels federal guidelines for subsidizing day-care/educational activities at both the federal and state levels. This does not describe a typical day-care facility. Chapters 16 and 17 contain special requirements for typical, noneducational day-care facilities.

The requirement of 14/15.1.4.3 is not as significant as it was when places of higher education were encompassed by 14/15.1.4.1 in earlier editions of the *Code*. The following examples describe uses that would, nevertheless, be exempted from the requirements for educational occupancies by 14/15.1.4.1.

In an office building or factory, a few rooms might be used for orientation or instruction in job performance; these rooms are subject to the *Code* requirements for business or industrial occupancies. Barber colleges and beauty schools are frequently located in commercial buildings and should be governed by the requirements applicable to the buildings in which they are located.

15.1.5 Classification of Hazard of Contents.

The contents of educational occupancies shall be classified in accordance with the provisions of Section 6.2.

for additional egress requirements for areas with high hazard contents.

15.1.6 Minimum Construction Requirements.

(No requirements)

CHAPTER 14 • New

14.1.7 Occupant Load.

14.1.7.1 The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

14.1.7.2 The occupant load of an educational occupancy, or a portion thereof, shall be permitted to be modified from that specified in 14.1.7.1 if the necessary aisles and exits are provided.

14.1.7.3 An approved aisle or seating diagram shall be required by the authority having jurisdiction to substantiate the modification permitted in 14.1.7.2.

Because occupant load is calculated on the basis of the use of a space, regardless of occupancy classification, occupant load factors appear in Chapter 7, a general chapter. Occupant load factors appear in Table 7.3.1.2.

It is not the intent that occupant load factors be applied to require a minimum area per student for functional purposes. Rather, the occupant load factors are used to determine the occupant load for purposes of sizing the means of egress system. The intent is to require adequate egress capacity for those pres-

CHAPTER 15 • Existing

15.1.7 Occupant Load.

15.1.7.1 The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

15.1.7.2 The occupant load of an educational occupancy, or a portion thereof, shall be permitted to be modified from that specified in 15.1.7.1 if the necessary aisles and exits are provided.

15.1.7.3 An approved aisle or seating diagram shall be required by the authority having jurisdiction to substantiate the modification permitted in 15.1.7.2.

ent. Efficient use of classroom space might result in the presence of a greater number of occupants than that determined by calculation using the occupant load factors of Table 7.3.1.2. Paragraph 14/15.1.7.2 permits the occupant load to be established as the maximum probable population if that number exceeds the number determined by calculation using the occupant load factors. However, the means of egress must adequately accommodate all occupants, and all other requirements dependent on the calculated occupant load must be met.

Section 14.2 Means of Egress Requirements**14.2.1 General.**

14.2.1.1 Means of egress shall be in accordance with Chapter 7 and Section 14.2.

14.2.1.2 Rooms normally occupied by preschool, kindergarten, or first-grade students shall be located on a level of exit discharge, unless otherwise permitted by 14.2.1.4.

14.2.1.3 Rooms normally occupied by second-grade students shall not be located more than one story above a level of exit discharge, unless otherwise permitted by 14.2.1.4.

14.2.1.4 Rooms or areas located on floor levels other than as specified in 14.2.1.2 and 14.2.1.3 shall be permitted to be used where provided with independent means of egress dedicated for use by the preschool, kindergarten, first-grade, or second-grade students.

Section 15.2 Means of Egress Requirements**15.2.1 General.**

15.2.1.1 Means of egress shall be in accordance with Chapter 7 and Section 15.2.

15.2.1.2 Rooms normally occupied by preschool, kindergarten, or first-grade students shall be located on a level of exit discharge, unless otherwise permitted by 15.2.1.4.

15.2.1.3 Rooms normally occupied by second-grade students shall not be located more than one story above a level of exit discharge, unless otherwise permitted by 15.2.1.4.

15.2.1.4 Rooms or areas located on floor levels other than as specified in 15.2.1.2 and 15.2.1.3 shall be permitted to be used where provided with independent means of egress dedicated for use by the preschool, kindergarten, first-grade, or second-grade students.

CHAPTER 14 • New

The restrictions on the location of rooms used by preschool, kindergarten, or first- or second-grade pupils were developed to avoid the danger of older—and larger—children overrunning the very young on stairs or ramps during a fire or other incident requiring rapid evacuation. The exemption offered by 14/

14.2.2 Means of Egress Components.

14.2.2.1 Components of means of egress shall be limited to the types described in 14.2.2.2 through 14.2.2.10.

14.2.2.2 Doors.

14.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

14.2.2.2.2 Any door in a required means of egress from an area having an occupant load of 100 or more persons shall be permitted to be provided with a latch or lock only if the latch or lock is panic hardware or fire exit hardware complying with 7.2.1.7.

14.2.2.2.3 Special locking arrangements complying with 7.2.1.6 shall be permitted.

14.2.2.3* Stairs. Stairs complying with 7.2.2 shall be permitted.

A.14.2.2.3 See A.7.2.2.4.4.4 regarding additional handrails on stairs that are used extensively by children 5 years of age or less.

14.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

14.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

14.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

14.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

14.2.2.8 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

CHAPTER 15 • Existing

15.2.1.4 recognizes that the younger students—often with the help of teachers and staff—can use the stairs and ramps effectively if they don't have to compete with the older, larger, and faster students. For a definition of the term *level of exit discharge*, see 3.3.64.1.

15.2.2 Means of Egress Components.

15.2.2.1 Components of means of egress shall be limited to the types described in 15.2.2.2 through 15.2.2.10.

15.2.2.2 Doors.

15.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

15.2.2.2.2 Any required exit door subject to use by 100 or more persons shall be permitted to be provided with a latch or lock only if the latch or lock is panic hardware or fire exit hardware complying with 7.2.1.7.

15.2.2.2.3 Special locking arrangements complying with 7.2.1.6 shall be permitted.

15.2.2.3* Stairs.

A.15.2.2.3 See A.7.2.2.4.4.4 regarding additional handrails on stairs that are used extensively by children 5 years of age or less.

15.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

15.2.2.3.2 Existing Class A stairs shall be permitted.

15.2.2.3.3 Existing Class B stairs shall be permitted where not used for student access.

15.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

15.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

15.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

15.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

15.2.2.8 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

CHAPTER 14 • New

14.2.2.9 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

14.2.2.10 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

Subsection 14/15.2.2 lists those components acceptable for use in the means of egress serving an educational occupancy. Some of the components described in Chapter 7 were judged to be unacceptable for educational occupancy egress system use. Note that slide escapes, escalators, fire escape stairs, and revolving doors are not permitted to be credited as providing any of the required means of egress in an educational occupancy.

The panic hardware and fire exit hardware provisions of 14/15.2.2.2 include application thresholds expressed in terms of occupant load. For new construction, the occupant load addressed by 14.2.2.2 is the total occupant load of the area served and not only the required capacity of the door. For example, if an area of a new educational occupancy has an occupant load of 180 persons and is served by 3 doors, each door is required to have sufficient capacity for 60 persons. However, because the doors serve an overall area with 100 or more persons, any latches on these doors must be arranged to be released by panic hardware or fire exit hardware. The requirement for panic hardware or fire exit hardware in existing educational occupancies is slightly less restrictive than for new educational occupancies. In accordance with 15.2.2.2, panic hardware or fire exit hardware is required only on exit doors rather than all egress doors; therefore, the requirement does not apply to exit access doors—such as corridor doors and smoke barrier doors. In addition, 15.2.2.2 establishes its criteria on the basis of the number of people using the door for egress. For example, if a single-story existing educa-

14.2.3 Capacity of Means of Egress.

14.2.3.1 Capacity of means of egress shall be in accordance with Section 7.3.

14.2.3.2 Minimum Corridor Width. Exit access corridors shall have not less than 1830 mm (72 in.) of clear width.

Note that the minimum corridor width requirement of 14/15.2.3.2 applies regardless of the required capac-

CHAPTER 15 • Existing

15.2.2.9 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

15.2.2.10 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

tional occupancy building with an occupant load of 180 persons has 3 exit doors, each door can be considered as providing egress capacity for 60 persons. Because no individual exit door is required to have a capacity for 100 or more occupants, panic hardware is not required.

Paragraph 14/15.2.2.3 references 7.2.1.6. The provisions of 7.2.1.6 include 7.2.1.6.1, which applies to delayed-egress locks, and 7.2.1.6.2, which applies to access-controlled egress doors. Both sets of features are recognized for use in educational occupancies. To use the provisions for delayed-egress locks, the building must be either fully sprinklered or fully protected by an automatic fire detection system. Although many occupancies recognize use of the Chapter 7 provisions for delayed-egress locks, the original hardware was developed for educational occupancies. Delayed-egress locking provisions were added to Chapter 7 based on hardware development that addresses security concerns in schools.

Although 14/15.2.2.8 and 14/15.2.2.9 permit fire escape ladders and alternating tread devices as components of the means of egress, some Chapter 7 provisions limit the use of such ladders and devices. For example, the provisions of 7.2.9 and 7.2.11 restrict the use of fire escape ladders and alternating tread devices to normally unoccupied areas, such as rooftops or mechanical equipment platforms. Chapter 7 further restricts their use to spaces subject to occupancy by not more than three persons who are all capable of using the ladder or alternating tread device.

15.2.3 Capacity of Means of Egress.

15.2.3.1 Capacity of means of egress shall be in accordance with Section 7.3.

15.2.3.2 Minimum Corridor Width. Exit access corridors shall have not less than 1830 mm (72 in.) of clear width.

ity of the corridor. Based on egress capacity considerations, larger widths might be necessary for corridors

CHAPTER 14 • New

handling large numbers of students; see 14/15.2.3.1 and Section 7.3. Paragraph 14/15.2.3.2 applies to exit access corridors and not to nonrequired service corridors provided for convenience only.

The term *clear width* means a 1830-mm- (72-in.-) wide clear space with no obstructions other than those permitted by 7.3.2.2. Subsection 7.3.2 details the required method for measuring the width of a component of the means of egress. Paragraph 7.3.2.2 permits projections of not more than 114 mm (4½ in.) on each side of the corridor. The projections are

14.2.4 Number of Exits.

Not less than two separate exits shall be as follows:

- (1) Provided on every story
- (2) Accessible from every part of every story and mezzanine

Access must be provided to a minimum of two exits, both of which must be located on the floor or story in question. Contrast this requirement with a related provision for industrial occupancies that requires access to two exits but mandates that only one of those required exits is to be located on the floor or story. Thus, in an educational occupancy, an open exit access stair, if it were allowed without violating the

14.2.5 Arrangement of Means of Egress.

See also Section 7.5.

14.2.5.1 Means of egress shall be arranged in accordance with Section 7.5.

14.2.5.2 No dead-end corridor shall exceed 6100 mm (240 in.), other than in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, in which case dead-end corridors shall not exceed 15 m (50 ft).

14.2.5.3 No common path of travel shall exceed 23 m (75 ft), other than for the first 30 m (100 ft) in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

Paragraph 7.5.1.1.4 permits individual occupancy chapters to allow, and set limits for, common paths of travel. The 23-m (75-ft) limit established by 14/

CHAPTER 15 • Existing

permitted to be located at or below a handrail height of 965 mm (38 in.), and the maximum 114-mm (4½-in.) width is to be ignored when determining clear width.

The intent of an 1830-mm (72-in.) corridor is to permit two files of students to move simultaneously with sufficient room for teachers or monitors to supervise. Extremely short corridor sections serving only one or two rooms might warrant consideration for some reduction in required width.

15.2.4 Number of Exits.

Not less than two separate exits shall be as follows:

- (1) Provided on every story
- (2) Accessible from every part of every story and mezzanine

provisions applicable to the protection of vertical openings, is not permitted to serve as access to either of the two required exits. In a multistory educational occupancy building, the requirements of 14/15.2.4 are typically met by providing two properly enclosed exit stairs that can be accessed from all floors above or below the level of exit discharge.

15.2.5 Arrangement of Means of Egress.

15.2.5.1 Means of egress shall be arranged in accordance with Section 7.5.

15.2.5.2 No dead-end corridor shall exceed 6100 mm (240 in.), other than in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, in which case dead-end corridors shall not exceed 15 m (50 ft).

15.2.5.3 No common path of travel shall exceed 23 m (75 ft), other than for the first 30 m (100 ft) in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

15.2.5.3 is reasonable enough that small rooms are not required to be provided with a second exit access door, yet strict enough to help ensure that occupants

CHAPTER 14 • New

CHAPTER 15 • Existing

can safely tolerate traveling in only one direction for a limited distance before reaching a point where travel in independent directions becomes possible. Paragraph 14/15.2.5.3 permits the common path of travel to be increased to 30 m (100 ft) in recognition of the fire-controlling capabilities of a sprinkler system.

Paragraph 7.5.1.5 allows individual occupancy chapters to establish limits for dead-end corridors. The standard dead-end requirement for educational occupancies in the past has been 6100 mm (240 in.), as allowed by 14/15.2.5.2—and the limitation still appears reasonable. However, 14/15.2.5.2 permits the dead end to be increased by 9140 mm (360 in.) in recognition of the fire-controlling capabilities of a sprinkler system.

A floor arrangement with outside doors or stairways at both ends of a central corridor typically creates no dead-end corridors. Small dead-end corridor pockets might be created where stairways are not located at the end of corridors but are located at intermediate points. See Exhibit 14/15.1. Illustration (a) in Exhibit 14/15.1 indicates no dead-end corridors. This arrangement is preferred but is not always practical in terms of building layout and use. At each end of the corridor in illustration (b), dead-end pockets are shown into which occupants might mistakenly travel, only to have to retrace their path to find an exit. However, the length of the dead-end corridor does not exceed the permitted 6100 mm (240 in.). All classrooms have been arranged so that the common path of travel does not exceed the 23-m (75-ft) limitation. This arrangement is acceptable. In an educational occupancy building that is protected

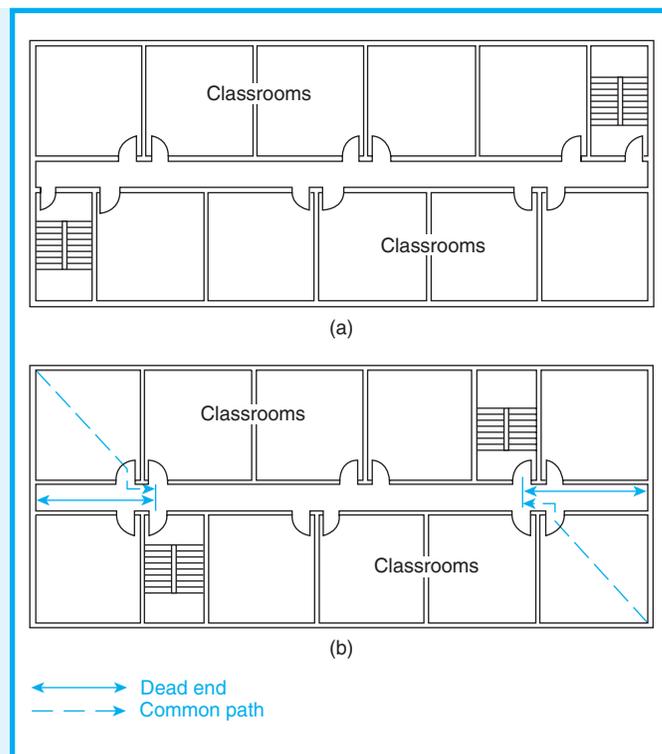

Exhibit 14/15.1 Dead-end corridors and common path of travel in an educational occupancy.

throughout by an approved, supervised automatic sprinkler system, the 6100-mm (240-in.) dead-end corridor can be increased to 15 m (50 ft); and the 23-m (75-ft) common path of travel can be increased to 30 m (100 ft).

14.2.5.4 Every room that is normally subject to student occupancy shall have an exit access door leading directly to an exit access corridor or exit, unless otherwise permitted by the following:

- (1) This requirement shall not apply where an exit door opens directly to the outside or to an exterior balcony or corridor as described in 14.2.5.8.
- (2) One room shall be permitted to intervene between a normally occupied student room and an exit access corridor, provided that all of the following criteria are met:
 - (a) The travel from a room served by an intervening room to the corridor door or exit shall not exceed 23 m (75 ft).
 - (b) Clothing, personal effects, or other materials deemed hazardous by the authority having jurisdic-

15.2.5.4 Every room that is normally subject to student occupancy shall have an exit access door leading directly to an exit access corridor or exit, unless otherwise permitted by the following:

- (1) This requirement shall not apply where an exit door opens directly to the outside or to an exterior balcony or corridor as described in 15.2.5.8.
- (2) One room shall be permitted to intervene between a normally occupied student room and an exit access corridor, provided that all of the following criteria are met:
 - (a) The travel from a room served by an intervening room to the corridor door or exit shall not exceed 23 m (75 ft).
 - (b) Clothing, personal effects, or other materials deemed hazardous by the authority having jurisdic-

CHAPTER 14 • New

tion shall be stored in metal lockers, provided that they do not obstruct the exit access, or the intervening room shall be sprinklered in accordance with Section 9.7.

- (c) One of the following means of protection shall be provided:
- The intervening room shall have approved fire detection that activates the building alarm.
 - The building shall be protected by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

To ensure ready access to the exit access corridor—which is intended to be a safer portion of the exit access than an occupied room with furnishings—14/15.2.5.4 requires most normally occupied rooms to have a door open directly into an exit access corridor. The use of such a door avoids the need for occupants to pass through intervening rooms that might not be arranged or maintained to permit orderly evacuation.

Normally occupied rooms that have doors opening directly to the outside at grade or to an exterior exit access balcony are exempted from the base requirement. Also exempted are normally occupied rooms having only one intervening room that meets the following criteria:

- Travel distance through the intervening room to the corridor door is limited to 23 m (75 ft).
- Personal effects—such as coats and other belongings or other contents deemed hazardous by the authority having jurisdiction—must be kept in metal lockers, or the intervening room must be sprinklered.
- Either the intervening room is supplied with fire detectors connected to the building alarm system, or the entire building is protected throughout by an approved automatic sprinkler system.

It is the *Code's* intent that, if metal lockers are chosen as the intervening room fire detection option, smoke detectors rather than heat detectors should be selected to provide for rapid occupant notification. However, heat detectors are allowed to be used if nuisance alarms are anticipated (for example, in automotive or wood shops with attached classrooms).

Exhibits 14/15.2 and 14/15.3 illustrate several possible intervening room configurations that comply with the *Code*. In Exhibit 14/15.2, Room A has no limit

CHAPTER 15 • Existing

tion shall be stored in metal lockers, provided that they do not obstruct the exit access, or the intervening room shall be sprinklered in accordance with Section 9.7.

- (c) One of the following means of protection shall be provided:
- The intervening room shall have approved fire detection that activates the building alarm.
 - The building shall be protected by an approved automatic sprinkler system in accordance with Section 9.7.
- (3) Approved existing arrangements shall be permitted to continue in use.

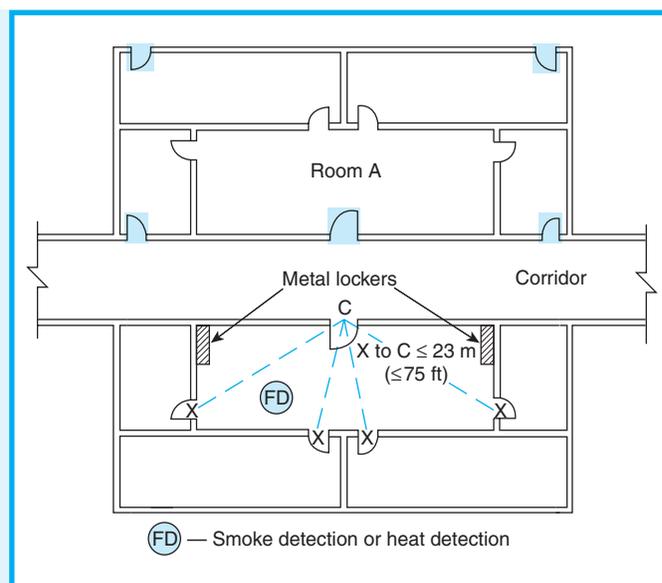

Exhibit 14/15.2 Room arrangements complying with 14/15.2.5.4.

on its size other than to satisfy the arrangement and travel distance provisions of 14/15.2.5 and 14/15.2.6. Each normally occupied room has a door opening either directly to the corridor or to the exterior (opening at grade or to an exterior exit access balcony) as permitted by 14/15.2.5.4(1). The arrangement shown in the lower portion of Exhibit 14/15.2 is permitted as long as travel distance from the normally occupied rooms to the corridor (from point X to point C) does not exceed 23 m (75 ft), and clothing and other personal effects in the intervening room are stored in metal lockers along with a fire detection system designed to provide occupant notification (preferably smoke detection for earliest possible notification).

In Exhibit 14/15.3, illustrations (a) and (b) represent acceptable intervening room arrangements. Illustration (a) depicts the limited travel distance from point X to point C along with the intervening room sprinkler system addressed in 14/15.2.5.4(2)(b) and the intervening room fire detection system addressed in 14/15.2.5.4(2)(c)i. Illustration (b) represents a building protected throughout by an automatic sprinkler system satisfying both 14/15.2.5.4(2)(b) and 14/15.2.5.4(2)(c)ii. In effect, even the installation within an intervening room of an automatic sprinkler system that is connected to the building fire alarm system would satisfy the criteria of 14/15.2.5.4(2)(c)i, because automatic sprinklers are considered heat detectors. Therefore, this approach would satisfy both 14/15.2.5.4(2)(b) and 14/15.2.5.4(2)(c).

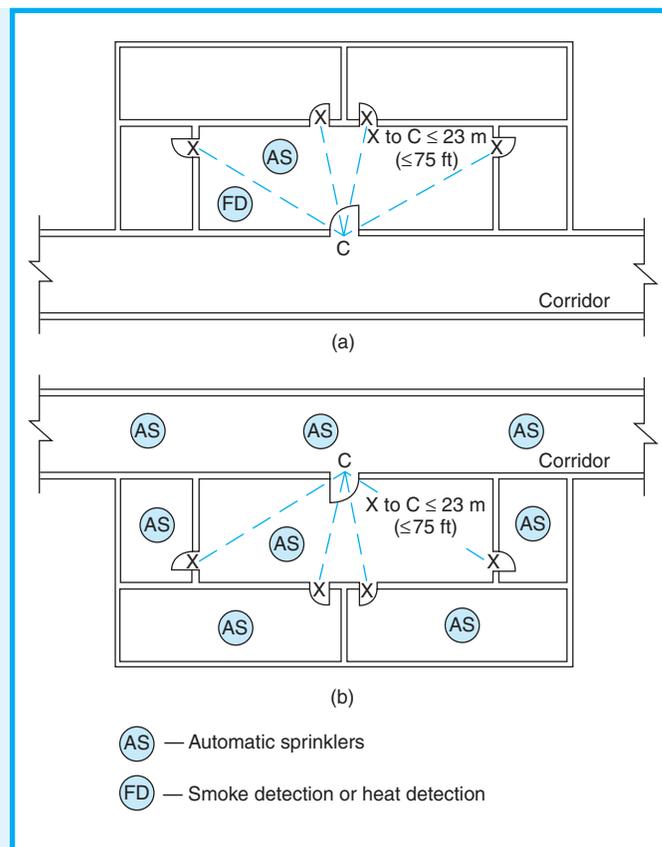

Exhibit 14/15.3 Additional room arrangements complying with 14/15.2.5.4.

14.2.5.5 Doors that swing into an exit access corridor shall be arranged to prevent interference with corridor travel. (See also 7.2.1.4.4.)

14.2.5.6 Aisles shall be not less than 760 mm (30 in.) wide.

14.2.5.7 The space between parallel rows of seats shall not be subject to the minimum aisle width, provided that the number of seats that intervene between any seat and an aisle does not exceed six.

14.2.5.8* Exterior Corridors or Balconies. Exterior exit access shall comply with 7.5.3.

A.14.2.5.8 A corridor roofed over and enclosed on its long side and open to the atmosphere at the end is permitted to be considered an exterior corridor if either of the following criteria is met:

- (1) Clear story openings for the corridor are provided on both sides of the corridor and above adjacent roofs or buildings, and such clear openings are not less than one-half the height of the corridor walls.

15.2.5.5 Doors that swing into an exit access corridor shall be arranged to prevent interference with corridor travel. (See also 7.2.1.4.4.)

15.2.5.6 Aisles shall be not less than 760 mm (30 in.) wide.

15.2.5.7 The space between parallel rows of seats shall not be subject to the minimum aisle width, provided that the number of seats that intervene between any seat and an aisle does not exceed six.

15.2.5.8* Exterior Corridors or Balconies. Exterior exit access shall comply with 7.5.3.

A.15.2.5.8 A corridor roofed over and enclosed on its long side and open to the atmosphere at the end is permitted to be considered an exterior corridor if either of the following criteria is met:

- (1) Clear story openings for the corridor are provided on both sides of the corridor and above adjacent roofs or buildings, and such clear openings are not less than one-half the height of the corridor walls.

CHAPTER 14 • New

- (2) The corridor roof has unobstructed openings to the sky not less than 50 percent of the area of the roof.

The openings detailed in A.14.2.5.8(1) and A.14.2.5.8(2) are to be equally distributed, and, if louvers are installed, they are to be fixed open with a clear area based on the actual openings between louver vanes.

Exhibit 14/15.4 illustrates exterior exit access arranged in accordance with 7.5.3. The stairs have been positioned to comply with 7.5.3.3; the arrangement permits an occupant to reach at least one of the stairs without having to travel past an unprotected opening. The distance from any room to nearest stair must not exceed the allowable travel distance.

Exhibits 14/15.5 and 14/15.6 illustrate the use of roofed-over exterior exit access corridors as suggested by A.14/A.15.2.5.8. In Exhibit 14/15.5, the openings labeled A, B, C, and D are clear story openings. The building height is 3050 mm (120 in.). For a corridor to be considered an outside corridor, the minimum height for the corridor roof is 1525 mm (60 in.). In this figure, the minimum clear story height requirements have been met.

In Exhibit 14/15.6, the alternative to the clear story openings is a roof with unobstructed openings to the

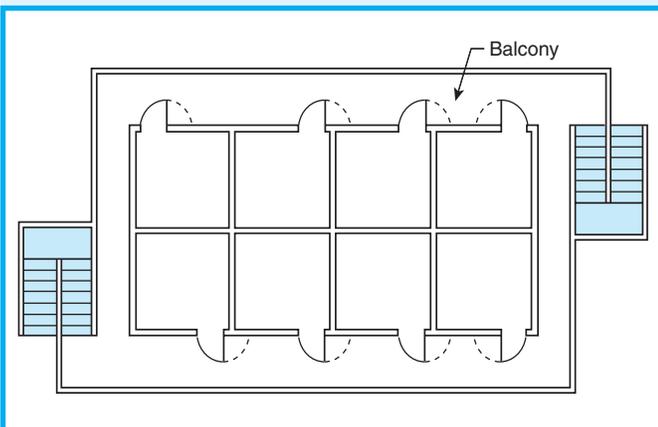

Exhibit 14/15.4 Exterior exit access via balcony and stairs.

14.2.6 Travel Distance to Exits.

14.2.6.1 Travel distance to an exit shall not exceed 46 m (150 ft) from any point in a building. (See also Section 7.6.)

CHAPTER 15 • Existing

- (2) The corridor roof has unobstructed openings to the sky not less than 50 percent of the area of the roof.

The openings detailed in A.15.2.5.8(1) and A.15.2.5.8(2) are to be equally distributed, and, if louvers are installed, they are to be fixed open with a clear area based on the actual openings between louver vanes.

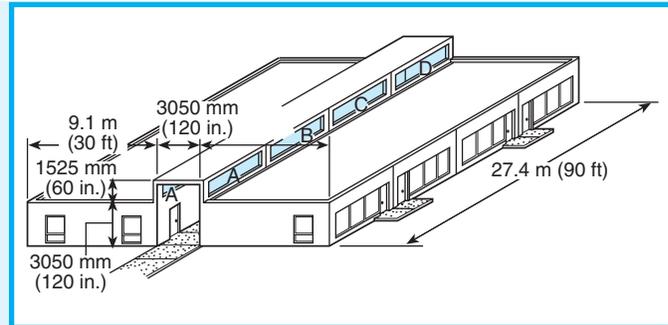

Exhibit 14/15.5 Exterior corridor using clear story openings.

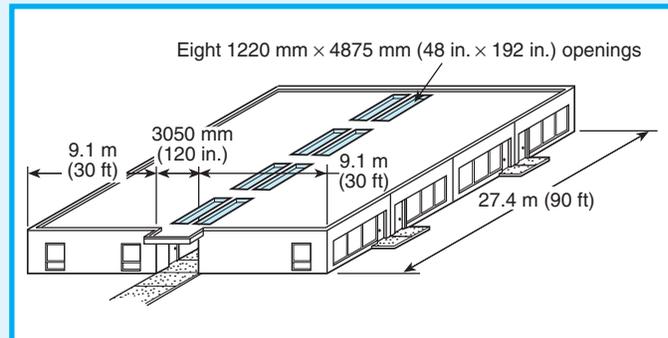

Exhibit 14/15.6 Exterior corridor using roof openings.

sky that are equal to not less than 50 percent of the corridor roof area. The example shown has eight openings. Each opening is 1220 mm × 4875 mm (48 in. × 192 in.), or 5.9 m² (64 ft²). The total corridor roof area is 84 m² (900 ft²). The total unobstructed opening equals 48 m² (512 ft²)—greater than 50 percent of the total roof area. This example is considered an acceptable design.

15.2.6 Travel Distance to Exits.

15.2.6.1 Travel distance to an exit shall not exceed 46 m (150 ft) from any point in a building, unless otherwise permitted by 15.2.6.2 or 15.2.6.3 (see also Section 7.6).

CHAPTER 14 • New

14.2.6.2 Travel distance shall not exceed 61 m (200 ft) in educational occupancies protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

14.2.7 Discharge from Exits.

Discharge from exits shall be arranged in accordance with Section 7.7.

14.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

14.2.9 Emergency Lighting.

Emergency lighting shall be provided in accordance with Section 7.9.

In earlier editions of the *Code*, emergency lighting was required in shops, laboratories, assembly use spaces (such as lecture halls, auditoriums, and dining rooms), and interior and windowless portions of edu-

14.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

14.2.11 Special Means of Egress Features.

14.2.11.1* Windows for Rescue.

A.14.2.11.1 It is highly desirable that all windows be of a type that can be readily opened from inside and to have them large enough and low enough for use by students, teachers, and fire fighters. Windows are permitted to serve as a supplementary means of emergency escape, particularly where ladders can be raised by fire fighters or others.

14.2.11.1.1 Every room or space greater than 23.2 m² (250 ft²) and used for classroom or other educational purposes or

CHAPTER 15 • Existing

15.2.6.2 Travel distance shall not exceed 61 m (200 ft) in educational occupancies protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

15.2.6.3 Approved existing travel distances shall be permitted to continue in use.

15.2.7 Discharge from Exits.

Discharge from exits shall be arranged in accordance with Section 7.7.

15.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

15.2.9 Emergency Lighting.

educational occupancies. The *Code* now requires that educational occupancies be provided with emergency lighting in accordance with Section 7.9.

15.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9 unless otherwise permitted by 15.2.9.2.

15.2.9.2 Approved existing emergency lighting installations shall be permitted to be continued in use.

15.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

15.2.11 Special Means of Egress Features.

15.2.11.1* Windows for Rescue.

A.15.2.11.1 It is highly desirable that all windows be of a type that can be readily opened from inside and to have them large enough and low enough for use by students, teachers, and fire fighters. Windows are permitted to serve as a supplementary means of emergency escape, particularly where ladders can be raised by fire fighters or others.

15.2.11.1.1 Every room or space greater than 23.2 m² (250 ft²) and used for classroom or other educational purposes or

CHAPTER 14 • New

normally subject to student occupancy shall have not less than one outside window for emergency rescue that complies with the following unless otherwise permitted by 14.2.11.1.2:

- (1) Such windows shall be openable from the inside without the use of tools and shall provide a clear opening of not less than 510 mm (20 in.) in width, 610 mm (24 in.) in height, and 0.5 m² (5.7 ft²) in area.
- (2) The bottom of the opening shall be not more than 1120 mm (44 in.) above the floor, and any latching device shall be capable of being operated from not more than 1370 mm (54 in.) above the finished floor.
- (3) The clear opening shall allow a rectangular solid, with a width and height that provides not less than the required 0.5-m² (5.7-ft²) opening and a depth of not less than 510 mm (20 in.), to pass fully through the opening.
- (4) Such windows shall be accessible by the fire department and shall open into an area having access to a public way.

14.2.11.1.2 The requirements of 14.2.11.1.1 shall not apply to the following:

- (1) Buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7
- (2) Where the room or space has a door leading directly to the outside of the building
- (3) Rooms located higher than three stories above grade

CHAPTER 15 • Existing

normally subject to student occupancy shall have not less than one outside window for emergency rescue that complies with the following, unless otherwise permitted by 15.2.11.1.2:

- (1) Such windows shall be openable from the inside without the use of tools and shall provide a clear opening of not less than 510 mm (20 in.) in width, 610 mm (24 in.) in height, and 0.5 m² (5.7 ft²) in area.
- (2) The bottom of the opening shall be not more than 1120 mm (44 in.) above the floor, and any latching device shall be capable of being operated from not more than 1370 mm (54 in.) above the finished floor.
- (3) The clear opening shall allow a rectangular solid, with a width and height that provides not less than the required 0.5-m² (5.7-ft²) opening and a depth of not less than 510 mm (20 in.), to pass fully through the opening.

15.2.11.1.2 The requirements of 15.2.11.1.1 shall not apply to the following:

- (1) Buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.
- (2) Where the room or space has a door leading directly to the outside of the building.
- (3) Rooms located higher than three stories above grade.
- (4) Where awning-type or hopper-type windows that are hinged or subdivided to provide a clear opening of not less than 0.38 m² (4 ft²) or any dimension of not less than 560 mm (22 in.), the following shall apply:
 - (a) Such windows shall be permitted to continue in use.
 - (b) wScreen walls or devices located in front of required windows shall not interfere with rescue requirements.
- (5) Where the room or space complies with the following:
 - (a) Doors shall exist that allow travel between adjacent classrooms.
 - (b) Where doors are used to travel from classroom to classroom, they shall provide one of the following:
 - i. Direct access to exits in both directions
 - ii. Direct access to an exit in one direction and to a separate smoke compartment that provides access to another exit in the other direction
 - (c) The corridor shall be separated from the classrooms by a wall that resists the passage of smoke, and all doors between the classrooms and the corridor shall be self-closing or automatic-closing in accordance with 7.2.1.8.
 - (d) The length of travel to exits along such paths shall not exceed 46 m (150 ft).

CHAPTER 14 • New

CHAPTER 15 • Existing

Small rooms of 23.2 m² (250 ft²) or less, such as those used for music instruction and student counseling and subject to occupancy by very few students, are exempt from the rescue window requirement.

The dimensions specified for windows used for emergency rescue are based on simulations of emer-

gency rescue conducted by the San Diego Fire Department. Windows providing clear openings of identical dimensions are also required for rescue in dwellings. Exhibit 14/15.7 illustrates two configurations that provide the required area of 0.5 m² (5.7 ft²) and the minimum opening height and width.

Awning and hopper-type windows might provide the required opening within the plane of the building exterior wall. However, when the window is open, the sash and glazing are outside that plane and might prevent occupants from passing through the opening. Therefore, the criterion for providing an opening through which a minimum size rectangular solid can pass is intended to ensure that occupants can pass through the opening. For existing awning-type windows, 15.2.11.1.2(4) offers some relief from the rectangular solid and minimum opening size requirements. The exemption in 15.2.11.1.2(4) is provided in acknowledgment of a feature that was formerly recognized by the *Code*. Although the exemption is no longer allowed in new construction, it is still permitted in existing facilities. Exhibit 14/15.8 illustrates the use of 15.2.11.1.2(4).

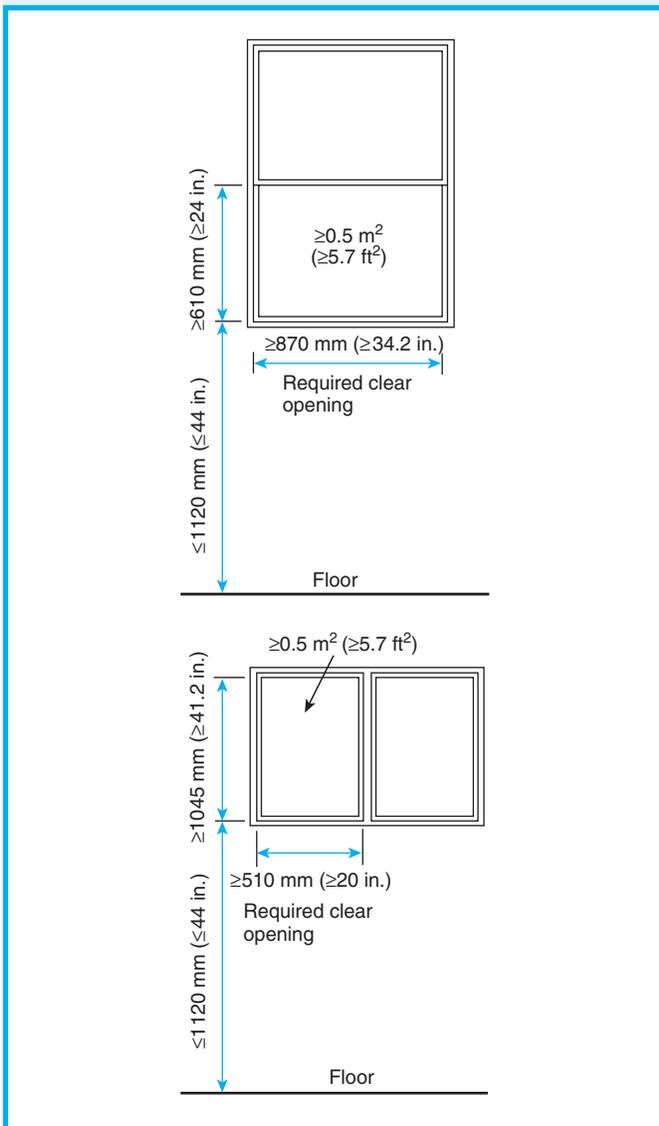

Exhibit 14/15.7 Windows for rescue, minimum required dimensions.

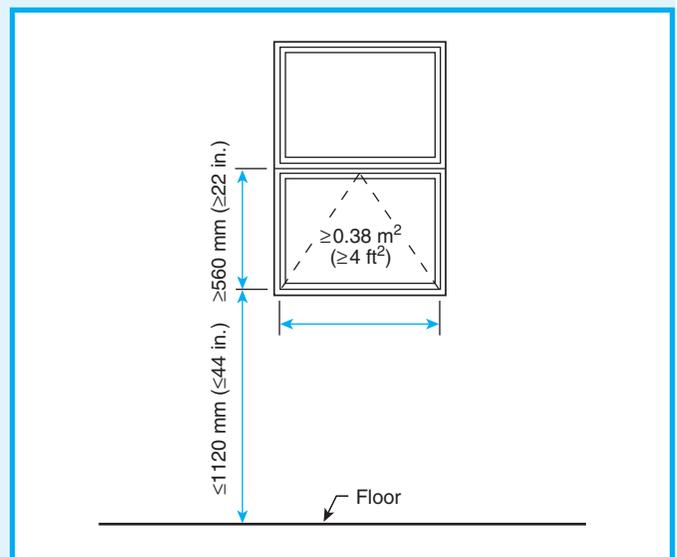

Exhibit 14/15.8 Existing awning window minimum dimensions permitted by 15.2.11.1.2(4).

CHAPTER 14 • New

The *Code* intends that the fire department or others are to assist students, especially over ladders. If these emergency rescue windows must be used as a supplementary means of escape, the windows must permit small children in the lower grades to escape unaided. Therefore, storm sashes, screens, or devices in front of the windows must be easy to open or remove, and the sills must be low enough for children to reach.

The *Code* also requires that such windows be accessible to the fire department and that occupants, once they escape through the window to the outside, have access to a public way.

Emergency rescue windows are not required if a classroom has a door leading directly to the outside or if the building is totally sprinklered. Note that 14/15.2.11.1.2(1) requires that the building be protected throughout by an automatic sprinkler system. The purpose of the window is to provide means of escape when the interior corridor is blocked by smoke from a fire in another part of the building. Installing sprinklers in only some rooms does not provide protection from smoke that is emanating from other areas.

Paragraph 15.2.11.1.2(5) applies only in existing buildings. Exhibit 14/15.9 illustrates how the exemption can be used.

CHAPTER 15 • Existing

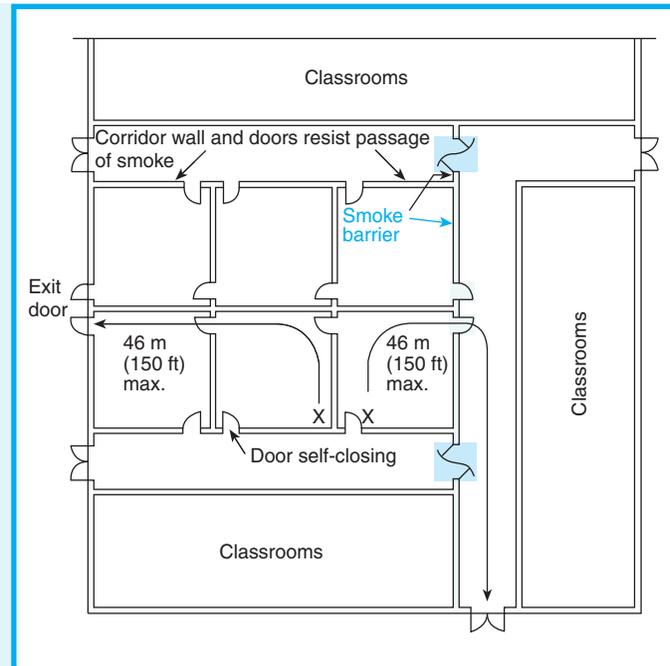

Exhibit 14/15.9 One method of compensating for windowless classroom in existing buildings as permitted by 15.2.11.1.2(5).

Section 14.3 Protection

14.3.1 Protection of Vertical Openings.

14.3.1.1 Any vertical opening, other than unprotected vertical openings in accordance with 8.6.8.2, shall be enclosed or protected in accordance with Section 8.6.

14.3.1.2 Where the provisions of 8.6.6 are used, the requirements of 14.3.5.4 shall be met.

Chapters 14 and 15 require all vertical openings, with the exception of an open and unobstructed “mini-

Section 15.3 Protection

15.3.1 Protection of Vertical Openings.

15.3.1.1 Any vertical opening, other than unprotected vertical openings in accordance with 8.6.8.2, shall be enclosed or protected in accordance with Section 8.6.

15.3.1.2 Where the provisions of 8.6.6 are used, the requirements of 15.3.5.2 shall be met.

15.3.1.3 Stairway enclosures shall not be required under the following conditions:

- (1) Where a stairway serves only one adjacent floor, other than a basement
- (2) Where a stairway is not connected with stairways serving other floors
- (3) Where a stairway is not connected with corridors serving other than the two floors involved

atrium” opening connecting three floors or less (see 8.6.6), an atrium (see 8.6.7), and a convenience open-

CHAPTER 14 • New

ing (see 8.6.8.2), to be enclosed in accordance with Section 8.6. While not specified by the mini-atrium provisions of 8.6.6, 14/15.3.1.2 and 14/15.3.5.4 require a building to be fully sprinklered to permit the maximum 3-story unenclosed vertical opening. The convenience opening addressed by 8.6.8.2 might be useful, especially for 2-story libraries or offices within schools.

The two-story stair permitted by 15.3.1.3 differs

14.3.2 Protection from Hazards.

14.3.2.1 Rooms or spaces for the storage, processing, or use of materials shall be protected in accordance with the following:

- (1) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour or protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
 - (a) Boiler and furnace rooms, unless such rooms enclose only air-handling equipment
 - (b) Rooms or spaces used for the storage of combustible supplies in quantities deemed hazardous by the authority having jurisdiction
 - (c) Rooms or spaces used for the storage of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
 - (d) Janitor closets [*see also 14.3.2.1(4).*]
- (2) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour and protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
 - (a) Laundries
 - (b) Maintenance shops, including woodworking and painting areas
 - (c) Rooms or spaces used for processing or use of combustible supplies deemed hazardous by the authority having jurisdiction
 - (d) Rooms or spaces used for processing or use of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
- (3) Where automatic extinguishing is used to meet the requirements of 14.3.2.1(1) or (2), the protection shall be permitted in accordance with 9.7.1.2.
- (4) Where janitor closets addressed in 14.3.2.1(1)(d) are protected in accordance with the sprinkler option of

CHAPTER 15 • Existing

from the convenience opening detailed in 8.6.8.2; paragraph 15.3.1.3 permits an existing two-story school building to have open egress stairs between the first and second floors. Open egress stairs are not permitted in new construction. Basements are excluded from use of the exemption in 15.3.1.3, because basements usually contain hazardous contents areas with high fuel loads, such as storage rooms, boiler rooms, or workshops.

15.3.2 Protection from Hazards.

15.3.2.1 Rooms or spaces for the storage, processing, or use of materials shall be protected in accordance with the following:

- (1) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour or protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
 - (a) Boiler and furnace rooms, unless such rooms enclose only air-handling equipment
 - (b) Rooms or spaces used for the storage of combustible supplies in quantities deemed hazardous by the authority having jurisdiction
 - (c) Rooms or spaces used for the storage of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
 - (d) Janitor closets [*see also 15.3.2.1(4).*]
- (2) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour and protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
 - (a) Laundries
 - (b) Maintenance shops, including woodworking and painting areas
 - (c) Rooms or spaces used for processing or use of combustible supplies deemed hazardous by the authority having jurisdiction
 - (d) Rooms or spaces used for processing or use of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
- (3) Where automatic extinguishing is used to meet the requirements of 15.3.2.1(1) or 15.3.2.1(2), the protection shall be permitted in accordance with 9.7.1.2.
- (4) Where janitor closets addressed in 15.3.2.1(1)(d) are protected in accordance with the sprinkler option of

CHAPTER 14 • New

14.3.2.1(1), the janitor closet doors shall be permitted to have ventilating louvers.

14.3.2.2 Cooking facilities shall be protected in accordance with 9.2.3. Openings shall not be required to be protected between food preparation areas and dining areas.

14.3.2.3 Stages shall be protected in accordance with Chapter 12.

Where janitor closets abut and are entered from a corridor, a louvered door is usually provided for ventilation. It is necessary to provide these spaces with automatic sprinkler protection, because a fire in the janitor closet might directly affect the usability of the corridor for exit access. Paragraph 9.7.1.2 describes an economical method of providing sprinkler protection for such closets by using the normal building water supply. To achieve this protection at reasonable cost, these sprinklers (not more than six for a given room or space) are permitted to be supplied from the building water supply if the supply is capable of providing the required flow of water. It is advisable to provide a waterflow switch to initiate an alarm when a sprinkler is opened.

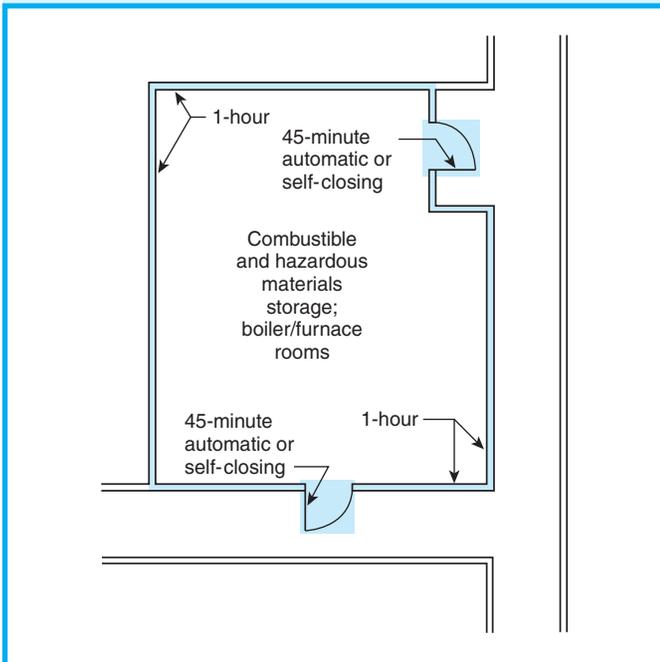

Exhibit 14/15.10 Protection of hazardous contents areas—rated enclosure complying with 14/15.3.2.1(1).

CHAPTER 15 • Existing

15.3.2.1(1), the janitor closet doors shall be permitted to have ventilating louvers.

15.3.2.2 Cooking facilities shall be protected in accordance with 9.2.3. Openings shall not be required to be protected between food preparation areas and dining areas.

15.3.2.3 Stages shall be protected in accordance with Chapter 13.

Exhibits 14/15.10 through 14/15.12 illustrate the various protection requirements of 14/15.3.2.1.

The intent of 14/15.3.2.1 is to specify the degree of protection necessary for certain hazardous contents areas. The hazards noted in subpart (1) are required to be enclosed in 1-hour construction or protected by automatic sprinklers. If the sprinkler option is chosen for new construction, an enclosure is still required by 8.7.1.2. However, the enclosure is not required to be rated; it is only required to form a membrane against the passage of smoke.

In accordance with 14/15.3.2.2, openings in the

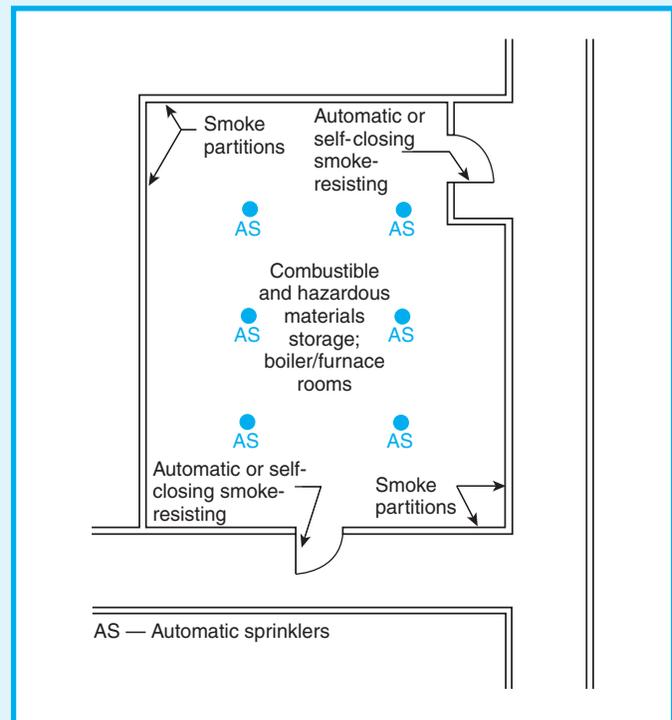

Exhibit 14/15.11 Protection of new hazardous contents areas—sprinkler protection and smoke partitions enclosure complying with 14.3.2.1(1).

CHAPTER 14 • New

CHAPTER 15 • Existing

wall between kitchens and dining areas are not restricted and do not need to be protected. The *Code* relies on the specialized automatic extinguishing system required by 9.2.3 to control any fire on the cooking surfaces and, thus, does not require openings between the kitchen and dining areas to be protected.

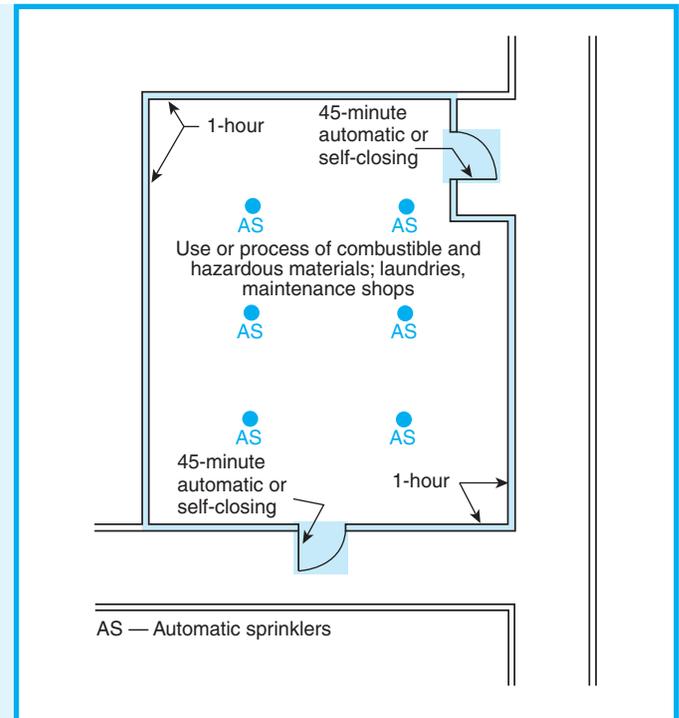

Exhibit 14/15.12 Protection of hazardous contents areas—separation by 1-hour rated enclosure and automatic sprinkler protection complying with 14/15.3.2.1(2).

14.3.3 Interior Finish.

14.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

14.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be permitted as follows:

- (1) Exits—Class A
- (2) Other than exits—Class A or Class B
- (3) Low-height partitions not exceeding 1525 mm (60 in.) and used in locations other than exits—Class A, Class B, or Class C

14.3.3.3 Interior Floor Finish.

14.3.3.3.1 Interior floor finish shall comply with Section 10.2.

14.3.3.3.2 Interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 14.3.6 shall be not less than Class II.

14.3.3.3.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

15.3.3 Interior Finish.

15.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

15.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be permitted as follows:

- (1) Exits—Class A
- (2) Corridors and lobbies—Class A or Class B
- (3) Low-height partitions not exceeding 1525 mm (60 in.) and used in locations other than exits—Class A, Class B, or Class C

15.3.3.3 Interior Floor Finish. (No requirements.)

CHAPTER 14 • New

For the 2003 edition of the *Code*, effort was made to standardize the requirements for new interior floor finish. Floor finish in corridors is susceptible to ignition and flame spread when exposed to a well-developed fire such as might occur if a room fire were to grow to flashover and the room door remained

14.3.4 Detection, Alarm, and Communications Systems.

14.3.4.1 General.

14.3.4.1.1 Educational occupancies shall be provided with a fire alarm system in accordance with Section 9.6.

14.3.4.1.2 The requirement of 14.3.4.1.1 shall not apply to buildings meeting all of the following criteria:

- (1) Buildings having an area not exceeding 93 m² (1000 ft²)
- (2) Buildings containing a single classroom
- (3) Buildings located not less than 15 m (50 ft) from another building

The limited-size, single-classroom building addressed by 14/15.3.4.1.2 does not need an alarm system because the fire will be immediately obvious to the occupants. Emergency egress can begin upon first notice of fire. A fire within a building located at least

14.3.4.2 Initiation.

14.3.4.2.1 General. Initiation of the required fire alarm system, other than as permitted by 14.3.4.2.3, shall be by manual means in accordance with 9.6.2.1(1).

14.3.4.2.2 Automatic Initiation. In buildings provided with automatic sprinkler protection, the operation of the sprinkler system shall automatically activate the fire alarm system in addition to the initiation means required in 14.3.4.2.1.

CHAPTER 15 • Existing

open. Paragraph 14.3.3.3.2 addresses this concern. Paragraph 14.3.3.3.3 references the generalized criteria of 10.2.7.1 and 10.2.7.2, which are intended to identify and prohibit the use of floor finish materials that have little or no resistance to ignition.

15.3.4 Detection, Alarm, and Communications Systems.

15.3.4.1 General.

15.3.4.1.1 Educational occupancies shall be provided with a fire alarm system in accordance with Section 9.6.

15.3.4.1.2 The requirement of 15.3.4.1.1 shall not apply to buildings meeting all of the following criteria:

- (1) Buildings having an area not exceeding 93 m² (1000 ft²)
- (2) Buildings containing a single classroom
- (3) Buildings located not less than 15 m (50 ft) from another building

15 m (50 ft) from another building should not prove to be detrimental to the occupants of the other building if egress is delayed even though no alarm system is required.

15.3.4.2 Initiation.

15.3.4.2.1 General. Initiation of the required fire alarm system shall be by manual means in accordance with 9.6.2.1(1), unless otherwise permitted by the following:

- (1) Manual fire alarm boxes shall not be required where permitted by 15.3.4.2.3.
- (2) In buildings where all normally occupied spaces are provided with a two-way communication system between such spaces and a constantly attended receiving station from where a general evacuation alarm can be sounded, the manual fire alarm boxes shall not be required, except in locations specifically designated by the authority having jurisdiction.

15.3.4.2.2 Automatic Initiation. In buildings provided with automatic sprinkler protection, the operation of the sprinkler system shall automatically activate the fire alarm system in addition to the initiation means required in 15.3.4.2.1.

CHAPTER 14 • New

14.3.4.2.3 Alternative Protection System. Manual fire alarm boxes shall be permitted to be eliminated in accordance with 14.3.4.2.3.1 or 14.3.4.2.3.2.

14.3.4.2.3.1* Manual fire alarm boxes pull stations shall be permitted to be eliminated where all of the following conditions apply:

- (1) Interior corridors are protected by smoke detectors using an alarm verification system as described in *NFPA 72®*, *National Fire Alarm Code®*.
- (2) Auditoriums, cafeterias, and gymnasiums, etc., are protected by heat or other approved detection devices.
- (3) Shops and laboratories involving dusts or vapors are protected by heat or other approved detection devices.
- (4) Provision is made at a central point to manually activate the evacuation signal or to evacuate only affected areas.

A.14.3.4.2.3.1 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal.

14.3.4.2.3.2* Manual fire alarm boxes shall be permitted to be eliminated where all of the following conditions apply:

- (1) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) Provision is made at a central point to manually activate the evacuation signal, or to evacuate only affected areas.

A.14.3.4.2.3.2 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal.

Paragraph 14/15.3.4.2.3 provides alternatives to the manual fire alarm boxes required by 14/15.3.4.2.1. These alternatives are offered as means to avoid the nuisance alarms initiated through unauthorized use of the building manual fire alarm boxes. By relying on the automatic initiation that is provided by the detection systems addressed in 14/15.3.4.2.3.1(1) through (3), equivalent protection is provided. By relying on the fire control that is provided by the automatic sprinkler system addressed in 14/15.3.4.2.3.2, equivalent protection is provided.

Paragraph 15.3.4.2.1(2)—which applies only to existing educational occupancies—recognizes an alternative to a dedicated fire alarm system. Where there

CHAPTER 15 • Existing

15.3.4.2.3 Alternative Protection System. Manual fire alarm boxes shall be permitted to be eliminated in accordance with 15.3.4.2.3.1 or 15.3.4.2.3.2.

15.3.4.2.3.1* Manual fire alarm boxes shall be permitted to be eliminated where all of the following conditions apply:

- (1) Interior corridors are protected by smoke detectors using an alarm verification system as described in *NFPA 72®*, *National Fire Alarm Code®*.
- (2) Auditoriums, cafeterias, and gymnasiums are protected by heat or other approved detection devices.
- (3) Shops and laboratories involving dusts or vapors are protected by heat or other approved detection devices.
- (4) Provision is made at a central point to manually activate the evacuation signal or to evacuate only affected areas.

A.15.3.4.2.3.1 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal.

15.3.4.2.3.2* Manual fire alarm boxes shall be permitted to be eliminated where all of the following conditions apply:

- (1) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) Provision is made at a central point to manually activate the evacuation signal, or to evacuate only affected areas.

A.15.3.4.2.3.2 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal.

is a two-way communication system between classrooms and a constantly attended location where a general alarm can be sounded, the requirement for an alarm system—and its requisite manual fire alarm boxes—is exempted. To use this exemption, the authority having jurisdiction must designate those manual fire alarm boxes that are allowed to be omitted. For the purposes of this provision, a “constantly attended” location is a location that is attended while the school building is in use as a school. Compliance might involve providing personnel at this location during night classes, when the regular school office staff is not present. The exemption is not permitted for new construction due to reliability concerns.

CHAPTER 14 • New

14.3.4.3 Notification.**14.3.4.3.1 Occupant Notification.**

14.3.4.3.1.1* Occupant notification shall be accomplished automatically in accordance with 9.6.3.

A.14.3.4.3.1.1 Use of the distinctive three-pulse temporal pattern fire alarm evacuation signal that is required by *NFPA 72®*, *National Fire Alarm Code®*, will help educate students to recognize the need to evacuate when they are in other occupancies.

14.3.4.3.1.2 Positive alarm sequence shall be permitted in accordance with 9.6.3.4.

14.3.4.3.1.3 Where acceptable to the authority having jurisdiction, the fire alarm system shall be permitted to be used for other emergency signaling or for class changes, provided that the fire alarm is distinctive in signal and overrides all other use.

14.3.4.3.1.4 To prevent students from being returned to a building that is burning, the recall signal shall be separate and distinct from any other signals, and such signal shall be permitted to be given by use of distinctively colored flags or banners.

14.3.4.3.1.5 If the recall signal required by 14.3.4.3.1.4 is electric, the push buttons or other controls shall be kept under lock, the key for which shall be in the possession of the principal or another designated person in order to prevent a recall at a time when there is an actual fire.

14.3.4.3.1.6 Regardless of the method of recall signal, the means of giving the recall signal shall be kept under lock.

14.3.4.3.2 Emergency Forces Notification. Fire department notification shall be accomplished in accordance with 9.6.4.

14.3.5 Extinguishment Requirements.

14.3.5.1 Every portion of educational buildings below the level of exit discharge shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

14.3.5.2 Reserved.

CHAPTER 15 • Existing

15.3.4.3 Notification.**15.3.4.3.1 Occupant Notification.**

15.3.4.3.1.1* Occupant notification shall be accomplished automatically in accordance with 9.6.3.

A.15.3.4.3.1.1 The audible occupant notification signal for evacuation of an educational occupancy building should be the distinctive three-pulse temporal pattern fire alarm evacuation signal that is required of new systems by *NFPA 72®*, *National Fire Alarm Code®*. The temporal pattern will help educate students to recognize the need to evacuate when they are in other occupancies. Existing fire alarm systems should be modified, as feasible, to sound the three-pulse temporal pattern.

15.3.4.3.1.2 Positive alarm sequence shall be permitted in accordance with 9.6.3.4.

15.3.4.3.1.3 Where acceptable to the authority having jurisdiction, the fire alarm system shall be permitted to be used for other emergency signaling or for class changes, provided that the fire alarm is distinctive in signal and overrides all other use.

15.3.4.3.1.4 To prevent students from being returned to a building that is burning, the recall signal shall be separate and distinct from any other signals and such signal shall be permitted to be given by use of distinctively colored flags or banners.

15.3.4.3.1.5 If the recall signal required by 15.3.4.3.1.4 is electric, the push buttons or other controls shall be kept under lock, the key for which shall be in the possession of the principal or another designated person in order to prevent a recall at a time when there is an actual fire.

15.3.4.3.1.6 Regardless of the method of recall signal, the means of giving the recall signal shall be kept under lock.

15.3.4.3.2 Emergency Forces Notification. Wherever any of the school authorities determine that an actual fire exists, they shall immediately call the local fire department using the public fire alarm system or other available facilities.

15.3.5 Extinguishment Requirements.

15.3.5.1 Where student occupancy exists below the level of exit discharge, every portion of such floor shall be protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

15.3.5.2 Where student occupancy does not exist on floors below the level of exit discharge, such floors shall be sepa-

CHAPTER 14 • New

14.3.5.3 Reserved.

14.3.5.4 Buildings with unprotected openings in accordance with 8.6.6 shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

14.3.5.5 Where another provision of this chapter requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with 9.7.1.1(1).

The provisions of 14/15.3.5 address the need for sprinklers based on whether there are levels or floors below the level of exit discharge. For new construction, this provision will normally require basements

14.3.6 Corridors.

Corridors shall be separated from other parts of the story by walls having a 1-hour fire resistance rating in accordance with Section 8.3, unless otherwise permitted by the following:

- (1) Corridor protection shall not be required where all spaces normally subject to student occupancy have not less than one door opening directly to the outside or to an exterior exit access balcony or corridor in accordance with 7.5.3.
- (2) In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, corridor walls shall not be required to be rated, provided that such walls form smoke partitions in accordance with Section 8.4.

CHAPTER 15 • Existing

rated from the rest of the building by 1-hour fire resistance-rated construction or shall be protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

15.3.5.3 Automatic sprinkler protection shall not be required where student occupancy exists below the level of exit discharge, provided that both of the following criteria are met:

- (1) The approval of the authority having jurisdiction shall be required.
- (2) Windows for rescue and ventilation shall be provided in accordance with 15.2.11.1.

15.3.5.4 Buildings with unprotected openings in accordance with 8.6.6 shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

15.3.5.5 Where another provision of this chapter requires an automatic sprinkler system, the sprinkler system shall be installed in accordance with 9.7.1.1(1).

of schools to be sprinklered; for existing educational occupancies, the basement will need to be sprinklered if it is used for student occupancy.

15.3.6 Corridors.

Corridors shall be separated from other parts of the story by walls having a ½-hour fire resistance rating in accordance with Section 8.3, unless otherwise permitted by the following.

- (1) Corridor protection shall not be required where all spaces normally subject to student occupancy have not less than one door opening directly to the outside or to an exterior exit access balcony or corridor in accordance with 7.5.3.
- (2)* In buildings protected throughout by an approved automatic sprinkler system with valve supervision in accordance with Section 9.7, corridor walls shall not be required to be rated, provided that such walls form smoke partitions in accordance with Section 8.4.

A.15.3.6(2) This provision permits valve supervision in accordance with Section 9.7 rather than requiring that the entire automatic sprinkler system be electrically supervised. It is intended that the valve supervision be performed electrically, not by chaining and locking the valves in the open position.

CHAPTER 14 • New

- (3) Where the corridor ceiling is an assembly having a 1-hour fire resistance rating where tested as a wall, the corridor walls shall be permitted to terminate at the corridor ceiling.
- (4) Lavatories shall not be required to be separated from corridors, provided that they are separated from all other spaces by walls having not less than a 1-hour fire resistance rating in accordance with Section 8.3.
- (5) Lavatories shall not be required to be separated from corridors, provided the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

Given the protection provided by an automatic sprinkler system installed throughout the building, 14/15.3.6(2) allows the corridor walls to be unrated, provided they form smoke partitions. See Section 8.4 for applicable criteria.

Paragraph 14/15.3.6(3) legitimizes the practice of designing a corridor protection system by building a tunnel with walls and ceilings constructed to meet the requirements of a 1-hour rated wall assembly for new construction and a ½-hour rating for existing assemblies.

The walls and doors that typically separate a school lavatory from the corridor often serve to isolate the lavatory, making incidents of violence or illegal drug use difficult to monitor by staff. In recognition of this problem, and given the typically low fuel loads associated with lavatories, 14/15.3.6(4) exempts the wall separating the lavatory from the corridor from the rated construction requirement, provided that the rated corridor wall continuously separates the lavatory from adjacent rooms. This separation method permits lavatory doors to be omitted from the doorways. Exhibit 14/15.13 illustrates this arrangement.

The intent of 14/15.3.6(5) is to combine parts of the concepts addressed in 14/15.3.6(2) and 14/15.3.6(4).

14.3.7 Subdivision of Building Spaces.

14.3.7.1 Educational occupancies shall be subdivided into compartments by smoke partitions having not less than a 1-hour fire resistance rating and complying with Section 8.4 where one or both of the following conditions exist:

CHAPTER 15 • Existing

- (3) Where the corridor ceiling is an assembly having a ½-hour fire resistance rating where tested as a wall, the corridor wall shall be permitted to terminate at the corridor ceiling.
- (4) Lavatories shall not be required to be separated from corridors, provided that they are separated from all other spaces by walls having not less than a ½-hour fire resistance rating in accordance with Section 8.3.
- (5) Lavatories shall not be required to be separated from corridors, provided the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (6) Existing doors in ½-hour fire resistance-rated corridor walls shall be permitted to be 44-mm (1-in.) thick solid-bonded wood core doors or the equivalent.

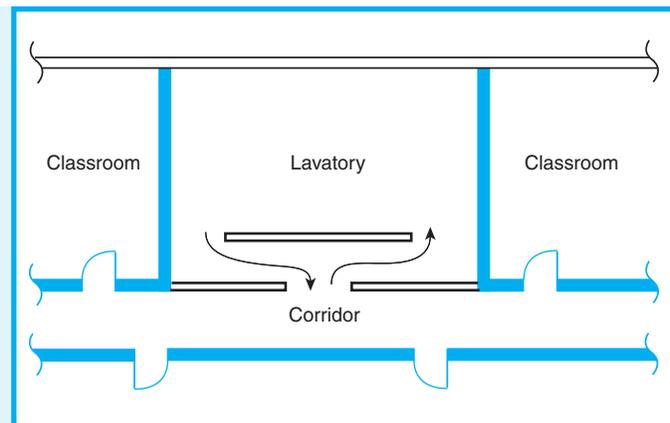

Exhibit 14/15.13 Lavatory open to corridor but separated from adjacent rooms by continuous, rated corridor wall to building exterior walls.

Where the entire building is protected by automatic sprinklers, the lavatory can be open to the corridor, and the walls separating the lavatory from other rooms do not need to be fire rated, but do need to form smoke partitions. The *Code* language does not fully explain this.

15.3.7 Subdivision of Building Spaces.

15.3.7.1 Educational occupancies shall be subdivided into compartments by smoke partitions having not less than a 1-hour fire resistance rating and complying with Section 8.4 where one or both of the following conditions exist:

CHAPTER 14 • New

- (1) The maximum floor area, including the aggregate area of all floors having a common atmosphere, exceeds 2800 m² (30,000 ft²).
- (2) The length or width of the building exceeds 91 m (300 ft).

14.3.7.2 The requirement of 14.3.7.1 shall not apply to the following:

- (1) Where all spaces normally subject to student occupancy have not less than one door opening directly to the outside or to an exterior or exit access balcony or corridor in accordance with 7.5.3
- (2) Buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7

14.3.7.3 The area of any smoke compartment required by 14.3.7.1 shall not exceed 2800 m² (30,000 ft²), with no dimension exceeding 91 m (300 ft).

The *Code* requires smoke barriers at maximum intervals of 91 m (300 ft) so that the products of combustion will not affect large numbers of occupants and their exits simultaneously. A primary concern is a situation where a corridor becomes clogged with smoke, resulting in the loss of the exit access. Rooms with exterior exit access provide the occupants a readily available, alternate means of escape in the event that a corridor fills with smoke.

Section 14.4 Special Provisions

14.4.1 Limited Access Buildings and Underground Buildings.

Limited access buildings and underground buildings shall comply with Section 11.7.

14.4.2 High-Rise Buildings.

High-rise buildings shall comply with Section 11.8.

An educational occupancy high-rise building poses many of the same problems for occupants and fire-fighting forces that are posed by other occupancies located in high-rise buildings. Thus, the package of

CHAPTER 15 • Existing

- (1) The maximum area of a compartment, including the aggregate area of all floors having a common atmosphere, exceeds 2800 m² (30,000 ft²).
- (2) The length or width of the building exceeds 91 m (300 ft).

15.3.7.2 The requirements of 15.3.7.1 shall not apply to the following:

- (1) Where all classrooms have exterior exit access in accordance with 7.5.3.
- (2) Buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7

15.3.7.3 The area of any smoke compartment required by 15.3.7.1 shall not exceed 2800 m² (30,000 ft²), with no dimension exceeding 91 m (300 ft).

The excellent record of automatic fire sprinklers permits the compartmentation requirements to be exempted in buildings with such systems.

The provision of 14/15.3.7.3 limits the area of a smoke compartment only if such compartmentation is required by 14/15.3.7.1 and 14/15.3.7.2.

Section 15.4 Special Provisions

15.4.1 Limited Access Buildings and Underground Buildings.

Limited access buildings and underground buildings shall comply with Section 11.7.

15.4.2 High-Rise Buildings.

High-rise buildings shall comply with 11.8.2.1.

protection addressed by Section 11.8 is mandatorily referenced for new construction; the sprinkler provisions of 11.8.2.1 are mandatorily referenced for existing educational occupancy high-rise buildings.

CHAPTER 14 • New

14.4.3 Flexible Plan and Open Plan Buildings.

14.4.3.1 Flexible plan and open plan buildings shall comply with the requirements of this chapter as modified by 14.4.3.2 through 14.4.3.5.

14.4.3.2 Each room occupied by more than 300 persons shall have two or more means of egress entering into separate atmospheres.

14.4.3.3 Where three or more means of egress are required, the number of means of egress permitted to enter into the same atmosphere shall not exceed two.

14.4.3.4 Flexible plan buildings shall be permitted to have walls and partitions rearranged periodically only if revised plans or diagrams have been approved by the authority having jurisdiction.

14.4.3.5 Flexible plan buildings shall be evaluated while all folding walls are extended and in use as well as when they are in the retracted position.

Flexible plan and open plan buildings are addressed in 14/15.4.3. Rooms occupied by more than 300 persons require special treatment in flexible plan and open plan schools. To ensure the safety of this large number of persons occupying one room, means of egress must be arranged so that each of the egress paths traverses atmospheres that are separate from each other. If more than two separate means of egress paths are required, no more than two are permitted to pass through the same atmosphere. Using this arrangement should prevent one fire from contaminating or blocking all exits in an open plan or flexible plan building.

Exhibit 14/15.14 illustrates a room in an open plan building that requires two or more means of egress into separate atmospheres.

In accordance with 14/15.4.3.4, approval of revised plans or diagrams is necessary to avoid the possibility of circuitous egress paths or other arrangements that do not comply with the intent of the *Code*. Also, flexible plan buildings are required to meet the requirements for corridor protection as well as those for the subdivision of building spaces using smoke barriers.

CHAPTER 15 • Existing

15.4.3 Flexible Plan and Open Plan Buildings.

15.4.3.1 Flexible plan and open plan buildings shall comply with the requirements of this chapter as modified by 15.4.3.2 through 15.4.3.5.

15.4.3.2 Each room occupied by more than 300 persons shall have two or more means of egress entering into separate atmospheres.

15.4.3.3 Where three or more means of egress are required, the number of means of egress permitted to enter into the same atmosphere shall not exceed two.

15.4.3.4 Flexible plan buildings shall be permitted to have walls and partitions rearranged periodically only if revised plans or diagrams have been approved by the authority having jurisdiction.

15.4.3.5 Flexible plan buildings shall be evaluated while all folding walls are extended and in use as well as when they are in the retracted position.

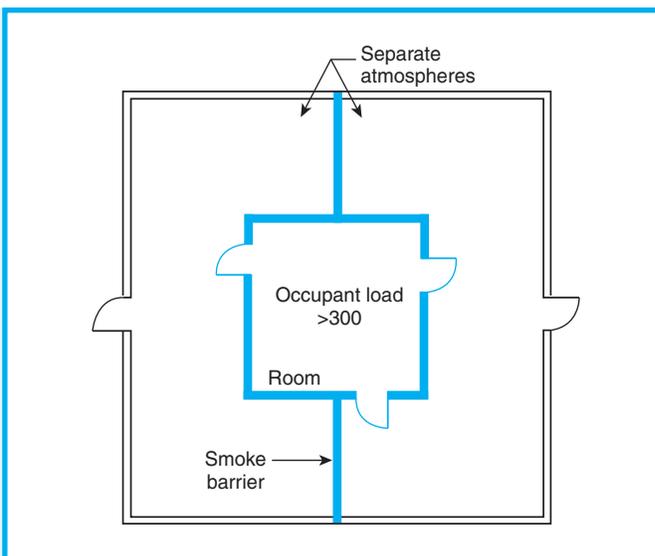

Exhibit 14/15.14 Room in open plan building requiring two or more means of egress into separate atmospheres.

CHAPTER 14 • New

Section 14.5 Building Services**14.5.1 Utilities.**

Utilities shall comply with the provisions of Section 9.1.

14.5.2 Heating, Ventilating, and Air Conditioning Equipment.

14.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

14.5.2.2 Unvented fuel-fired heating equipment, other than gas space heaters in compliance with NFPA 54/ANSI Z223.1, *National Fuel Gas Code*, shall be prohibited.

It is not in the interest of reasonable life safety to allow unvented, fuel-fired equipment in a school building occupied by children; the typical use of such equipment might jeopardize the life safety of the students. Improper venting and potential misuse by students

14.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

14.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 14.6 Reserved**Section 14.7 Operating Features****14.7.1 Emergency Plan.**

Emergency plans shall be provided in accordance with Section 4.8.

14.7.2 Emergency Egress and Relocation Drills.

14.7.2.1* Emergency egress and relocation drills shall be conducted in accordance with Section 4.7 and the applicable provisions of 14.7.2.2.

CHAPTER 15 • Existing

Section 15.5 Building Services**15.5.1 Utilities.**

Utilities shall comply with the provisions of Section 9.1.

15.5.2 Heating, Ventilating, and Air Conditioning Equipment.

15.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

15.5.2.2 Unvented fuel-fired heating equipment, other than gas space heaters in compliance with NFPA 54/ANSI Z223.1, *National Fuel Gas Code*, shall be prohibited.

might result in injury to students, especially younger children. Paragraph 14/15.5.2.2 recognizes a special form of gas space heater that—although not vented in the conventional way—can be used safely.

15.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

15.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 15.6 Reserved**Section 15.7 Operating Features****15.7.1 Emergency Plan.**

Emergency plans shall be provided in accordance with Section 4.8.

15.7.2 Emergency Egress and Relocation Drills.

15.7.2.1* Emergency egress and relocation drills shall be conducted in accordance with Section 4.7 and the applicable provisions of 15.7.2.2.

CHAPTER 14 • New

A.14.7.2.1 The requirements are, of necessity, general in scope, as it is recognized that they apply to all types of educational occupancies as well as conditions of occupancies, such as truant schools; schools for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; and public schools. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements.

14.7.2.2 Emergency egress and relocation drills shall be conducted as follows:

- (1) Not less than one emergency egress and relocation drill shall be conducted every month the facility is in session, unless both of the following criteria are met:
 - (a) In climates where the weather is severe, the monthly emergency egress and relocation drills shall be permitted to be deferred.
 - (b) The required number of emergency egress and relocation drills shall be conducted, and not less than four shall be conducted before the drills are deferred.
- (2) All occupants of the building shall participate in the drill.
- (3) One additional emergency egress and relocation drill, other than for educational occupancies that are open on a year-round basis, shall be required within the first 30 days of operation.

14.7.2.3 All emergency and relocation drill alarms shall be sounded on the fire alarm system.

Emergency egress and relocation drills for educational occupancies, particularly those at the grade school level, are essential to ensure an orderly response during a fire. Unfortunately, the predictability of such drills often leads to their ineffectiveness. When an alarm bell sounds and a fire department monitor appears in a corridor, some teachers ignore the bell, assuming that it is a false alarm. If the bell sounds and a fire department monitor is not seen, teachers opt to either evacuate or remain in the building. This decision is made in the hallway. While the

14.7.3 Inspection.

14.7.3.1* It shall be the duty of principals and teachers to inspect all exit facilities daily to ensure that all stairways, doors, and other exits are in proper condition.

CHAPTER 15 • Existing

A.15.7.2.1 The requirements are, of necessity, general in scope, as it is recognized that they apply to all types of educational occupancies as well as conditions of occupancies, such as truant schools; schools for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; and public schools. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements.

15.7.2.2 Emergency egress and relocation drills shall be conducted as follows:

- (1) Not less than one emergency egress and relocation drill shall be conducted every month the facility is in session, unless both of the following criteria are met:
 - (a) In climates where the weather is severe, the monthly emergency egress and relocation drills shall be permitted to be deferred.
 - (b) The required number of emergency egress and relocation drills shall be conducted, and not less than four shall be conducted before the drills are deferred.
- (2) All occupants of the building shall participate in the drill.
- (3) One additional emergency egress and relocation drill, other than for educational occupancies that are open on a year-round basis, shall be required within the first 30 days of operation.

15.7.2.3 All emergency and relocation drill alarms shall be sounded on the fire alarm system.

bell continues to ring, the students remain in their classrooms. Therefore, when a bell sounds, the primary emphasis should be placed on evacuation or relocation, regardless of who is or is not present in the hallways, or whether or not fire equipment is parked in front of the school. Essentially, the fire department and the school should vary the timing and arrangement of the drills but not the required response, which is orderly evacuation. See also Section 4.7.

15.7.3 Inspection.

15.7.3.1* It shall be the duty of principals and teachers to inspect all exit facilities daily to ensure that all stairways, doors, and other exits are in proper condition.

CHAPTER 14 • New

A.14.7.3.1 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building.

Any condition likely to interfere with safe egress should be corrected immediately, if possible, or otherwise should be reported at once to the appropriate authorities.

14.7.3.2 Open plan buildings shall require extra surveillance to ensure that exit paths are maintained clear of obstruction and are obvious.

14.7.4 Furnishings and Decorations.

14.7.4.1 Draperies, curtains, and other similar furnishings and decorations in educational occupancies shall be in accordance with the provisions of 10.3.1.

14.7.4.2 Clothing and personal effects shall not be stored in corridors, unless otherwise permitted by the following:

- (1) This requirement shall not apply to corridors protected by an automatic sprinkler system in accordance with Section 9.7.
- (2) This requirement shall not apply to corridor areas protected by a smoke detection system in accordance with Section 9.6.
- (3) This requirement shall not apply to storage in metal lockers, provided that the required egress width is maintained.

Clothing hung on hooks along corridor walls or on racks in school lobbies greatly increases the combustible load and will generally allow flame to spread quickly. Because Chapters 14 and 15 regulate the interior wall finish for corridors and lobbies, surfaces covered by combustible clothing that would allow flame to spread more quickly than is permitted by

14.7.4.3 Artwork and teaching materials shall be permitted to be attached directly to the walls in accordance with the following:

- (1) The artwork and teaching materials shall not exceed 20 percent of the wall area in a building that is not protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7

CHAPTER 15 • Existing

A.15.7.3.1 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building.

Any condition likely to interfere with safe egress should be corrected immediately, if possible, or otherwise should be reported at once to the appropriate authorities.

15.7.3.2 Open plan buildings shall require extra surveillance to ensure that exit paths are maintained clear of obstruction and are obvious.

15.7.4 Furnishings and Decorations.

15.7.4.1 Draperies, curtains, and other similar furnishings and decorations in educational occupancies shall be in accordance with the provisions of 10.3.1.

15.7.4.2 Clothing and personal effects shall not be stored in corridors, unless otherwise permitted by the following:

- (1) This requirement shall not apply to corridors protected by an automatic sprinkler system in accordance with Section 9.7.
- (2) This requirement shall not apply to corridor areas protected by a smoke detection system in accordance with Section 9.6.
- (3) This requirement shall not apply to storage in metal lockers, provided that the required egress width is maintained.

wall surfaces should not be created. The provisions of each of the exemptions to 14/15.7.4.2 (control of fire by sprinklers, early warning of incipient stage fire via smoke detection, or isolating fuel packages by locating the clothing in metal lockers) help to mitigate the potential for a clothing fire to render the exit access unusable.

15.7.4.3 Artwork and teaching materials shall be permitted to be attached directly to the walls in accordance with the following:

- (1) The artwork and teaching materials shall not exceed 20 percent of the wall area in a building that is not protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

CHAPTER 14 • New

- (2) The artwork and teaching materials shall not exceed 50 percent of the wall area in a building that is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7

It is advantageous not only to limit the quantity of artwork displayed but also to avoid placing such materials near a room's exit access doors. Because the combustibility of the artwork cannot be effectively controlled, the quantity, in terms of the percentage of wall area covered, is regulated to avoid creating a con-

14.7.5 Open Flames.

Approved open flames shall be permitted in laboratories and vocational/technical areas.

CHAPTER 15 • Existing

- (2) The artwork and teaching materials shall not exceed 50 percent of the wall area in a building that is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

tinuous combustible surface that will spread flame across the room. Where the building is protected throughout by automatic sprinklers, the percentage of wall area permitted to be covered with artwork and teaching materials is increased to 50 percent.

15.7.5 Open Flames.

Approved open flames shall be permitted in laboratories and vocational/technical areas.

CHAPTERS 16 and 17

New and Existing Day-Care Occupancies

Chapters 16 and 17 address not only traditional child day care, but also the growing field of adult day care. In both cases, these chapters recognize that many of the individuals who occupy these facilities are not totally capable of self-preservation. Very young children will require a certain amount of assistance from the day-care staff to help with relocation or evacuation. Likewise, some adults in adult day care will also require staff assistance during a fire emergency. For these reasons, Chapters 16 and 17 mandate select features that anticipate that these occupants will respond to a fire more slowly than is normal. The requirements address a range of protection features, including the physical location of the day-care facility

as it relates to the level of exit discharge (see Table 16.1.6.1 and Table 17.1.6). In reviewing the tables, note that the building construction features become more stringent where the day-care occupancy is located above or below the level of exit discharge. These tables also establish a threshold at which automatic sprinkler protection is required.

The complement of fire alarm systems, sprinkler systems, and other building construction features are addressed in these chapters. Section 16/17.7 addresses staffing, training, and drilling necessary to carry out an effective and efficient fire emergency response plan.

Section 16.1 General Requirements

16.1.1* Application.

A.16.1.1 Day-care occupancies do not provide for the full-time maintenance of a client. Occupancies that provide a primary place of residence are addressed in other occupancy chapters. (See Chapter 24 through Chapter 33.)

The requirements of Chapter 16 are based on the need to adequately protect the occupants in case of fire. The requirements assume that adequate staffing will be available and are based on staffing similar to that outlined in Table A.16.1.1.

If staff-to-client ratios fall below that suggested by Table A.16.1.1, it is the responsibility of the authority having jurisdiction to determine the additional safeguards beyond the requirements of Chapter 16 that are necessary. Typical additional provisions might include restricting the day-care occupancy to the level of exit discharge, requiring additional

Section 17.1 General Requirements

17.1.1* Application.

A.17.1.1 Day-care occupancies do not provide for the full-time maintenance of a client. Occupancies that provide a primary place of residence are addressed in other occupancies. (See Chapter 24 through Chapter 33.)

The requirements of Chapter 17 are based on the need to adequately protect the occupants in case of fire. The requirements assume that adequate staffing will be available and are based on staffing similar to that outlined in Table A.17.1.1.

If staff-to-client ratios fall below that suggested by Table A.17.1.1, it is the responsibility of the authority having jurisdiction to determine what additional safeguards beyond the requirements of Chapter 17 are necessary. Typical additional provisions might include restricting the day-care occupancy to the level of exit discharge, requiring additional

CHAPTER 16 • New

Table A.16.1.1 Staffing

Staff-to-Client Ratio	Age (months)
1:3	0–24
1:4	25–36
1:7	37–60
1:10	61–96
1:12	≥97
1:3	Clients incapable of self-preservation

smoke detection, requiring automatic sprinkler protection, requiring better or additional means of egress, and similar types of items, depending on the situation.

16.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as day-care occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, a day-care occupancy (*see 4.6.7*)
- (3) Alterations, modernizations, or renovations of existing day-care occupancies (*see 4.6.8*)
- (4) Existing buildings or portions thereof upon change of occupancy to a day-care occupancy (*see 4.6.12*)

16.1.1.2 The requirements of Section 16.1 through Section 16.5 and Section 16.7 shall apply to day-care occupancies in which more than 12 clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day.

16.1.1.3 The requirements of Section 16.1 (other than 16.1.6) and Section 16.4 through Section 16.7 shall apply to day-care homes as defined in 16.1.3.

16.1.1.4 Where a facility houses more than one age group or self-preservation capability, the strictest requirements applicable to any group present shall apply throughout the day-care occupancy or building, as appropriate to a given area,

CHAPTER 17 • Existing

Table A.17.1.1 Staffing

Staff-to-Client Ratio	Age (months)
1:3	0–24
1:4	25–36
1:7	37–60
1:10	61–96
1:12	≥97
1:3	Clients incapable of self-preservation

smoke detection, requiring automatic sprinkler protection, requiring better or additional means of egress, and similar types of items, depending on the situation.

17.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as day-care occupancies. (*See also 16.1.1.1.*)

17.1.1.2 The requirements of Section 17.1 through Section 17.5 and Section 17.7 shall apply to existing day-care occupancies in which more than 12 clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day. An existing day-care occupancy shall be permitted the option of meeting the requirements of Chapter 16 in lieu of Chapter 17. An existing day-care occupancy that meets the requirements of Chapter 16 shall be judged as meeting the requirements of Chapter 17.

17.1.1.3 The requirements of Section 17.1 (other than 17.1.6) and Section 17.4 through Section 17.7 shall apply to existing day-care homes as defined in 17.1.3. An existing day-care home shall be permitted the option of meeting the requirements of Chapter 16 in lieu of Chapter 17. An existing day-care home that meets the requirements of Chapter 16 shall be judged as meeting the requirements of Chapter 17.

17.1.1.4 Where a facility houses clients of more than one self-preservation capability, the strictest requirements applicable to any group present shall apply throughout the day-care occupancy or building, as appropriate to a given area,

CHAPTER 16 • New

unless the area housing such a group is maintained as a separate fire area.

16.1.1.5 Places of religious worship shall not be required to meet the provisions of this chapter where providing day care while services are being held in the building.

The intent of 16/17.1.1.2 is to differentiate between institutions where clients are in residence 24 hours a day (such as orphanages) and day-care facilities where clients who normally reside at another location are provided care. A facility supplying “total care” for each client would provide laundries, dormitories, cafeterias, and other ancillary services not found in a day-care center. The life safety requirements of such a facility would be governed by other occupancy provisions of the *Code*.

Note that, per 17.1.1.2 and 17.1.1.3, an existing day-care center or an existing day-care home meeting the requirements of Chapter 16 is to be judged as meeting the requirements of Chapter 17. Thus, if a new day-care center or day-care home is built in accordance with the requirements of Chapter 16, it later becomes an existing facility. Because the requirements of Chapters 16 and 17 differ, it would be unfair to re-examine the existing facility under the requirements of Chapter 17, because the protection package provided in accordance with Chapter 16 is as good as, if not better than, the package provided by compliance with the requirements of Chapter 17.

The provisions of 16/17.1.1.4 tailor the protection package to the client group with the greatest needs. This concept is similar to that applied by 6.1.14.3 to a multiple occupancy protected as a mixed occupancy.

16.1.2 Multiple Occupancies.

16.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

16.1.2.2 Where the mixed occupancies provisions of 6.1.14.3 are utilized, the following provisions shall also apply:

- (1) General. The day-care occupancy shall be separated from the other occupancies by not less than 1-hour fire resistance-rated barriers constructed in accordance with Section 8.3.
- (2) Day-Care Occupancies in Apartment Buildings. If the two exit accesses from a day-care occupancy enter the same corridor as an apartment occupancy, the exit ac-

CHAPTER 17 • Existing

unless the area housing such a group is maintained as a separate fire area.

17.1.1.5 Places of religious worship shall not be required to meet the provisions of this chapter where providing day care while services are being held in the building.

Paragraph 6.1.14.3.2 requires that the most stringent *Code* provisions applicable to any of the occupancies present must be applied throughout the facility.

For example, 16.1.6.2 requires smoke partitions in new day-care centers if clients are 2 years old or less. If any client in a facility is 2 years old or younger, the floors of the building that client occupies must be provided with smoke partitions. A portion of the facility separated from that occupied by a client ≤ 2 years old is not required to have smoke partitions. A separated fire area is usually constructed with walls that have a fire resistance rating of 2 hours, as required by Table 6.1.14.4.1.

Paragraph 16/17.1.1.5 addresses day care provided within a place of worship while religious services are being held. The parents of the clients of the day-care center would be among those attending a worship service; they and others assembled for the worship service would be expected to assist the day-care staff with any necessary evacuation. The requirements of Chapters 16 and 17, therefore, do not apply under such circumstances. On the other hand, if day-care operations are conducted in the same building when religious services are not being conducted—such as during the work week—the day-care provisions of Chapters 16 and 17 would apply.

17.1.2 Mixed Occupancies.

17.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

17.1.2.2 Where the mixed occupancies provisions of 6.1.14.3 are utilized, the following provisions shall also apply:

- (1) General. The day-care occupancy shall be separated from the other occupancies by not less than 1-hour fire resistance-rated barriers constructed in accordance with Section 8.3.
- (2) Day-Care Occupancies in Apartment Buildings. If the two exit accesses from a day-care occupancy enter the same corridor as an apartment occupancy, the exit ac-

CHAPTER 16 • New

cesses shall be separated in the corridor by a smoke partition complying with both of the following:

- (a) Having not less than a 1-hour fire resistance rating and constructed in accordance with Section 8.4
- (b) Located so that it has an exit on each side

Where a day-care occupancy is located in a building housing another occupancy, the operators of the day-care facility usually have no control over the safety procedures and precautions practiced by that occupancy. Subsection 16/17.1.2 requires additional protection to minimize the clients' exposure to potential hazards outside the day-care occupancy.

A day-care use with more than 3 clients is not permitted to be considered incidental to a predominant occupancy within the same building, except for a specialized case involving places of religious worship as specified in 16/17.1.1.5. See 6.1.14.1.2(2). Thus, the presence of a day-care use for more than 3 clients in a building with some other occupancy creates a multiple occupancy. As required by 16/17.1.2.1, the multiple occupancy must be protected in accordance

16.1.3 Definitions.

A list of terms used in this chapter follows:

- (1) **Day-Care Home.** See 3.3.110.1.
- (2) **Flexible Plan and Open Plan Educational or Day-Care Building.** See 3.3.27.6.
- (3) **Self-Preservation (Day-Care Occupancy).** See 3.3.191.
- (4) **Separate Atmosphere.** See 3.3.20.2.

16.1.4 Classification of Occupancy.

See 6.1.4.

16.1.4.1 General. Occupancies that include part-day preschools, kindergartens, and other schools whose purpose is primarily educational, even though the children who attend such schools are of preschool age, shall comply with the provisions of Chapter 14.

16.1.4.2 Adult-Day-Care Occupancies.

16.1.4.2.1 Adult day-care occupancies shall include any building or portion thereof used for less than 24 hours per day to house more than three adults requiring care, maintenance, and supervision by other than their relative(s).

16.1.4.2.2 Clients in adult day-care occupancies shall be ambulatory or semiambulatory and shall not be bedridden.

CHAPTER 17 • Existing

cesses shall be separated in the corridor by a smoke partition complying with both of the following:

- (a) Having not less than a 1-hour fire resistance rating and constructed in accordance with Section 8.4
- (b) Located so that it has an exit on each side

with 6.1.14. Two protection options are offered: The multiple occupancy can be protected as a mixed occupancy, or it can be protected as separated occupancies.

The reason for requiring corridor subdivision by smoke partitions in accordance with Section 8.4 where day-care centers are located in an apartment building, and the multiple occupancy is protected as a mixed occupancy, is the same as that used in Chapters 18 and 19 for health care facilities. This minimum construction will provide sufficient protection against flame and smoke spread. The 1-hour wall provides a barrier that either will contain a fire within a space for a limited time after the space has been evacuated or will prevent a fire from entering an occupied space for a period of time.

17.1.3 Definitions.

A list of terms used in this chapter follows:

- (1) **Day-Care Home.** See 3.3.110.1.
- (2) **Flexible Plan and Open Plan Educational or Day-Care Building.** See 3.3.27.6.
- (3) **Self-Preservation (Day-Care Occupancy).** See 3.3.191.
- (4) **Separate Atmosphere.** See 3.3.20.2.

17.1.4 Classification of Occupancy.

See 6.1.4.

17.1.4.1 General. Occupancies that include part-day preschools, kindergartens, and other schools whose purpose is primarily educational, even though the children who attend such schools are of preschool age, shall comply with the provisions of Chapter 15.

17.1.4.2 Adult Day-Care Occupancies.

17.1.4.2.1 Adult day-care occupancies shall include any building or portion thereof used for less than 24 hours per day to house more than three adults requiring care, maintenance, and supervision by other than their relative(s).

17.1.4.2.2 Clients in adult day-care occupancies shall be ambulatory or semiambulatory and shall not be bedridden.

CHAPTER 16 • New

16.1.4.2.3 Clients in adult day-care occupancies shall not exhibit behavior that is harmful to themselves or to others.

16.1.4.3* Conversions. A conversion from a day-care home to a day-care occupancy with more than 12 clients shall be permitted only if the day-care occupancy conforms to the requirements of this chapter for new day-care occupancies with more than 12 clients.

A.16.1.4.3 A conversion from a day-care occupancy with more than 12 clients to a day-care home is not considered a change of occupancy. The resulting day-care home should be permitted to meet the requirements of Chapter 17 for existing day-care homes.

The specific reference to an adult day-care occupancy in 16/17.1.4.2 acknowledges that more and more senior citizens are being cared for in day-care centers similar to child day-care centers. The definition of an adult day-care occupancy includes the characteristics of clients who might be cared for in this type of occupancy. Essentially, the capabilities of adult day-care clients clarify that these occupancies are not nursing homes or old age homes but occupancies used by adults who are capable of self-preservation but who are in need of limited attendance, supervision, or observation.

Earlier editions of the *Code* included several cues for identifying adults who meet the criteria of this description of these clients. However, to avoid the implication that medical training is necessary for assessing such adults, these cues were removed from the *Code*. It might be appropriate, however, to use some of the following guidelines from previous editions to determine the acceptability of a client for adult day-care:

16.1.5 Classification of Hazard of Contents.

The contents of day-care occupancies shall be classified as ordinary hazard in accordance with Section 6.2.

16.1.6 Location and Construction.

16.1.6.1 Day-care occupancies, other than day-care homes, shall be limited to the locations, construction types, and sprinkler protection features specified in Table 16.1.6.1.

CHAPTER 17 • Existing

17.1.4.2.3 Clients in adult day-care occupancies shall not exhibit behavior that is harmful to themselves or to others.

17.1.4.3* Conversions. A conversion from a day-care home to a day-care occupancy with more than 12 clients shall be permitted only if the day-care occupancy conforms to the requirements of Chapter 16 for new day-care occupancies with more than 12 clients.

A.17.1.4.3 A conversion from a day-care occupancy with more than 12 clients to a day-care home is not considered a change of occupancy. The resulting day-care home should be permitted to meet the requirements of Chapter 17 for existing day-care homes.

- (1) Client does not require medical injections from staff but might require the administration of oral medication by staff personnel when and as prescribed by a licensed medical examiner.
- (2) Client might require limited supervision, attendance, or observation.
- (3) Client exhibits acceptable behavior (not harmful to self or others).

Paragraph 16/17.1.4.3 addresses conversions that result in an increase in the number of clients to a number greater than 12. The conversion from a day-care home to a day-care center places a sufficiently greater number of clients at risk so as to justify imposing the requirements for new construction. If the conversion is made in reverse (that is, from an existing day-care center to a day-care home), fewer clients are placed at risk. The existing protection package for the day-care center would be considered adequate to permit treating the post-conversion day-care home as an existing occupancy.

17.1.5 Classification of Hazard of Contents.

The contents of day-care occupancies shall be classified as ordinary hazard in accordance with Section 6.2.

17.1.6 Location and Construction.

Day-care occupancies, other than day-care homes, shall be limited to the locations, construction types, and sprinkler protection features specified in Table 17.1.6.

CHAPTER 16 • New

Table 16.1.6.1 Location and Construction Type Limitations

Location of Day-Care Occupancy	Sprinklered Building	Construction Type
1 story below LED	Yes	I(443), I(332), II(222), II(111), II(000), III(211), IV(2HH), or V(111)
	No	Not permitted

High-rise	Yes	I(443), I(332), or II(222)
	No	Not permitted

LED: Level of exit discharge.

16.1.6.2 Where day-care occupancies, other than day-care homes, with clients who are 24 months or less in age or who are incapable of self-preservation are located one or more stories above the level of exit discharge, or where day-care occupancies are located two or more stories above the level of exit discharge, smoke partitions shall be provided to divide such stories into not less than two compartments. The smoke partitions shall be constructed in accordance with Section 8.4 but shall not be required to have a fire resistance rating.

Tables 16.1.6.1 and 17.1.6 relate the building construction type, the automatic sprinkler protection, and the floor level permitted to be occupied as a day-care center. For example, a day-care center is permitted to be located on the story of exit discharge in any building, regardless of construction type or automatic sprinkler protection. For a day-care center located one story above the level of exit discharge in a non-sprinklered building, the building must be of Type I(443), Type I(332), or Type II(222) construction. In the

CHAPTER 17 • Existing

LED: Level of exit discharge.

*Permitted only if clients capable of self-preservation.

case of an existing day-care center where the clients are capable of self-preservation, Type II(111), Type III(211), and Type V(111) construction are also permitted. If the building is of any other construction type, the day-care center is permitted to be located one story above the level of exit discharge only if the building is protected by automatic sprinklers. For other possible combinations of floor levels, building construction type, and building sprinklering, see Tables 16.1.6.1 and 17.1.6.

CHAPTER 16 • New

CHAPTER 17 • Existing

Although Table 16.1.6.1 permits new day-care occupancies on floors above the level of exit discharge if the building is of the required construction type and is sprinklered, the *Code* recognizes that rapid vertical movement to the level of exit discharge might be difficult. Therefore, per 16.1.6.2, where clients 24 months old or younger or incapable of self-preservation are located above the level of exit discharge, the floor must be subdivided into two compartments

using smoke partitions. The intent is that at least one of the two compartments on the floor is expected to be unaffected by any fire for the time necessary to summon assistance and evacuate, or for the time necessary to control the fire, so that evacuation is unnecessary. This requirement was added to the *Code* in 1994 for new day-care occupancies, but justification for making the provision retroactive to existing day-care centers was insufficient.

16.1.7 Occupant Load.

16.1.7.1 The occupant load, in number of persons for whom means of egress and other provisions are required, either shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

16.1.7.2 Where the occupant load is determined as the maximum probable population of the space in accordance with 16.1.7.1, an approved aisle, seating, and exiting diagram shall be required by the authority having jurisdiction to substantiate such a modification.

Many jurisdictions that license day-care centers require such facilities to provide a net area of 3.3 m² (35 ft²) per client for functional reasons other than life safety. In Table 7.3.1.2, the *Code* establishes the 3.3-m² (35-ft²) net area occupant load factor solely for the purpose of calculating occupant load and associated egress capacity. The occupant load is required

17.1.7 Occupant Load.

17.1.7.1 The occupant load, in number of persons for whom means of egress and other provisions are required, either shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

17.1.7.2 Where the occupant load is determined as the maximum probable population of the space in accordance with 17.1.7.1, an approved aisle, seating, and exiting diagram shall be required by the authority having jurisdiction to substantiate such a modification.

to be the maximum number of persons expected to occupy the floor but not less than the number calculated using the occupant load factor.

Where a day-care center occupies a portion of a floor on which another occupancy exists, the occupant load for that floor is the sum of the occupant loads of the two occupancies.

Section 16.2 Means of Egress Requirements

16.2.1 General.

Means of egress shall be in accordance with Chapter 7 and Section 16.2.

16.2.2 Means of Egress Components.

16.2.2.1 General. Components of means of egress shall be limited to the types described in 16.2.2.2 through 16.2.2.10.

16.2.2.2 Doors.

16.2.2.2.1 General. Doors complying with 7.2.1 shall be permitted.

Section 17.2 Means of Egress Requirements

17.2.1 General.

Means of egress shall be in accordance with Chapter 7 and Section 17.2.

17.2.2 Means of Egress Components.

17.2.2.1 General. Components of means of egress shall be limited to the types described in 17.2.2.2 through 17.2.2.10.

17.2.2.2 Doors.

17.2.2.2.1 General. Doors complying with 7.2.1 shall be permitted.

CHAPTER 16 • New

16.2.2.2.2 Panic Hardware or Fire Exit Hardware. Any door in a required means of egress from an area having an occupant load of 100 or more persons shall be permitted to be provided with a latch or lock only if the latch or lock is panic hardware or fire exit hardware complying with 7.2.1.7.

16.2.2.2.3 Special Locking Arrangements. Special locking arrangements complying with 7.2.1.6 shall be permitted.

16.2.2.2.4* Closet Doors. Every closet door latch shall be such that clients can open the door from inside the closet.

A.16.2.2.2.4 The purpose of this requirement is to prevent arrangements whereby a child can be trapped in a closet. It is intended that this provision be broadly interpreted by the authority having jurisdiction to include equipment such as refrigerators and freezers.

16.2.2.2.5 Bathroom Doors. Every bathroom door lock shall be designed to allow opening of the locked door from the outside by an opening device that shall be readily accessible to the staff.

The requirement of 16/17.2.2.2.2 for panic hardware or fire exit hardware is based on the total occupant load of the area served, not on the required capacity of the door. For example, if an area has an occupant load of 120 persons and is served by 3 doors, each door is required only to have a capacity for 40 persons. However, since each of these doors serves an area with 100 or more persons, any latches on these doors must be arranged to be released by panic hardware or fire exit hardware. The concept employed recognizes

16.2.2.3* Stairs. Stairs complying with 7.2.2 shall be permitted.

A.16.2.2.3 See A.7.2.2.4.4.4 regarding additional handrails on stairs that are used extensively by children 5 years of age or less.

Table 17.1.6 would permit the continued use of an existing day-care center located above the third story of a nonsprinklered building if the building were of minimum 2-hour fire resistance-rated construction.

CHAPTER 17 • Existing

17.2.2.2.2 Panic Hardware or Fire Exit Hardware. Any door in a required means of egress from an area having an occupant load of 100 or more persons shall be permitted to be provided with a latch or lock only if the latch or lock is panic hardware or fire exit hardware complying with 7.2.1.7.

17.2.2.2.3 Special Locking Arrangements. Special locking arrangements complying with 7.2.1.6 shall be permitted.

17.2.2.2.4* Closet Doors. Every closet door latch shall be such that clients can open the door from inside the closet.

A.17.2.2.2.4 The purpose of this requirement is to prevent arrangements where a client can be trapped in a closet. It is intended that this provision be broadly interpreted by the authority having jurisdiction to include equipment such as refrigerators and freezers.

17.2.2.2.5 Bathroom Doors. Every bathroom door lock shall be designed to allow opening of the locked door from the outside by an opening device that shall be readily accessible to the staff.

that it is not possible to predict how many occupants will move to any one of the doors serving the area. The number of persons from the assembled group of 100 or more who travel to any one of the doors might be sufficiently large to cause crowding and shoving. Panic hardware and fire exit hardware are designed to release the door latch when building occupants push up against the actuating mechanism (typically a push pad or bar that must extend across at least one-half the width of the door).

17.2.2.3* Stairs.

A.17.2.2.3 See A.7.2.2.4.4.4 regarding additional handrails on stairs that are used extensively by children 5 years of age and under.

17.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

17.2.2.3.2 Existing Class A stairs shall be permitted.

17.2.2.3.3 Existing Class B stairs shall be permitted where not used by clients.

However, such continued use would not be permitted within the high-rise portion of that building. If an existing day-care center is located in the high-rise portion of a building [that is, on a floor more than

CHAPTER 16 • New

CHAPTER 17 • Existing

23 m (75 ft) above the lowest level of fire department vehicle access], Table 17.1.6 requires sprinkler protection for the entire building and further requires that the building be of minimum 2-hour fire resistance-rated construction.

Paragraph 17.2.2.5.2 requires an existing, non-sprinklered building with a day-care occupancy located above the fifth floor to have horizontal exits or smokeproof enclosures to help ensure that clients

will survive a fire. The smokeproof enclosures or the areas of refuge created by the horizontal exit provide the occupant protection needed where no sprinklers are provided to control or extinguish the fire. A similar provision does not apply to new day-care centers, because Table 16.1.6.1 requires sprinklers in buildings that house day-care centers on any floors that are two or more stories above the level of exit discharge.

16.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

16.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

16.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

16.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

16.2.2.8 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

16.2.2.9 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

16.2.2.10 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

16.2.3 Capacity of Means of Egress.

Capacity of means of egress shall be in accordance with Section 7.3.

16.2.4 Number of Exits.

Not less than two separate exits shall be as follows:

- (1) Provided on every story
- (2) Accessible from every part of every story and mezzanine

17.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

17.2.2.5 Horizontal Exits.

17.2.2.5.1 Horizontal exits complying with 7.2.4 shall be permitted.

17.2.2.5.2 Areas of refuge, other than in buildings provided with smokeproof enclosures or buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, shall be provided by horizontal exits for occupants of day-care occupancies located above the fifth story.

17.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

17.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

17.2.2.8 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

17.2.2.9 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

17.2.2.10 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

17.2.3 Capacity of Means of Egress.

Capacity of means of egress shall be in accordance with Section 7.3.

17.2.4 Number of Exits.

17.2.4.1 Not less than two separate exits shall be as follows:

- (1) Provided on every story
- (2) Accessible from every part of every story and mezzanine

Paragraph 17.2.4.2 contains requirements for existing day-care centers located below the level of exit discharge. (Similar provisions do not appear in Chapter 16 because Table 16.1.6.1 requires complete sprinklering of the building if a new day-care center is located below the level of exit discharge.) This requirement helps to ensure that the occupants of the lower level have a protected egress path that doesn't force them to traverse the street floor. The requirement does help but doesn't guarantee safe egress, because a convenience door is permitted from the street floor into the lower level's stair enclosure. If a fire were to occur on the street floor and if someone were to wedge the door open, smoke and other effects of fire could enter the stair designated for use by the occupants of the lower level. Diligent enforcement is needed to ensure that the self-closing door will not be improperly held open. The intent of 17.2.4.2 is illustrated in Exhibit 16/17.1.

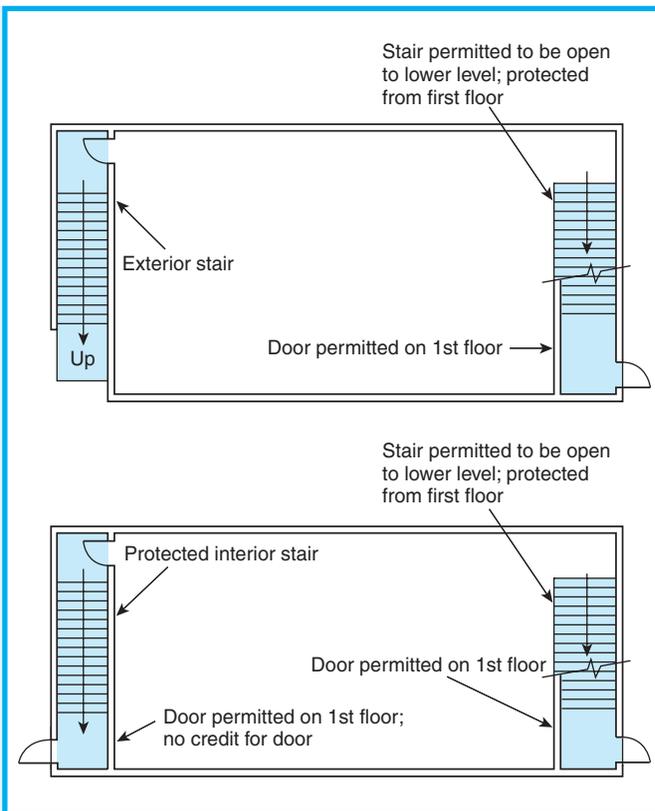

Exhibit 16/17.1 Egress for levels below level of exit discharge—existing day-care centers.

17.2.4.2 Where the story below the level of exit discharge is occupied as a day-care occupancy, 17.2.4.2.1 and 17.2.4.2.2 shall apply.

17.2.4.2.1 One means of egress shall be an outside or interior stair in accordance with 7.2.2. An interior stair, if used, shall serve only the story below the level of exit discharge. The interior stair shall be permitted to communicate with the level of exit discharge; however, the exit route from the level of exit discharge shall not pass through the stair enclosure.

17.2.4.2.2 The second means of egress shall be permitted to be via an unenclosed stairway separated from the level of exit discharge in accordance with 8.6.5.

17.2.4.2.3 The path of egress travel on the level of exit discharge shall be protected in accordance with 7.1.3.1, unless one of the following criteria is met:

- (1) The path of egress on the level of exit discharge shall be permitted to be unprotected if the level of exit dis-

CHAPTER 16 • New

CHAPTER 17 • Existing

16.2.5 Arrangement of Means of Egress.

See also 16.1.6.2.

16.2.5.1 Means of egress shall be arranged in accordance with Section 7.5.

16.2.5.2 No dead-end corridor shall exceed 6100 mm (240 in.), other than in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, in which case dead-end corridors shall not exceed 15 m (50 ft).

16.2.5.3 No common path of travel shall exceed 23 m (75 ft), other than for the first 30 m (100 ft) in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

The provisions of Chapter 7 give an occupancy chapter the responsibility for permitting or prohibiting dead-end corridors and common path of travel and for limiting the length of such areas. The dead-end

16.2.6 Travel Distance to Exits.

16.2.6.1 Travel distance shall be measured in accordance with Section 7.6.

16.2.6.2 Travel distance shall meet the following criteria unless otherwise permitted by 16.2.6.3:

- (1) The travel distance between any room door intended as an exit access and an exit shall not exceed 30 m (100 ft).
- (2) The travel distance between any point in a room and an exit shall not exceed 46 m (150 ft).
- (3) The travel distance between any point in a sleeping room and an exit access door in that room shall not exceed 15 m (50 ft).

- charge and the level below the level of exit discharge are protected throughout by a smoke detection system
- (2) The path of egress on the level of exit discharge shall be permitted to be unprotected if the level of exit discharge and the level below the level of exit discharge are protected throughout by an approved automatic sprinkler system.

17.2.5 Arrangement of Means of Egress.

17.2.5.1 Means of egress shall be arranged in accordance with Section 7.5.

17.2.5.2 No dead-end corridor shall exceed 6100 mm (240 in.), other than in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, in which case dead-end corridors shall not exceed 15 m (50 ft).

17.2.5.3 No common path of travel shall exceed 23 m (75 ft), other than for the first 30 m (100 ft) in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
