17.2.5.4 The story used below the level of exit discharge shall be in accordance with 17.2.4.2.

corridor and common path permitted by 16/17.2.5.2 and 16/17.2.5.3 use limits that other occupancies established years ago. Their applicability to day-care centers seems reasonable.

17.2.6 Travel Distance to Exits.

17.2.6.1 Travel distance shall be measured in accordance with Section 7.6.

17.2.6.2 Travel distance shall meet the following criteria unless otherwise permitted by 17.2.6.3:

- (1) The travel distance between any room door intended as an exit access and an exit shall not exceed 30 m (100 ft).
- (2) The travel distance between any point in a room and an exit shall not exceed 46 m (150 ft).
- (3) The travel distance between any point in a sleeping room and an exit access door in that room shall not exceed 15 m (50 ft).

CHAPTER 16 • New

16.2.6.3 The travel distance required by 16.2.6.2(1) and 16.2.6.2(2) shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

As shown in Exhibit 16/17.2, the maximum permitted travel distance from a room door (exit access door to the corridor) to an exit (door to enclosed exit stair) is 30 m (100 ft); if the building is sprinklered, the maximum distance is 46 m (150 ft). The maximum travel distance from a point in a sleeping room to an exit access door from that room is 15 m (50 ft). This within-room travel distance limit is not permitted to be increased, even if the building is sprinklered. The total travel distance permitted from any point (such as the point farthest from the room door) to an exit is 46 m (150 ft), unless additional corridor travel is permitted for sprinklered buildings, as explained in 16/17.2.6.3. In a sprinklered building the total permitted travel distance is 60 m (200 ft) only if the full 15 m (50 ft) of within-room exit access and the full 46 m (150 ft) of corridor exit access are used.

Note that for new construction, the *Code* requires that the sprinkler system be supervised to permit the allowance for additional travel distance.

16.2.7 Discharge from Exits.

Discharge from exits shall be arranged in accordance with Section 7.7.

16.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

16.2.9 Emergency Lighting.

Emergency lighting shall be provided in accordance with Section 7.9 in the following areas:

- (1) Interior stairs and corridors
- (2) Assembly use spaces
- (3) Flexible and open plan buildings
- (4) Interior or limited access portions of buildings
- (5) Shops and laboratories

16.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

CHAPTER 17 • Existing

17.2.6.3 The travel distance required by 17.2.6.2(1) and 17.2.6.2(2) shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

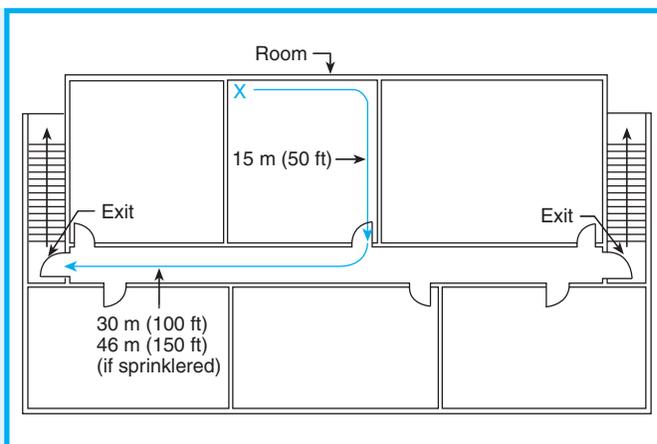

Exhibit 16/17.2 Maximum travel distance in a day-care center.

17.2.7 Discharge from Exits.

Discharge from exits shall be arranged in accordance with Section 7.7, unless otherwise provided in 17.2.4.2.

17.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

17.2.9 Emergency Lighting.

Emergency lighting shall be provided in accordance with Section 7.9 in the following areas:

- (1) Interior stairs and corridors
- (2) Assembly use spaces
- (3) Flexible and open plan buildings
- (4) Interior or limited access portions of buildings
- (5) Shops and laboratories

17.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

CHAPTER 16 • New

16.2.11 Special Means of Egress Features.**16.2.11.1 Windows for Rescue.**

16.2.11.1.1 Every room or space normally subject to client occupancy, other than bathrooms, shall have not less than one outside window for emergency rescue that complies with the following unless otherwise permitted by 16.2.11.1.2:

- (1) Such windows shall be openable from the inside without the use of tools and shall provide a clear opening of not less than 510 mm (20 in.) in width, 610 mm (24 in.) in height, and 0.5 m² (5.7 ft²) in area.
- (2) The bottom of the opening shall be not more than 1120 mm (44 in.) above the floor.
- (3) The clear opening shall allow a rectangular solid, with a width and height that provides not less than the required 0.5-m² (5.7-ft²) opening and a depth of not less than 510 mm (20 in.), to pass fully through the opening.

16.2.11.1.2 The requirements of 16.2.11.1.1 shall not apply to the following:

- (1) Buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7
- (2) Where the room or space has a door leading directly to the outside of the building

CHAPTER 17 • Existing

17.2.11 Special Means of Egress Features.**17.2.11.1 Windows for Rescue.**

17.2.11.1.1 Every room or space greater than 23.2 m² (250 ft²) and normally subject to client occupancy shall have not less than one outside window for emergency rescue that complies with the following unless otherwise permitted by 17.2.11.1.2:

- (1) Such windows shall be openable from the inside without the use of tools and shall provide a clear opening of not less than 510 mm (20 in.) in width, 610 mm (24 in.) in height, and 0.5 m² (5.7 ft²) in area.
- (2) The bottom of the opening shall be not more than 1120 mm (44 in.) above the floor.
- (3) The clear opening shall allow a rectangular solid, with a width and height that provides not less than the required 0.5 m² (5.7 ft²) opening and a depth of not less than 510 mm (20 in.), to pass fully through the opening.

17.2.11.1.2 The requirements of 17.2.11.1.1 shall not apply to the following:

- (1) Buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7
- (2) Where the room or space has a door leading directly to the outside of the building
- (3) Rooms located higher than three stories above grade
- (4) Where awning-type or hopper-type windows that are hinged or subdivided to provide a clear opening of not less than 0.38 m² (4 ft²) or any dimension of not less than 560 mm (22 in.), the following shall apply:
 - (a) Such windows shall be permitted to continue to be used.
 - (b) Screen walls or devices in front of required windows shall not interfere with normal rescue requirements.
- (5) Where the room or space complies with the following:
 - (a) Doors shall exist that allow travel between adjacent classrooms.
 - (b) Where doors are used to travel from classroom to classroom, they shall provide one of the following:
 - i. Direct access to exits in both directions
 - ii. Direct access to an exit in one direction and to a separate smoke compartment that provides access to another exit in the other direction
 - (c) The corridor shall be separated from the classrooms by a wall that resists the passage of smoke, and all doors between the classrooms and the corridor shall be self-closing in accordance with 7.2.1.8.
 - (d) The length of travel to exits along such paths shall not exceed 46 m (150 ft).

- (e) Each communicating door shall be marked in accordance with Section 7.10.
- (f) No locking device shall be permitted on the communicating doors.

The dimensions specified for windows used for emergency rescue in day-care occupancies, which are identical to those required for secondary escape from dwelling units, are based on simulations of emergency rescue conducted by the San Diego Fire Department. Exhibit 16/17.3 illustrates two configurations that achieve the required area of 0.5 m² (5.7 ft²).

The *Code* assumes that the fire department or others will assist day-care center clients, especially over ladders. If these emergency rescue windows must be used as a supplementary means of escape, the windows should permit younger children to escape unaided. Therefore, storm sashes, screens, or devices in front of the windows must be easy to open or remove, and the sills must be low enough for children to reach.

According to 16/17.2.11.1.2(1) and 16/17.2.11.1.2(2), emergency rescue windows are not required if a room has a door leading directly to the outside or if the building is totally sprinklered.

It might not be practical to use a window above the third story as an escape window. Therefore, 17.2.11.1.2(3) exempts windows above the third story in existing day-care centers. This exemption will have limited application, because Table 17.1.6 requires most day-care centers located more than three stories above the level of exit discharge to be sprinklered, and, per 17.2.11.1.2(1), sprinklers negate the need for the rescue window. Similarly, the exemption is not needed for new construction, because Table 16.1.6.1 requires day-care centers located more than three stories above the level of exit discharge to be sprinklered.

Awning-type and hopper-type windows might provide the required opening within the plane of the building's exterior wall. However, when the window is open, the sash and glazing are located outside that plane and might prevent occupants from passing through the opening. Therefore, the criterion for providing an opening through which a minimum-size, rectangular solid can pass is intended to ensure that occupants can pass through the opening. For existing awning-type windows, 17.2.11.1.2(4) offers some re-

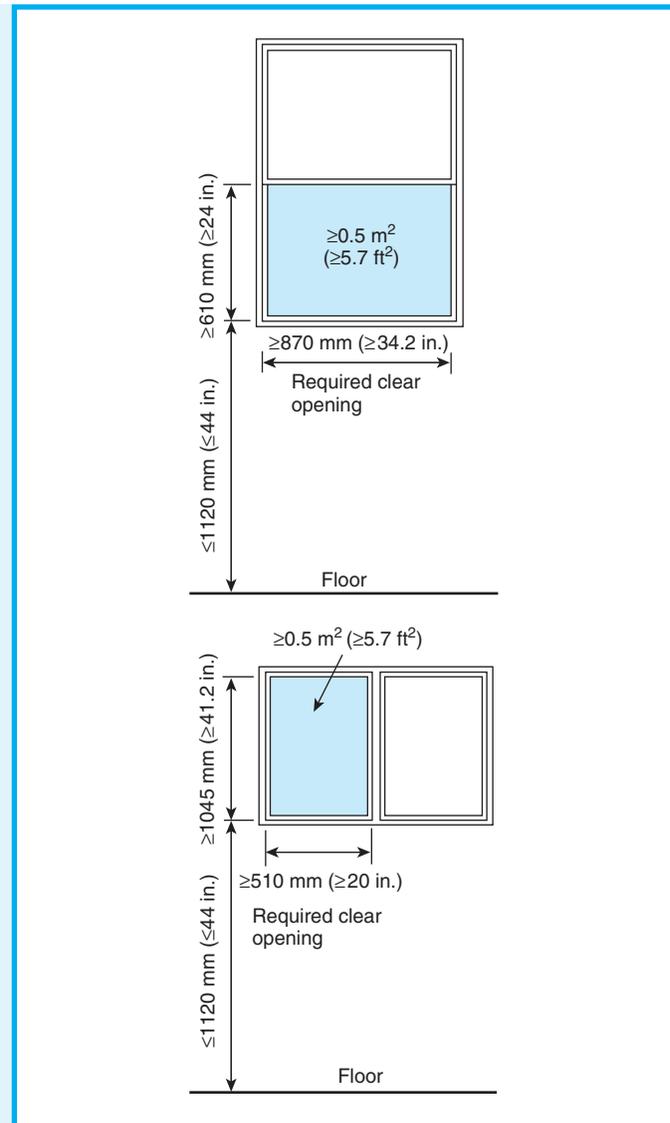

Exhibit 16/17.3 Windows for rescue or ventilation—minimum dimensions.

lief from the rectangular solid and minimum-size opening requirements. Exhibit 16/17.4 illustrates the use of 17.2.11.1.2(4).

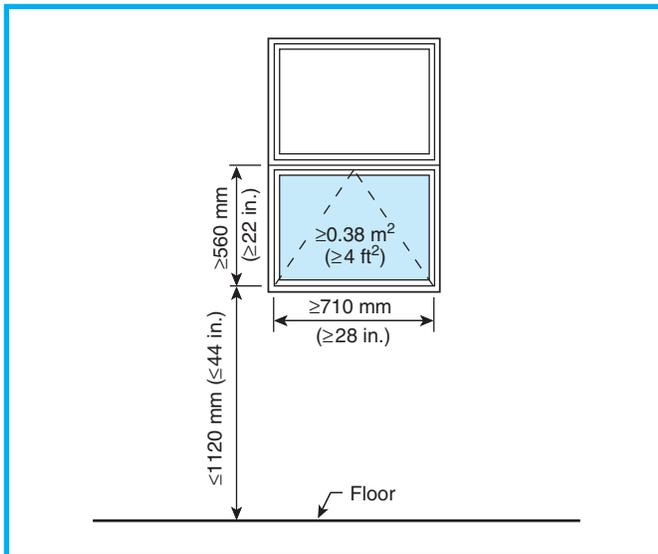

Exhibit 16/17.4 Existing awning window—minimum dimensions.

Section 16.3 Protection

16.3.1 Protection of Vertical Openings.

Any vertical opening, other than unprotected vertical openings in accordance with 8.6.8.2, shall be enclosed or protected in accordance with Section 8.6.

16.3.2 Protection from Hazards.

16.3.2.1 Rooms or spaces for the storage, processing, or use of materials specified in 16.3.2.1(1) through 16.3.2.1(3) shall be protected in accordance with the following:

- (1) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour, or protection of such rooms by automatic extinguishing systems as specified in Section 8.7, in the following areas:
 - (a) Boiler and furnace rooms, unless such rooms enclose only air-handling equipment
 - (b) Rooms or spaces used for the storage of combustible supplies in quantities deemed hazardous by the authority having jurisdiction
 - (c) Rooms or spaces used for the storage of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
 - (d) Janitor closets

Section 17.3 Protection

17.3.1 Protection of Vertical Openings.

Any vertical opening, other than unprotected vertical openings in accordance with 8.6.8.2, shall be enclosed or protected in accordance with Section 8.6.

17.3.2 Protection from Hazards.

17.3.2.1 Rooms or spaces for the storage, processing, or use of materials specified in 17.3.2.1(1) through 17.3.2.1(3) shall be protected in accordance with the following:

- (1) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour or protection of such rooms, by automatic extinguishing systems as specified in Section 8.7, in the following areas:
 - (a) Boiler and furnace rooms, unless such rooms enclose only air-handling equipment
 - (b) Rooms or spaces used for the storage of combustible supplies in quantities deemed hazardous by the authority having jurisdiction
 - (c) Rooms or spaces used for the storage of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
 - (d) Janitor closets

CHAPTER 16 • New

- (2) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour and protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
- (a)* Laundries

A.16.3.2.1(2)(a) It is not the intent to classify a room with a domestic-type clothes washer and a domestic-type clothes dryer as a laundry.

- (b) Maintenance shops, including woodworking and painting areas
 - (c) Rooms or spaces used for processing or use of combustible supplies deemed hazardous by the authority having jurisdiction
 - (d) Rooms or spaces used for processing or use of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
- (3) Where automatic extinguishing is used to meet the requirements of 16.3.2.1(1) and 16.3.2.1(2), the protection shall be permitted in accordance with 9.7.1.2.

16.3.2.2 Janitor closets protected in accordance with 16.3.2.1(1)(d) shall be permitted to have doors fitted with ventilating louvers where the space is protected by automatic sprinklers.

16.3.2.3 Cooking facilities shall be protected in accordance with 9.2.3 unless otherwise permitted by 16.3.2.4 or 16.3.2.5.

16.3.2.4 Openings shall not be required to be protected between food preparation areas and dining areas.

16.3.2.5 Approved domestic cooking equipment used for food warming or limited cooking shall not be required to be protected.

The intent of 16/17.3.2.1 is to specify the degree of protection necessary for certain hazardous contents areas. The hazards noted in 16/17.3.2.1(1) are required to be enclosed in 1-hour construction or protected by automatic sprinklers. In new construction, if the

CHAPTER 17 • Existing

- (2) Separation from the remainder of the building by fire barriers having a fire resistance rating of not less than 1 hour and protection of such rooms by automatic extinguishing systems as specified in Section 8.7 in the following areas:
- (a)* Laundries

A.17.3.2.1(2)(a) It is not the intent to classify a room with a domestic-type clothes washer and a domestic-type clothes dryer as a laundry.

- (b) Maintenance shops, including woodworking and painting areas
 - (c) Rooms or spaces used for processing or use of combustible supplies deemed hazardous by the authority having jurisdiction
 - (d) Rooms or spaces used for processing or use of hazardous materials or flammable or combustible liquids in quantities deemed hazardous by recognized standards
- (3) Where automatic extinguishing is used to meet the requirements of 17.3.2.1(1) and 17.3.2.1(2), the protection shall be permitted in accordance with 9.7.1.2.

17.3.2.2 Janitor closets protected in accordance with 17.3.2.1(1)(d) shall be permitted to have doors fitted with ventilating louvers where the space is protected by automatic sprinklers.

17.3.2.3 Cooking facilities shall be protected in accordance with 9.2.3 unless otherwise permitted by 17.3.2.4 or 17.3.2.5.

17.3.2.4 Openings shall not be required to be protected between food preparation areas and dining areas.

17.3.2.5 Approved domestic cooking equipment used for food warming or limited cooking shall not be required to be protected.

sprinkler option is chosen, 8.7.1.2 would still require an enclosure comprised of smoke partitions.

Exhibits 16/17.5, 16/17.6, and 16/17.7 illustrate the various protection requirements of 16/17.3.2.1.

CHAPTER 16 • New

CHAPTER 17 • Existing

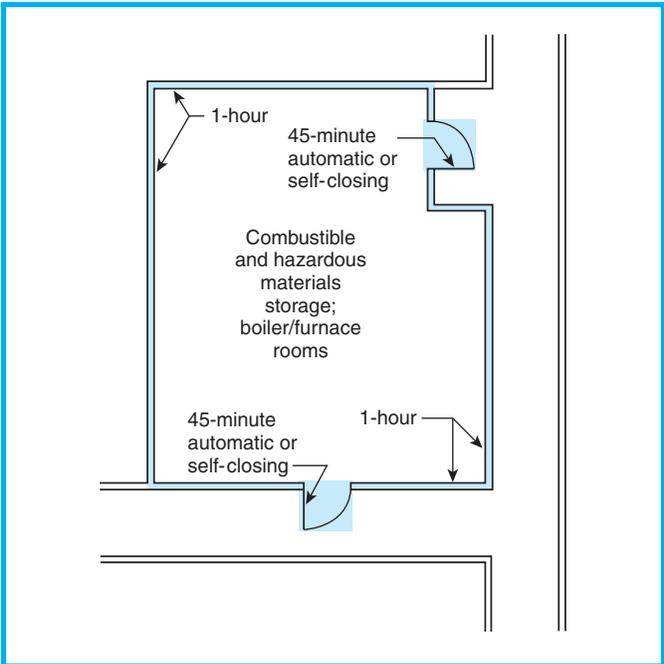

Exhibit 16/17.5 Protection of hazardous contents areas—rated enclosure complying with 16/17.3.2.1(1).

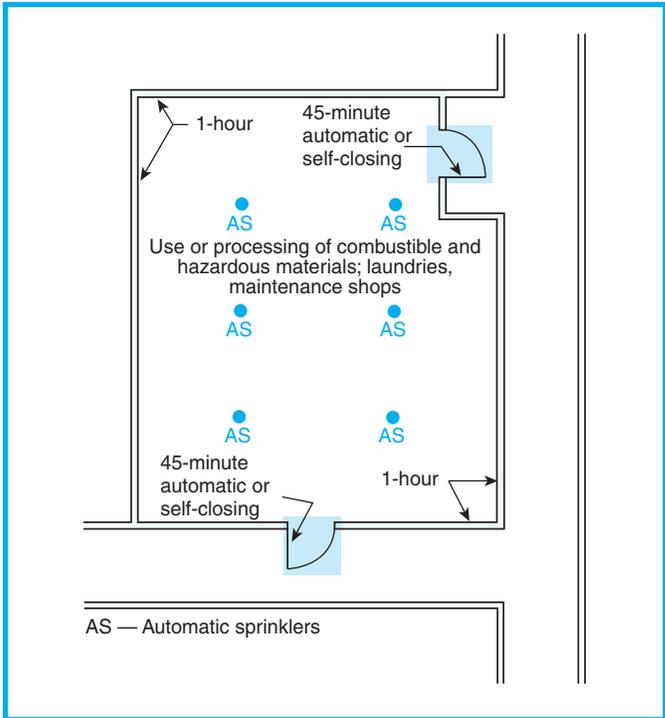

Exhibit 16/17.7 Protection of hazardous areas—rated enclosure and sprinkler protection complying with 16/17.3.2.1(2).

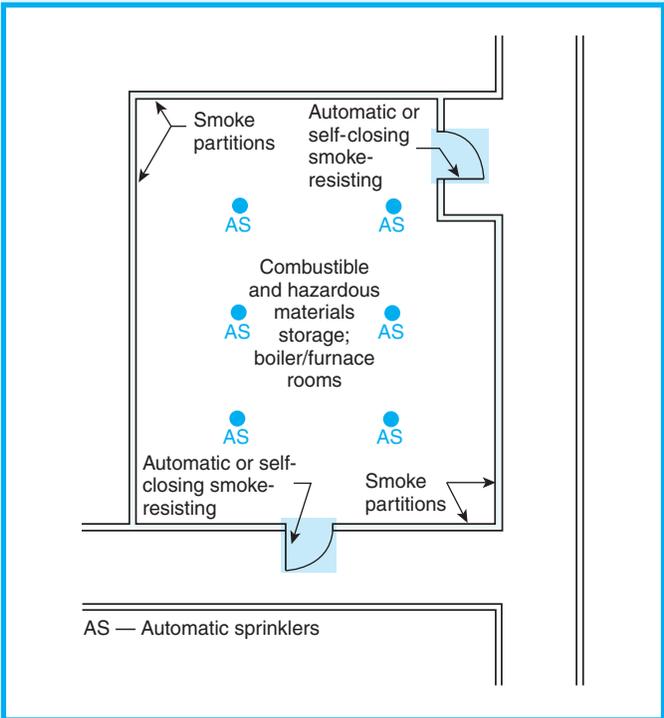

Exhibit 16/17.6 Protection of new hazardous contents areas—sprinkler protection and smoke partitions enclosure complying with 16.3.2.1(1).

CHAPTER 16 • New

16.3.3 Interior Finish.

16.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

16.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A in stairways, corridors, and lobbies; in all other occupied areas, interior wall and ceiling finish shall be Class A or Class B.

16.3.3.3 Interior Floor Finish.

16.3.3.3.1 Interior floor finish shall comply with Section 10.2.

16.3.3.3.2 Interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 14.3.6 shall be not less than Class II.

16.3.3.3.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

16.3.4 Detection, Alarm, and Communications Systems.

16.3.4.1 General. Day-care occupancies, other than day-care occupancies housed in one room, shall be provided with a fire alarm system in accordance with Section 9.6.

16.3.4.2 Initiation. Initiation of the required fire alarm system shall be by manual means and by operation of any required smoke detectors and required sprinkler systems. (See 16.3.4.5.)

16.3.4.3 Occupant Notification.

16.3.4.3.1 Occupant notification shall be in accordance with 9.6.3.

16.3.4.3.2 Positive alarm sequence shall be permitted in accordance with 9.6.3.4.

16.3.4.3.3 Where occupant notification appliances are provided in all occupied rooms and corridors, the private operating mode as described in *NFPA 72*[®], *National Fire Alarm Code*[®], shall be permitted to be used in either or both of the following locations:

- (1) The occupied rooms
- (2) The corridors

16.3.4.4 Emergency Forces Notification. Fire department notification shall be accomplished in accordance with 9.6.4.

CHAPTER 17 • Existing

17.3.3 Interior Finish.

17.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

17.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B throughout.

17.3.3.3 Interior Floor Finish. (No requirements.)**17.3.4 Detection, Alarm, and Communications Systems.**

17.3.4.1 General. Day-care occupancies, other than day-care occupancies housed in one room, shall be provided with a fire alarm system in accordance with Section 9.6.

17.3.4.2 Initiation. Initiation of the required fire alarm system shall be by manual means and by operation of any required smoke detectors and required sprinkler systems. (See 17.3.4.5.)

17.3.4.3 Occupant Notification.

17.3.4.3.1 Occupant notification shall be in accordance with 9.6.3.

17.3.4.3.2 Positive alarm sequence shall be permitted in accordance with 9.6.3.4.

17.3.4.3.3 Where occupant notification appliances are provided in all occupied rooms and corridors, the private operating mode as described in *NFPA 72*[®], *National Fire Alarm Code*[®], shall be permitted to be used in either or both of the following locations:

- (1) The occupied rooms
- (2) The corridors

17.3.4.4 Emergency Forces Notification. Fire department notification, other than for day-care occupancies with not more than 100 clients, shall be accomplished in accordance with 9.6.4.

CHAPTER 16 • New

16.3.4.5 Detection. A smoke detection system in accordance with Section 9.6 shall be installed in day-care occupancies, other than those housed in one room, and such system shall comply with both of the following:

- (1) Detectors shall be installed on each story in front of the doors to the stairways and in the corridors of all floors occupied by the day-care occupancy.
- (2) Detectors also shall be installed in lounges, recreation areas, and sleeping rooms in the day-care occupancy.

Both new and existing day-care centers, other than those housed in a single room, are required to have a fire alarm system. The alarm system is for purposes of both occupant notification and fire department notification. Existing day-care centers are exempt from the fire department notification requirement if there are 100 or fewer clients.

Neither new nor existing day-care centers are permitted to use a presignal system. A delay in occupant notification is permitted only if positive alarm sequence in accordance with 9.6.3.4 is provided. Positive alarm sequence includes some fail-safe features not found in presignal systems. For example, if the person staffing the control panel does not acknowledge the signal, general occupant notification occurs automatically. Also, if a second initiation device re-

16.3.5 Extinguishment Requirements.

16.3.5.1 Any required sprinkler systems shall be in accordance with Section 9.7.

16.3.5.2 Required sprinkler systems shall be installed in accordance with 9.7.1.1(1).

16.3.5.3 Buildings with unprotected openings in accordance with 8.6.6 shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

16.3.6 Corridors.

Every interior corridor shall be constructed of walls having not less than a 1-hour fire resistance rating in accordance with Section 8.3, unless otherwise permitted by the following:

CHAPTER 17 • Existing

17.3.4.5 Detection. A smoke detection system in accordance with Section 9.6 shall be installed in day-care occupancies, other than those housed in one room or those housing clients capable of self-preservation if no sleeping facilities are provided, and such system shall comply with both of the following:

- (1) Detectors shall be installed on each story in front of the doors to the stairways and in the corridors of all floors occupied by the day-care occupancy.
- (2) Detectors shall be installed in lounges, recreation areas, and sleeping rooms in the day-care occupancy.

ports a fire condition to the control panel, the delay ends and general occupant notification occurs immediately.

Some day-care centers make provisions for clients to nap. Also, parents who work at night might place their children in day-care centers for the purpose of sleeping through the night. Regardless of whether occupants sleep in the center, the smoke detectors required by 16/17.3.4.5 will provide critical extra time to evacuate clients. This requirement does not apply to centers housed in a single room where a fire will be obvious simultaneously to all occupants or to existing day-care centers where the clients are capable of self-preservation and there are no sleeping facilities.

17.3.5 Extinguishment Requirements.

17.3.5.1 Any required sprinkler system shall be in accordance with Section 9.7.

17.3.5.2 Required sprinkler systems, other than approved existing systems, shall be installed in accordance with 9.7.1.1(1).

17.3.5.3 Buildings with unprotected openings in accordance with 8.6.6 shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

17.3.6 Corridors.

Every interior corridor shall be constructed of walls having not less than a ½-hour fire resistance rating in accordance with Section 8.3, unless otherwise permitted by the following:

CHAPTER 16 • New

- (1) Corridor protection shall not be required where all spaces normally subject to client occupancy have not less than one door opening directly to the outside or to an exterior exit access balcony or corridor in accordance with 7.5.3.
- (2) In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, corridor walls shall not be required to be rated, provided that such walls form smoke partitions in accordance with Section 8.4.
- (3) Where the corridor ceiling is an assembly having a 1-hour fire resistance rating where tested as a wall, the corridor walls shall be permitted to terminate at the corridor ceiling.
- (4) Lavatories shall not be required to be separated from corridors, provided that they are separated from all other spaces by walls having not less than a 1-hour fire resistance rating in accordance with Section 8.3.
- (5) Lavatories shall not be required to be separated from corridors, provided the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

Section 16.4 Special Provisions

16.4.1 Limited Access Buildings and Underground Buildings.

Limited access buildings and underground buildings shall comply with Section 11.7.

16.4.2 High-Rise Buildings.

High-rise buildings that house day-care occupancies on floors more than 23 m (75 ft) above the lowest level of fire department vehicle access shall comply with Section 11.8.

Subsection 16/17.4.2 requires compliance with Section 11.8 (that is, automatic sprinkler, standpipe, alarm and communications, standby power, and central control station requirements) where a day-care center is located on a floor above the 23-m (75-ft) level, whether that center is a new or existing one.

CHAPTER 17 • Existing

- (1) Corridor protection shall not be required where all spaces normally subject to student occupancy have not less than one door opening directly to the outside or to an exterior exit access balcony or corridor in accordance with 7.5.3.
- (2) In buildings protected throughout by an approved automatic sprinkler system with valve supervision in accordance with Section 9.7, corridor walls shall not be required to be rated, provided that such walls form smoke partitions in accordance with Section 8.4.
- (3) Where the corridor ceiling is an assembly having a ½-hour fire resistance rating where tested as a wall, the corridor walls shall be permitted to terminate at the corridor ceiling.
- (4) Lavatories shall not be required to be separated from corridors, provided that they are separated from all other spaces by walls having not less than a ½-hour fire resistance rating in accordance with Section 8.3.
- (5) Lavatories shall not be required to be separated from corridors, provided the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (6) Existing doors in ½-hour fire resistance-rated corridors shall be permitted to be 44-mm (1¾-in.) thick, solid-bonded wood core doors or the equivalent.

Section 17.4 Special Provisions

17.4.1 Limited Access Buildings and Underground Buildings.

Limited access buildings and underground buildings shall comply with Section 11.7.

17.4.2 High-Rise Buildings.

High-rise buildings that house day-care occupancies on floors more than 23 m (75 ft) above the lowest level of fire department vehicle access shall comply with Section 11.8.

This requirement will force careful review when considering the placement of a new day-care center above the 23-m (75-ft) level in an existing high-rise building. If the building does not already comply with the requirements of Section 11.8, it will need to be brought into compliance.

CHAPTER 16 • New

16.4.3 Flexible Plan and Open Plan Buildings.

16.4.3.1 Flexible plan and open plan buildings shall comply with the requirements of this chapter as modified by 16.4.3.2 through 16.4.3.5.

16.4.3.2 Flexible plan buildings shall be permitted to have walls and partitions rearranged periodically only if revised plans or diagrams have been approved by the authority having jurisdiction.

16.4.3.3 Flexible plan buildings shall be evaluated while all folding walls are extended and in use as well as when they are in the retracted position.

16.4.3.4 Each room occupied by more than 300 persons shall have two or more means of egress entering into separate atmospheres.

16.4.3.5 Where three or more means of egress are required from a single room, the number of means of egress permitted to enter into a common atmosphere shall not exceed two.

Section 16.5 Building Services**16.5.1 Utilities.**

16.5.1.1 Utilities shall comply with the provisions of Section 9.1.

16.5.1.2 Special protective covers for all electrical receptacles shall be installed in all areas occupied by clients.

16.5.2 Heating, Ventilating, and Air Conditioning Equipment.

16.5.2.1 Heating, ventilating, and air conditioning equipment shall be in accordance with Section 9.2.

16.5.2.2 Unvented fuel-fired heating equipment, other than gas space heaters in compliance with NFPA 54/ANSI Z223.1, *National Fuel Gas Code*, shall be prohibited.

16.5.2.3 Any heating equipment in spaces occupied by clients shall be provided with partitions, screens, or other means to protect clients from hot surfaces and open flames; if solid partitions are used to provide such protection, provisions shall be made to ensure adequate air for combustion and ventilation for the heating equipment.

16.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors, other than those in day-care homes, shall comply with the provisions of Section 9.4.

CHAPTER 17 • Existing

17.4.3 Flexible Plan and Open Plan Buildings.

17.4.3.1 Flexible plan and open plan buildings shall comply with the requirements of this chapter as modified by 17.4.3.2 and 17.4.3.3.

17.4.3.2 Flexible plan buildings shall be permitted to have walls and partitions rearranged periodically only if revised plans or diagrams have been approved by the authority having jurisdiction.

17.4.3.3 Flexible plan buildings shall be evaluated while all folding walls are extended and in use as well as when they are in the retracted position.

Section 17.5 Building Services**17.5.1 Utilities.**

17.5.1.1 Utilities shall comply with the provisions of Section 9.1.

17.5.1.2 Special protective covers for all electrical receptacles shall be installed in all areas occupied by clients.

17.5.2 Heating, Ventilating, and Air Conditioning Equipment.

17.5.2.1 Heating, ventilating, and air conditioning equipment shall be in accordance with Section 9.2.

17.5.2.2 Unvented fuel-fired heating equipment, other than gas space heaters in compliance with NFPA 54/ANSI Z223.1, *National Fuel Gas Code*, shall be prohibited.

17.5.2.3 Any heating equipment in spaces occupied by clients shall be provided with partitions, screens, or other means to protect clients from hot surfaces and open flames; if solid partitions are used to provide such protection, provisions shall be made to ensure adequate air for combustion and ventilation for the heating equipment.

17.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors, other than those in day-care homes, shall comply with the provisions of Section 9.4.

CHAPTER 16 • New

16.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes, other than those in day-care homes, shall comply with the provisions of Section 9.5.

Paragraph 16/17.5.1.2 requires that protective covers be provided and maintained on all electrical receptacles to avoid serious injuries resulting from clients' inserting objects into those receptacles.

The interest of reasonable life safety is not served by allowing the use of unvented, fuel-fired equipment in buildings occupied by day-care center clients. Thus, 16/17.5.2.2 prohibits such equipment, within the exception of a special form of gas space heater that can be used safely.

CHAPTER 17 • Existing

17.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes, other than those in day-care homes, shall comply with the provisions of Section 9.5.

Day-care center clients do not always understand the dangers of hot surfaces; paragraph 16/17.5.2.3 recognizes the importance of providing safeguards to protect them from the hot surfaces of heating equipment. It is important that such safeguards allow adequate air for combustion, as incomplete or inadequate combustion could cause serious injury or death.

Section 16.6 Day-Care Homes**16.6.1 General Requirements.****16.6.1.1 Application.**

16.6.1.1.1 The requirements of Section 16.6 shall apply to the following:

- (1) New buildings or portions thereof used as day-care homes (*see 1.3.1*)
- (2) Additions made to, or used as, a day-care home (*see 4.6.7*)
- (3) Alterations, modernizations, or renovations of existing day-care homes (*see 4.6.8*)
- (4) Existing buildings or portions thereof upon change of occupancy to a day-care home (*see 4.6.12*)

16.6.1.1.2 The requirements of Section 16.6 shall apply to day-care homes in which more than 3, but not more than 12, clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day, generally within a dwelling unit. (*See also 16.6.1.4.*)

Section 17.6 Day-Care Homes**17.6.1 General Requirements.****17.6.1.1 Application.****17.6.1.1.1 Reserved.**

17.6.1.1.2* The requirements of Section 17.6 shall apply to existing day-care homes in which more than 3, but not more than 12, clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day, generally within a dwelling unit. An existing day-care home shall be permitted the option of meeting the requirements of Section 16.6 in lieu of Section 17.6. Any existing day-care home that meets the requirements of Chapter 16 shall be judged as meeting the requirements of this chapter. (*See also 17.6.1.4.*)

A.17.6.1.1.2 Day-care homes do not provide for the full-time maintenance of a client. Day-care occupancies that provide a primary place of residence are addressed in other day-care occupancy chapters. (*See Chapter 24 through Chapter 33.*)

CHAPTER 16 • New

16.6.1.1.3 Where a facility houses more than one age group or one self-preservation capability, the strictest requirements applicable to any group present shall apply throughout the day-care home or building, as appropriate to a given area, unless the area housing such a group is maintained as a separate fire area.

16.6.1.1.4 Facilities that supervise clients on a temporary basis with a parent or guardian in close proximity shall not be required to meet the provisions of Section 16.6.

16.6.1.1.5 Places of religious worship shall not be required to meet the provisions of Section 16.6 where operating a nursery while services are being held in the building.

16.6.1.2 Multiple Occupancies. See 16.1.2.

16.6.1.3 Definitions. See 16.1.3.

16.6.1.4 Classification of Occupancy.

16.6.1.4.1 Subclassification of Day-Care Homes. Subclassification of day-care homes shall comply with 16.6.1.4.1(A) and 16.6.1.4.1(B).

(A) Family Day-Care Home. A family day-care home shall be a day-care home in which more than three, but fewer than seven, clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day, generally within a dwelling unit.

(B) Group Day-Care Home. A group day-care home shall be a day-care home in which not less than 7, but not more than 12, clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day, generally within a dwelling unit.

Section 16/17.6 addresses both family day-care homes (4 to 6 clients) and group day-care homes (7 to 12 clients). Where the requirements vary between the two sizes of day-care homes, Section 16/17.6 references the applicable size.

The provisions of Section 16/17.6 recognize that day-care homes are typically located in residential settings. However, a day-care home, whether it be a family day-care home or a group day-care home, is to be treated via the day-care home requirements of Section 16/17.6 even if it is located in a nonresidential setting, such as an office building.

Day-care homes and group day-care homes are

CHAPTER 17 • Existing

17.6.1.1.3 Where a facility houses clients of more than one self-preservation capability, the strictest requirements applicable to any group present shall apply throughout the day-care home or building, as appropriate to a given area, unless the area housing such a group is maintained as a separate fire area.

17.6.1.1.4 Facilities that supervise clients on a temporary basis with a parent or guardian in close proximity shall not be required to meet the provisions of Section 17.6.

17.6.1.1.5 Places of religious worship shall not be required to meet the provisions of Section 17.6 where operating a day-care home while services are being held in the building.

17.6.1.2 Multiple Occupancies. See 17.1.2.

17.6.1.3 Definitions. See 17.1.3.

17.6.1.4 Classification of Occupancy.

17.6.1.4.1 Subclassification of Day-Care Homes. Subclassification of day-care homes shall comply with 17.6.1.4.1(A) and 17.6.1.4.1(B).

(A) Family Day-Care Home. A family day-care home shall be a day-care home in which more than three, but fewer than seven, clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day, generally within a dwelling unit.

(B) Group Day-Care Home. A group day-care home shall be a day-care home in which not less than 7, but not more than 12, clients receive care, maintenance, and supervision by other than their relative(s) or legal guardian(s) for less than 24 hours per day, generally within a dwelling unit.

often found in buildings primarily composed of apartment, mercantile, business, or assembly occupancies. Where a day-care facility is located in a building housing another occupancy, the operators of the day-care facility usually have no control over the safety procedures and precautions practiced outside the day-care facility. Thus, 6.1.14.1.2 does not permit a day-care operation with four or more clients to be considered incidental to another occupancy. This means that day-care occupancy provisions of the *Code* must be followed because the provisions applicable to the predominant occupancy might not be adequate to protect the day-care clients.

CHAPTER 16 • New

16.6.1.4.2* Conversions. A conversion from a day-care home to a day-care occupancy with more than 12 clients shall be permitted only if the day-care occupancy conforms with the requirements of Chapter 16 for new day-care occupancies with more than 12 clients.

A.16.6.1.4.2 A conversion from a day-care occupancy with more than 12 clients to a day-care home is not considered a change of occupancy. The resulting day-care home should be permitted to meet the requirements of Chapter 17 for existing day-care homes.

16.6.1.5 Classification of Hazard of Contents. See 16.1.5.

16.6.1.6 Location and Construction. No day-care home shall be located more than one story below the level of exit discharge.

16.6.1.7 Occupant Load.

16.6.1.7.1 In family day-care homes, the following shall apply:

- (1) The minimum staff-to-client ratio shall be not less than one staff for up to six clients, including the caretaker's own children under age six.
- (2) There shall be not more than two clients incapable of self-preservation.

16.6.1.7.2 In group day-care homes the following shall apply:

- (1) The minimum staff-to-client ratio shall be not less than two staff for up to 12 clients.
- (2) There shall be not more than three clients incapable of self-preservation.
- (3) The staff-to-client ratio shall be permitted to be modified by the authority having jurisdiction where safeguards in addition to those specified by Section 16.6 are provided.

16.6.2 Means of Escape Requirements.

16.6.2.1 General. Means of escape shall comply with Section 24.2.

16.6.2.2 Reserved.

16.6.2.3 Reserved.

16.6.2.4 Number of Means of Escape. The number of means of escape shall comply with Section 24.2 and 16.6.2.4.1 through 16.6.2.4.4.

16.6.2.4.1 In group day-care homes, every story occupied by clients shall have not less than two remotely located means of escape.

CHAPTER 17 • Existing

17.6.1.4.2* Conversions. A conversion from a day-care home to a day-care occupancy with more than 12 clients shall be permitted only if the day-care occupancy conforms to the requirements of Chapter 16 for new day-care occupancies with more than 12 clients.

A.17.6.1.4.2 A conversion from a day-care occupancy with more than 12 clients to a day-care home is not considered a change of occupancy. The resulting day-care home should be permitted to meet the requirements of Chapter 17 for existing day-care homes.

17.6.1.5 Classification of Hazard of Contents. See 17.1.5.

17.6.1.6 Location and Construction. No day-care home shall be located more than one story below the ground.

17.6.1.7 Occupant Load.

17.6.1.7.1 In family day-care homes the following shall apply:

- (1) The minimum staff-to-client ratio shall be not less than one staff for up to six clients, including the caretaker's own children under age six.
- (2) There shall be not more than two clients incapable of self-preservation.

17.6.1.7.2 In group day-care homes the following shall apply:

- (1) The minimum staff-to-client ratio shall be not less than two staff for up to 12 clients.
- (2) There shall be not more than three clients incapable of self-preservation.
- (3) The staff-to-client ratio shall be permitted to be modified by the authority having jurisdiction where safeguards in addition to those specified by Section 17.6 are provided.

17.6.2 Means of Escape Requirements.

17.6.2.1 General. Means of escape shall comply with Section 24.2.

17.6.2.2 Reserved.

17.6.2.3 Reserved.

17.6.2.4 Number of Means of Escape. The number of means of escape shall comply with Section 24.2 and 17.6.2.4.1 through 17.6.2.4.4.

17.6.2.4.1 In group day-care homes, every story occupied by clients shall have not less than two remotely located means of escape.

CHAPTER 16 • New

16.6.2.4.2 Every room used for sleeping, living, or dining purposes shall comply with the following:

- (1) There shall be not less than two means of escape, not less than one of which shall be a door or stairway providing a means of unobstructed travel to the outside of the building at street or ground level.
- (2) The second means of escape shall be permitted to be a window in accordance with 16.2.11.1.
- (3) No room or space that is accessible only by a ladder or folding stairs or through a trap door shall be occupied for living or sleeping purposes.

16.6.2.4.3 In group day-care homes where spaces on the story above the level of exit discharge are used by clients, not less than one means of escape shall be an exit discharging directly to the outside, and the second means of escape shall be permitted to be a window in accordance with 16.2.11.1.

16.6.2.4.4 Where clients occupy a story below the level of exit discharge, not less than one means of escape shall be an exit discharging directly to the outside, the vertical travel to ground level shall not exceed 2440 mm (96 in.), and the second means of escape shall be permitted to be a window in accordance with 16.2.11.1.

The concept of means of escape is well developed in Chapter 24 for one- and two-family dwellings. However, 16/17.6.2.4.3 and 16/17.6.2.4.4 require the primary means of escape to discharge directly to the outside if day-care home clients occupy the second story or basement.

The second floor of a typical single-family dwelling is served by an open stair. The requirement of 16/17.6.2.4.3 mandates that the second floor is to be served by an enclosed exit stair or an exterior stair (not a fire escape) if clients are occupying the second floor. See also subsection 16/17.6.3.1.

The requirement of 16/17.6.2.4.4 is similar to that of 16/17.6.2.4.3 for a second floor and mandates that, where clients are below the level of exit discharge, at least one true exit shall be provided. In addition, per the requirements of subsection 16/17.6.3.1, any stairway to the first floor requires a minimum 20-minute rated door as a separation between the stair and the first floor.

As illustrated in Exhibit 16/17.8, where a group day-care home is located in a basement, an exit is required that opens directly to the outside, with verti-

CHAPTER 17 • Existing

17.6.2.4.2 Every room used for sleeping, living, or dining purposes shall comply with the following:

- (1) There shall be not less than two means of escape, not less than one of which shall be a door or stairway providing a means of unobstructed travel to the outside of the building at street or ground level.
- (2) The second means of escape shall be permitted to be a window in accordance with 17.2.11.1.
- (3) No room or space that is accessible only by a ladder or folding stairs or through a trap door shall be occupied for living or sleeping purposes.

17.6.2.4.3 In group day-care homes where spaces on the story above the level of exit discharge are used by clients, not less than one means of escape shall be an exit discharging directly to the outside, and the second means of escape shall be permitted to be a window in accordance with 17.2.11.1.

17.6.2.4.4 Where clients occupy a story below the level of exit discharge, not less than one means of escape shall be an exit discharging directly to the outside, the vertical travel to ground level shall not exceed 2440 mm (96 in.), and the second means of escape shall be permitted to be a window in accordance with 17.2.11.1.

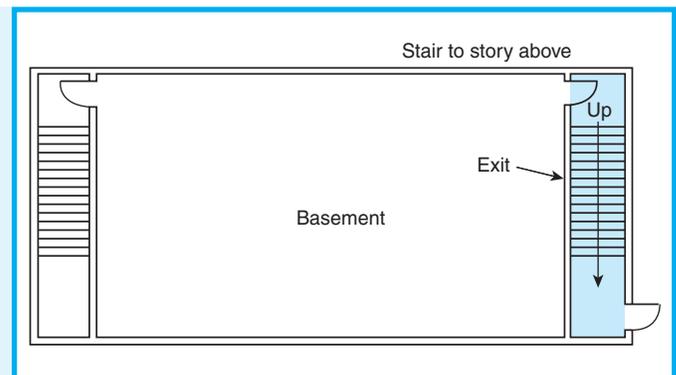

Exhibit 16/17.8 Egress requirements for group day-care home occupying basement.

cal travel to the ground level not exceeding 2440 mm (96 in.). If a stairway to the story above were provided, it would have to be cut off from the basement by a fire barrier containing a door with a fire protection rating of at least 20 minutes. This separation is required at the top or bottom of the stair, but not at both. See also subsection 16/17.6.3.1.

CHAPTER 16 • New

16.6.2.5 Arrangement of Means of Egress.

16.6.2.5.1 A story used above or below the level of exit discharge shall be in accordance with 16.6.2.4.3 and 16.6.2.4.4.

16.6.2.5.2 For group day-care homes, means of egress shall be arranged in accordance with Section 7.5.

16.6.2.5.3 No dead-end corridors shall exceed 6100 mm (240 in.).

16.6.2.6 Travel Distance.

16.6.2.6.1 Travel distance shall meet the following criteria unless otherwise permitted by 16.6.2.6.2:

- (1) The travel distance between any room door intended as an exit access and an exit shall not exceed 30 m (100 ft).
- (2) The travel distance between any point in a room and an exit shall not exceed 46 m (150 ft).
- (3) The travel distance between any point in a sleeping room and an exit access to that room shall not exceed 15 m (50 ft).

16.6.2.6.2 The travel distance in 16.6.2.6(1) and 16.6.2.6(2) shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

16.6.2.7 Discharge from Exits. See 16.6.2.4.

16.6.2.8 Illumination of Means of Egress. Means of egress shall be illuminated in accordance with Section 7.8.

16.6.2.9 Emergency Lighting. (No requirements.)

16.6.2.10 Marking of Means of Egress. (No requirements.)

16.6.3 Protection.**16.6.3.1 Protection of Vertical Openings.**

16.6.3.1.1 For group day-care homes, the doorway between the level of exit discharge and any story below shall be equipped with a fire door assembly having a 20-minute fire protection rating.

16.6.3.1.2 Where the story above the level of exit discharge is used for sleeping purposes, there shall be a fire door

CHAPTER 17 • Existing

17.6.2.5 Arrangement of Means of Egress.

17.6.2.5.1 A story used above or below the level of exit discharge shall be in accordance with 17.6.2.4.3 or 17.6.2.4.4.

17.6.2.5.2 For group day-care homes, means of egress shall be arranged in accordance with Section 7.5.

17.6.2.5.3 No dead-end corridor shall exceed 6100 mm (240 in.), other than in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, in which case dead-end corridors shall not exceed 15 m (50 ft).

17.6.2.6 Travel Distance.

17.6.2.6.1 Travel distance shall meet the following criteria unless otherwise permitted by 17.6.2.6.2:

- (1) The travel distance between any room door intended as an exit access and an exit shall not exceed 30 m (100 ft).
- (2) The travel distance between any point in a room and an exit shall not exceed 46 m (150 ft).
- (3) The travel distance between any point in a sleeping room and an exit access to that room shall not exceed 15 m (50 ft).

17.6.2.6.2 The travel distance required by 17.6.2.6.1(1) and 17.6.2.6.1(2) shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

17.6.2.7 Discharge from Exits. See 17.6.2.4.

17.6.2.8 Illumination of Means of Egress. Means of egress shall be illuminated in accordance with Section 7.8.

17.6.2.9 Emergency Lighting. (No requirements.)

17.6.2.10 Marking of Means of Egress. (No requirements.)

17.6.3 Protection.**17.6.3.1 Protection of Vertical Openings.**

17.6.3.1.1 For group day-care homes, the doorway between the level of exit discharge and any story below shall be equipped with a fire door assembly having a 20-minute fire protection rating.

17.6.3.1.2 Where the story above the level of exit discharge is used for sleeping purposes, there shall be a fire door

CHAPTER 16 • New

assembly having a 20-minute fire protection rating at the top or bottom of each stairway.

16.6.3.2 Protection from Hazards. (No requirements.)

16.6.3.3 Interior Finish.

16.6.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

16.6.3.3.2 Interior Wall and Ceiling Finish.

16.6.3.3.2.1 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in corridors, stairways, lobbies, and exits. In the exits of family day-care homes, interior wall and ceiling finish materials in accordance with Section 10.2 shall be Class A or Class B.

16.6.3.3.2.2 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A, Class B, or Class C in occupied spaces.

16.6.3.3.3 Interior Floor Finish.

16.6.3.3.3.1 Interior floor finish shall comply with Section 10.2.

16.6.3.3.3.2 Interior floor finish in exit enclosures shall be not less than Class II.

16.6.3.3.3.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

16.6.3.4 Detection, Alarm, and Communications Systems.

16.6.3.4.1 Smoke alarms shall be installed within day-care homes in accordance with 9.6.2.10.

16.6.3.4.2 Where a day-care home is located within a building of another occupancy, such as in an apartment building or office building, any corridors serving the day-care home shall be provided with a smoke detection system in accordance with Section 9.6.

16.6.3.4.3 One of the following shall be provided in all rooms used for sleeping:

- (1) Single-station or multiple-station smoke alarms in accordance with 9.6.2.10 that are powered by the building electrical system

CHAPTER 17 • Existing

assembly having a 20-minute fire protection rating at the top or bottom of each stairway unless otherwise permitted by 17.6.3.1.3.

17.6.3.1.3 Approved existing self-closing 44-mm (1¾-in.) thick, solid-bonded wood doors without rated frames shall be permitted to continue in use.

17.6.3.2 Protection from Hazards. (No requirements.)

17.6.3.3 Interior Finish.

17.6.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

17.6.3.3.2 Interior Wall and Ceiling Finish.

17.6.3.3.2.1 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in exits.

17.6.3.3.2.2 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A, Class B, or Class C in occupied spaces.

17.6.3.3.3 Interior Floor Finish. (No requirements.)

17.6.3.4 Detection, Alarm, and Communications Systems.

17.6.3.4.1 Smoke alarms shall be installed within day-care homes in accordance with 9.6.2.10.

17.6.3.4.2 Where a day-care home is located within a building of another occupancy, such as in an apartment building or office building, any corridors serving the day-care home shall be provided with a smoke detection system in accordance with Section 9.6.

17.6.3.4.3 One of the following shall be provided in all rooms used for sleeping:

- (1) Single-station or multiple-station smoke alarms in accordance with 9.6.2.10 that are powered by the building electrical system

CHAPTER 16 • New

- (2) System detectors with integral sounding devices in accordance with 9.6.1.3

The provisions of 16/17.6.3.4 are as follows:

- (1) To provide smoke alarms within the day-care home
 (2) To provide a smoke detection system in the corri-

16.6.3.5 Extinguishment Requirements. Any required sprinkler systems shall be in accordance with Section 9.7 and shall be installed in accordance with 9.7.1.1(1), 9.7.1.1(2), or 9.7.1.1(3), as appropriate with respect to the scope of the installation standard.

Section 16.7 Operating Features

16.7.1* Emergency Plans.

Emergency plans shall be provided in accordance with Section 4.8.

A.16.7.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; adult day-care; care of infants; and day-care occupancies. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators, through the written fire emergency response plan, to issue supplements to these requirements; however, all supplements should be consistent with these requirements. Additionally, it is recommended that fire safety be a part of the educational programs of the occupancy for clients.

Fire emergency response plans need to be written and made available to all employees, including temporary or substitute staff, so that all employees know what is expected of them during a fire emergency. The elements needed in the written plan should be identified in coordination with the authority having jurisdiction.

CHAPTER 17 • Existing

- (2) System detectors with integral sounding devices in accordance with 9.6.1.3

17.6.3.4.4 Approved existing battery-powered smoke alarms, rather than house electrical service-powered smoke alarms required by 17.6.3.4.3, shall be permitted where the facility has testing, maintenance, and battery replacement programs that ensure reliability of power to the smoke alarms.

- dor serving the day-care home in a building of mixed occupancy
 (3) To require that smoke alarms be installed in each sleeping room

17.6.3.5 Extinguishment Requirements. Any required sprinkler systems shall be in accordance with Section 9.7 and, other than approved existing systems, shall be installed in accordance with 9.7.1.1(1), 9.7.1.1(2), or 9.7.1.1(3), as appropriate with respect to the scope of the installation standard.

Section 17.7 Operating Features

17.7.1* Emergency Plans.

Emergency plans shall be provided in accordance with Section 4.8.

A.17.7.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; adult day-care; care of infants; and day-care occupancies. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators, through the written fire emergency response plan, to issue supplements to these requirements; however, all supplements should be consistent with these requirements. Additionally, it is recommended that fire safety be a part of the educational programs of the occupancy for clients.

Fire emergency response plans need to be written and made available to all employees, including temporary or substitute staff, so that all employees know what is expected of them during a fire emergency. The elements needed in the written plan should be identified in coordination with the authority having jurisdiction.

CHAPTER 16 • New

The facility fire emergency response plan might be a module of a facility disaster plan that covers other emergencies.

The proper safeguarding of clients during a fire emergency requires prompt and effective response by the facility employees in accordance with the fire emergency response plan. Duties covered under the plan should be assigned by position rather than by employee name. Such assignment ensures that, in the absence of an employee, the duties of the position will be performed by a substitute or temporary employee assigned to the position. Temporary or substitute employees should be instructed in advance regarding their duties under the plan for the position to which they are assigned.

Written fire emergency response plans should include, but should not be limited to, information for employees regarding methods and devices available for alerting occupants of a fire emergency. Employees should know how the fire department is to be alerted. Even where automatic systems are expected to alert the fire department, the written plan should provide for backup alerting procedures by staff. Other responses of employees to a fire emergency should include the following:

- (1) Removal of clients in immediate danger to areas of safety, as set forth in the plan
- (2) Methods of using building features to confine the fire and its byproducts to the room or area of origin
- (3) The control of actions and behaviors of clients during removal or evacuation activities and at predetermined safe assembly areas

The written plan should state clearly the facility policy regarding the actions staff are to take or not take to extinguish a fire. It should also incorporate the emergency egress and relocation drill procedures set forth in 16.7.2.

16.7.2 Emergency Egress and Relocation Drills.

16.7.2.1* Emergency egress and relocation drills shall be conducted in accordance with Section 4.7 and the applicable provisions of 16.7.2.2.

A.16.7.2.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; day-care occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements.

CHAPTER 17 • Existing

The facility fire emergency response plan might be a module of a facility disaster plan that covers other emergencies.

The proper safeguarding of clients during a fire emergency requires prompt and effective response by the facility employees in accordance with the fire emergency response plan. Duties covered under the plan should be assigned by position rather than by employee name. Such assignment ensures that, in the absence of an employee, the duties of the position will be performed by a substitute or temporary employee assigned to the position. Temporary or substitute employees should be instructed in advance regarding their duties under the plan for the position to which they are assigned.

Written fire emergency response plans should include, but should not be limited to, information for employees about methods and devices available for alerting occupants of a fire emergency. Employees should know how the fire department is to be alerted. Even where automatic systems are expected to alert the fire department, the written plan should provide for backup alerting procedures by staff. Other responses of employees to a fire emergency should include the following:

- (1) Removal of clients in immediate danger to areas of safety, as set forth in the plan
- (2) Methods of using building features to confine the fire and its byproducts to the room or area of origin
- (3) The control of actions and behaviors of clients during removal or evacuation activities and at predetermined safe assembly areas

The written plan should state clearly the facility policy regarding the actions staff are to take or not take to extinguish a fire. It should also incorporate the emergency egress and relocation drill procedures set forth in 17.7.2.

17.7.2 Emergency Egress and Relocation Drills.

17.7.2.1* Emergency egress and relocation drills shall be conducted in accordance with Section 4.7 and the applicable provisions of 17.7.2.2.

A.17.7.2.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; day-care occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements.

CHAPTER 16 • New

16.7.2.2 Emergency egress and relocation drills shall be conducted as follows:

- (1) Not less than one emergency egress and relocation drill shall be conducted every month the facility is in session, unless both of the following criteria are met:
 - (a) In climates where the weather is severe, the monthly emergency egress and relocation drills shall be permitted to be deferred.
 - (b) The required number of emergency egress and relocation drills shall be conducted, and not less than four shall be conducted before the drills are deferred.
- (2) All occupants of the building shall participate in the drill.
- (3) One additional emergency egress and relocation drill, other than for day-care occupancies that are open on a year-round basis, shall be required within the first 30 days of operation.

16.7.3 Inspections.

16.7.3.1 Fire prevention inspections shall be conducted monthly by a trained senior member of the staff, after which a copy of the latest inspection report shall be posted in a conspicuous place in the day-care facility.

16.7.3.2* It shall be the duty of site administrators and staff members to inspect all exit facilities daily to ensure that all stairways, doors, and other exits are in proper condition.

A.16.7.3.2 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building.

16.7.3.3 Open plan buildings shall require extra surveillance to ensure that exit paths are maintained clear of obstruction and are obvious.

16.7.4 Furnishings and Decorations.

16.7.4.1 Draperies, curtains, and other similar furnishings and decorations in day-care occupancies shall be in accordance with the provisions of 10.3.1.

16.7.4.2 Clothing and personal effects shall not be stored in corridors, unless otherwise permitted by the following:

CHAPTER 17 • Existing

17.7.2.2 Emergency egress and relocation drills shall be conducted as follows:

- (1) Not less than one emergency egress and relocation drill shall be conducted every month the facility is in session, unless both of the following criteria are met:
 - (a) In climates where the weather is severe, the monthly emergency egress and relocation drills shall be permitted to be deferred.
 - (b) The required number of emergency egress and relocation drills shall be conducted, and not less than four shall be conducted before the drills are deferred.
- (2) All occupants of the building shall participate in the drill.
- (3) One additional emergency egress and relocation drill, other than for day-care occupancies that are open on a year-round basis, shall be required within the first 30 days of operation.

17.7.3 Inspections.

17.7.3.1 Fire prevention inspections shall be conducted monthly by a trained senior member of the staff, after which a copy of the latest inspection report shall be posted in a conspicuous place in the day-care facility.

17.7.3.2* It shall be the duty of site administrators and staff members to inspect all exit facilities daily to ensure that all stairways, doors, and other exits are in proper condition.

A.17.7.3.2 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building.

17.7.3.3 Open plan buildings shall require extra surveillance to ensure that exit paths are maintained clear of obstruction and are obvious.

17.7.4 Furnishings and Decorations.

17.7.4.1 Draperies, curtains, and other similar furnishings and decorations in day-care occupancies shall be in accordance with the provisions of 10.3.1.

17.7.4.2 Clothing and personal effects shall not be stored in corridors, unless otherwise permitted by the following:

CHAPTER 16 • New

- (1) This requirement shall not apply to corridors protected by an automatic sprinkler system in accordance with Section 9.7.
- (2) This requirement shall not apply to corridor areas protected by a smoke detection system in accordance with Section 9.6.
- (3) This requirement shall not apply to storage in metal lockers, provided that the required egress width is maintained.

16.7.4.3 Artwork and teaching materials shall be permitted to be attached directly to the walls in accordance with the following:

- (1) The artwork and teaching materials shall not exceed 20 percent of the wall area in a building that is not protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (2) The artwork and teaching materials shall not exceed 50 percent of the wall area in a building that is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

16.7.5* Day-Care Staff.

Adequate adult staff shall be on duty, alert, awake, and in the facility at all times where clients are present.

A.16.7.5 It is the intent that the requirement for adequate adult staff to be awake at all times when clients are present be applied to family day-care and group day-care homes that are operated at night, as well as day-care occupancies.

CHAPTER 17 • Existing

- (1) This requirement shall not apply to corridors protected by an automatic sprinkler system in accordance with Section 9.7.
- (2) This requirement shall not apply to corridor areas protected by a smoke detection system in accordance with Section 9.6.
- (3) This requirement shall not apply to storage in metal lockers, provided that the required egress width is maintained.

17.7.4.3 Artwork and teaching materials shall be permitted to be attached directly to the walls in accordance with the following:

- (1) The artwork and teaching materials shall not exceed 20 percent of the wall area in a building that is not protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.
- (2) The artwork and teaching materials shall not exceed 50 percent of the wall area in a building that is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

17.7.5* Day-Care Staff.

Adequate adult staff shall be on duty, alert, awake, and in the facility at all times where clients are present.

A.17.7.5 It is the intent that the requirement for adequate adult staff to be awake at all times when clients are present be applied to family day-care and group day-care homes that are operated at night, as well as day-care occupancies.

CHAPTERS 18 and 19

New and Existing Health Care Occupancies

Life safety in health care occupancies is so encompassing that it includes nearly the entire gamut of systems, options, and features addressed in the core chapters. Unlike most other buildings and use groups addressed by the *Code*, the least desirable emergency action in a health care occupancy is the wholesale relocation or evacuation of patients. For this reason, a “defend-in-place” strategy is used.

The defend-in-place strategy is implemented using a *total concept* approach. As detailed in 18/19.1.1.3, the total concept approach provides an assortment of features that are deemed necessary to avoid the movement of patients to the outside during a fire. Of course, those patients who might be perilously close to the effects of the fire are given a range of protection features such as being moved to an adjacent smoke compartment on the same floor.

Requirements for allowable building construction types, sprinklers, alarm and detection systems, and staff training work in harmony to help ensure that a patient can be safely and adequately protected regardless of where a fire starts.

Chapters 18 and 19 also address an allowance for locking doors, but only when the clinical needs of the patient demand such measures (see

18/19.1.1.1.5). In response to a small number of infant abductions at health care facilities, some facility operators have inquired about the appropriateness of using 18/19.1.1.5 to secure infant care areas via locked doors. However, because infant abduction is a security needs issue, not a patient clinical need, other precautions and approaches must be considered to address this problem.

Staff action is an integral part of the life safety features required in a health care facility. The proper response from staff in terms of availability, actions, and management of the fire can readily influence the outcome of a fire. Health care facility staff are charged with the responsibility of preserving the safety of their charges, whether that involves informing patients who are not in jeopardy from the fire or helping relocate those who are.

Staff training, coupled with the traditional built-in systems and features (for example, construction; compartmentation; interior finish; alarm, detection, and sprinkler systems; and control of contents and furnishings), provides one of the safest environments for one of the most vulnerable population groups addressed by the *Code*.

Section 18.1 General Requirements

Chapters 18 and 19 cover the requirements for health care occupancies. Prior to the 1976 edition of the *Code*, these occupancies were grouped with penal facilities (currently addressed by Chapters 22 and 23) and were known as “institutional occupancies.”

Section 19.1 General Requirements

Health care occupancies are those facilities used for the medical care or treatment of four or more persons suffering from physical or mental illness, disease, or infirmity, and for the care of infants, convalescents, or infirm aged persons.

CHAPTER 18 • New

Health care occupancies addressed in these chapters include the following:

- (1) Hospitals
- (2) Nursing homes
- (3) Limited care facilities

Hospitals, nursing homes, and limited care facilities provide sleeping facilities for occupants incapable

18.1.1 Application.**18.1.1.1 General.**

18.1.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as health care occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, a health care occupancy (*see 4.6.7 and 18.1.1.4*), unless all of the following criteria are met:
 - (a) The addition is classified as other than a health care occupancy.
 - (b) The addition is separated from the health care occupancy in accordance with 18.1.2.2(2).
 - (c) The addition conforms to the requirements for the specific occupancy in accordance with Chapter 12 through Chapter 17 and Chapter 20 through Chapter 42, as appropriate.
- (3) Alterations, modernizations, or renovations of existing health care occupancies (*see 4.6.8 and 18.1.1.4*)
- (4)* Existing buildings or portions thereof upon change of occupancy to a health care occupancy (*see 4.6.12*), unless the authority having jurisdiction has determined equivalent safety has been provided in accordance with Section 1.4.

A.18.1.1.1.1(4) In determining equivalency for conversions, modernizations, renovations, or unusual design concepts of hospitals or nursing homes, the authority having jurisdiction is permitted to accept evaluations based on the health care occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, utilizing the parameters for new construction.

Renovations, alterations, and modernizations must be performed in accordance with the requirements for new construction—contained in Chapter 18—to the maximum extent possible, as required by 4.6.8.

CHAPTER 19 • Existing

of self-preservation due to age, physical or mental disabilities, or security measures not under their control.

Ambulatory health care facilities differ from other health care occupancies in that they do not provide sleeping facilities; they are addressed separately in Chapters 20 and 21.

19.1.1 Application.**19.1.1.1 General.**

19.1.1.1.1* The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as health care occupancies, unless the authority having jurisdiction has determined equivalent safety has been provided in accordance with Section 1.4. (*See also 18.1.1.1.1.*)

A.19.1.1.1.1 In determining equivalency for existing hospitals or nursing homes, the authority having jurisdiction is permitted to accept evaluations based on the health care occupancies fire safety evaluation system (FSES) NFPA 101A, *Guide on Alternative Approaches to Life Safety*, utilizing the parameters for existing buildings.

Paragraphs 18.1.1.1.1(4) and 19.1.1.1.1 emphasize that Section 1.4 permits alternative designs in lieu of literally implementing *Code* requirements. The alternative design can be judged by the authority having

CHAPTER 18 • New

jurisdiction as achieving compliance with *Code* requirements; the AHJ ultimately determines whether equivalent safety has been provided.

Paragraphs 18.1.1.1(4) and 19.1.1.1 are not intended to limit the methods that an authority having jurisdiction might use to determine equivalency. However, as noted in A.18.1.1.1(4) and A.19.1.1.1, NFPA 101A, *Guide on Alternative Approaches to Life Safety*,¹ provides an “equivalency system” that uses numerical values to analyze the fire safety effectiveness of a building design and arrangement. This system, known as the fire safety evaluation system (FSES), provides a method for evaluating alternative designs as options to literal *Code* compliance. It is not the intent of the *Code* to limit equivalency evaluations solely to this system. The authority having jurisdiction does retain the power to evaluate and approve alternative designs on the basis of appropriate supporting data, whether or not the FSES is used to aid in that evaluation. Paragraphs 18.1.1.1(4) and 19.1.1.1 in no way mandate the use of the FSES, nor do they require the AHJ accept the results of an evaluation using the system.

The FSES is a tool to help determine equiva-

18.1.1.1.2 The requirements established by this chapter shall apply to the design of all new hospitals, nursing homes, and limited care facilities. The term *hospital*, wherever used in this *Code*, shall include general hospitals, psychiatric hospitals, and specialty hospitals. The term *nursing home*, wherever used in this *Code*, shall include nursing and convalescent homes, skilled nursing facilities, intermediate care facilities, and infirmaries in homes for the aged. Where requirements vary, the specific subclass of health care occupancy is named in the paragraph pertaining thereto. The requirements established by Chapter 20 shall apply to all new ambulatory health care facilities. The operating feature requirements established by Section 18.7 shall apply to all health care occupancies.

18.1.1.1.3 The health care facilities regulated by this chapter shall be those that provide sleeping accommodations for their occupants and are occupied by persons who are mostly incapable of self-preservation because of age, because of physical or mental disability, or because of security measures not under the occupants’ control.

18.1.1.1.4 Buildings, or sections of buildings, that primarily house patients who, in the opinion of the governing body of the facility and the governmental agency having jurisdic-

CHAPTER 19 • Existing

tion—it should not be used to circumvent *Code* requirements. *Code* requirements must be met, or equivalent safety must be provided by alternative means approved by the authority having jurisdiction. Although the FSES was developed primarily to evaluate alternative designs in existing buildings, it is particularly useful in determining equivalency for conversions, modernizations, renovations, or unusual design concepts, all of which would be considered new construction.

The 2001 edition of NFPA 101A was calibrated so that its measurement tools would compare alternative designs against the requirements of the 2000 edition of the *Life Safety Code*. It does not measure equivalency against the requirements of the 2003 edition of the *Code* and, therefore, must not be used in such an attempt. At the time this handbook went to press, the 2004 edition of NFPA 101A was being processed via the NFPA consensus-based standards-making process. The 2004 edition, to be published early in 2004, will have the proper calibration for measuring equivalency against the requirements of the 2003 edition of the *Code*.

19.1.1.1.2 The requirements established by this chapter shall apply to all existing hospitals, nursing homes, and limited care facilities. The term *hospital*, wherever used in this *Code*, shall include general hospitals, psychiatric hospitals, and specialty hospitals. The term *nursing home*, wherever used in this *Code*, shall include nursing and convalescent homes, skilled nursing facilities, intermediate care facilities, and infirmaries in homes for the aged. Where requirements vary, the specific subclass of health care occupancy is named in the paragraph pertaining thereto. The requirements established by Chapter 21 shall apply to all existing ambulatory health care facilities. The operating features requirements established by Section 19.7 shall apply to all health care occupancies.

19.1.1.1.3 The health care facilities regulated by this chapter shall be those that provide sleeping accommodations for their occupants and are occupied by persons who are mostly incapable of self-preservation because of age, because of physical or mental disability, or because of security measures not under the occupants’ control.

19.1.1.1.4 Buildings, or sections of buildings, that primarily house patients who, in the opinion of the governing body of the facility and the governmental agency having jurisdic-

CHAPTER 18 • New

tion, are capable of exercising judgment and appropriate physical action for self-preservation under emergency conditions shall be permitted to comply with chapters of this *Code* other than Chapter 18.

18.1.1.1.5 It shall be recognized that, in buildings housing certain types of patients or having detention rooms or a security section, it might be necessary to lock doors and bar windows to confine and protect building inhabitants. In such instances, the authority having jurisdiction shall make appropriate modifications to those sections of this *Code* that would otherwise require means of egress to be kept unlocked.

18.1.1.1.6 Buildings, or sections of buildings, that house older persons and that provide activities that foster continued independence but that do not include services distinctive to health care occupancies (*see 18.1.3*) as defined in 3.3.152.7 shall be permitted to comply with the requirements of other chapters of this *Code*, such as Chapter 30 or Chapter 32.

18.1.1.1.7 Facilities that do not provide housing on a 24-hour basis for their occupants shall be classified as other occupancies and shall be covered by other chapters of this *Code*.

18.1.1.1.8* The requirements of this chapter are based on the assumption that staff is available in all patient-occupied areas to perform certain fire safety functions as required in other paragraphs of this chapter.

A.18.1.1.1.8 The *Code* recognizes that certain functions necessary for the life safety of building occupants—such as the closing of corridor doors, the operation of manual fire alarm devices, and the removal of patients from the room of fire origin—require the intervention of facility staff. It is not the intent of 18.1.1.1.8 to specify the levels or locations of staff necessary to meet this requirement.

Paragraphs 18/19.1.1.1.2 through 18/19.1.1.1.8 contain general material applicable to health care occupancies. Occupants in a health care facility are housed primarily for treatment of mental or physical infirmities, though they might be restrained. Where occupants are restrained for penal or correctional purposes, the building would be classified as a detention and correctional occupancy and the provisions of Chapters 22 and 23 would apply.

If a building is used for the treatment or housing of patients, including those with mental disabilities or older persons (*see 18/19.1.1.1.4 and 18/19.1.1.1.6*), the building can be classified as an occupancy other than health care under the following conditions:

CHAPTER 19 • Existing

tion, are capable of exercising judgment and appropriate physical action for self-preservation under emergency conditions shall be permitted to comply with chapters of the *Code* other than Chapter 19.

19.1.1.1.5 It shall be recognized that, in buildings housing certain types of patients or having detention rooms or a security section, it might be necessary to lock doors and bar windows to confine and protect building inhabitants. In such instances, the authority having jurisdiction shall make appropriate modifications to those sections of this *Code* that would otherwise require means of egress to be kept unlocked.

19.1.1.1.6 Buildings, or sections of buildings, that house older persons and that provide activities that foster continued independence but do not include services distinctive to health care occupancies (*see 19.1.3*) as defined in 3.3.152.7 shall be permitted to comply with the requirements of other chapters of this *Code*, such as Chapter 31 or Chapter 33.

19.1.1.1.7 Facilities that do not provide housing on a 24-hour basis for their occupants shall be classified as other occupancies and shall be covered by other chapters of this *Code*.

19.1.1.1.8* The requirements of this chapter are based on the assumption that staff is available in all patient-occupied areas to perform certain fire safety functions as required in other paragraphs of this chapter.

A.19.1.1.1.8 The *Code* recognizes that certain functions necessary for the life safety of building occupants—such as the closing of corridor doors, the operation of manual fire alarm devices, and the removal of patients from the room of fire origin—require the intervention of facility staff. It is not the intent of 19.1.1.1.8 to specify the levels or locations of staff necessary to meet this requirement.

- (1) Occupants are not restrained by locked doors or other devices.
- (2) Patients are ambulatory.
- (3) Occupants are capable of perceiving threats and taking appropriate action for self-preservation.

Occupants of health care facilities are considered to be incapable of self-preservation (*see 18/19.1.1.1.3*) due to age, physical or mental disabilities, or security measures not under their control. A significant number of occupants in health care facilities are assumed to be nonambulatory or bedridden. Other occupants, while capable of self-movement, might have impaired judgment.

CHAPTER 18 • New

Although locked exit doors and barred windows are undesirable in terms of life safety, the *Code* recognizes that, in some cases, such measures are necessary to restrain people. In these instances, provisions need to be made for the continuous supervision and prompt release of those restrained (see 18/19.1.1.1.5). Release of occupants should be achieved by a system capable of automatically unlocking doors in the means of egress or by continuously available attendants equipped with keys. In either case, continuous supervision is considered essential. Also see 18/19.2.2.2.4 and 18/19.2.2.2.5.

The *Code* assumes that staff will be in continuous attendance in all health care facilities. In fact, staff are assigned certain critical functions during a fire emergency, such as rescuing patients from the room

18.1.1.2* Goals and Objectives. The goals and objectives of Section 4.1 and Section 4.2 shall be met with due consideration for functional requirements, which are accomplished by limiting the development and spread of a fire emergency to the room of fire origin and reducing the need for occupant evacuation, except from the room of fire origin.

A.18.1.1.2 This objective is accomplished in the context of the physical facilities, the type of activities undertaken, the provisions for the capabilities of staff, and the needs of all occupants through requirements directed at the following:

- (1) Prevention of ignition
- (2) Detection of fire
- (3) Control of fire development
- (4) Confinement of the effects of fire
- (5) Extinguishment of fire
- (6) Provision of refuge or evacuation facilities, or both
- (7) Staff reaction

18.1.1.3 Total Concept.

18.1.1.3.1 All health care facilities shall be designed, constructed, maintained, and operated to minimize the possibility of a fire emergency requiring the evacuation of occupants.

18.1.1.3.2 Because the safety of health care occupants cannot be ensured adequately by dependence on evacuation of the building, their protection from fire shall be provided by appropriate arrangement of facilities, adequate, trained staff, and development of operating and maintenance procedures composed of the following:

- (1) Design, construction, and compartmentation
- (2) Provision for detection, alarm, and extinguishment

CHAPTER 19 • Existing

of origin, closing the door to the room, and activating the fire alarm system. The *Code* does not specify minimum staff/patient ratios, because such provisions are included in licensing criteria and compliance with licensing criteria will normally satisfy the *Code*. Paragraph 18/19.1.1.1.8, in effect, mandates that staff be present. A staff person should be situated to supervise each smoke compartment housing patients. A nursing station located to allow visual supervision of two or more smoke compartments is considered adequate. If, because of some unusual arrangement, staff is not available 24 hours a day to provide supervision, alternative means should be provided to ensure an adequate level of fire safety that is in compliance with the *Code*.

19.1.1.2* Goals and Objectives. The goals and objectives of Section 4.1 and Section 4.2 shall be met with due consideration for functional requirements, which are accomplished by limiting the development and spread of a fire emergency to the room of fire origin and reducing the need for occupant evacuation, except from the room of fire origin.

A.19.1.1.2 This objective is accomplished in the context of the physical facilities, the type of activities undertaken, the provisions for the capabilities of staff, and the needs of all occupants through requirements directed at the following:

- (1) Prevention of ignition
- (2) Detection of fire
- (3) Control of fire development
- (4) Confinement of the effects of fire
- (5) Extinguishment of fire
- (6) Provision of refuge or evacuation facilities, or both
- (7) Staff reaction

19.1.1.3 Total Concept.

19.1.1.3.1 All health care facilities shall be designed, constructed, maintained, and operated to minimize the possibility of a fire emergency requiring the evacuation of occupants.

19.1.1.3.2 Because the safety of health care occupants cannot be ensured adequately by dependence on evacuation of the building, their protection from fire shall be provided by appropriate arrangement of facilities, adequate staffing, and development of operating and maintenance procedures composed of the following:

- (1) Design, construction, and compartmentation
- (2) Provision for detection, alarm, and extinguishment

CHAPTER 18 • New

- (3) Fire prevention procedures and the planning, training, and drilling programs for the isolation of fire, transfer of occupants to areas of refuge, or evacuation of the building

The well-being of an individual located in the room of fire origin can be reasonably ensured only through complete control of that environment, including construction materials, wall and ceiling finishes, furnishings, decorations, clothing, linens, bedding, and the like. However, no code can prevent injury resulting from a person's careless actions.

Although an effort should be made to protect the individual through fire prevention, the primary objective of the requirements of Chapters 18 and 19 is to limit fire size or to prevent fire from escaping the room of origin and thereby limit the threat to individuals outside the room of origin. In accordance with the goals of 4.1.1, the same protection scheme should have the benefit of additionally improving the survivability of those occupants who are intimate with the fire development.

Vertical movement of patients within a health care facility is an inefficient, time-consuming process.

18.1.1.4 Additions, Conversions, Modernization, Renovation, and Construction Operations.

18.1.1.4.1 Additions. Additions shall be separated from any existing structure not conforming to the provisions within Chapter 19 by a fire barrier having not less than a 2-hour fire resistance rating and constructed of materials as required for the addition. (See 4.6.12 and 4.6.7.)

18.1.1.4.2 Communicating openings in dividing fire barriers required by 18.1.1.4.1 shall be permitted only in corridors and shall be protected by approved self-closing fire door assemblies. (See also Section 8.3.)

18.1.1.4.3 Doors in barriers required by 18.1.1.4.1 shall normally be kept closed unless otherwise permitted by 18.1.1.4.4.

18.1.1.4.4 Doors shall be permitted to be held open if they meet the requirements of 18.2.2.2.6.

18.1.1.4.5 Changes of Occupancy. Changes of occupancy shall comply with 4.6.12, and the following also shall apply:

- (1) A change from one health care occupancy subclassification to another shall require compliance with the requirements for new construction.

CHAPTER 19 • Existing

- (3) Fire prevention procedures and the planning, training, and drilling programs for the isolation of fire, transfer of occupants to areas of refuge, or evacuation of the building

In particular, patients in critical care areas might be connected to life-support equipment, making movement difficult and, in some cases, impossible. One study demonstrated, through the simulated evacuation of patients from a second-story ward to ground level, that more than 30 minutes might be required for evacuation during a fire.

The provisions of Chapters 18 and 19, therefore, are based on a defend-in-place strategy, which minimizes the probability of a fire dictating vertical movement of occupants. Barriers are required to provide for the horizontal movement of patients to safe areas on a single-floor level and to maintain a manageable limit on the number of occupants exposed to any single fire. Vertical means of egress (stairs or ramps) should be considered as escape routes for visitors and staff and as a "last line of defense" for the movement of patients.

19.1.1.4 Additions, Conversions, Modernization, Renovation, and Construction Operations.

19.1.1.4.1 Additions. Additions shall be separated from any existing structure not conforming to the provisions within Chapter 19 by a fire barrier having not less than a 2-hour fire resistance rating and constructed of materials as required for the addition. (See 4.6.12 and 4.6.7.)

19.1.1.4.2 Communicating openings in dividing fire barriers required by 19.1.1.4.1 shall be permitted only in corridors and shall be protected by approved self-closing fire door assemblies. (See also Section 8.3.)

19.1.1.4.3 Doors in barriers required by 19.1.1.4.1 shall normally be kept closed unless otherwise permitted by 19.1.1.4.4.

19.1.1.4.4 Doors shall be permitted to be held open if they meet the requirements of 19.2.2.2.6.

19.1.1.4.5 Changes of Occupancy. Changes of occupancy shall comply with 4.6.12, and the following also shall apply:

- (1) A change from one health care occupancy subclassification to another shall require compliance with the requirements for new construction.

CHAPTER 18 • New

- (2) A change from a hospital to a nursing home or from a nursing home to a hospital shall not be considered a change in occupancy or occupancy subclassification.
- (3) A change from a hospital or nursing home to a limited care facility shall not be considered a change in occupancy or occupancy subclassification.
- (4) A change from a hospital or nursing home to an ambulatory health care facility shall not be considered a change in occupancy or occupancy subclassification.

18.1.1.4.6 Rehabilitation.

18.1.1.4.6.1 For purposes of the provisions of this chapter, the following shall apply:

- (1) A major rehabilitation shall involve the modification of more than 50 percent, or more than 420 m² (4500 ft²), of the area of the smoke compartment.
- (2) A minor rehabilitation shall involve the modification of not more than 50 percent, and not more than 420 m² (4500 ft²), of the area of the smoke compartment.

18.1.1.4.6.2 Work that is exclusively plumbing, mechanical, fire protection system, electrical, medical gas, or medical equipment shall not be included in the computation of the modification area within the smoke compartment.

18.1.1.4.6.3* Where major rehabilitation is made in a non-sprinklered smoke compartment, the automatic sprinkler requirements of 18.3.5.1 shall apply to the smoke compartment undergoing the rehabilitation, and, in cases where the building is not protected throughout by an approved automatic sprinkler system, the requirements of 18.4.3.2 and 18.4.3.3(2) shall also apply.

A.18.1.1.4.6.3 For the purpose of this requirement, a floor that is not divided by a smoke barrier is considered one smoke compartment.

18.1.1.4.6.4* Where minor rehabilitation is done in a non-sprinklered smoke compartment, the requirements of 18.3.5.1 shall not apply, but, in such cases, the rehabilitation shall not reduce life safety below the level that previously existed or below the level of requirements of 18.4.3 for nonsprinklered smoke compartment rehabilitation. (See 4.6.8.)

A.18.1.1.4.6.4 In minor rehabilitation, only the rehabilitation itself—not the entire smoke compartment or building—is required to be brought up to the requirements for new nonsprinklered facilities.

18.1.1.4.7 Construction, Repair, and Improvement Operations. (See 4.6.11.)

CHAPTER 19 • Existing

- (2) A change from a hospital to a nursing home or from a nursing home to a hospital shall not be considered a change in occupancy or occupancy subclassification.
- (3) A change from a hospital or nursing home to a limited care facility shall not be considered a change in occupancy or occupancy subclassification.
- (4) A change from a hospital or nursing home to an ambulatory health care facility shall not be considered a change in occupancy or occupancy subclassification.

19.1.1.4.6 Rehabilitation.

19.1.1.4.6.1 For purposes of the provisions of this chapter, the following shall apply:

- (1) A major rehabilitation shall involve the modification of more than 50 percent, or more than 420 m² (4500 ft²), of the area of the smoke compartment.
- (2) A minor rehabilitation shall involve the modification of not more than 50 percent, and not more than 420 m² (4500 ft²), of the area of the smoke compartment.

19.1.1.4.6.2 Work that is exclusively plumbing, mechanical, fire protection system, electrical, medical gas, or medical equipment shall not be included in the computation of the modification area within the smoke compartment.

19.1.1.4.6.3* Where major rehabilitation is made in a non-sprinklered smoke compartment, the automatic sprinkler requirements of Chapter 18 shall apply to the smoke compartment undergoing the rehabilitation, and, in cases where the building is not protected throughout by an approved automatic sprinkler system, the requirements of 18.4.3.2 and 18.4.3.3(2) shall also apply.

A.19.1.1.4.6.3 For the purpose of this requirement, a floor that is not divided by a smoke barrier is considered one smoke compartment.

19.1.1.4.6.4* Where minor rehabilitation is done in a non-sprinklered smoke compartment, the requirements of 18.3.5.1 shall not apply but, in such cases, the rehabilitation shall not reduce life safety below the level that previously existed or below the level of requirements of 18.4.3 for nonsprinklered smoke compartment rehabilitation. (See 4.6.8.)

A.19.1.1.4.6.4 In minor rehabilitation, only the rehabilitation itself is required to be brought up to the requirements for new nonsprinklered facilities, not the entire smoke compartment or building.

19.1.1.4.7 Construction, Repair, and Improvement Operations. See 4.6.11.

CHAPTER 18 • New

Paragraph 18/19.1.1.4.1 establishes separation criteria for additions to existing structures when those structures do not conform to the provisions of Chapter 19. However, if the existing building does meet the provisions of Chapter 19, a new addition complying with Chapter 18 would not be required to be separated from it.

Where additions are required to be separated from existing portions of buildings, barriers must be constructed of assemblies that provide no less than a 2-hour fire resistance rating. If the structural framing of the addition or the existing buildings consists of assemblies that provide less than 2-hour fire resistance, special provision must be made to ensure that the necessary separation will be maintained for a 2-hour period.

Exhibit 18/19.1 illustrates the provisions of 18/19.1.1.4.1. In illustration (a) the new addition that complies with Chapter 18 must be separated from the existing portion of the building that does not comply with the requirements of Chapter 19 for existing health care occupancies. In illustration (b) the new addition that complies with Chapter 18 is permitted to be open to the existing portion of the building that complies with the requirements of Chapter 19.

Materials used in the construction of the separation barrier should meet the standards applicable to the addition under construction. That is, if the addition is required to be constructed of noncombustible or limited-combustible materials (construction Types I or II), the materials used in the barrier should be noncombustible or limited-combustible as defined in NFPA 220, *Standard on Types of Building Construction*². Conversely, if the addition is permitted to be constructed of combustible materials, combustible materials are permitted to be used in the fire-rated barrier.

Openings in fire barriers separating additions that comply with Chapter 18 from portions of the building not in compliance with the requirements of Chapter 19 are limited to those that are absolutely necessary—that is, cross-corridor doors (see 18/19.1.1.4.2). Openings are required to be protected by 1½-hour fire protection-rated door assemblies. The fire doors are required to be self-closing and to remain closed; they may, however, be held open by an automatic release device in accordance with 18/19.2.2.2.6. In illustration (a) of Exhibit 18/19.1 no openings other than the cross-corridor doors would be permitted in the separating barrier. This means there

CHAPTER 19 • Existing

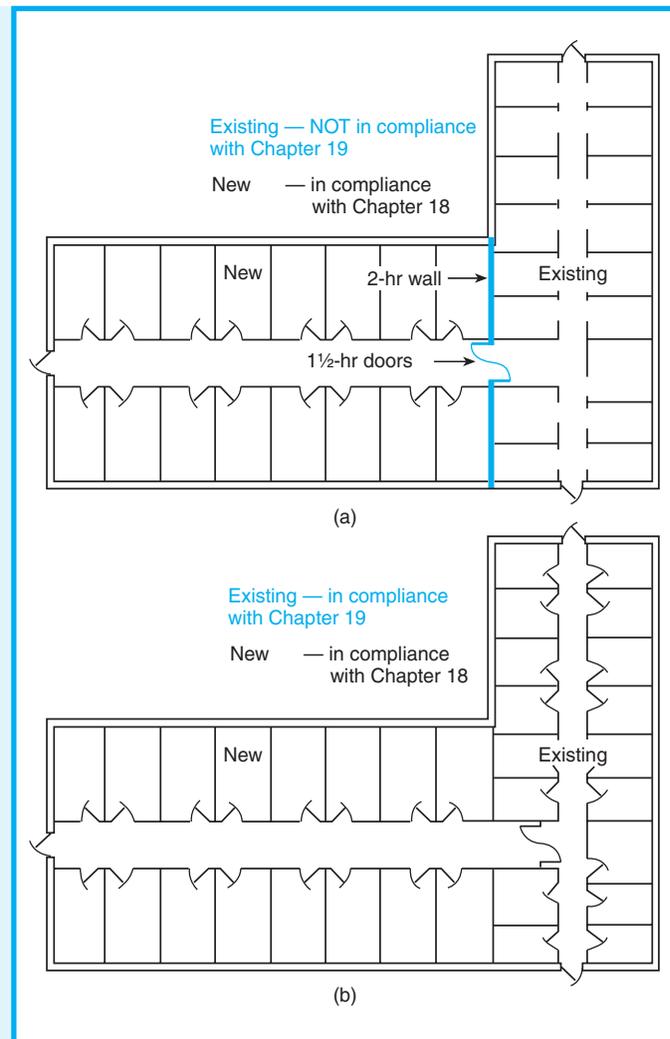

Exhibit 18/19.1 Separation of new construction from existing building.

can be no penetrations by ductwork. A convenience door between two rooms on opposite sides of the barrier also would be prohibited. However, as shown in illustration (b) of Exhibit 18/19.1, if the existing section of the building is in compliance with the requirements of Chapter 19, no separation is required. Therefore, unlimited openings are permitted.

Paragraph 18/19.1.1.4.5, via its reference to 4.6.12, requires any building converted to a health care facility from some other type of occupancy—dormitory, for example—to comply with the provisions of Chapter 18 for new health care facilities. Also see

CHAPTER 18 • New

18.1.1.1.1(4). The exemptions offered by 18/19.1.1.4.5(2) through 18/19.1.1.4.5(4) address changes from one health care occupancy subclassification to another health care occupancy subclassification. Provided the change involves going from a subclassification that is heavily regulated by the *Code* to a subclassification that is either less regulated or at least as regulated, the resulting facility is permitted to be judged by the requirements applicable to an existing facility. However, if the change is in the opposite direction—for example, from an ambulatory health care facility, which the *Code* regulates with a modest package of requirements, to a hospital or nursing home, which the *Code* regulates via an extensive package of requirements—then the resulting facility must be judged against the requirements applicable to a new facility.

The provisions of 4.6.8 for alterations, modernizations, or renovations apply as mandated by 18.1.1.1.1(3). Alterations, modernizations, or renovations must not reduce existing life safety features that do not meet the requirements for new construction but exceed the requirements for existing buildings. For example, a portion of an existing hospital with a 1830-mm (72-in.) wide corridor is to be renovated. Although the hospital is an existing building and existing health care occupancies require minimum 1220-mm- (48-in.-) wide corridors, the 1830-mm (72-in.) wide corridor must be maintained. Conversely, if a portion of an existing hospital with a 3050-mm- (120-in.-) wide corridor is to be altered, the corridor may be reduced to 2440 mm (96 in.) wide, the minimum requirement for new construction. As a minimum, in all instances, whether or not alterations, modernizations, or renovations are planned, existing health care occupancies must comply with the requirements of Chapter 19.

Automatic sprinkler protection is required for all new health care facilities (see 18.3.5.1). Existing health care facilities might be nonsprinklered. When major rehabilitation is made in a nonsprinklered existing facility, in addition to performing those planned renovations in accordance with the requirements for new construction, 18/19.1.1.4.6.3 requires that the smoke compartment in which the major rehabilitation occurs be sprinklered. Therefore, although the rehabilitation was not originally planned to include the installation of sprinklers, such installation is required within the smoke compartment being rehabilitated.

CHAPTER 19 • Existing

Paragraph 18/19.1.1.4.6.1 defines major and minor rehabilitation with reference to the word *modification*. The definition of *modification* in 3.3.143 originated in *NFPA 5000™*, *Building Construction and Safety Code™*, in its Chapter 15, Rehabilitation³. The *NFPA 5000* hierarchy of rehabilitation methods includes repair, renovation, modification, reconstruction, and change of use. Repair and renovation do not trigger classification as a major rehabilitation. Change of use is addressed above with respect to 18/19.1.1.4.5.

Modification and reconstruction can trigger the major rehabilitation classification, depending on floor area involved, as detailed in 18/19.1.1.4.6.1(1). Note that, per 18/19.1.1.4.6.2, work that is exclusively plumbing, mechanical, fire protection system, electrical, medical gas, or medical equipment is not included in the computation of the modification area within the smoke compartment undergoing the rehabilitation.

Minor rehabilitation—as defined by 18/19.1.1.4.6.1(2)—does not trigger the requirement for installing sprinklers.

Only that smoke compartment undergoing major rehabilitation is required to be sprinklered at the time of rehabilitation. Therefore, if a floor of a hospital is subdivided into three smoke compartments, and only one smoke compartment is undergoing major rehabilitation, only that particular smoke compartment would require sprinkler installation. Over a few years of multiple major rehabilitation projects, the entire building would eventually become fully sprinklered. Because the building would then be only partially protected with sprinklers, the construction requirements of 18.4.3.2 for nonsprinklered buildings must be met, and egress capacity must be based on nonsprinklered criteria in the nonsprinklered portions of the building. [For example, stair capacity is calculated at 15 mm (0.6 in.) per person rather than the typical 7.6 mm (0.3 in.) per person.] Smoke dampers are permitted to be omitted for ducted penetrations of smoke barriers only where the smoke compartments on both sides of the smoke barrier are fully sprinklered as specified in 18.4.3.8.

Although effort should be made to satisfy the criteria for new construction during a building alteration or the installation of new equipment, the *Code* recognizes that such modifications cannot always be achieved. Guidance for achieving equivalency to life safety is provided in Section 1.4. Regardless of cir-

CHAPTER 18 • New

cumstances, building alterations or the installation of new service equipment must achieve a level of life safety equivalent to or exceeding the level prescribed for existing buildings.

The introduction of “outside” workers and activities associated with the construction of an addition creates unusual risks of fire in health care occupancies. Special precautions should be taken to guard against the potential exposure created by the introduction of flammable substances or by other hazardous practices that could pose a threat to occupants. See 4.6.11.3.

Temporary fire-resistant barriers should be erected

18.1.2 Multiple Occupancies.

18.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

18.1.2.2* Sections of health care facilities shall be permitted to be classified as other occupancies, provided that they meet all of the following conditions:

- (1) They are not intended to serve health care occupants for purposes of housing, treatment, or customary access by patients incapable of self-preservation.
- (2) They are separated from areas of health care occupancies by construction having a fire resistance rating of not less than 2 hours.

A.18.1.2.2 Doctors’ offices and treatment and diagnostic facilities that are intended solely for outpatient care and are physically separated from facilities for the treatment or care of inpatients, but that are otherwise associated with the management of an institution, might be classified as business occupancies rather than health care occupancies.

18.1.2.3* Ambulatory care facilities, medical clinics, and similar facilities that are contiguous to health care occupancies but are primarily intended to provide outpatient services shall be permitted to be classified as business occupancies or ambulatory health care facilities, provided that the facilities are separated from the health care occupancy by not less than 2-hour fire resistance–rated construction and the facility is not intended to provide services simultaneously for four or more in-patients who are litterborne.

A.18.1.2.3 It is the intent that these requirements apply to mobile, transportable, and relocatable structures (in accordance with 1.3.2) where such structures are used to provide shared medical services on an extended or a temporary basis. Where properly separated from the health care occupancy

CHAPTER 19 • Existing

ted to separate the new construction and associated activity from the functioning areas of the existing buildings. Care should be taken to ensure that these temporary barriers do not block means of egress for the existing building and that all existing equipment for fire protection and all portions of the required means of egress are maintained in full working order. See 4.6.11.1.

Adequate escape facilities should be provided and continuously maintained for the use of construction workers. See 4.6.11.2 and NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*⁴.

19.1.2 Multiple Occupancies.

19.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

19.1.2.2* Sections of health care facilities shall be permitted to be classified as other occupancies, provided that they meet all of the following conditions:

- (1) They are not intended to serve health care occupants for purposes of housing, treatment, or customary access by patients incapable of self-preservation.
- (2) They are separated from areas of health care occupancies by construction having a fire resistance rating of not less than 2 hours.

A.19.1.2.2 Doctors’ offices and treatment and diagnostic facilities that are intended solely for outpatient care and are physically separated from facilities for the treatment or care of inpatients, but that are otherwise associated with the management of an institution, might be classified as business occupancies rather than health care occupancies.

19.1.2.3* Ambulatory care facilities, medical clinics, and similar facilities that are contiguous to health care occupancies but are primarily intended to provide outpatient services shall be permitted to be classified as business occupancies or ambulatory health care facilities, provided that the facilities are separated from the health care occupancy by not less than 2-hour fire resistance–rated construction and the facility is not intended to provide services simultaneously for four or more inpatients who are litterborne.

A.19.1.2.3 It is the intent that these requirements apply to mobile, transportable, and relocatable structures (in accordance with 1.3.2) when such structures are used to provide shared medical services on an extended or a temporary basis. When properly separated from the health care occupancy

CHAPTER 18 • New

and intended to provide services simultaneously for three or fewer health care patients who are litterborne, the level of protection for such structures should be based on the appropriate occupancy classification of other chapters of this *Code*. Mobile, transportable, or relocatable structures that are not separated from a contiguous health care occupancy or that are intended to provide services simultaneously for four or more health care patients who are litterborne should be classified and designed as health care occupancies.

18.1.2.4 All means of egress from health care occupancies that traverse non-health care spaces shall conform to the requirements of this *Code* for health care occupancies, unless otherwise permitted by 18.1.2.5.

18.1.2.5 Exit through a horizontal exit into other contiguous occupancies that do not conform to health care egress provisions, but that do comply with requirements set forth in the appropriate occupancy chapter of this *Code*, shall be permitted, provided that both of the following criteria apply:

- (1) The occupancy does not contain high hazard contents.
- (2) The horizontal exit complies with the requirements of 18.2.2.5.

18.1.2.6 Egress provisions for areas of health care facilities that correspond to other occupancies shall meet the corresponding requirements of this *Code* for such occupancies, and, where the clinical needs of the occupant necessitate the locking of means of egress, staff shall be present for the supervised release of occupants during all times of use.

18.1.2.7 Auditoriums, chapels, staff residential areas, or other occupancies provided in connection with health care facilities shall have means of egress provided in accordance with other applicable sections of this *Code*.

18.1.2.8 Any area with a hazard of contents classified higher than that of the health care occupancy and located in the same building shall be protected as required by 18.3.2.

18.1.2.9 Non-health care–related occupancies classified as containing high hazard contents shall not be permitted in buildings housing health care occupancies.

Paragraph 18/19.1.2.1 directs the user to the multiple occupancies provisions of 6.1.14, which permit protecting the multiple occupancies either as mixed occupancies or as separated occupancies. The provisions of 18/19.1.2.2 through 18/19.1.2.9 have the effect of modifying those of 6.1.14 for the very specific situations described.

CHAPTER 19 • Existing

and intended to provide services simultaneously for three or fewer health care patients who are litterborne, the level of protection for such structures should be based on the appropriate occupancy classification of other chapters of this *Code*. Mobile, transportable, or relocatable structures that are not separated from a contiguous health care occupancy or that are intended to provide services simultaneously for four or more health care patients who are litterborne should be classified and designed as health care occupancies.

19.1.2.4 All means of egress from health care occupancies that traverse non-health care spaces shall conform to the requirements of this *Code* for health care occupancies, unless otherwise permitted by 19.1.2.5.

19.1.2.5 Exit through a horizontal exit into other contiguous occupancies that do not conform to health care egress provisions but that do comply with requirements set forth in the appropriate occupancy chapter of this *Code* shall be permitted, provided that both of the following criteria apply:

- (1) The occupancy does not contain high hazard contents.
- (2) The horizontal exit complies with the requirements of 19.2.2.5.

19.1.2.6 Egress provisions for areas of health care facilities that correspond to other occupancies shall meet the corresponding requirements of this *Code* for such occupancies, and, where the clinical needs of the occupant necessitate the locking of means of egress, staff shall be present for the supervised release of occupants during all times of use.

19.1.2.7 Auditoriums, chapels, staff residential areas, or other occupancies provided in connection with health care facilities shall have means of egress provided in accordance with other applicable sections of this *Code*.

19.1.2.8 Any area with a hazard of contents classified higher than that of the health care occupancy and located in the same building shall be protected as required by 19.3.2.

19.1.2.9 Non-health care–related occupancies classified as containing high hazard contents shall not be permitted in buildings housing health care occupancies.

Paragraphs 18/19.1.2.2 and 18/19.1.2.3 contain criteria for classifying spaces as other occupancies, although those spaces are located in buildings used primarily for health care purposes. For example, 18/19.1.2.2 would allow offices to be classified as business occupancies, cafeterias to be classified as assembly occupancies, or dormitories for other than

CHAPTER 18 • New

patients to be classified as residential occupancies if the requirements of both 18/19.1.2.2(1) and 18/19.1.2.2(2) are met. Paragraph 18/19.1.2.2(1) notes that customary access by patients incapable of self-preservation is not permitted within the other occupancy. This paragraph is intended to allow an occasional, ambulatory inpatient to visit a doctor's office in an adjacent business occupancy, for example, without requiring classification of the business occupancy as a health care facility. Further, emergency egress from the health care occupancy into the other occupancy would be permitted because emergency egress is not considered customary access.

If the requirements of 18/19.1.2.2(1) and 18/19.1.2.2(2) are not met, the area would be considered a multiple occupancy requiring protection as mixed occupancies. The most restrictive life safety requirements applicable to any one occupancy present would be required for all the occupancies. In most cases, the requirements of the health care occupancy would be stricter than those of the other occupancies, requiring that health care occupancy requirements be met throughout the building. See 6.1.14.

Paragraph 18/19.1.2.3 addresses a subject similar to that of 18/19.1.2.2 but specifically covers ambulatory care facilities, medical clinics, and similar areas that primarily provide outpatient services and are associated with or attached to a health care facility. If these facilities are separated by 2-hour fire resistance-rated construction, they are permitted to be classified as ambulatory health care facilities or as business occupancies, whichever applies. The provisions applicable to business occupancies and ambulatory health care facilities are based on the assumption that most people are treated on an outpatient basis. If four or more litterborne inpatients are treated simultaneously, the facility must meet the requirements for health care occupancies. Conversely, if three or fewer litterborne inpatients are present in the outpatient facility on a regular basis, the facility would be classified as an occupancy other than health care.

Paragraph 18/19.1.2.4 specifies that the means of egress from health care occupancies that traverse non-health care spaces must conform to the requirements for health care occupancies. However, an exemption is allowed by 18/19.1.2.5 where a 2-hour separating barrier is provided to meet the requirements for a horizontal exit. Where a 2-hour barrier serves as a horizontal exit, it is acceptable to exit from

CHAPTER 19 • Existing

a health care occupancy into a different occupancy if the other occupancy complies with the *Code* provisions applicable to that occupancy and does not contain high hazard contents. For example, if a horizontal exit is provided between a hospital and a business occupancy, inpatients are permitted to exit into the business occupancy through a horizontal exit. In this instance, corridor width, corridor partitions, stairway details, and similar features must conform to the provisions of either Chapter 38 or 39, which address business occupancies. However, the horizontal exit must comply with all the requirements of 18/19.2.2.5.

Health care occupancy patients are sometimes moved to nonmedical areas—such as a chapel for religious services or an auditorium for recreation—that typically do not meet the provisions applicable to health care occupancies. Paragraph 18/19.1.2.6 permits such areas to be regulated by the provisions applicable to the corresponding occupancy (which would be an assembly occupancy, in the case of chapels or auditoriums). This paragraph addresses a subject similar to that addressed in 18/19.1.2.7 but adds the requirement that, where the clinical needs of the occupants necessitate the locking of doors, staff must be present for the supervised unlocking of doors and release of occupants. This additional requirement ensures that procedures are in place for the ready release of occupants.

Auditoriums, chapels, and other areas separated from the health care occupancy by construction meeting the criteria of 6.1.14.4 for separated occupancies are permitted to be designed in accordance with the appropriate occupancy chapter governing their use rather than in accordance with those applicable to the health care occupancy.

Paragraph 18/19.1.2.8 regulates spaces in other occupancies in the same building as a health care facility that, although comprising only a portion of the facility, contain more hazardous materials (in quantity or type) than are usually found in health care occupancies. Spaces such as rooms used for the storage of combustible materials, trash collection rooms, gift shops, and paint shops must be protected in accordance with 18/19.3.2.

Paragraph 18/19.1.2.9 prohibits another occupancy, such as storage, that contains highly hazardous contents, such as flammable liquids, from being located in a building housing a health care occupancy. This paragraph limits use, based on occupancy classification, with regard to hazard of contents. For exam-

CHAPTER 18 • New

CHAPTER 19 • Existing

ple, the paragraph does not intend to exclude laboratory operations from being part of a health care facility. The intent is to prevent a portion of a hospital from being designed and used as an educational or

research facility—which would be classified as an educational occupancy, business occupancy, or possibly an industrial occupancy—where laboratories use and store sizable quantities of flammable liquids.

18.1.3 Definitions.

A list of terms used in this chapter follows:

- (1) **Ambulatory Health Care Occupancy.** See 3.3.152.1.
- (2) **Hospital.** See 3.3.112.
- (3) **Limited Care Facility.** See 3.3.69.2.
- (4) **Nursing Home.** See 3.3.110.2.

Section 3.3 defines the terms *hospital*, *nursing home*, and *limited care facility*. Each must house four or more people incapable of self-preservation on a 24-hour basis to be classified as a health care occupancy.

Occupants of hospitals or nursing homes are assumed to be nonambulatory and incapable of self-preservation. In making this judgment, due consideration should be given to the use of physical restraints and tranquilizing drugs, which can render occupants immobile. Variable staffing criteria and levels of care differentiate hospitals from nursing homes. The difference between nursing homes and limited care facilities is less clear.

Although limited care facilities house four or more occupants incapable of self-preservation due to age or physical or mental limitations, occupants are generally considered to be ambulatory and to require only limited assistance during emergency evacuation. Buildings that house ambulatory occupants who are mentally handicapped or undergoing treatment for alcohol or drug abuse and who can be expected to evacuate a structure with limited assistance meet the criteria for limited care facilities. Day-care facilities that provide care for the aged, children, mentally handicapped, or others would be classified as other than health care if the care or treatment is not provided on a 24-hour basis. See Chapters 16 and 17.

Although age itself is not sufficient justification for developing a separate classification for a health care occupancy, the elderly pose a unique problem in the achievement of fire safety. Experiences in buildings where the elderly are housed demonstrate that the response of the elderly to a fire might not be in the interest of self-preservation. Upon discovering a fire, elderly occupants might ignore it, become transfixed by it, or seek refuge from it in their rooms and fail to notify anyone of the fire. In some

19.1.3 Definitions.

A list of terms used in this chapter follows:

- (1) **Ambulatory Health Care Occupancy.** See 3.3.152.1.
- (2) **Hospital.** See 3.3.112.
- (3) **Limited Care Facility.** See 3.3.69.2.
- (4) **Nursing Home.** See 3.3.110.2.

cases, the elderly have resisted efforts to remove them from the building and familiar surroundings.

Terms such as *residential*, *lodging* and *boarding*, and *custodial care* were used in the health care occupancy chapters of earlier editions of the *Code* but have been deleted to avoid confusion with the residential board and care occupancy classification addressed by Chapters 32 and 33. Board and care facilities, personal care homes, halfway houses, or similar facilities house occupants who might require medication and personal care but do not require the close supervision and services typical of the occupants in a health care facility. Therefore, these facilities would be classified as residential occupancies. Occupant capability must be carefully evaluated to determine whether application of health care criteria (contained in Chapters 18 and 19) or application of lesser safeguards associated with residential occupancies (prescribed by Chapters 32 and 33) is more appropriate.

Prior to the 1981 edition of the *Code*, occupancies that offered medical services on an outpatient basis would have been regulated within the chapter covering business occupancies. The threat to life in an outpatient facility where four or more patients might be subject to medical procedures requiring general anesthesia, treatments such as hemodialysis, or free-standing emergency service is significantly greater than that typical of a business occupancy. Conversely, application of the requirements for health care facilities that contemplate 24-hour care would be unnecessarily restrictive. In establishing the occupancy classification of an ambulatory health care facility, the intent was to develop requirements that fall between the restrictions applicable to business occupancies and health care facilities in terms of the level of life safety provided. See Chapters 20 and 21.

CHAPTER 18 • New

18.1.4 Classification of Occupancy.

See 18.1.3.

18.1.5 Classification of Hazard of Contents.

The classification of hazard of contents shall be as defined in Section 6.2.

18.1.6 Minimum Construction Requirements.

18.1.6.1 For the purpose of 18.1.6, the number of stories shall be counted starting with the primary level of exit discharge and ending with the highest occupiable level.

18.1.6.2 For the purposes of 18.1.6.1, the primary level of exit discharge of a building shall be the lowest story whose floor is level with or above finished grade on the exterior wall line for 50 percent or more of its perimeter.

18.1.6.3 For the purposes of 18.1.6.2, building levels below the primary level shall not be counted as a story.

18.1.6.4 Health care occupancies shall be limited to the types of building construction shown in Table 18.1.6.4, unless otherwise permitted by 18.1.6.5. (See 8.2.1.)

Table 18.1.6.4 Construction Type Limitations

Construction Type	Stories			
	1	2	3	4 or More
I(443)	X	X	X	X
I(332)	X	X	X	X
II(222)	X	X	X	X
II(111)	X	X	X	NP
II(000)	X	NP	NP	NP
III(211)	X	NP	NP	NP

V(111)	X*	X*	NP	NP
V(000)	X*	NP	NP	NP

X: Permitted type of construction.
NP: Not permitted.

*Building requires automatic sprinkler protection (See 19.3.5.1.)

19.1.6.5* Any building of Type I(443), Type I(332), Type II(222), or Type II(111) construction shall be permitted to include roofing systems involving combustible supports, decking, or roofing, provided that the following criteria are met:

CHAPTER 18 • New

- (1) The roof covering shall meet Class A requirements in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.
- (2) The roof shall be separated from all occupied portions of the building by a noncombustible floor assembly having not less than a 2-hour fire resistance rating that includes not less than 63 mm (2½ in.) of concrete or gypsum fill.
- (3) The structural elements supporting the 2-hour fire resistance-rated floor assembly specified in 18.1.6.5(2) shall be required to have only the fire resistance rating required of the building.

18.1.6.6 All interior walls and partitions in buildings of Type I or Type II construction shall be of noncombustible or limited-combustible materials.

18.1.6.7 Fire-retardant-treated wood that serves as supports for the installation of fixtures and equipment shall be permitted to be installed behind noncombustible or limited-combustible sheathing.

18.1.6.8 All buildings with more than one level below the level of exit discharge shall have all such lower levels separated from the level of exit discharge by not less than Type II(111) construction.

Allowable building construction types are determined according to the number of stories in a building. The first story is considered to be the primary level of exit discharge. Only occupiable levels are counted in determining the number of stories. For example, an unoccupied attic would not constitute a story.

Determining the story height of a building located on a sloping grade can be difficult. Paragraph 18/19.1.6.2 notes that a story on a sloping site that is partially below grade should be counted as a story if the floor is level with or above grade along 50 percent or more of the perimeter of the building at the exterior wall. Application of the 50 percent perimeter guide-

CHAPTER 19 • Existing

- (1) The roof covering shall meet Class C requirements in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.
- (2) The roof shall be separated from all occupied portions of the building by a noncombustible floor assembly that includes not less than 63 mm (2½ in.) of concrete or gypsum fill.
- (3) The attic or other space shall be either unoccupied or protected throughout by an approved automatic sprinkler system.

A.19.1.6.5 Unoccupied space, for the purposes of 19.1.6.5(3), is space not normally occupied by persons, fuel-fired equipment, or hazardous contents.

19.1.6.6 All interior walls and partitions in buildings of Type I or Type II construction shall be of noncombustible or limited-combustible materials, unless otherwise permitted by 19.1.6.7.

19.1.6.7* Listed, fire-retardant-treated wood studs shall be permitted within non-load-bearing 1-hour fire-rated partitions.

A.19.1.6.7 There is a finish capacity in a 1-hour fire-rated partition that would be expected to prevent the generation of smoke and gases from fire retardant-treated wood studs for an extended time during fire exposure. This *Code* does not intend to permit the use of fire-retardant wood studs and partitions of only 20-minute fire resistance.

19.1.6.8 Each exterior wall of frame construction and all interior stud partitions shall be firestopped to cut off all concealed draft openings, both horizontal and vertical, between any cellar or basement and the first floor, and such firestopping shall consist of wood not less than 51 mm (2 in.) (nominal) thick or shall be of noncombustible material.

line is illustrated in Exhibit 18/19.2. Because of sloping grade, the primary level of exit discharge is not obvious. The 50 percent perimeter guideline of 18/19.1.6.2 clarifies that, for the arrangement illustrated, the first story is the primary level of exit discharge. Number of stories includes primary level of exit discharge and all occupiable floors located above. This is an example of a three-story building.

Building construction types permitted to be occupied as health care facilities are indicated as a function of number of stories in Table 18/19.1.6.4. See NFPA 220, *Standard on Types of Building Construction*, for definitions of construction types.

CHAPTER 18 • New

CHAPTER 19 • Existing

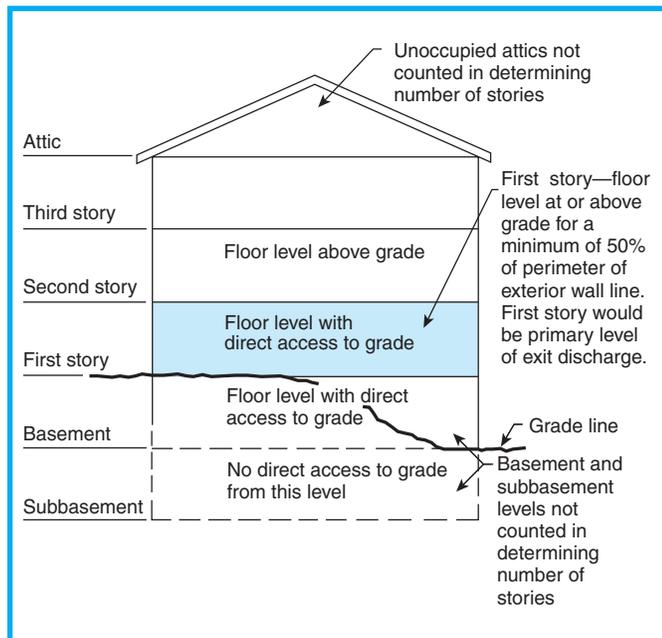

Exhibit 18/19.2 Determining number of stories for application of minimum construction requirements.

New multistory health care facilities and existing, nonsprinklered multistory health care facilities are required to be constructed of noncombustible materials. A minimum 2-hour fire resistance rating is required for building members of structures exceeding three stories. It is recognized that in the event of a fire, it might not be possible to move patients and that occupants of a health care facility might be required to remain in the structure for the duration of the fire. In specifying 2-hour fire resistance, it is intended that building members be adequately protected against the effects of fire to ensure building stability for the projected fire duration.

Existing two-story buildings that use combustible elements are allowed where completely protected by automatic sprinklers. Type II(111) structures can continue to be occupied with up to three stories where a complete system of electrically supervised automatic sprinklers is provided.

In certain areas, it has been common practice to erect a building with a flat, concrete roof deck. A

18.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, either shall be

wood deck on a wood frame peaked roof is then added for weather protection. Paragraph 18/19.1.6.5 contains an exemption that permits, under certain conditions, construction of such a combustible roof system on a multistory building without affecting the classification of the building construction. In other words, a Type I or Type II building, which by definition has a roof constructed wholly of noncombustible materials, is permitted to retain its Type I or Type II classification and have a combustible wood “roof” in accordance with the provisions of 18/19.1.6.5. The exemption detailed in 19.1.6.5 specifies that the existing attic space must be unoccupied or protected with automatic sprinklers. The term *unoccupied* is meant to disallow routine, regular use of the attic, which might increase the likelihood of fire or add a “fuel load” to the nonsprinklered space. Office or combustible storage spaces, for example, would be prohibited. The term *unoccupied* is not intended to prohibit the presence of mechanical equipment requiring periodic maintenance, such as air-handling units. Although 8.2.3.3 requires fire-rated assemblies to be supported by fire-rated structural members, 18.1.6.5 specifically exempts the 2-hour fire resistance-rated floor assembly (that separates the roof from the occupied floors below) from having to be supported on the floors below by 2-hour-rated structural members if the required fire resistance rating of the building is less than 2 hours.

Although NFPA 220, *Standard on Types of Building Construction*, does not set combustibility requirements for nonbearing interior walls and partitions, 18/19.1.6.6 adds requirements that exceed those of NFPA 220. Paragraph 18/19.1.6.6 requires that, in Type I and Type II construction, all interior walls and partitions be constructed of noncombustible or limited-combustible materials. The terms *noncombustible* and *limited-combustible* are defined within NFPA 220, and the definitions are repeated in Chapter 3 of the *Code* for easy reference.

Note that 19.1.6.7 for existing installations allows listed fire-retardant-treated wood studs within non-load bearing, 1-hour fire resistance-rated partitions. It does not allow them in 30-minute partitions, because the studs would be exposed to fire sooner.

19.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, either shall be

CHAPTER 18 • New

determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

Section 18.2 Means of Egress Requirements

18.2.1 General.

Every aisle, passageway, corridor, exit discharge, exit location, and access shall be in accordance with Chapter 7, unless otherwise modified by 18.2.2 through 18.2.11.

18.2.2* Means of Egress Components.

A.18.2.2 In planning egress, arrangements should be made to transfer patients from one section of a floor to another section of the same floor that is separated by a fire barrier or smoke barrier in such a manner that patients confined to their beds can be transferred in their beds. Where the building design will allow, the section of the corridor containing an entrance or elevator lobby should be separated from corridors leading from it by fire or smoke barriers. Such arrangement, where the lobby is centrally located, will, in effect, produce a smoke lock, placing a double barrier between the area to which patients might be taken and the area from which they need to be evacuated because of threatening smoke and fire.

18.2.2.1 Components of means of egress shall be limited to the types described in 18.2.2.2 through 18.2.2.10.

18.2.2.2 Doors.

18.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

18.2.2.2.2 Locks shall not be permitted on patient sleeping room doors, unless otherwise permitted by the following:

- (1) Key-locking devices that restrict access to the room from the corridor and that are operable only by staff from the corridor side shall be permitted, provided that such devices do not restrict egress from the room.
- (2) Door-locking arrangements shall be permitted in health care occupancies, or portions of health care occupancies, where the clinical needs of the patients require specialized security measures for their safety, provided that keys are carried by staff at all times.

18.2.2.2.3 Doors not located in a required means of egress shall be permitted to be subject to locking.

CHAPTER 19 • Existing

determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

Section 19.2 Means of Egress Requirements

19.2.1 General.

Every aisle, passageway, corridor, exit discharge, exit location, and access shall be in accordance with Chapter 7, unless otherwise modified by 19.2.2 through 19.2.11.

19.2.2 Means of Egress Components.

19.2.2.1 Components of means of egress shall be limited to the types described in 19.2.2.2 through 19.2.2.10.

19.2.2.2 Doors.

19.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

19.2.2.2.2 Locks shall not be permitted on patient sleeping room doors, unless otherwise permitted by the following:

- (1) Key-locking devices that restrict access to the room from the corridor and that are operable only by staff from the corridor side shall be permitted, provided that such devices do not restrict egress from the room.
- (2) Door-locking arrangements shall be permitted in health care occupancies, or portions of health care occupancies, where the clinical needs of the patients require specialized security measures for their safety, provided that keys are carried by staff at all times.

19.2.2.2.3 Doors not located in a required means of egress shall be permitted to be subject to locking.

CHAPTER 18 • New

18.2.2.2.4 Doors within a required means of egress shall not be equipped with a latch or lock that requires the use of a tool or key from the egress side, unless otherwise permitted by the following:

- (1) Door-locking arrangements without delayed egress shall be permitted in health care occupancies, or portions of health care occupancies, where the clinical needs of the patients require specialized security measures for their safety, provided that staff can readily unlock such doors at all times. (See 18.1.1.1.5 and 18.2.2.2.5.)
- (2)* Delayed-egress locks complying with 7.2.1.6.1 shall be permitted, provided that not more than one such device is located in any egress path.

A.18.2.2.2.4(2) The intent of the provision is that a person following the natural path of the means of egress not encounter more than one delayed release device along that path of travel to an exit. Thus, each door from the multiple floors of a building that opens into an enclosed stair is permitted to have its own delayed release device, but an additional delayed release device is not permitted at the level of exit discharge on the door that discharges people from the enclosed stair to the outside.

- (3) Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

18.2.2.2.5 Doors that are located in the means of egress and are permitted to be locked under other provisions of this chapter shall have provisions made for the rapid removal of occupants by means such as the following:

- (1) Remote control of locks
- (2) Keying of all locks to keys carried by staff at all times
- (3) Other such reliable means available to the staff at all times

18.2.2.2.5.1 Only one locking device as specified in 18.2.2.2.5 shall be permitted on each door.

18.2.2.2.5.2 Locks in accordance with 18.2.2.2.4(2) and 18.2.2.2.4(3) shall be permitted.

18.2.2.2.6* Any door in an exit passageway, stairway enclosure, horizontal exit, smoke barrier, or hazardous area enclosure (except boiler rooms, heater rooms, and mechanical equipment rooms) shall be permitted to be held open only by an automatic release device that complies with 7.2.1.8.2. The automatic sprinkler system and the fire alarm system, and the systems required by 7.2.1.8.2, shall be arranged to initiate the closing action of all such doors throughout the smoke compartment or throughout the entire facility.

CHAPTER 19 • Existing

19.2.2.2.4 Doors within a required means of egress shall not be equipped with a latch or lock that requires the use of a tool or key from the egress side, unless otherwise permitted by the following:

- (1) Door-locking arrangements without delayed egress shall be permitted in health care occupancies, or portions of health care occupancies, where the clinical needs of the patients require specialized security measures for their safety, provided that staff can readily unlock such doors at all times. (See 19.1.1.1.5 and 19.2.2.2.5.)
- (2)* Delayed-egress locks complying with 7.2.1.6.1 shall be permitted, provided that not more than one such device is located in any egress path.

A.19.2.2.2.4(2) The intent of the provision is that a person following the natural path of the means of egress not encounter more than one delayed release device along that path of travel to an exit. Thus, each door from the multiple floors of a building that opens into an enclosed stair is permitted to have its own delayed release device, but an additional delayed release device is not permitted at the level of exit discharge on the door that discharges people from the enclosed stair to the outside.

- (3) Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

19.2.2.2.5 Doors that are located in the means of egress and are permitted to be locked under other provisions of this chapter shall have adequate provisions made for the rapid removal of occupants by means such as the following:

- (1) Remote control of locks
- (2) Keying of all locks to keys carried by staff at all times
- (3) Other such reliable means available to the staff at all times

19.2.2.2.5.1 Only one such locking device as specified in 19.2.2.2.5 shall be permitted on each door.

19.2.2.2.5.2 Locks in accordance with 19.2.2.2.4(2) and 19.2.2.2.4(3) shall be permitted.

19.2.2.2.5.3 More than one lock shall be permitted on each door, subject to approval of the authority having jurisdiction.

19.2.2.2.6* Any door in an exit passageway, stairway enclosure, horizontal exit, smoke barrier, or hazardous area enclosure shall be permitted to be held open only by an automatic release device that complies with 7.2.1.8.2. The automatic sprinkler system, if provided, and the fire alarm system, and the systems required by 7.2.1.8.2 shall be arranged to initiate the closing action of all such doors throughout the smoke compartment or throughout the entire facility.

CHAPTER 18 • New

A.18.2.2.2.6 It is desirable to keep doors in exit passageways, stair enclosures, horizontal exits, smoke barriers, and required enclosures around hazardous areas closed at all times to impede the travel of smoke and fire gases. Functionally, however, this involves decreased efficiency and limits patient observation by the staff of an institution. To accommodate such needs, it is practical to presume that such doors will be kept open, even to the extent of employing wood chocks and other makeshift devices. Doors in exit passageways, horizontal exits, and smoke barriers should, therefore, be equipped with automatic hold-open devices activated by the methods described, regardless of whether the original installation of the doors was predicated on a policy of keeping them closed.

18.2.2.2.7 Where doors in a stair enclosure are held open by an automatic release device as permitted in 18.2.2.2.6, initiation of a door-closing action on any level shall cause all doors at all levels in the stair enclosure to close.

18.2.2.2.8 High-rise health care occupancies shall comply with the re-entry provisions of 7.2.1.5.7.

18.2.2.2.9 Horizontal sliding doors, as permitted by 7.2.1.14, that are not automatic-closing shall be limited to a single leaf and shall have a latch or other mechanism that ensures that doors will not rebound into a partially open position if forcefully closed in an emergency.

Paragraphs 18/19.2.2.2.1 through 18/19.2.2.2.9 address the door provisions of 7.2.1 and provide any modifications particular to health care occupancies.

In the 1991 and earlier editions of the *Code*, numerous provisions of Chapters 18 and 19 specified minimum door width requirements as a leaf width rather than as a clear width. For example, doors from patient rooms to the corridor in new construction were required to be 1120 mm (44 in.) wide. The intent was that, after allowing for the stops built into the door frame and the thickness of the protruding hinge stile edge, a 1120-mm- (44-in.-) wide door leaf would provide approximately 1055 mm (41½ in.) of clear, unobstructed width. However, there was no requirement for the door to swing a minimum of 90 degrees

CHAPTER 19 • Existing

A.19.2.2.2.6 It is desirable to keep doors in exit passageways, stair enclosures, horizontal exits, smoke barriers, and required enclosures around hazardous areas closed at all times to impede the travel of smoke and fire gases. Functionally, however, this involves decreased efficiency and limits patient supervision by the staff of a facility. To accommodate such needs, it is practical to presume that such doors will be kept open, even to the extent of employing wood chocks and other makeshift devices. Doors in exit passageways, horizontal exits, and smoke barriers should, therefore, be equipped with automatic hold-open devices actuated by the methods described regardless of whether the original installation of the doors was predicated on a policy of keeping them closed.

19.2.2.2.7 Where doors in a stair enclosure are held open by an automatic release device as permitted in 19.2.2.2.6, initiation of a door-closing action on any level shall cause all doors at all levels in the stair enclosure to close.

19.2.2.2.8* Existing health care occupancies shall be exempt from the re-entry provisions of 7.2.1.5.7.

A.19.2.2.2.8 Doors to the enclosures of interior stair exits should be arranged to open from the stair side at not less than every third floor so that it will be possible to leave the stairway at such floor if fire renders the lower part of the stair unusable during egress or if occupants seek refuge on another floor.

19.2.2.2.9 Horizontal sliding doors, as permitted by 7.2.1.14, that are not automatic-closing shall be limited to a single leaf and shall have a latch or other mechanism that ensures that doors will not rebound into a partially open position if forcefully closed in an emergency.

from the plane of the door opening, so the intended 1055 mm (41½ in.) of clear, unobstructed width was not assured. Since the 1994 edition of the *Code*, all minimum door width requirements for new health care occupancies have been specified as clear, unobstructed width. For existing doors in health care occupancies, all minimum door width requirements have been specified as clear, unobstructed width, but exceptions continue to recognize existing doors with the minimum door leaf widths previously specified.

Paragraph 18/19.2.2.2.2(1) allows for access from the corridor to a room to be limited via a locked door that staff can unlock with keys they keep readily available. Limited access would permit, for example, patient isolation rooms to have doors locked from the

CHAPTER 18 • New

corridor side only so that other patients could not wander into the room and thus endanger themselves. However, the patient within the isolation room with the door locked from the corridor side needs to be able to open the door from the room side without the use of a key or tool.

Paragraph 18/19.2.2.2.2(2) addresses the locking of doors for patient clinical needs. Some health care facilities might need to lock patient room doors against egress for functional purposes involving the clinical needs of patients. For example, if certain patients require confinement because they would otherwise leave their rooms and endanger themselves, locking patient room doors would provide specialized security. If patient room doors are locked against egress, the *Code* requires that staff carry keys at all times so as to be able to unlock doors immediately. Also see 18/19.2.2.2.5 and 18/19.2.2.2.5.1, which limit the number of locks to one per door and specify that staff must carry keys at all times or that other provisions must be made for the immediate release of patients, for example, by using remotely controlled locking devices.

Paragraph 18/19.2.2.2.4(1) permits doors encountered along the egress path to the outside the same opportunity for locking that 18/19.2.2.2.2(2) permits for patient sleeping room doors, provided that staff can readily unlock such doors at all times. Note that 18/19.1.1.1.5 allows the authority having jurisdiction to make appropriate modifications to compensate for locking of egress doors.

Paragraph 18/19.2.2.2.4(2) addresses the delayed-egress lock described in 7.2.1.6.1. Paragraph 7.2.1.6.1 specifies detailed requirements for delayed egress locking hardware, including the requirement that the building be protected throughout by automatic sprinklers or automatic fire detection. The exemption permits the use of the delayed egress lock on any door in a health care facility. However, only one delayed-egress lock can be encountered along any egress path. For example, in a three-story hospital with an enclosed exit stair at each of the two ends of the building, the doors into the stair enclosures on each of the floors could be equipped with a delayed-egress locking device. However, the door to the outside at the base of each stair enclosure could not be equipped with an additional delayed-egress lock.

In buildings where the locking of doors is necessary, staff must provide continuous supervision in

CHAPTER 19 • Existing

accordance with 18/19.2.2.2.5. Provisions must be made for the prompt release of persons who are restrained either by equipping staff with keys, by providing remote unlocking capabilities for doors, or by other reliable means available to staff at all times. If staff relies on the use of keys, a master key system for facilitating the quick release of occupants should be considered. In existing buildings, given the approval of the authority having jurisdiction, more than one lock on a door is permitted by 19.2.2.2.5.3.

Paragraph 18/19.2.2.2.6 modifies the requirements of 7.2.1.8.2 addressing automatic-closing doors. According to 7.2.1.8.2 and *NFPA 72*[®], *National Fire Alarm Code*^{®5}, the doors must be designed to close automatically by actuation of smoke detectors installed to detect smoke on either side of the door. In addition, where health care occupancy doors that are required to be self-closing are held open, an automatic device must close doors upon operation of the building fire alarm system and upon operation of the building sprinkler system. As a further safeguard for stairways, any automatic action that closes a stairway door on one level must close the doors on the other levels of that stairway in accordance with 18/19.2.2.2.7.

Paragraph 18.2.2.2.8 regulates stairway re-entry in new health care occupancies having occupied floor levels more than 75 ft (23 m) above the lowest level of fire department access. In doing so, the *Code* exempts low-rise health care occupancies from the requirements of 7.2.1.5.7 (see 19.2.2.2.8). Stair doors in new high-rise health care facilities must allow for re-entry in accordance with Chapter 7. All stair doors must be unlocked, or they must be interlocked with the building fire alarm to unlock automatically in the event of alarm actuation. As for all occupancies, use of 7.2.1.5.7.1 is permitted. Paragraph 7.2.1.5.7.1 permits stair doors to be locked provided that the following requirements are met:

- (1) A minimum of two doors are maintained unlocked.
- (2) There are no more than four intervening floors between unlocked doors.
- (3) Re-entry must be possible at either of the two top floor levels that provides access to a different exit.
- (4) Unlocked doors must be appropriately marked on the stairwell side.
- (5) Locked doors must have signage regarding the location of unlocked doors.

CHAPTER 18 • New

Existing health care occupancies—even those that are in high-rise buildings—are exempt from the stairwell re-entry provisions (see 19.2.2.2.8).

Paragraph 18/19.2.2.2.9 establishes requirements exceeding those of 7.2.1.14 for horizontal sliding doors. If sliding doors are to be closed manually, they must consist of a single leaf to avoid openings at the meeting edges of the two leaves, and provisions must be made, by use of a latch or other means, to prevent the door from contacting the frame and rebounding

18.2.2.3 Stairs. Stairs complying with 7.2.2 shall be permitted.

18.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

18.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 and the modifications of 18.2.2.5.1 through 18.2.2.5.6 shall be permitted.

18.2.2.5.1 Accumulation space shall be provided in accordance with 18.2.2.5.1.1 and 18.2.2.5.1.2.

18.2.2.5.1.1 Not less than 2.8 net m² (30 net ft²) per patient in a hospital or nursing home, or not less than 1.4 net m² (15 net ft²) per resident in a limited care facility, shall be provided within the aggregated area of corridors, patient rooms, treatment rooms, lounge or dining areas, and other similar areas on each side of the horizontal exit.

18.2.2.5.1.2 On stories not housing bed or litterborne patients, not less than 0.56 net m² (6 net ft²) per occupant shall be provided on each side of the horizontal exit for the total number of occupants in adjoining compartments.

18.2.2.5.2 The total egress capacity of the other exits (stairs, ramps, doors leading outside the building) shall not be reduced below one-third of that required for the entire area of the building.

18.2.2.5.3 A single door shall be permitted in a horizontal exit if the following conditions apply:

- (1) The exit serves one direction only.
- (2) Such door is a swinging door or a horizontal sliding door complying with 7.2.1.14.
- (3) The door is not less than 1055 mm (41½ in.) in clear width.

CHAPTER 19 • Existing

to a partially open position when closed forcefully. The requirements of 7.2.1.14 should be closely reviewed. The sliding door described is highly specialized, and all requirements of 7.2.1.14 must be met. One unique requirement that differentiates this special door from a typical horizontal sliding door is that it must slide to the side to allow passage through the door opening when force is applied in the direction of egress travel to the door actuator.

19.2.2.3 Stairs. Stairs complying with 7.2.2 shall be permitted.

19.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

19.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 and the modifications of 19.2.2.5.1 through 19.2.2.5.4 shall be permitted.

19.2.2.5.1 Accumulation space shall be provided in accordance with 19.2.2.5.1.1 and 19.2.2.5.1.2.

19.2.2.5.1.1 Not less than 2.8 net m² (30 net ft²) per patient in a hospital or nursing home, or not less than 1.4 net m² (15 net ft²) per resident in a limited care facility, shall be provided within the aggregated area of corridors, patient rooms, treatment rooms, lounge or dining areas, and other similar areas on each side of the horizontal exit.

19.2.2.5.1.2 On stories not housing bed or litterborne patients, not less than 0.56 net m² (6 net ft²) per occupant shall be provided on each side of the horizontal exit for the total number of occupants in adjoining compartments.

19.2.2.5.2 The total egress capacity of the other exits (stairs, ramps, doors leading outside the building) shall not be reduced below one-third of that required for the entire area of the building.

19.2.2.5.3* A door in a horizontal exit shall not be required to swing with egress travel as specified in 7.2.4.3.7(1).

A.19.2.2.5.3 The waiver of the requirement for doors to swing in the direction of egress travel is based on the assumption that, in this occupancy, there is no possibility of a panic rush that might prevent the opening of doors that swing against egress travel.

A desirable arrangement, which is possible with corridors 2.4 m (8 ft) or more in width, is to have two 107-cm (42-in.) doors, normally closed, each swinging with the egress travel (in opposite directions).

CHAPTER 18 • New

18.2.2.5.4 A horizontal exit involving a corridor 2440 mm (96 in.) or more in width and serving as a means of egress from both sides of the doorway shall have the opening protected by a pair of swinging doors arranged to swing in opposite directions from each other, with each door having a clear width of not less than 1055 mm (41½ in.), or by a horizontal sliding door that complies with 7.2.1.14 and provides a clear width of not less than 2110 mm (83 in.).

18.2.2.5.5 A horizontal exit involving a corridor 1830 mm (72 in.) or more in width and serving as a means of egress from both sides of the doorway shall have the opening protected by a pair of swinging doors, arranged to swing in opposite directions from each other, with each door having a clear width of not less than 810 mm (32 in.), or by a horizontal sliding door that complies with 7.2.1.14 and provides a clear width of not less than 1625 mm (64 in.).

18.2.2.5.6 An approved vision panel shall be required in each horizontal exit.

18.2.2.5.7 Center mullions shall be prohibited in horizontal exit door openings.

Special recognition is given to horizontal travel and the use of horizontal exits in health care facilities because of practical difficulties involving vertical egress travel, such as on stairways. Up to two-thirds of the total required egress capacity for a given fire area is permitted to be provided by horizontal exits. Every floor and every fire section must have at least one exit consisting of a door leading directly outside the building, an interior stair, an outside stair, a smokeproof enclosure, a ramp, or an exit passageway (see 18/19.2.4.2). No fire area can be served by horizontal exits only (see 18/19.2.2.5.2). In the event a horizontal exit also serves as a smoke barrier, see commentary associated with 18/19.2.4, and also see 18/19.3.7.

The requirements for horizontal exits in 18/19.2.2.5 are illustrated in Exhibits 18/19.3, 18/19.4, and 18/19.5.

Doors in new horizontal exits are required to swing in the direction of egress travel. In the case of a fire barrier that serves as a new horizontal exit for two adjoining fire areas, a pair of doors arranged with each leaf to swing in a direction opposite from the other, or some equivalent arrangement, must be used. If a fire barrier serves as a horizontal exit from only one fire area, the door opening may be protected by a single door providing 1055-mm (41½-in.) clear

CHAPTER 19 • Existing

19.2.2.5.4 Door openings in horizontal exits shall be protected by one of the following methods:

- (1) Such doors shall be protected by a swinging door providing a clear width of not less than 810 mm (32 in.).
- (2) Such doors shall be protected by a horizontal sliding door that complies with 7.2.1.14 and provides a clear width of not less than 810 mm (32 in.).
- (3) Existing 865-mm (34-in.) swinging doors shall not be required to be protected.

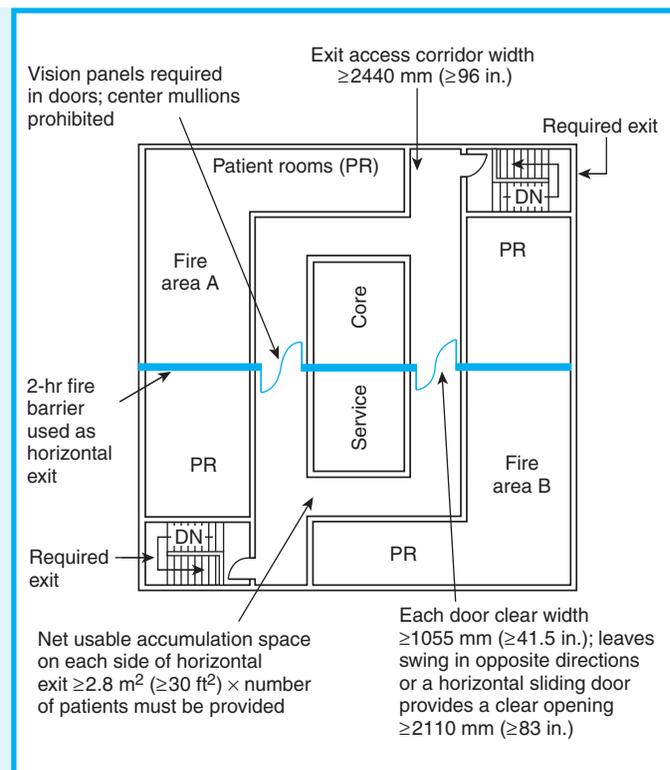

Exhibit 18/19.3 Horizontal exit in a new general hospital or nursing home.

CHAPTER 18 • New

CHAPTER 19 • Existing

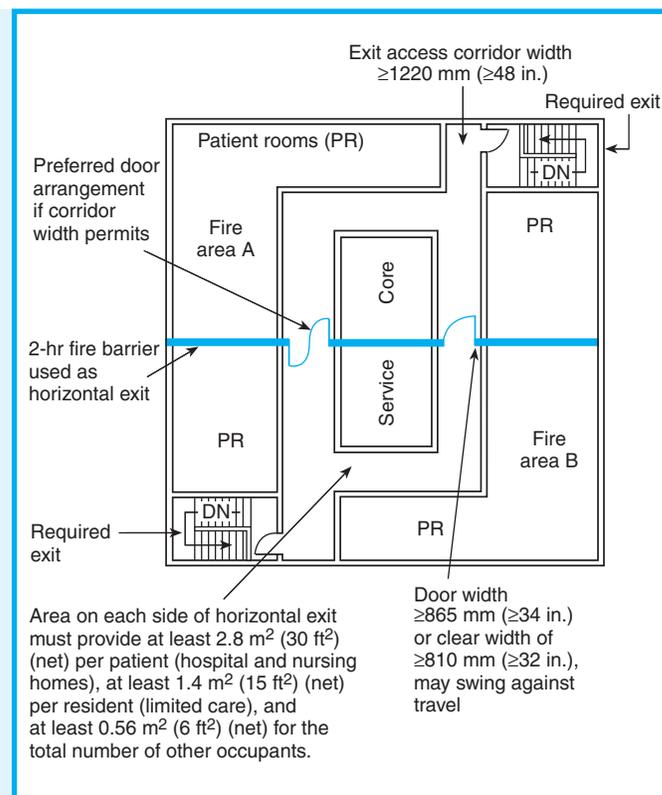

Exhibit 18/19.5 Horizontal exit in existing health care occupancy.

width in new hospitals and nursing homes or 810-mm (32-in.) clear width in new limited care facilities. See Exhibit 18/19.3.

The *Code* recognizes the use of sliding doors complying with 7.2.1.14 for the protection of openings in horizontal exits. The use of power-operated sliding doors results in an obstruction-free opening for normal traffic while providing adequate fire protection for openings under fire emergency conditions.

Corridors in new limited care facilities and new psychiatric hospitals are required to be 1830 mm (72 in.) wide; therefore, it would not be practical to install a pair of 1055-mm (41½-in.) clear width doors to protect corridor openings in a horizontal exit. Recognizing this practical consideration and that no obstructions, such as mullions mounted at the center of a two-door opening, are permitted, doors protecting openings in horizontal exits of such facilities are required to provide a minimum of 810-mm (32-in.) clear width. See Exhibit 18/19.4.

Prohibiting center mullions in new construction provides one, large, usable door opening where two doors are positioned within a door frame and eliminates any obstructions that would restrict the movement of patients in beds, in wheelchairs, or on litters.

The *Code* permits corridors in existing health care occupancies to be 1220 mm (48 in.) wide, and it is therefore impractical in many instances to install a pair of cross-corridor doors in a horizontal exit. However, the 1220-mm (48-in.) corridor width will permit the opening of a single door against the flow of travel with minimal difficulty. A power-operated sliding door might be used to reduce problems associated with door swing. The *Code* permits sliding doors complying with 7.2.1.14 for the protection of openings in horizontal exits. The use of power-operated sliding doors results in an obstruction-free opening for normal traffic, while still providing adequate fire protection for openings.

In the case of an existing fire barrier serving as

CHAPTER 18 • New

a horizontal exit for two adjoining fire areas, and where corridor widths will permit, a pair of doors arranged with each leaf to swing in a direction opposite from the other should be used. Each leaf in the pair of doors must either be a minimum of 865 mm (34 in.) wide or provide a clear opening of 810 mm (32 in.). See Exhibit 18/19.5.

18.2.2.6 Ramps.

18.2.2.6.1 Ramps complying with 7.2.5 shall be permitted.

18.2.2.6.2 Ramps enclosed as exits shall be of sufficient width to provide egress capacity in accordance with 18.2.3.

Ramps with a slope minimally graduated so as not to be dangerous to use in both normal and emergency traffic require so much space that they would be impracticable in most situations. They are, however, the only practicable method of moving bedridden patients from one story to another, except by elevators, which may not be available during fire conditions. The best plan is to provide for horizontal egress to

18.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

18.2.2.8 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

18.2.2.9 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

18.2.2.10 Areas of Refuge. Areas of refuge used as part of a required accessible means of egress shall comply with 7.2.12.

18.2.3 Capacity of Means of Egress.

18.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

18.2.3.2 Reserved.

18.2.3.3 Reserved.

CHAPTER 19 • Existing

New horizontal exits in an existing facility are considered to be a renovation and must be installed in accordance with Chapter 18 to the extent feasible (see commentary following 18/19.1.1.4.7 and 4.6.8).

19.2.2.6 Ramps.

19.2.2.6.1 Ramps complying with 7.2.5 shall be permitted.

19.2.2.6.2 Ramps enclosed as exits shall be of sufficient width to provide egress capacity in accordance with 19.2.3.

another section of the building, minimizing the need for complete evacuation.

Ramps might be the best means for providing egress from doors two or three steps above or below grade level (see 7.1.7) and might compensate for minor differences in floor levels between adjoining sections of buildings. Such ramps must be constructed in accordance with 18/19.2.2.6 and 7.2.5.

19.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

19.2.2.8 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

19.2.2.9 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

19.2.2.10 Areas of Refuge. Areas of refuge used as part of a required accessible means of egress shall comply with 7.2.12.

19.2.3 Capacity of Means of Egress.

19.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

19.2.3.2 The capacity of means of egress providing travel by means of stairs shall be 15 mm (0.6 in.) per person, and the capacity of means of egress providing horizontal travel (without stairs) by means such as doors, ramps, or horizontal exits shall be 13 mm (½ in.) per person, unless otherwise permitted by 19.2.3.3.

19.2.3.3 The capacity of means of egress in health care occupancies protected throughout by an approved, super-

CHAPTER 18 • New

18.2.3.4* Aisles, corridors, and ramps required for exit access in a hospital or nursing home shall be not less than 2440 mm (96 in.) in clear and unobstructed width, unless otherwise permitted by the following:

- (1)* Aisles, corridors, and ramps in adjunct areas not intended for the housing, treatment, or use of inpatients shall be not less than 1120 mm (44 in.) in clear and unobstructed width.

A.18.2.3.4(1) Occupant characteristics are an important factor to be evaluated in setting egress criteria. Egress components in nonpatient use areas, such as administrative office spaces, should be evaluated based on actual use. A clear corridor width of not less than 112 cm (44 in.) is specified, assuming occupants in nonpatient areas will be mobile and capable of evacuation without assistance.

- (2)* Exit access within a room or suite of rooms complying with the requirements of 18.2.5 shall be permitted.

A.18.2.3.4(2) Exit access should be arranged to avoid any obstructions to the convenient removal of nonambulatory persons carried on stretchers or on mattresses serving as stretchers.

A.18.2.3.4 It is not the intent that the required corridor width be maintained clear and unobstructed at all times. Projections into the required width are permitted by 7.3.2.2. It is not the intent that 18.2.3.4 supersede 7.3.2.2. Also, it is recognized that wheeled items in use (such as food service carts, housekeeping carts, gurneys, beds, and similar items) and wheeled crash carts not in use (because they need to be immediately accessible during a clinical emergency) are encountered in health care occupancy corridors. The health care occupancy's fire plan and training program should address the relocation of these items during a fire. Note that "not in use" is not the same as "in storage." Storage is not permitted to be open to the corridor unless it meets one of the provisions permitted by 18.3.6.1 and is not a hazardous area.

18.2.3.5 Aisles, corridors, and ramps required for exit access in a limited care facility or hospital for psychiatric care shall be not less than 1830 mm (72 in.) in clear and unobstructed width, unless otherwise permitted by the following:

- (1)* Aisles, corridors, and ramps in adjunct areas not intended for the housing, treatment, or use of inpatients

CHAPTER 19 • Existing

vised automatic sprinkler system in accordance with 19.3.5.2 shall be 7.6 mm (0.3 in.) per person for travel by means of stairs and 5 mm (0.2 in.) per person for horizontal travel without stairs.

19.2.3.4* Any required aisle, corridor, or ramp shall be not less than 1220 mm (48 in.) in clear width where serving as means of egress from patient sleeping rooms, unless otherwise permitted by the following:

- (1) Aisles, corridors, and ramps in adjunct areas not intended for the housing, treatment, or use of inpatients shall be not less than 1120 mm (44 in.) in clear and unobstructed width.

- (2) Exit access within a room or suite of rooms complying with the requirements of 19.2.5 shall be permitted.

A.19.2.3.4 It is not the intent that the required corridor width be maintained clear and unobstructed at all times. Projections into the required width are permitted by 7.3.2.2. It is not the intent that 19.2.3.4 supersede 7.3.2.2. Also, it is recognized that wheeled items in use (such as food service carts, housekeeping carts, gurneys, beds, and similar items) and wheeled crash carts not in use (because they need to be immediately accessible during a clinical emergency) are encountered in health care occupancy corridors. The health care occupancy's fire plan and training program should address the relocation of these items during a fire. Note that "not in use" is not the same as "in storage." Storage is not permitted to be open to the corridor unless it meets one of the provisions permitted by 19.3.6.1 and is not a hazardous area.

19.2.3.5 The aisle, corridor, or ramp shall be arranged to avoid any obstructions to the convenient removal of nonambulatory persons carried on stretchers or on mattresses serving as stretchers.

CHAPTER 18 • New

shall be not less than 1120 mm (44 in.) in clear and unobstructed width.

A.18.2.3.5(1) See A.18.2.3.4(1).

(2)* Exit access within a room or suite of rooms complying with the requirements of 18.2.5 shall be permitted.

A.18.2.3.5(2) See A.18.2.3.4(2).

18.2.3.6 The minimum clear width for doors in the means of egress from sleeping rooms; diagnostic and treatment areas, such as x-ray, surgery, or physical therapy; and nursery rooms shall be as follows:

- (1) Hospitals and nursing homes—1055 mm (41½ in.)
- (2) Psychiatric hospitals and limited care facilities—810 mm (32 in.)

18.2.3.7 The requirements of 18.2.3.6 shall not apply where otherwise permitted by the following:

- (1) Doors that are located so as not to be subject to use by any health care occupant shall be not less than 810 mm (32 in.) in clear width.
- (2) Doors in exit stair enclosures shall be not less than 810 mm (32 in.) in clear width.
- (3) Doors serving newborn nurseries shall be not less than 810 mm (32 in.) in clear width.
- (4) Where a pair of doors is provided, the following criteria shall be met:
 - (a) Not less than one of the doors shall provide not less than a 810 mm (32 in.) clear width opening.
 - (b) A rabbet, bevel, or astragal shall be provided at the meeting edge.
 - (c) The inactive door leaf shall have an automatic flush bolt to provide positive latching.

The method used in calculating egress capacity acknowledges that increasing the width of egress systems results in increasing the occupant flow through that system. The provisions of 19.2.3.2 and 19.2.3.3 (as well as the reference 18.2.3.1 makes to Section 7.3) compute stair egress capacity in sprinklered health care occupancies on the basis of 7.6 mm (0.3 in.) per person. Therefore, a 1120-mm (44-in.) stair provides egress capacity for 146 persons [1120 mm/7.6 mm per person (44 in./0.3 in. per person) = 146 persons]. Similarly, a 1270-mm (50-in.) stair provides capacity for 167 persons. In nonsprinklered existing health care occupancies, stair egress capacity is computed

CHAPTER 19 • Existing

19.2.3.6 The minimum clear width for doors in the means of egress from hospitals; nursing homes; limited care facilities; psychiatric hospital sleeping rooms; and diagnostic and treatment areas, such as x-ray, surgery, or physical therapy, shall be not less than 810 mm (32 in.) wide.

19.2.3.7 The requirement of 19.2.3.6 shall not apply where otherwise permitted by the following:

- (1) Existing 865-mm (34-in.) doors shall be permitted.
- (2) Existing 710-mm (28-in.) corridor doors in facilities where the fire plans do not require evacuation by bed, gurney, or wheelchair shall be permitted.

on the basis of 15 mm (0.6 in.) per person. The capacity of level surfaces and doors in fully sprinklered health care occupancy smoke compartments is computed on the basis of 5 mm (0.2 in.) per person, and on 13 mm (0.5 in.) per person in nonsprinklered existing health care occupancy smoke compartments. Egress capacity calculations must use clear width as defined in 7.2.1.2.

In earlier editions of the *Code*, egress capacity for health care occupancies was calculated using more conservative egress capacity factors. For example, stair capacity for nonsprinklered health care occupancies was calculated on the basis of 25 mm (1 in.)

CHAPTER 18 • New

per person rather than the current factor of 7.6 mm (0.3 in.) per person on the basis of the belief that extra width was needed to create space that could serve as a refuge area. The capacity of health care egress system components was set conservatively in recognition of the slow rate of travel for patients and the fact that space was needed for patients on litters and in wheelchairs.

Recent editions of the *Code* use a different concept for egress system design in health care occupancies. Life safety from fire in health care facilities relies on a defend-in-place principle. Horizontal exits or smoke barriers are used to subdivide each story to provide an area of refuge on each story without requiring travel by means of stairs. Flow rates for exits (capacity) are established on the assumption that exit stairs will be used principally by able-bodied staff, visitors, and ambulatory patients for emergency evacuation. Nonambulatory patients will remain in the building, and those on the floor of fire origin will be moved horizontally to an area of refuge. The defend-in-place principle is complemented by the requirement that all new health care facilities be fully protected by automatic sprinklers.

Corridor width is addressed in 18/19.2.3.4 and 18.2.3.5. Exit access corridors in new hospitals and nursing homes are required to be at least 2440 mm (96 in.) in clear width, based on the assumption that, during a fire emergency, some patients might require movement on litters or in wheelchairs. Also, multiple files of persons should be able to use the corridor at one time, with those who move more quickly passing those who move more slowly. Exit access corridors in existing health care occupancies are required to be at least 1220 mm (48 in.) in clear width. This specified minimum leaves little safety margin. Care is necessary to prevent carts, furnishings, and other materials from obstructing or interfering with potential occupant movement. In both new and existing facilities, a minimum corridor width of 1120 mm (44 in.) is considered acceptable within areas not subject to use by inpatients, such as administrative office spaces, where occupants are assumed to be mobile and capable of evacuation without assistance.

Exhibits 18/19.6 and 18/19.7 illustrate the minimum clear width requirement of 18/19.2.3.4 and 18.2.3.5. For new limited care facilities and psychiatric hospitals, which by definition involve patients who are more ambulatory than those in general hospitals

CHAPTER 19 • Existing

and nursing homes, the required corridor width is 1830 mm (72 in.), as opposed to the minimum 2440 mm (96 in.) in new general hospitals and nursing homes. Actual corridor width is permitted to be considered as clear width if handrail encroachment does not exceed 114 mm (4½ in.) on each side of the corridor (see 7.3.2.2).

In editions of the *Code* prior to 1994, numerous health care occupancy provisions specified minimum requirements for door widths as a leaf width rather than as a clear width. For example, new doors from patient rooms to the corridor were required to be 1120 mm (44 in.) wide; existing doors were required to be 865 mm (34 in.) wide. The intent was that after allowing for the stops built into the door frame and for the thickness of the protruding hinge stile edge,

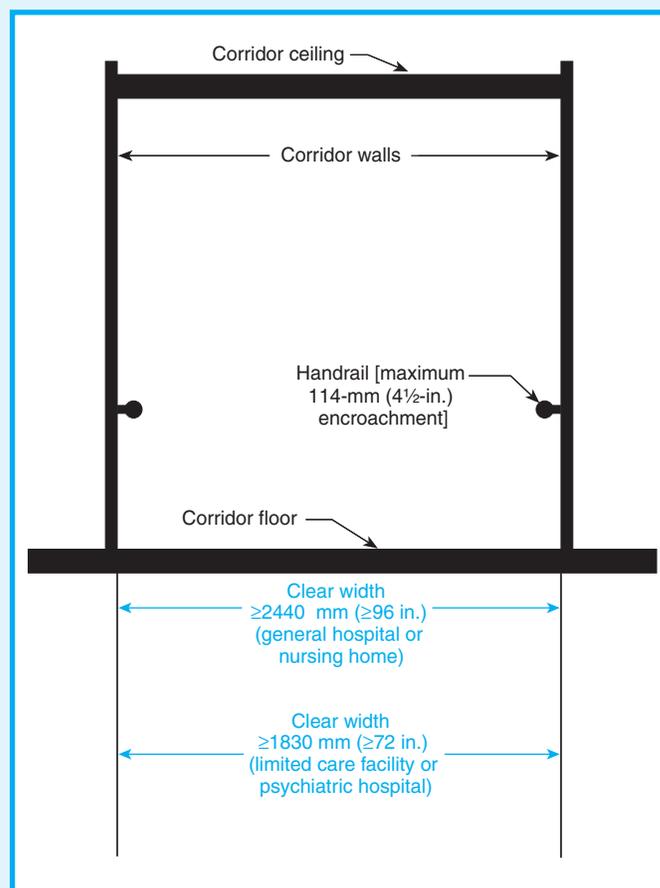

Exhibit 18/19.6 Exit access corridor in new health care facility.

CHAPTER 18 • New

CHAPTER 19 • Existing

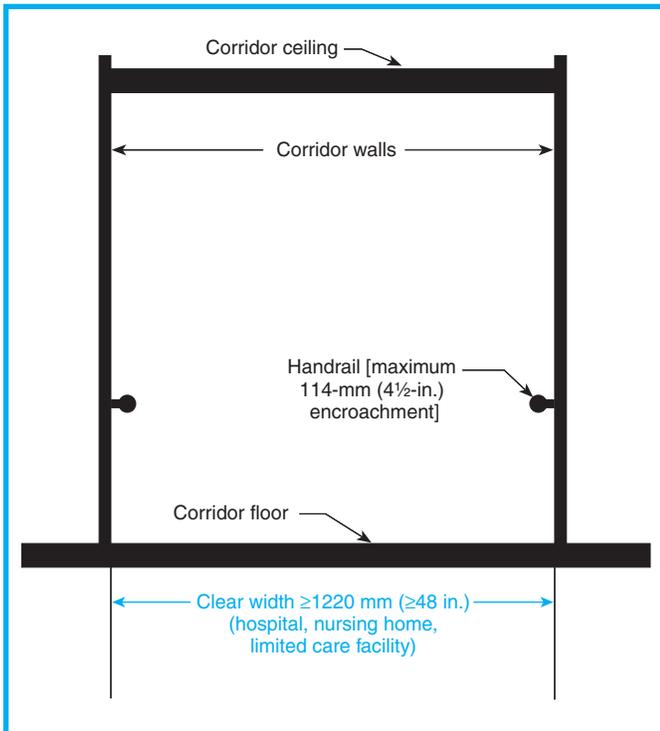

Exhibit 18/19.7 Exit access corridor in existing health care facility.

a 1120-mm (44-in.) wide door leaf would provide approximately 1055 mm (41½ in.) of clear, unobstructed width; a 865-mm (34-in.) wide door leaf would pro-

vide approximately 810 mm (32 in.) of clear, unobstructed width. However, there was no requirement for the door to swing a minimum of 90 degrees from the plane of the door opening, so the intended clear, unobstructed width was not assured. Since the 1994 edition, minimum door width requirements for health care occupancies have been specified as clear, unobstructed width; exemptions continue to recognize existing doors with the minimum door leaf widths previously specified. Exhibit 18/19.8 illustrates door leaf measurement, rather than clear opening measurement, as allowed by 19.2.3.7(1). Paragraphs 19.2.2.5.4(3), applicable to horizontal exit doors, and 19.3.7.8, applicable to smoke barrier doors, also permit existing doors to provide the minimum required width via a door leaf measurement.

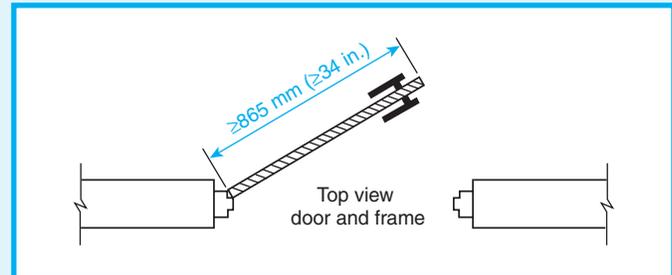

Exhibit 18/19.8 Minimum door width measurement for existing doors.

18.2.4 Number of Exits.

18.2.4.1 Not less than two exits of the types described in 18.2.2.2 through 18.2.2.10, remotely located from each other, shall be provided for each floor or fire section of the building.

18.2.4.2 Not less than one exit from each floor or fire section shall be one of the following:

- (1) A door leading directly outside the building
- (2) A stair
- (3) A smokeproof enclosure
- (4) A ramp
- (5) An exit passageway

18.2.4.3 Any fire section not meeting the requirements of 18.2.4.2 shall be considered part of an adjoining zone

19.2.4 Number of Exits.

19.2.4.1 Not less than two exits of the types described in 19.2.2.2 through 19.2.2.10, remotely located from each other, shall be provided for each floor or fire section of the building.

19.2.4.2 Not less than one exit from each floor or fire section shall be one of the following:

- (1) A door leading directly outside the building
- (2) A stair
- (3) A smokeproof enclosure
- (4) A ramp
- (5) An exit passageway

19.2.4.3 Any fire section not meeting the requirements of 19.2.4.2 shall be considered part of an adjoining zone

CHAPTER 18 • New

through which egress shall not require return through the zone of fire origin.

18.2.4.4* Not less than two exits of the types described in 18.2.2.2 through 18.2.2.10 shall be accessible from each smoke compartment, and egress shall be permitted through an adjacent compartment(s) but shall not require return through the compartment of fire origin.

A.18.2.4.4 An exit is not necessary for each individual smoke compartment if there is access to an exit through other smoke compartments without passing through the smoke compartment of fire origin.

Exhibit 18/19.9 can be used to illustrate the application of 18/19.2.4.2 and 18/19.2.4.3. Horizontal exits 1 and 2 form three fire compartments, areas A, B, and C. An enclosed exit stair (that is, an exit other than a horizontal exit) is provided from areas A and C;

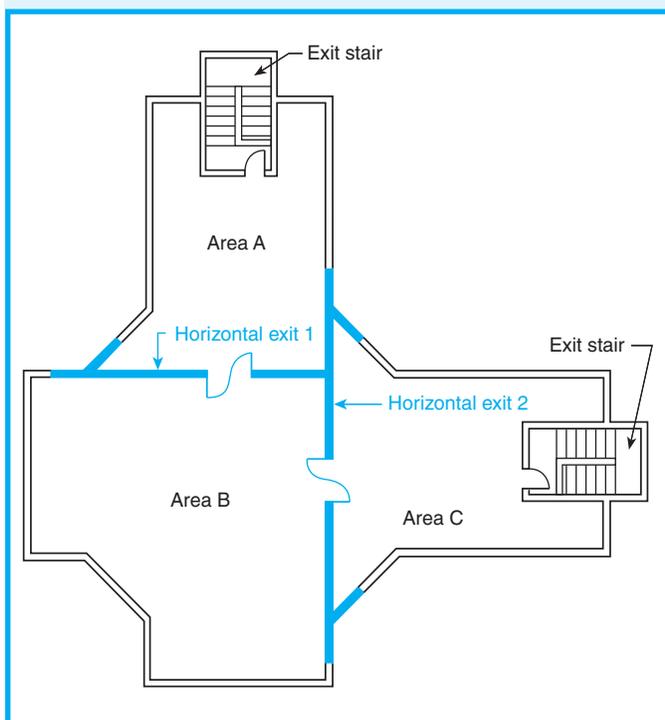

Exhibit 18/19.9 Arrangement of exits for fire compartments formed by horizontal exit fire barriers.

through which egress shall not require return through the zone of fire origin.

19.2.4.4* Not less than two exits of the types described in 19.2.2.2 through 19.2.2.10 shall be accessible from each smoke compartment, and egress shall be permitted through an adjacent compartment(s) but shall not require return through the compartment of fire origin.

A.19.2.4.4 An exit is not necessary for each individual smoke compartment if there is access to an exit through other smoke compartments without passing through the smoke compartment of fire origin.

area B is provided with two horizontal exits. Paragraph 18/19.2.4.2 requires that area B must be provided with at least one exit other than a horizontal exit. Area B is deficient in that it has no exit other than horizontal exits. Without this additional exit, area B is required by 18/19.2.4.3 to be considered part of one of the adjoining areas—either part of an enlarged area A, in which case horizontal exit 1 would receive no credit for providing egress capacity, or part of an enlarged area C, in which case horizontal exit 2 would receive no credit for providing egress capacity.

Exhibit 18/19.10 can be used to illustrate the application of 18/19.2.4.4. Smoke barriers 1 and 2 form three smoke compartments, areas A, B, and C. Access to two exits is provided from each smoke compartment. For area A, the enclosed exit stair provides access to one exit, and traveling through smoke barrier 1 into area B provides access to the second exit, also an enclosed exit stair. For area B, the enclosed exit stair provides access to one exit, and traveling through smoke barrier 1 into area A provides access to the second exit, also an enclosed exit stair. For area C, the two remotely located pairs of doors in smoke barrier 2 provide access to the enclosed exit stairs in areas A and B, but passage into area B is required. Area C is deficient in that both of its exit accesses require passage into area B, which might be the smoke compartment of fire origin. To satisfy the provision of 18/19.2.4.4—that egress not require return through the smoke compartment of fire origin—either an enclosed exit stair can be added to area C, or the doors at Z can be relocated to position XX.

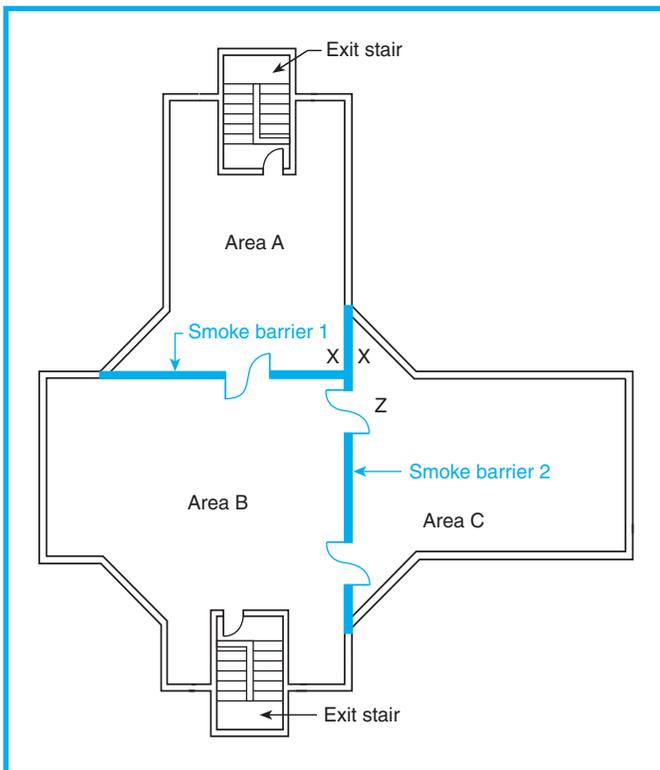

Exhibit 18/19.10 Arrangement of exits for smoke compartments formed by smoke barriers.

18.2.5 Arrangement of Means of Egress.

18.2.5.1 Every habitable room shall have an exit access door leading directly to an exit access corridor, unless otherwise permitted by the following:

- (1) The requirement of 18.2.5.1 shall not apply if there is an exit door opening directly to the outside from the room at ground level.
- (2) Exit access from a patient sleeping room with not more than eight patient beds shall be permitted to pass through one intervening room to reach the exit access corridor.
- (3) Exit access from a sleeping or nursing suite shall be permitted to pass through one intervening room to reach the exit access corridor where the arrangement allows for direct and constant visual supervision by nursing personnel.
- (4) Exit access from a suite of rooms, other than patient sleeping rooms, shall be permitted to pass through not more than two adjacent rooms to reach the exit access corridor where the travel distance within the suite is in accordance with 18.2.5.8.

19.2.5 Arrangement of Means of Egress.

19.2.5.1 Every habitable room shall have an exit access door leading directly to an exit access corridor, unless otherwise permitted by the following:

- (1) The requirement of 19.2.5.1 shall not apply if there is an exit door opening directly to the outside from the room at ground level.
- (2) Exit access from a patient sleeping room with not more than eight patient beds shall be permitted to pass through one intervening room to reach the exit access corridor.
- (3) Exit access from a sleeping or nursing suite shall be permitted to pass through one intervening room to reach the exit access corridor where the arrangement allows for direct and constant visual supervision by nursing personnel.
- (4) Exit access from a suite of rooms, other than patient sleeping rooms, shall be permitted to pass through not more than two adjacent rooms to reach the exit access corridor where the travel distance within the suite is in accordance with 19.2.5.8.

CHAPTER 18 • New

18.2.5.2 Any patient sleeping room, or any suite that includes patient sleeping rooms, of more than 93 m² (1000 ft²) shall have not less than two exit access doors remotely located from each other.

18.2.5.3 Any room or any suite of rooms, other than patient sleeping rooms, of more than 232 m² (2500 ft²) shall have not less than two exit access doors remotely located from each other.

18.2.5.4 Any suite of rooms that complies with the requirements of 18.2.5 shall be permitted to be subdivided with non-fire-rated, noncombustible, or limited-combustible partitions.

18.2.5.5 Intervening rooms shall not be hazardous areas as defined by 18.3.2.

18.2.5.6 Suites of sleeping rooms shall not exceed 465 m² (5000 ft²).

18.2.5.7 Suites of rooms, other than patient sleeping rooms, shall not exceed 929 m² (10,000 ft²).

18.2.5.8 Suites of rooms, other than patient sleeping rooms, shall be permitted to have one intervening room if the travel distance within the suite to the exit access door does not exceed 30 m (100 ft) and shall be permitted to have two intervening rooms where the travel distance within the suite to the exit access door does not exceed 15 m (50 ft).

18.2.5.9 Every corridor shall provide access to not less than two approved exits in accordance with Section 7.4 and Section 7.5 without passing through any intervening rooms or spaces other than corridors or lobbies.

18.2.5.10 Every exit or exit access shall be arranged so that no corridor, aisle, or passageway has a pocket or dead end exceeding 9140 mm (360 in.).

The term *habitable room* is used in 18/19.2.5.1 in lieu of *patient sleeping room* to clarify that all occupied rooms in a health care facility must have access to a corridor leading to an exit.

Exhibit 18/19.11 illustrates the intent of 18/19.2.5.1, 18/19.2.5.1(1), and 18/19.2.5.1(4). The in-

CHAPTER 19 • Existing

19.2.5.2 Any patient sleeping room, or any suite that includes patient sleeping rooms, of more than 93 m² (1000 ft²) shall have not less than two exit access doors remotely located from each other.

19.2.5.3 Any room or any suite of rooms, other than patient sleeping rooms, of more than 232 m² (2500 ft²) shall have not less than two exit access doors remotely located from each other.

19.2.5.4 Any suite of rooms that complies with the requirements of 19.2.5 shall be permitted to be subdivided with non-fire-rated, noncombustible, or limited-combustible partitions.

19.2.5.5 Intervening rooms shall not be hazardous areas as defined by 19.3.2.

19.2.5.6 Suites of sleeping rooms shall not exceed 465 m² (5000 ft²).

19.2.5.7 Suites of rooms, other than patient sleeping rooms, shall not exceed 929 m² (10,000 ft²).

19.2.5.8 Suites of rooms, other than patient sleeping rooms, shall be permitted to have one intervening room if the travel distance within the suite to the exit access door does not exceed 30 m (100 ft) and shall be permitted to have two intervening rooms where the travel distance within the suite to the exit access door does not exceed 15 m (50 ft).

19.2.5.9 Every corridor shall provide access to not less than two approved exits in accordance with Section 7.4 and Section 7.5 without passing through any intervening rooms or spaces other than corridors or lobbies.

19.2.5.10* Existing dead-end corridors shall be permitted to continue in use if it is impractical and unfeasible to alter them so that exits are accessible in not less than two different directions from all points in aisles, passageways, and corridors.

A.19.2.5.10 Every exit or exit access should be arranged, if practical and feasible, so that no corridor, passageway, or aisle has a pocket or dead end exceeding 30 ft (9.1 m). (*See also Table A.7.6.*)

tervening room is permitted between room A and the corridor because room A has an exit door directly to the outside at ground level. The intervening room is permitted between the examination room B and the corridor because room B is not used for patient sleeping.

CHAPTER 18 • New

CHAPTER 19 • Existing

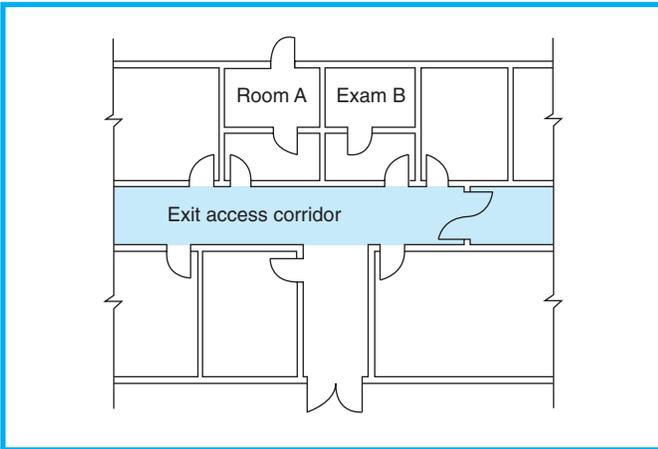

Exhibit 18/19.11 Direct access to corridor from habitable rooms.

Exit access from a patient sleeping room to the corridor is permitted to pass through an intervening room in accordance with 18/19.2.5.1(2). See Exhibit 18/19.12. Locking hardware on the two doors in the path to the corridor is permitted only under the special conditions addressed by 18/19.2.2.2.2. If the maximum eight-bed patient room (including the intervening room) exceeds 93 m² (1000 ft²), a second exit access door, remote from the first, is required in accordance with 18/19.2.5.2.

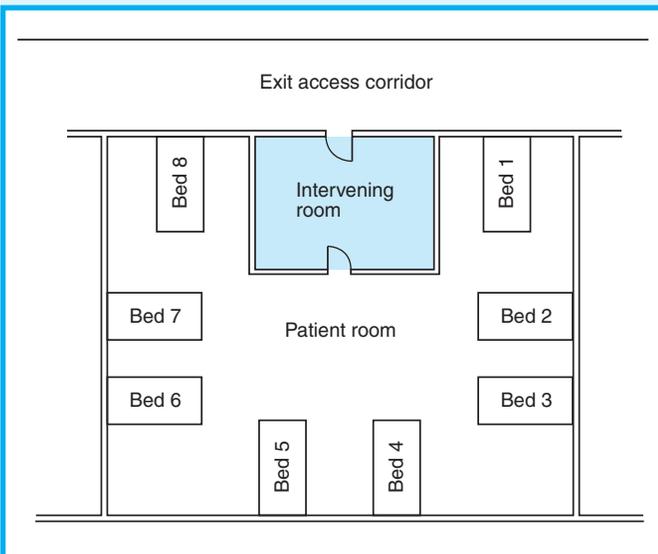

Exhibit 18/19.12 Intervening room between patient room and corridor.

Paragraph 18/19.2.5.1(3) permits an intervening room between a sleeping or nursing suite and the corridor. Exhibits 18/19.13 and 18/19.14 depict sleeping or nursing suites; Exhibit 18/19.14 utilizes the intervening room permitted by 18/19.2.5.1(3).

Various treatment areas are frequently arranged with an intervening workroom located between the exit access corridor and the treatment room. Paragraph 18/19.2.5.1(4), in combination with 18/19.2.5.8, allows egress through spaces that are closely related in function to the treatment room and, therefore, are under the immediate control of staff who, along with patients, would be forced to travel through such rooms. Where such an arrangement is used, locking hardware on doors is permitted only under the special conditions addressed by 18/19.2.2.2.2.

Maximum travel distance limitations to the exit access door of nonsleeping suites are specified in 18/19.2.5.8. For sleeping suites, see 18/19.2.6.2.6. Where applying 18/19.2.5.1(2), 18.2.5.1(3), or 18/19.2.5.1(4), note that 18/19.2.5.5 prohibits intervening rooms from being hazardous areas.

Per 18/19.2.5.2, patient sleeping rooms or sleeping suites larger than 93 m² (1000 ft²) require two exit access doors. The doors are permitted to open onto a common corridor but are required to be remotely

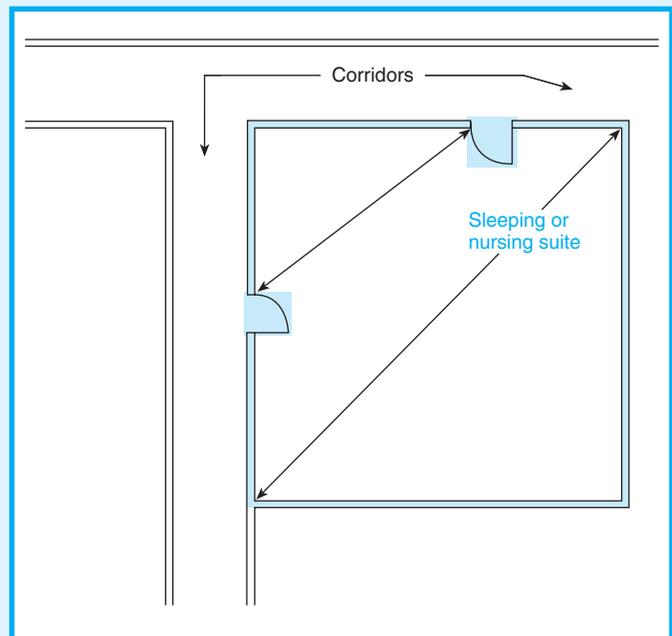

Exhibit 18/19.13 Patient sleeping suite.

CHAPTER 18 • New

CHAPTER 19 • Existing

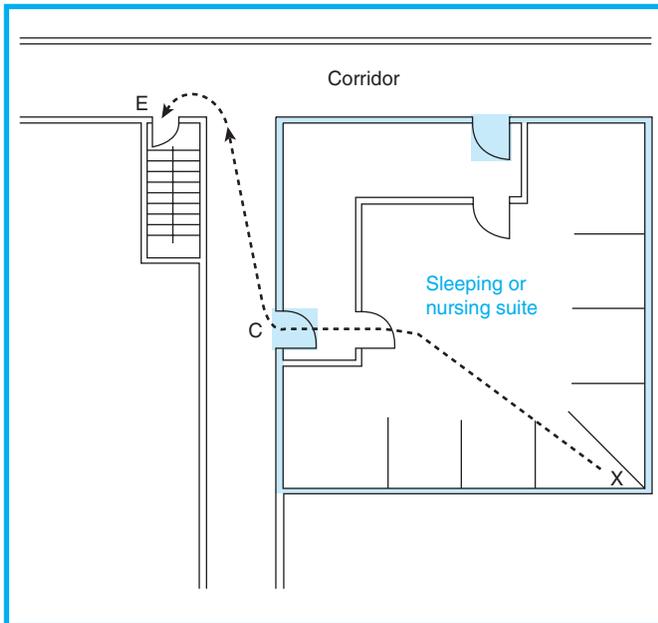

Exhibit 18/19.14 Patient sleeping suite with intervening room to corridor.

located from each other (see 7.5.1.3). Rooms or suites not used for patient sleeping purposes are permitted to be up to 232 m² (2500 ft²) in area and require only one exit access door, based on the premise that occupants are alert, ambulatory, or, in most instances, accompanied by staff who can assist in evacuating the space during fire or other emergency. For sleeping suites, refer to 18/19.2.5.1, 18/19.2.5.2, and 18/19.2.5.4 through 18/19.2.5.6 for requirements. For nonsleeping suites, refer to 18/19.2.5.1, 18/19.2.5.3 through 18/19.2.5.5, 18/19.2.5.7, and 18/19.2.5.8. Exhibits 18/19.13 and 18/19.14 illustrate the requirements for sleeping suites. Exhibits 18/19.15, 18/19.16, and 18/19.17 illustrate the requirements for nonsleeping suites.

In Exhibit 18/19.13, the arrangement within the sleeping suite is not required to comply with 18/19.2.3.4 and 18.2.3.5 relative to exit access minimum width, or with 18/19.3.6 relative to corridor walls and doors. However, the corridors outside the suite must comply with 18/19.3.6. The maximum area of the sleeping suite cannot exceed 465 m² (5000 ft²). If the area of the sleeping suite exceeds 93 m² (1000 ft²), two separate, remotely located exit access doors—as shown in the exhibit—are required. In new construction, their separation distance d must be at least $\frac{1}{3}D$ (see 7.5.1.3.3), based on the requirement that the new

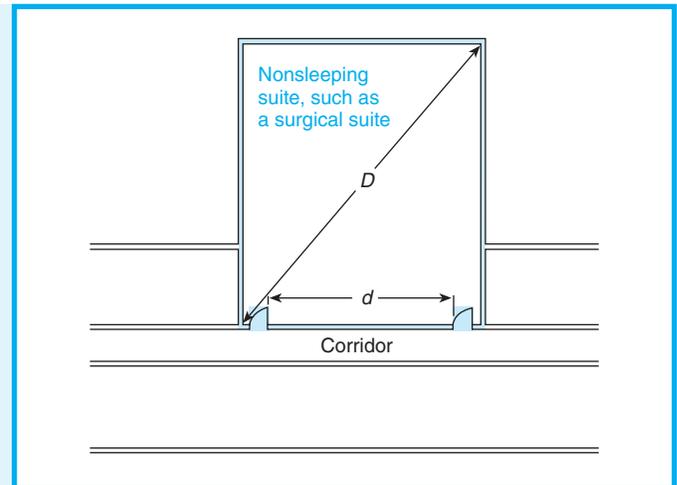

Exhibit 18/19.15 Treatment (nonsleeping) suite.

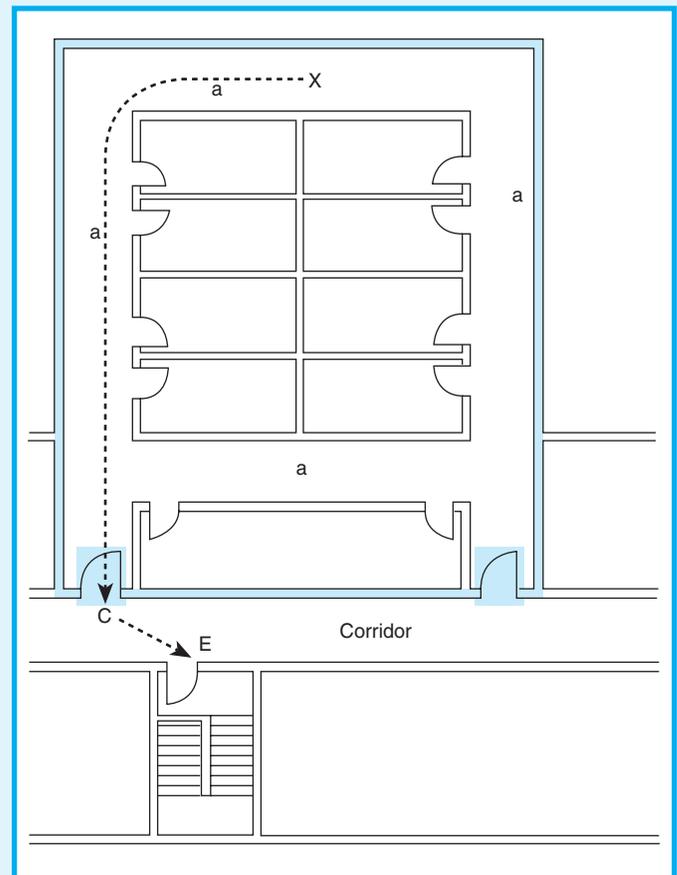

Exhibit 18/19.16 Treatment (nonsleeping) suite with one intervening room to corridor.

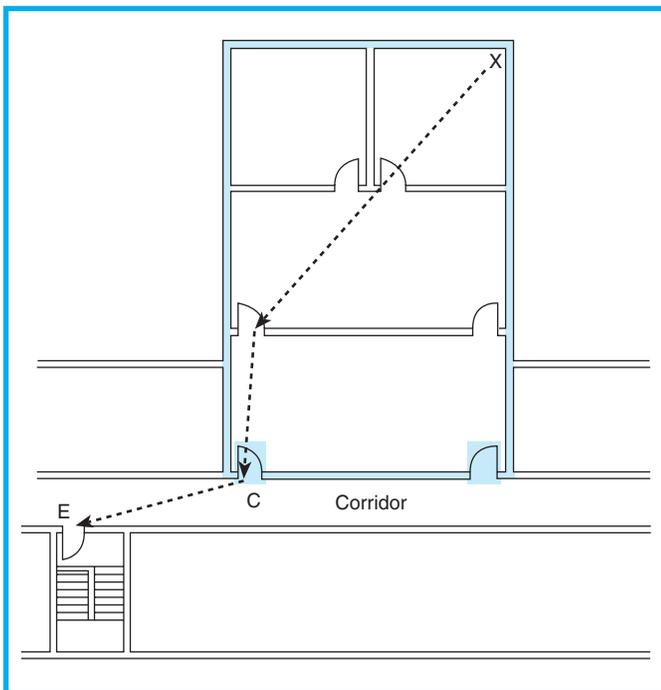

Exhibit 18/19.17 Treatment (nonsleeping) suite with two intervening rooms to corridor.

construction be sprinklered. In existing installations, the remoteness of the exit accesses is to be judged by the qualitative provisions of 7.5.1.3.1.

In Exhibit 18/19.14, all the points made for Exhibit 18/19.13 also apply. For example, interior corridors or circulation spaces within sleeping suites in new construction are not required to be 2440 mm (96 in.) wide. Doors to individual cubicles may be sliding doors or open doorways without a door leaf. Further, the suite is subdivided by cubicle walls using non-combustible or limited-combustible materials such as metal panels with glass or gypsum wallboard on steel studs. One intervening room is positioned between the special nursing (sleeping) suite and the corridor in accordance with 18/19.2.5.1(3), which imposes a requirement for constant visual supervision by nursing personnel. If the individual cubicles were to be enclosed so as to constitute rooms, then the intervening room to the corridor would be prohibited so as not to violate the single intervening room criterion. However, if those individual cubicles were truly to be enclosed, it is doubtful that the requirement for constant visual supervision could be met.

Travel distance within the patient sleeping suite

(that is, distance X to C in Exhibit 18/19.14) is addressed by 18/19.2.6.2.6 and is permitted to be 30 m (100 ft) rather than the 15-m (50-ft) limit imposed on a typical health care sleeping room. However, the total travel distance (that is, distance X to E in Exhibit 18/19.14), including the sum of the travel within the suite and that from the suite door to the exit (that is, corridor travel), is limited by 18/19.2.6.2.3 and 19.2.6.2.4. Thus, if the travel within the suite is between 15 m and 30 m (50 ft and 100 ft), the corridor travel allowance of 18/19.2.6.2.1 cannot be fully used. If it were fully used, the total travel distance specified in 18/19.2.6.2.3 would be exceeded. The concept permits extra travel within the suite by limiting the corridor travel so that the total travel distance is not excessive.

The concept employed in permitting the sleeping suite is one of ensuring sufficient openness to allow for staff awareness of conditions throughout the suite. Due to an editorial reformatting of these provisions in the 1991 edition of the *Code*, the current wording makes this concept less evident. It was never the intent to permit the patient sleeping suite to include separate television rooms, day rooms, activity alcoves, or similar nonsleeping areas within the suite. Rather, the sleeping suite provisions were intended to permit functions such as a critical care unit or a cardiac care unit with the minimum subdivision needed for privacy and effective functioning but without imposing the requirements of 18/19.2.3.4 and 18.2.3.5 relative to exit access minimum width or 18/19.3.6 relative to corridor walls and doors.

In Exhibit 18/19.15, the arrangement within the treatment (nonsleeping) suite—such as a surgical suite—is not required to comply with 18/19.2.3.4 or 18.2.3.5 relative to exit access minimum width or with 18/19.3.6 relative to corridor walls and doors. However, the corridors outside the suite must comply with 18/19.3.6. The maximum area of the suite cannot exceed 929 m² (10,000 ft²) as mandated by 18/19.2.5.7. If the area of the suite exceeds 232 m² (2500 ft²), 18/19.2.5.3 requires two separate, remotely located exit access doors—as shown in the exhibit. In new construction, their separation distance d must be at least $\frac{1}{3}D$ (see 7.5.1.3.3), based on the requirement that the new construction be sprinklered. In existing installations, the remoteness of the exit accesses is to be judged by the qualitative provisions of 7.5.1.3.1.

In Exhibit 18/19.16, all the points made for Exhibit 18/19.15 also apply. For example, interior corridors

CHAPTER 18 • New

or circulation space within treatment suites in new construction are not required to be 2440 mm (96 in.) wide. Doors to individual rooms can be sliding doors or open doorways without a door leaf. Further, the suite is subdivided by walls using noncombustible or limited-combustible materials such as metal panels with glass or gypsum wallboard on steel studs. Unlike the sleeping suite, the treatment suite does not require constant visual supervision by staff. For the occupants of the individual treatment rooms within the suite, the aisle (a) depicted in Exhibit 18/19.16 is the equivalent of an intervening room. Provided that there is only one intervening room between any treatment room and the corridor, the travel distance within the suite (that is, the distance from X to C) is permitted to be 30 m (100 ft) in accordance with 18/19.2.5.8. If the treatment suite were to exceed 930 m² (10,000 ft²) in area, it would cease to qualify for the suite provisions of 18/19.2.5. As such, this group of rooms and aisles would be required to comply with 18/19.2.3.4 and 18.2.3.5 relative to exit access minimum width and 18/19.3.6 relative to corridor walls and doors. This means that the treatment room walls and doors that face onto aisles would become corridor walls. Similarly, the aisles would become corridors.

In Exhibit 18/19.17, the treatment suite is shown with two intervening rooms between the innermost room and the corridor. A maximum of two intervening rooms is permitted by 18/19.2.5.8 but—unlike the treatment suite with a single intervening room and 30 m (100 ft) of permitted travel within the suite—the travel within the treatment suite (that is, distance X to C) is limited to 15 m (50 ft). The decrease in allowable travel within the suite is in consideration that with two intervening rooms an occupant's awareness of

CHAPTER 19 • Existing

fire within the suite decreases; it is important that the suite occupants not have far to travel to reach the safety afforded by the corridor.

Paragraph 18/19.2.5.9 specifically prohibits an exit access arrangement that takes an occupant into a corridor and then requires passage through an occupiable space, such as another patient sleeping or treatment room, to gain access to a required exit. Once an occupant reaches the exit access corridor, that corridor is thought to be a safer portion of the exit access than an occupiable room because of the features required by 18/19.3.6. The occupant must be able to reach an exit without having to leave the safety provided by the corridor.

Exhibit 18/19.18 illustrates the maximum 9140-mm (360-in.) dead-end corridor limitation imposed by 18.2.5.10 on new construction in health care occupancies.

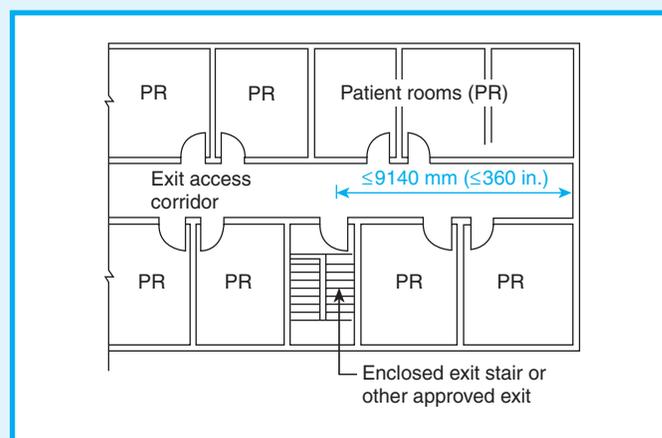

Exhibit 18/19.18 Dead-end corridor in a new health care occupancy.

18.2.6 Travel Distance to Exits.

18.2.6.1 Travel distance shall be measured in accordance with Section 7.6.

18.2.6.2 Travel distance shall comply with 18.2.6.2.1 through 18.2.6.2.6.

18.2.6.2.1 The travel distance between any room door required as an exit access and an exit shall not exceed 46 m (150 ft).

18.2.6.2.2 Reserved.

19.2.6 Travel Distance to Exits.

19.2.6.1 Travel distance shall be measured in accordance with Section 7.6.

19.2.6.2 Travel distance shall comply with 19.2.6.2.1 through 19.2.6.2.6.

19.2.6.2.1 The travel distance between any room door required as an exit access and an exit shall not exceed 30 m (100 ft), unless otherwise permitted by 19.2.6.2.2.

19.2.6.2.2 The maximum travel distance specified in 19.2.6.2.1 shall be permitted to be increased by 15 m (50 ft)

CHAPTER 18 • New

18.2.6.2.3 The travel distance between any point in a room and an exit shall not exceed 61 m (200 ft).

18.2.6.2.4 Reserved.

18.2.6.2.5 The travel distance between any point in a health care sleeping room and an exit access door in that room shall not exceed 15 m (50 ft).

18.2.6.2.6 The travel distance between any point in a suite of sleeping rooms as permitted by 18.2.5 and an exit access door of that suite shall not exceed 30 m (100 ft) and shall meet the requirements of 18.2.6.2.3.

The travel distance limitations set by 18/19.2.6.2 can be illustrated using Exhibit 18/19.19. Travel distance is measured only to the nearest exit (point E on the exhibit), not to the second exit required by 18/19.2.4.1. The smoke barrier depicted is not an exit although travel through the cross-corridor doors in the smoke barrier will eventually lead to the second required exit.

In evaluating travel distance for sleeping rooms, the following three tests are required.

(a) *Is the travel distance within the sleeping room excessive?* Regardless of the presence of sprinklers, this distance (X to C in Exhibit 18/19.19) is limited to 15 m (50 ft) by 18/19.2.6.2.5. If a fire were to start in a patient sleeping room, the ability to leave the room

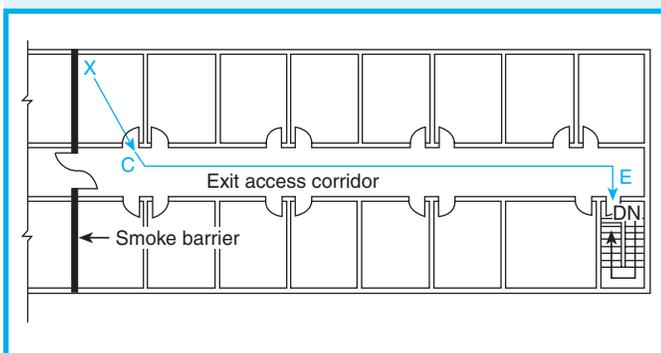

Exhibit 18/19.19 Travel distance measurement.

CHAPTER 19 • Existing

in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3.

19.2.6.2.3 The travel distance between any point in a room and an exit shall not exceed 46 m (150 ft), unless otherwise permitted by 19.2.6.2.4.

19.2.6.2.4 The maximum travel distance specified in 19.2.6.2.3 shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3.

19.2.6.2.5 The travel distance between any point in a health care sleeping room and an exit access door in that room shall not exceed 15 m (50 ft).

19.2.6.2.6 The travel distance between any point in a suite of sleeping rooms as permitted by 19.2.5 and an exit access door of that suite shall not exceed 30 m (100 ft) and shall meet the requirements of 19.2.6.2.3 and 19.2.6.2.4.

quickly would be important. Limiting the travel to 15 m (50 ft) does limit the room size. It should be possible to learn quickly of the fire within such a room and move, or be moved, to the corridor before the fire grows to such size that it would block patient and staff access to the door to the corridor. The 15-m (50-ft) travel distance restriction within a room applies only to sleeping rooms.

(b) *Is the travel distance from the room door to the nearest exit excessive?* This portion of the overall travel distance (C to E in Exhibit 18/19.19) will typically involve exit access corridor travel. For new construction and sprinklered existing buildings, such travel is limited to 46 m (150 ft) by 18.2.6.2.1 and 19.2.6.2.2. For nonsprinklered existing buildings, the distance is limited to 30 m (100 ft) by 19.2.6.2.1.

(c) *Is the overall travel distance excessive?* For new construction and sprinklered existing buildings, such travel is limited to 61 m (200 ft) by 18/19.2.6.2.3 and 19.2.6.2.4. For nonsprinklered existing buildings, the distance is limited to 46 m (150 ft) by 19.2.6.2.3. For a sleeping room, but not a sleeping suite, this consideration is relatively unimportant because compliance with paragraphs (a) and (b) will automatically allow compliance with the overall travel distance limitation. However, the limitation on overall travel distance is important for sleeping suites that avail themselves of more than 15 m (50 ft) of travel within the suite. This issue is explained further in the following paragraph.

For travel distance limitations where suites of

CHAPTER 18 • New

rooms are involved, see Exhibits 18/19.14, 18/19.16, and 18/19.17. For new construction and sprinklered existing buildings, where sleeping and nonsleeping suites avail themselves of more than 15 m (50 ft) of the permitted 30 m (100 ft) of travel within the suite, the corridor portion of travel distance might have to be limited to less than the 46 m (150 ft) permitted by 18/19.2.6.2.1 and 19.2.6.2.2 so that the total travel distance does not exceed the 61-m (200-ft) limitation established by 18/19.2.6.2.3 and 19.2.6.2.4. For nonsprinklered existing buildings, where sleeping and nonsleeping suites avail themselves of more than 15 m (50 ft) of the permitted 30 m (100 ft) of travel within the suite, the corridor portion of travel distance might have to be limited to less than the 30 m (100 ft) permitted by 19.2.6.2.1 so that the total travel distance does not exceed the 46-m (150-ft) limitation established by 19.2.6.2.3.

In evaluating travel distance for nonsleeping rooms, only two tests are required.

18.2.7 Discharge from Exits.

Discharge from exits shall be arranged in accordance with Section 7.7.

18.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

18.2.9 Emergency Lighting.

18.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9.

18.2.9.2 Buildings equipped with, or in which patients require the use of, life-support systems (*see 18.5.1.3*) shall have emergency lighting equipment supplied by the life safety branch of the electrical system as described in NFPA 99, *Standard for Health Care Facilities*.

18.2.10 Marking of Means of Egress.

18.2.10.1 Means of egress shall have signs in accordance with Section 7.10.

18.2.10.2 Illumination of required exit and directional signs in buildings equipped with, or in which patients use, life-support systems (*see 18.5.1.3*) shall be provided as follows:

CHAPTER 19 • Existing

(a) *Is the travel distance from the room door to the nearest exit excessive?* This portion of the overall travel distance (C to E in Exhibit 18/19.19) will typically involve exit access corridor travel. For new construction and sprinklered existing buildings, such travel is limited to 46 m (150 ft) by 18/19.2.6.2.1 and 19.2.6.2.2. For nonsprinklered existing buildings, it is limited to 30 m (100 ft) by 19.2.6.2.1.

(b) *Is the overall travel distance excessive?* For new construction and sprinklered existing buildings, such travel is limited to 61 m (200 ft) by 18/19.2.6.2.3 and 19.2.6.2.4. For nonsprinklered existing buildings, it is limited to 46 m (150 ft) by 19.2.6.2.3. Thus, if the corridor travel addressed in paragraph (a) is not utilized to its maximum, the travel within the nonsleeping room itself might be more than the 15-m (50-ft) limit imposed on sleeping rooms.

19.2.7 Discharge from Exits.

Discharge from exits shall be arranged in accordance with Section 7.7.

19.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

19.2.9 Emergency Lighting.

19.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9.

19.2.10 Marking of Means of Egress.

19.2.10.1 Means of egress shall have signs in accordance with Section 7.10, unless otherwise permitted by 19.2.10.2.

19.2.10.2 Where the path of egress travel is obvious, signs shall not be required in one-story buildings with an occupant load of fewer than 30 persons.

CHAPTER 18 • New

- (1) Illumination shall be supplied by the life safety branch of the electrical system as described in NFPA 99, *Standard for Health Care Facilities*.
- (2) Self-luminous exit signs complying with 7.10.4 shall be permitted.

Each new health care facility equipped with or requiring the use of life-support systems is required to have the marking of the means of egress and emergency lighting supplied by the life safety branch of the electrical systems described in NFPA 99, *Standard for Health Care Facilities*⁶.

A facility would not be required to have an emergency generator if the building is a freestanding unit in which, as a normal practice, all the following apply:

- (1) Management maintains admitting and discharge policies that preclude the provision of care for any patient or resident who might need to be sustained by electrical life-support equipment, such as respirators or suction apparatus.
- (2) No surgical treatment requiring general anesthesia is offered.
- (3) Battery-operated systems or equipment are provided to maintain power to exit lights and illumination of egress corridors, stairways, medical preparation areas, and the like, for a minimum of 1½ hours.

18.2.11 Special Means of Egress Features.

(Reserved)

Section 18.3 Protection

18.3.1 Protection of Vertical Openings.

Any vertical opening shall be enclosed or protected in accordance with Section 8.6, unless otherwise modified by 18.3.1.1 through 18.3.1.8.

18.3.1.1 Reserved.

18.3.1.2 Unprotected vertical openings in accordance with 8.6.8.2 shall be permitted.

18.3.1.3 Subparagraph 8.6.7(1)(b) shall not apply to patient sleeping and treatment rooms.

18.3.1.4 Multilevel patient sleeping areas in psychiatric facilities shall be permitted without enclosure protection

CHAPTER 19 • Existing

Additionally, battery power would be required to be supplied to all alarm systems. For additional information, refer to NFPA 99, *Standard for Health Care Facilities*.

NFPA 99 requires that emergency power supplies be arranged and protected to minimize the possibility of a single incident affecting both normal and emergency power supplies simultaneously. Circuits are to be run separately. Emergency and normal circuits are “joined” at the transfer switch, so damage to the transfer switch would interrupt normal and emergency power supplies simultaneously. The transfer switch is therefore a critical item and should be separated from any potential source of fire, including the emergency generator and attendant fuel supply.

NFPA 99, *Standard for Health Care Facilities*, specifies that emergency generators must be inspected at least weekly and exercised under load for a minimum of 30 minutes each month. See also 9.1.3.

19.2.11 Special Means of Egress Features.

(Reserved)

Section 19.3 Protection

19.3.1 Protection of Vertical Openings.

Any vertical opening shall be enclosed or protected in accordance with Section 8.6, unless otherwise modified by 19.3.1.1 through 19.3.1.8.

19.3.1.1 Where enclosure is provided, the construction shall have not less than a 1-hour fire resistance rating.

19.3.1.2 Unprotected vertical openings in accordance with 8.6.8.2 shall be permitted.

19.3.1.3 Subparagraph 8.6.7(1)(b) shall not apply to patient sleeping and treatment rooms.

19.3.1.4 Multilevel patient sleeping areas in psychiatric facilities shall be permitted without enclosure protection

CHAPTER 18 • New

between levels, provided that all of the following conditions are met:

- (1) The entire normally occupied area, including all communicating floor levels, is sufficiently open and unobstructed so that a fire or other dangerous condition in any part is obvious to the occupants or supervisory personnel in the area.
- (2) The egress capacity provides simultaneously for all the occupants of all communicating levels and areas, with all communicating levels in the same fire area being considered as a single floor area for purposes of determination of required egress capacity.
- (3) The height between the highest and lowest finished floor levels does not exceed 3960 mm (156 in.), and the number of levels is permitted to be unrestricted.

18.3.1.5 Unprotected openings in accordance with 8.6.6 shall not be permitted.

18.3.1.6 Reserved.

18.3.1.7 A door in a stair enclosure shall be self-closing and shall normally be kept in the closed position, unless otherwise permitted by 18.3.1.8.

18.3.1.8 Doors in stair enclosures shall be permitted to be held open under the conditions specified by 18.2.2.2.6 and 18.2.2.2.7.

Paragraph 18/19.3.1 specifies protection levels required to maintain floor-to-floor separation in health care facilities. For new construction, 18.3.1 references Section 8.6, which requires 2-hour enclosures around vertical openings connecting more than three stories in buildings. One-hour enclosure of vertical openings is required in all other new health care occupancies. For existing health care occupancies, 19.3.1.1 requires 1-hour enclosure of vertical openings. Note that this requirement is more than the ½ hour required by 8.6.5(3) for existing enclosures of vertical openings. Health care occupancies employ a defend-in-place strategy that recognizes the difficulty in evacuating patients to the outside. Thus, the ½ hour typically permitted for existing enclosures in existing buildings is not applicable to existing health care occupancies.

Although stairs, if not properly enclosed, create vertical openings, they are often enclosed to qualify as an exit. For existing exit stair enclosures, both the

CHAPTER 19 • Existing

between levels, provided that all of the following conditions are met:

- (1) The entire normally occupied area, including all communicating floor levels, is sufficiently open and unobstructed so that a fire or other dangerous condition in any part is obvious to the occupants or supervisory personnel in the area.
- (2) The egress capacity provides simultaneously for all the occupants of all communicating levels and areas, with all communicating levels in the same fire area being considered as a single floor area for purposes of determination of required egress capacity.
- (3) The height between the highest and lowest finished floor levels does not exceed 3960 mm (156 in.) and the number of levels is permitted to be unrestricted.

19.3.1.5 Unprotected openings in accordance with 8.6.6 shall not be permitted.

19.3.1.6 Where a full enclosure of a stairway that is not a required exit is impracticable, the required enclosure shall be permitted to be limited to that necessary to prevent a fire originating in any story from spreading to any other story.

19.3.1.7 A door in a stair enclosure shall be self-closing and shall normally be kept in the closed position, unless otherwise permitted by 19.3.1.8.

19.3.1.8 Doors in stair enclosures shall be permitted to be held open under the conditions specified by 19.2.2.2.6 and 19.2.2.2.7.

requirements of 7.1.3.2 applicable to exit enclosure and the requirements of 19.3.1 applicable to vertical opening protection must be met. For exit stair enclosures connecting more than three stories, the enclosure requirements of 7.1.3.2 are stricter than those of 19.3.1. Therefore, a four-story exit stair enclosure would require 2-hour fire resistance-rated enclosure instead of the 1-hour enclosure required for existing vertical openings in health care occupancies.

If a stairway is within the exit access or not used for egress, and full enclosure is not possible, the enclosure is permitted to be limited to that necessary to prevent fire or smoke originating in any one story from spreading to another story. For example, in a two-story building, the stair might be enclosed at the first floor level and left open at the second floor level.

Paragraph 18/19.3.1.2 references the convenience opening described in 8.6.8.2 and illustrated in Exhibit 18/19.20. This exemption applies to any nonconcealed

vertical opening, not only to a convenience stair. This exemption would allow a light well to connect two stories or allow a stair to connect two levels of a medical library, a file storage area, or an administrative office, for example. The exemption would not allow omission

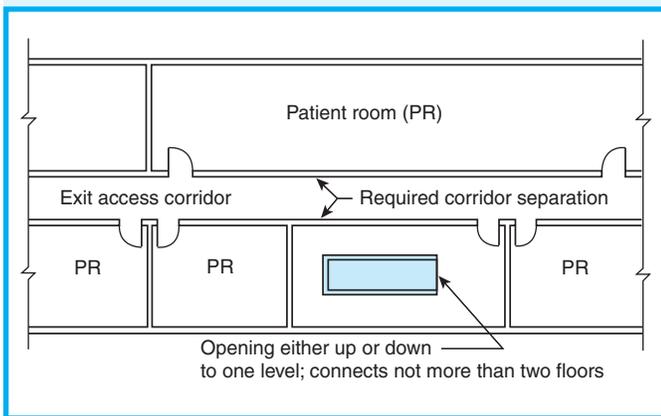

Exhibit 18/19.20 Permitted convenience opening.

of firestopping around pipe penetrations of a floor slab or omission of protection for duct penetrations.

Paragraph 18/19.3.1.3 modifies the atrium provisions of 8.6.7(1)(b) for applicability to health care occupancies. Patient sleeping and treatment rooms must be separated from the atrium by partitions complying with 8.6.7(1) or 8.6.7(1)(c)—either 1-hour-rated walls or glass protected by closely spaced sprinklers.

Paragraph 18/19.3.1.4 recognizes the vertical openings inherent in multilevel patient sleeping areas similar to those described for detention and correctional occupancies in 22.4.4.6 and 23.3.1.2.

Paragraph 18/19.3.1.7 requires fire doors protecting openings in stairway enclosures to be self-closing and normally maintained in a closed position. However, 18/19.3.1.8 permits stairway doors meeting specified conditions to be held open by an automatic-closing device. If stair enclosure doors are normally maintained in a closed position, they should be provided with a sign that states in large letters, “Fire Exit—Keep Door Closed.”

18.3.2 Protection from Hazards.

18.3.2.1* Hazardous Areas. Any hazardous areas shall be protected in accordance with Section 8.7, and the areas described in Table 18.3.2.1 shall be protected as indicated.

Table 18.3.2.1 Hazardous Area Protection

Hazardous Area Description	Separation/Protection
Boiler and fuel-fired heater rooms	1 hour
Central/bulk laundries larger than 9.3 m ² (100 ft ²)	1 hour
Laboratories employing flammable or combustible materials in quantities less than those that would be considered a severe hazard	See 18.3.6.3.9
Laboratories that use hazardous materials that would be classified as a severe hazard in accordance with NFPA 99, <i>Standard for Health Care Facilities</i>	1 hour
Paint shops employing hazardous substances and materials in quantities less than those that would be classified as a severe hazard	1 hour
Physical plant maintenance shops	1 hour
Soiled linen rooms	1 hour
Storage rooms larger than 4.6 m ² (50 ft ²) but not exceeding 9.3 m ² (100 ft ²) and storing combustible material	See 18.3.6.3.9
Storage rooms larger than 9.3 m ² (100 ft ²) and storing combustible material	1 hour
Trash collection rooms	1 hour

19.3.2 Protection from Hazards.

19.3.2.1 Hazardous Areas. Any hazardous areas shall be safeguarded by a fire barrier having a 1-hour fire resistance rating or shall be provided with an automatic extinguishing system in accordance with 8.7.1.

CHAPTER 18 • New

CHAPTER 19 • Existing

A.18.3.2.1 Provisions for the enclosure of rooms used for charging linen chutes and waste chutes or for rooms into which these chutes empty are provided in Section 9.5.

18.3.2.2* Laboratories. Laboratories employing quantities of flammable, combustible, or hazardous materials that are considered as a severe hazard shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

A.18.3.2.2 The hazard level of a laboratory is considered severe if quantities of flammable, combustible, or hazardous materials are present that are capable of sustaining a fire of sufficient magnitude to breach a 1-hour fire separation. See the NFPA *Fire Protection Handbook* for guidance.

18.3.2.3 Anesthetizing Locations. Anesthetizing locations shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

18.3.2.4 Medical Gas. Medical gas storage and administration areas shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

19.3.2.1.1 An automatic extinguishing system, where used in hazardous areas, shall be permitted to be in accordance with 19.3.5.5.

19.3.2.1.2 Where the sprinkler option of 19.3.2.1 is used, the areas shall be separated from other spaces by smoke-resisting partitions and doors.

19.3.2.1.3 The doors shall be self-closing or automatic-closing.

19.3.2.1.4 Doors in rated enclosures shall be permitted to have nonrated, factory- or field-applied protective plates extending not more than 1220 mm (48 in.) above the bottom of the door.

19.3.2.1.5 Hazardous areas shall include, but shall not be restricted to, the following:

- (1) Boiler and fuel-fired heater rooms
- (2) Central/bulk laundries larger than 9.3 m² (100 ft²)
- (3) Paint shops
- (4) Repair shops
- (5) Soiled linen rooms
- (6) Trash collection rooms
- (7) Rooms or spaces larger than 4.6 m² (50 ft²), including repair shops, used for storage of combustible supplies and equipment in quantities deemed hazardous by the authority having jurisdiction
- (8) Laboratories employing flammable or combustible materials in quantities less than those that would be considered a severe hazard

19.3.2.2* Laboratories. Laboratories employing quantities of flammable, combustible, or hazardous materials that are considered as a severe hazard shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

A.19.3.2.2 The hazard level of a laboratory is considered severe if quantities of flammable, combustible, or hazardous materials are present that are capable of sustaining a fire of sufficient magnitude to breach a 1-hour fire separation. See NFPA *Fire Protection Handbook* for guidance.

19.3.2.3 Anesthetizing Locations. Anesthetizing locations shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

19.3.2.4 Medical Gas. Medical gas storage and administration areas shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

CHAPTER 18 • New

18.3.2.5 Cooking Facilities.

18.3.2.5.1 Cooking facilities shall be protected in accordance with 9.2.3, unless otherwise permitted by 18.3.2.5.2.

18.3.2.5.2* Where domestic cooking equipment is used for food-warming or limited cooking, protection or separation of food preparation facilities shall not be required.

A.18.3.2.5.2 This exception is intended to permit small appliances used for reheating, such as microwave ovens, hot plates, toasters, and nourishment centers to be exempt from the requirements for commercial cooking equipment.

18.3.2.6 Heliports. Buildings that house health care occupancies, as indicated in 18.1.1.1.2, and have rooftop heliports shall be protected in accordance with NFPA 418, *Standard for Heliports*.

Hazardous areas are spaces containing materials that, due to their basic nature (as in the case of flammable liquids) or because of the quantity of combustible materials involved, represent a significantly higher hazard than would otherwise be typical in the general areas of health care facilities.

A list of typically hazardous areas is included in Table 18.3.2.1 and in 19.3.2.1.5. The lists are meant to be representative, not inclusive. The general reference in 18/19.3.2.1 to Section 8.7 provides the authority having jurisdiction with the opportunity to regulate any space judged to represent a significantly higher hazard than most spaces.

Chapter 18 requires automatic sprinkler protection throughout all new health care facilities. Therefore, all hazardous spaces in new construction must be sprinklered. Where a hazardous area is judged to represent a severe exposure, such as in the case of boiler rooms, laundries, paint shops, and soiled linen rooms, 1-hour fire resistance-rated separation is also necessary. Hazardous areas that are not judged to be severe also require a separation, but the separation is permitted to use a non-fire-rated smoke partition in accordance with Section 8.4 (see 8.7.1.2). Doors protecting openings in such partitions must be tight-fitting and equipped with a closing device (see 18.3.6.3.9 and 8.4.3.5). Door openings in 1-hour fire resistance-rated barriers must be protected with ¾-hour fire protection-rated door assemblies.

In existing health care occupancies, hazardous areas must be separated from other areas by barriers having a 1-hour fire resistance rating, complete with

CHAPTER 19 • Existing

19.3.2.5 Cooking Facilities.

19.3.2.5.1 Cooking facilities shall be protected in accordance with 9.2.3, unless otherwise permitted by 19.3.2.5.2.

19.3.2.5.2* Where domestic cooking equipment is used for food-warming or limited cooking, protection or separation of food preparation facilities shall not be required.

A.19.3.2.5.2 This provision is intended to permit small appliances used for reheating, such as microwave ovens, hot plates, toasters, and nourishment centers, to be exempt from the requirements for commercial cooking equipment.

approved fire doors protecting door openings; otherwise, automatic sprinkler protection must be installed. If automatic sprinkler protection is provided, the hazardous area must still be separated from the rest of the building by nonrated barriers designed to resist the passage of smoke. See 19.3.2.1.2.

Provisions for the enclosure of rooms used for charging linen and waste chutes or for the rooms into which these chutes empty are provided in Section 9.5. In addition to the fire-resistant construction requirements for these rooms, automatic sprinkler protection is considered essential.

If flammable liquids are handled or stored, NFPA 30, *Flammable and Combustible Liquids Code*⁷ must be consulted to establish the minimum criteria necessary to mitigate this hazard. Provisions for the use and storage of flammable gases and oxygen are covered in NFPA 99, *Standard for Health Care Facilities*.

Paragraph 19.3.2.1.4 recognizes the benefit of protective plates for the protection of doors that are frequently assaulted with carts and other wheeled vehicles. Without the exemption, the minimum 45-minute fire protection-rated doors to hazardous area rooms would be subject to the requirements of 8.3.3, which—via a mandatory reference to NFPA 80, *Standard for Fire Doors and Fire Windows*⁸—would not permit the field application of protective plates to fire-rated doors. The field application of protective plates must be accomplished without reducing the fire performance of the door—such as might result if the door is drilled through its entire thickness for the installation of through-bolts.

CHAPTER 18 • New

Laboratories are addressed in 18/19.3.2.2. Laboratories that contain ordinary combustibles and flammable liquids in sufficient quantity to threaten a 1-hour fire separation [for example, wood-equivalent fuel loads in the range of 25 to 50 kg/m² (5 to 10 lb/ft²)] are considered a severe hazard. Laboratories posing a severe hazard must be protected in accordance with NFPA 99, *Standard for Health Care Facilities*. Protection would include 1-hour fire resistance-rated separation and automatic sprinkler protection.

If fuel loads of lesser amounts are involved and quantities of flammable liquids are limited, laboratories would simply be considered hazardous areas and would be adequately protected by the automatic sprinklers required in all new health care occupan-

18.3.3 Interior Finish.

18.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

18.3.3.2* Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be permitted throughout if Class A except as indicated in 18.3.3.2.1 or 18.3.3.2.2.

A.18.3.3.2 The reductions in class of interior finish prescribed by 10.2.8.1 are permitted to be used.

18.3.3.2.1 Walls and ceilings shall be permitted to have Class A or Class B interior finish in individual rooms having a capacity not exceeding four persons.

18.3.3.2.2 Corridor wall finish not exceeding 1220 mm (48 in.) in height that is restricted to the lower half of the wall shall be permitted to be Class A or Class B.

18.3.3.3 Interior Floor Finish. (No requirements.)

New interior finishes on walls and ceilings are limited to Class A materials, with the exception of small rooms (see 18.3.3.2.1) and the lower portion of corridor walls (see 18.3.3.2.2). However, if the new interior wall and ceiling finish material is installed in a sprinklered smoke compartment (all new health care occupancies are required to be sprinklered by 18.3.5.1), the Class A requirement can be relaxed to Class B per the provisions of 10.2.8.1. Existing interior finish

CHAPTER 19 • Existing

materials are permitted to be Class A or Class B without requiring sprinkler protection.

ciens. In existing health care occupancies, either 1-hour separation or automatic sprinkler protection would be required.

Commercial cooking equipment is addressed in 18/19.3.2.5. It must be installed and protected in accordance with NFPA 96, *Standard for Ventilation Control and Fire Protection of Commercial Cooking Operations*.⁹ A regularly serviced, fixed, automatic fire-extinguishing system would be required for the protection of cooking surfaces and exhaust and duct systems where cooking operations involve the potential for grease-laden vapors. Paragraph 18/19.3.2.5.2 exempts domestic cooking equipment used for food-warming or limited cooking from the specialized extinguishment requirements of NFPA 96 and the separation requirements of 18/19.3.2.1.

19.3.3 Interior Finish.

19.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

19.3.3.2* Interior Wall and Ceiling Finish. Existing interior wall and ceiling finish materials complying with Section 10.2 shall be permitted to be Class A or Class B.

A.19.3.3.2 The reduction in class of interior or finish prescribed by 10.2.8.1 is permitted to be used.

19.3.3.3 Interior Floor Finish. No restrictions shall apply to existing interior floor finish.

materials are permitted to be Class A or Class B without requiring sprinkler protection.

Paragraph 18.3.3.2.1 permits Class B interior wall and ceiling finish materials in rooms with a capacity of four or fewer persons, but again the presence of automatic sprinklers would relax this requirement to permit Class C materials. Paragraph 18.3.3.2.2 allows wall finish in corridors to be of Class B materials where located 1220 mm (48 in.) or less above the floor,

CHAPTER 18 • New

but again the presence of automatic sprinklers would relax this requirement to permit Class C materials. This provision recognizes fire research that has shown the finish on the lower half of the wall to be far less significant in its influence on early fire growth than the finish on the upper half.¹⁰ In the case of textile materials on walls or ceilings, 10.2.4.1 would take precedence and require automatic sprinkler protection in conjunction with Class A materials, or such wall and ceiling materials must be proven safe by specialized fire testing.

Existing interior finishes on walls and ceilings are limited solely on the basis of flame spread. Paragraph 10.2.3.4.1 exempts existing interior finishes from the limitations based on smoke development.

18.3.4 Detection, Alarm, and Communications Systems.

18.3.4.1 General. Health care occupancies shall be provided with a fire alarm system in accordance with Section 9.6.

18.3.4.2* Initiation.

A.18.3.4.2 It is not the intent of this *Code* to require single-station smoke detectors that might be required by local codes to be connected to or to initiate the building fire alarm system.

18.3.4.2.1 Initiation of the required fire alarm systems shall be by manual means in accordance with 9.6.2 and by means of any required sprinkler system waterflow alarms, detection devices, or detection systems, unless otherwise permitted by 18.3.4.2.2.

18.3.4.2.2 Manual fire alarm boxes in patient sleeping areas shall not be required at exits if located at all nurses' control stations or other continuously attended staff location, provided that both of the following criteria are met:

- (1) Such manual fire alarm boxes are visible and continuously accessible.
- (2) Travel distances required by 9.6.2.4 are not exceeded

CHAPTER 19 • Existing

Paragraph 10.2.6.1 makes provision for application of approved, fire-retardant coatings to existing interior finish materials for the purpose of reducing the flame spread characteristics to an acceptable level. The commentary following 10.2.6 offers additional guidance.

It has been shown that floor coverings will not spread a fire until the fire approaches flashover (see A.10.2.7.3 and associated commentary). Automatic sprinklers will activate well in advance of any significant involvement of a floor covering. On the basis of requiring all new health care occupancies to be sprinklered, Chapter 18 does not limit new interior floor finish. Existing floor finish materials are permitted to continue to be used.

19.3.4 Detection, Alarm, and Communications Systems.

19.3.4.1 General. Health care occupancies shall be provided with a fire alarm system in accordance with Section 9.6.

19.3.4.2* Initiation.

A.19.3.4.2 It is not the intent of this *Code* to require single-station smoke detectors, which might be required by local codes, to be connected to or to initiate the building fire alarm system.

19.3.4.2.1 Initiation of the required fire alarm systems shall be by manual means in accordance with 9.6.2 and by means of any required sprinkler system waterflow alarms, detection devices, or detection systems, unless otherwise permitted by 19.3.4.2.2 through 19.3.4.2.4.

19.3.4.2.2 Manual fire alarm boxes in patient sleeping areas shall not be required at exits if located at all nurses' control stations or other continuously attended staff location, provided that both of the following criteria are met:

- (1) Such manual fire alarm boxes are visible and continuously accessible.
- (2) Travel distances required by 9.6.2.4 are not exceeded.

19.3.4.2.3 Fixed extinguishing systems protecting commercial cooking equipment in kitchens that are protected by a complete automatic sprinkler system shall not be required to initiate the fire alarm system.

19.3.4.2.4 Detectors required by 19.7.5.3 and 19.7.5.5 shall not be required to initiate the fire alarm system.

CHAPTER 18 • New

18.3.4.3 Notification.

18.3.4.3.1 Occupant Notification. Occupant notification shall be accomplished automatically in accordance with 9.6.3, unless otherwise modified by the following:

- (1) Paragraph 9.6.3.2.3 shall not be permitted to be used.
- (2)* In lieu of audible alarm signals, visible alarm-indicating appliances shall be permitted to be used in critical care areas.

A.18.3.4.3.1(2) It is the intent of this provision to permit a visible fire alarm signal instead of an audible signal to reduce interference between the fire alarm and medical equipment monitoring alarms.

18.3.4.3.2 Emergency Forces Notification.

18.3.4.3.2.1 Fire department notification shall be accomplished in accordance with 9.6.4.

18.3.4.3.2.2 Smoke detection devices, or smoke detection systems, equipped with reconfirmation features shall not be required to automatically notify the fire department unless the alarm condition is reconfirmed after a period not exceeding 120 seconds.

18.3.4.3.3 Alarm Annunciation.

18.3.4.3.3.1 Alarm annunciation shall be provided in accordance with 9.6.7, unless otherwise permitted by 18.3.4.3.3.2.

18.3.4.3.3.2 The alarm zone shall be permitted to coincide with the permitted area for smoke compartments.

18.3.4.4 Emergency Control. Operation of any activating device in the required fire alarm system shall be arranged to accomplish automatically any control functions to be performed by that device. (See 9.6.5.)

18.3.4.5 Detection.

18.3.4.5.1 Detection systems, where required, shall be in accordance with Section 9.6.

CHAPTER 19 • Existing

19.3.4.3 Notification.

19.3.4.3.1 Occupant Notification. Occupant notification shall be accomplished automatically in accordance with 9.6.3, unless otherwise modified by the following:

- (1)* In lieu of audible alarm signals, visible alarm-indicating appliances shall be permitted to be used in critical care areas.

A.19.3.4.3.1(1) It is the intent of this provision to permit a visible fire alarm signal instead of an audible signal to reduce interference between the fire alarm and medical equipment monitoring alarms.

- (2) Where visual devices have been installed in patient sleeping areas in place of an audible alarm, they shall be permitted where approved by the authority having jurisdiction.

19.3.4.3.2 Emergency Forces Notification.

19.3.4.3.2.1 Fire department notification shall be accomplished in accordance with 9.6.4.

19.3.4.3.2.2 Smoke detection devices or smoke detection systems equipped with reconfirmation features shall not be required to automatically notify the fire department unless the alarm condition is reconfirmed after a period not exceeding 120 seconds.

19.3.4.4 Emergency Control. Operation of any activating device in the required fire alarm system shall be arranged to accomplish automatically any control functions to be performed by that device. (See 9.6.5.)

19.3.4.5 Detection.

19.3.4.5.1 Corridors. An approved automatic smoke detection system in accordance with Section 9.6 shall be installed in all corridors of limited care facilities, unless otherwise permitted by the following:

- (1) Where each patient sleeping room is protected by an approved smoke detection system, and a smoke detector is provided at smoke barriers and horizontal exits in accordance with Section 9.6, the corridor smoke detection system shall not be required on the patient sleeping room floors.

CHAPTER 18 • New

18.3.4.5.2 Detection in Spaces Open to Corridors. See 18.3.6.1.

18.3.4.5.3* Nursing Homes. An approved automatic smoke detection system shall be installed in corridors throughout smoke compartments containing patient sleeping rooms and in spaces open to corridors as permitted in nursing homes by 18.3.6.1, unless otherwise permitted by the following:

- (1) Corridor systems shall not be required where each patient sleeping room is protected by an approved smoke detection system.
- (2) Corridor systems shall not be required where patient room doors are equipped with automatic door-closing devices with integral smoke detectors on the room side installed in accordance with their listing, provided that the integral detectors provide occupant notification.

A.18.3.4.5.3 The requirement for smoke detectors in spaces open to the corridors eliminates the requirements of 18.3.6.1(1)(c), 18.3.6.1(2)(b), and 18.3.6.1(5)(b) for direct supervision by the facility staff of nursing homes.

Paragraph 19.3.4.2.4 addresses smoke detectors installed for a special purpose—to provide an exemption to paragraphs 19.7.5.3 and 19.7.5.5, which require that newly introduced upholstered furniture and mattresses be resistant to cigarette ignition and have limited rates of heat release. Paragraph 19.3.4.2.4 exempts such smoke detectors from having to initiate the building alarm system.

Paragraph 18.3.4.3.1(1) specifically prohibits new health care occupancies from using 9.6.3.2.3, which exempts detectors at doors for the exclusive operation of automatic door release from the requirements for occupant notification. Note that the use of 9.6.3.2.1 and 9.6.3.2.2, which exempt detectors used for recalling elevators or closing dampers from initiating occupant notification, respectively, is not prohibited. Although such detectors must be arranged to initiate the alarm system in accordance with 18.3.4.2.1, subsequent occupant notification is not required.

Emergency forces notification is addressed in 18/19.3.4.3.2. An independent study by the National Bureau of Standards (currently the National Institute of Standards and Technology) indicates a high rate of

CHAPTER 19 • Existing

- (2) Smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3 shall be permitted.

19.3.4.5.2 Detection in Spaces Open to Corridors. See 19.3.6.1.

nuisance alarms for smoke detectors installed in health care facilities.¹¹ The study determined that 4.4 nuisance alarms occurred per 100 smoke detectors per year. Further, approximately 14 nuisance alarms occurred for every actual alarm. Because of the high incidence of nuisance alarms, 18/19.3.4.3.2.2 permits delaying fire department notification for up to 120 seconds where smoke detectors or smoke detection systems are equipped with a reconfirmation feature. However, staff notification, as required by 18/19.3.4.3.1, cannot be delayed.

Paragraphs 18/19.3.4.1 through 18/19.3.4.5 address required fire alarm equipment. Reliability is of primary importance; therefore, electrical supervision of the system and system components is specified by reference to Section 9.6. In the event of circuit fault, component failure, or other trouble, continuous trouble indication is required and should be provided at a constantly attended location.

A manual fire alarm system is required by 18/19.3.4.1 and 18/19.3.4.2. Manual fire alarm boxes are normally located along the natural routes of egress and are also located to cover all portions of the build-

ing. Paragraph 18/19.3.4.2.2 allows manual fire alarm boxes, under certain conditions, to be located only at continuously attended staff positions in sleeping areas. This arrangement provides the opportunity for prompt notification of fire without requiring staff to leave their normal work stations. In new installations, it would normally be desirable to have manual fire alarm boxes at all attended staff locations and at entrances to exits, because the additional cost of the extra fire alarm boxes would be minimal. However, the exemptions recognize that the fire alarm boxes located near the exits might lead to nuisance alarms if patients misuse them.

Manual fire alarm boxes should be located so that those qualified to send an alarm can summon aid without having to leave their zone of ordinary activity or pass out of the sight and hearing of people immediately exposed to, or in direct view of, a fire. The operation of a manual fire alarm box should automatically summon attendants who can assist in removing physically helpless occupants and controlling mentally disabled occupants.

The alarm system initiation required by 18/19.3.4.2 is permitted to be incorporated into an automatic system equipped to detect a fire and initiate an alarm.

The alarm must automatically transmit to a point outside the facility. Where automatic transmission of the alarm to the fire department legally committed to serve the facility is not permitted, arrangements are to be made for the prompt notification of the fire department or such other assistance as may be available in the case of fire or other emergency. Paragraph 9.6.4.2 lists various methods acceptable for au-

tomatically notifying the fire department. The fire department should also be called manually to verify and confirm the automatic transmission of the alarm. In larger facilities, this might be the responsibility of the facility telephone operator; in smaller facilities, it might be the responsibility of the nursing staff.

Actuation of the fire alarm must initiate the operation of alerting devices throughout the affected zone or building, as appropriate. See 9.6.3.6.2 and 9.6.3.6.3, which address occupant notification by zone. Visible alerting devices are permitted to substitute for audible devices in critical care areas. See A.18.3.4.3.1(2) and A.19.3.4.3.1(1).

Although 18/19.3.4.3.1 requires occupant notification, coded messages are permitted to be used to notify staff and trained responders. As part of their emergency duties, staff will then keep patients and visitors informed of expected actions.

Paragraph 19.3.4.5.1 requires smoke detectors in the corridors of existing limited care facilities. Staffing levels in hospitals and nursing homes reasonably ensure discovery of a fire at an early stage. In existing hospitals and nursing homes, it is considered reasonable to rely on staff to sound the alert.

Paragraph 18.3.4.5.3 requires corridor smoke detection systems in new nursing homes. The justification provided during the *Code* revision process that produced this requirement stated that corridor smoke detectors are needed for redundancy; for some fire scenarios, the corridor detector might be the first device to provide notification of fire; and the cost of installing a corridor smoke detection system as part of new construction is minor.

18.3.5 Extinguishment Requirements.

18.3.5.1* Buildings containing health care occupancies shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, unless otherwise permitted by 18.3.5.3.

A.18.3.5.1 In areas where the replenishment of water supplies is not immediately available from on-site sources, alternate provisions for the water-fill rate requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 22, *Standard for Water Tanks for Private Fire Protection*, that are acceptable to the authority having jurisdiction should be provided. Appropriate means for the replenishment of these supplies from other sources, such as fire

19.3.5 Extinguishment Requirements.

19.3.5.1 Where required by 19.1.6, health care facilities shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, unless otherwise permitted by 19.3.5.3.

CHAPTER 18 • New

department tankers, public safety organizations, or other independent contractors should be incorporated into the overall fire safety plan of the facility.

With automatic sprinkler protection required throughout new health care facilities and quick-response sprinklers required in smoke compartments containing patient sleeping rooms, a fire and its life-threatening byproducts can be reduced, thereby allowing the defend-in-place concept to continue. The difficulty in maintaining the proper integrity of life safety elements has been considered and it has been judged that the probability of a sprinkler system operating as designed is equal to or greater than other life safety features.

18.3.5.2 The sprinkler system required by 18.3.5.1 shall be installed in accordance with 9.7.1.1(1).

18.3.5.3 In Type I and Type II construction, alternative protection measures shall be permitted to be substituted for sprinkler protection, without causing a building to be classified as nonsprinklered, in specified areas where the authority having jurisdiction has prohibited sprinklers.

18.3.5.4* Listed quick-response or listed residential sprinklers shall be used throughout smoke compartments containing patient sleeping rooms.

CHAPTER 19 • Existing

19.3.5.2 In Type I and Type II construction, alternative protection measures shall be permitted to be substituted for sprinkler protection, without causing a building to be classified as nonsprinklered, in specified areas where the authority having jurisdiction has prohibited sprinklers.

19.3.5.3* Where this *Code* permits exceptions for fully sprinklered buildings or smoke compartments, the sprinkler system shall meet the following criteria:

- (1) It shall be in accordance with Section 9.7.
- (2) It shall be installed in accordance with 9.7.1.1(1) unless it is an approved existing system.
- (3) It shall be electrically connected to the fire alarm system.
- (4) It shall be fully supervised.
- (5) In Type I and Type II construction, where the authority having jurisdiction has prohibited sprinklers, approved alternative protection measures shall be permitted to be substituted for sprinkler protection in specified areas without causing a building to be classified as nonsprinklered.

A.19.3.5.3 It is intended that any valve that controls automatic sprinklers in the entire building or portions of the building, including sectional and floor control valves, be electrically supervised. Valves that control isolated sprinkler heads, such as in laundry and trash chutes, are not required to be electrically supervised. Appropriate means should be taken to ensure that valves that are not electrically supervised remain open.

19.3.5.4* Where this *Code* permits exceptions for fully sprinklered buildings or smoke compartments and specifically references this paragraph, the sprinkler system shall meet the following criteria:

- (1) It shall be installed throughout the building in accordance with Section 9.7.
- (2) It shall be installed in accordance with 9.7.1.1(1) unless it is an approved existing system.
- (3) It shall be electrically connected to the fire alarm system.

CHAPTER 18 • New

A.18.3.5.4 The requirements for use of quick-response sprinklers intend that quick-response sprinklers be the predominant type of sprinkler installed in the smoke compartment. It is recognized, however, that quick-response sprinklers might not be approved for installation in all areas such as those where NFPA 13, *Standard for the Installation of Sprinkler Systems*, requires sprinklers of the intermediate- or high-temperature classification. It is not the intent of the 18.3.5.5 requirements to prohibit the use of standard sprinklers in limited areas of a smoke compartment where intermediate- or high-temperature sprinklers are required.

Where the installation of quick-response sprinklers is impracticable in patient sleeping room areas, appropriate equivalent protection features acceptable to the authority having jurisdiction should be provided. It is recognized that the use of quick-response sprinklers might be limited in facilities housing certain types of patients or by the installation limitations of quick-response sprinklers.

18.3.5.5 Reserved.

18.3.5.6* Sprinklers in areas where cubicle curtains are installed shall be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

A.18.3.5.6 For the proper operation of sprinkler systems, cubicle curtains and sprinkler locations need to be coordinated. Improperly designed systems might obstruct the sprinkler spray from reaching the fire or might shield the heat from the sprinkler. Many options are available to the designer including, but not limited to, hanging the cubicle curtains 46 cm (18 in.) below the sprinkler deflector; using a 1.3-cm (½-in.) diagonal mesh or a 70 percent open weave top panel that extends 46 cm (18 in.) below the sprinkler

CHAPTER 19 • Existing

- (4) It shall be fully supervised.
- (5) It shall be equipped with listed quick-response or listed residential sprinklers throughout all smoke compartments containing patient sleeping rooms.
- (6) Standard response sprinklers shall be permitted to be continued to be used in approved existing sprinkler systems where quick-response and residential sprinklers were not listed for use in such locations at the time of installation.
- (7) Standard response sprinklers shall be permitted for use in hazardous areas protected in accordance with 19.3.2.1.

A.19.3.5.4 The provisions of 19.3.5.4(6) and 19.3.5.4(7) are not intended to supplant NFPA 13, *Standard for the Installation of Sprinkler Systems*, which requires that residential sprinklers with more than a 5.6°C (10°F) difference in temperature rating not be mixed within a room. Currently there are no additional prohibitions in NFPA 13 on the mixing of sprinklers having different thermal response characteristics. Conversely, there are no design parameters to make practical the mixing of residential and other types of sprinklers.

19.3.5.5 Isolated hazardous areas shall be permitted to be protected in accordance with 9.7.1.2. For new installations in existing health care occupancies, where more than two sprinklers are installed in a single area, waterflow detection shall be provided to sound the building fire alarm, or to notify by a signal any constantly attended location, such as PBX, security, or emergency room, at which the necessary corrective action shall be taken.

19.3.5.6* Newly introduced cubicle curtains in sprinklered areas shall be installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

A.19.3.5.6 For the proper operation of sprinkler systems, cubicle curtains and sprinkler locations need to be coordinated. Improperly designed systems might obstruct the sprinkler spray from reaching the fire or might shield the heat from the sprinkler. Many options are available to the designer including, but not limited to, hanging the cubicle curtains 46 cm (18 in.) below the sprinkler deflector; using 1.3-cm (½-in.) diagonal mesh or a 70 percent open weave top panel that extends 46 cm (18 in.) below the sprinkler deflector;

CHAPTER 18 • New

deflector; or designing the system to have a horizontal and minimum vertical distance that meets the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*. The test data that form the basis of the NFPA 13 requirements are from fire tests with sprinkler discharge that penetrated a single privacy curtain.

18.3.5.7 Portable fire extinguishers shall be provided in all health care occupancies in accordance with 9.7.4.1.

Paragraph 18.3.5.1 requires automatic sprinkler protection throughout all new health care facilities; 18.3.5.4 requires the use of quick-response or residential sprinklers throughout all smoke compartments containing patient sleeping rooms.

Where sprinkler protection is specified, complete building coverage in accordance with the provisions of NFPA 13, *Standard for the Installation of Sprinkler Systems*¹², is required (see 18.3.5.2). The Code does not exempt any area of the building from sprinkler protection (see Section 9.7). However, where automatic sprinkler protection is omitted from certain spaces in Type I and Type II construction at the mandate of the authority having jurisdiction and the AHJ approves alternative protective measures, the building is still considered fully protected throughout in accordance with the 18.3.5.3 and 19.3.5.2. Sprinklers are allowed to be omitted only from areas in buildings of fire-rated, noncombustible construction, where the building will have sufficient structural fire resistance to outlast most fires. Use of alternative protective measures should be carefully evaluated to ensure protection equivalent to that provided by automatic sprinklers. Where other automatic fire-extinguishing systems are used as an alternative to sprinklers for specific spaces, it is suggested that the spaces also be separated by fire resistance-rated construction.

The term *supervised* as used in 18.3.5.1 means that a distinct, supervisory signal must be provided to a constantly attended location in the event of any malfunction or action that would impair sprinkler performance. Supervision must be provided, for example, for water supply and sprinkler control valves, fire pump power and running conditions, water tank

18.3.6 Corridors.

Subsection 18/19.3.6 essentially stipulates that all areas that contain combustibles in sufficient quanti-

CHAPTER 19 • Existing

or designing the system to have a horizontal and minimum vertical distance that meets the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*. The test data that forms the basis of the NFPA 13 requirements is from fire tests with sprinkler discharge that penetrated a single privacy curtain.

19.3.5.7 Portable fire extinguishers shall be provided in all health care occupancies in accordance with 9.7.4.1.

levels and temperatures, pressure in pressure tanks, air pressure in dry-pipe systems, building temperature, and city water pressure. Supervision should include all sprinkler sectional control valves in addition to main control valves. See also 9.7.2.

The intent of 19.3.5.3 is to allow deletion of redundant features of fire protection within an individual smoke compartment that is sprinklered. This paragraph, for example, could be used to allow higher flame spread wall/ceiling finish or nonrated corridor partitions within the sprinklered smoke compartment. In a limited care facility, the corridor smoke detection could be eliminated within the sprinklered smoke compartment as detailed in 19.3.4.5.1(2). However, certain general building protection features must be maintained unless the building is fully sprinklered. For example, no relaxation in exit features (see Section 19.2) or building construction requirements (see 19.1.6) should be granted unless the building is fully protected by automatic sprinklers.

Paragraph 19.3.5.4 allows deletion of a number of redundant features of protection where automatic sprinkler protection is provided and where quick-response sprinklers are used throughout smoke compartments having sleeping rooms. For example, 19.3.7.3(2) permits elimination of dampers in ducts penetrating smoke barriers where compartments on both sides of the barriers are sprinkler protected under certain conditions. It will permit elimination of dampers where compartments not used for patient sleeping are sprinklered, using either standard or quick-response sprinklers, or where compartments having patient sleeping rooms use quick-response or residential sprinklers.

19.3.6 Corridors.

ties to produce a life-threatening fire must be separated from exit access corridors by partitions.

CHAPTER 18 • New

Corridor partitions in new health care occupancies and sprinklered existing health care occupancies must be able to retard the transfer of smoke but need not be fire-rated. In nonsprinklered existing health care occupancies, the corridor partitions must have a minimum ½-hour fire resistance rating.

Paragraph 18/19.3.6.1 establishes requirements for the existence and location of corridor partitions.

18.3.6.1 Corridors shall be separated from all other areas by partitions complying with 18.3.6.2 through 18.3.6.5 (*see also 18.2.5.9*), unless otherwise permitted by the following:

- (1) Spaces shall be permitted to be unlimited in area and open to the corridor, provided that the following criteria are met:
 - (a) The spaces are not used for patient sleeping rooms, treatment rooms, or hazardous areas.
 - (b) The corridors onto which the spaces open in the same smoke compartment are protected by an electrically supervised automatic smoke detection system in accordance with 18.3.4, or the smoke compartment in which the space is located is protected throughout by quick-response sprinklers.
 - (c) The open space is protected by an electrically supervised automatic smoke detection system in accordance with 18.3.4, or the entire space is arranged and located to allow direct supervision by the facility staff from a nurses' station or similar space.
 - (d) The space does not obstruct access to required exits.
- (2) Waiting areas shall be permitted to be open to the corridor, provided that the following criteria are met:
 - (a) The aggregate waiting area in each smoke compartment does not exceed 55.7 m² (600 ft²).
 - (b) Each area is protected by an electrically supervised automatic smoke detection system in accordance with 18.3.4, or each area is arranged and located to allow direct supervision by the facility staff from a nursing station or similar space.
 - (c) The area does not obstruct access to required exits.
- (3)* This requirement shall not apply to spaces for nurses' stations.

CHAPTER 19 • Existing

Paragraph 18/19.3.6.2 establishes construction requirements for corridor partitions.

Paragraph 18/19.3.6.3 establishes requirements for doors in corridor partitions.

Paragraph 18/19.3.6.4 addresses transfer grilles.

Paragraph 18/19.3.6.5 permits miscellaneous openings such as mail slots.

19.3.6.1 Corridors shall be separated from all other areas by partitions complying with 19.3.6.2 through 19.3.6.5 (*see also 19.2.5.9*), unless otherwise permitted by the following:

- (1) Smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3 shall be permitted to have spaces that are unlimited in size and open to the corridor, provided that the following criteria are met:
 - (a) The spaces are not used for patient sleeping rooms, treatment rooms, or hazardous areas.
 - (b) The corridors onto which the spaces open in the same smoke compartment are protected by an electrically supervised automatic smoke detection system in accordance with 19.3.4, or the smoke compartment in which the space is located is protected throughout by quick-response sprinklers.
 - (c) The open space is protected by an electrically supervised automatic smoke detection system in accordance with 19.3.4, or the entire space is arranged and located to allow direct supervision by the facility staff from a nurses' station or similar space.
 - (d) The space does not obstruct access to required exits.
- (2) In smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3, waiting areas shall be permitted to be open to the corridor, provided that the following criteria are met:
 - (a) The aggregate waiting area in each smoke compartment does not exceed 55.7 m² (600 ft²).
 - (b) Each area is protected by an electrically supervised automatic smoke detection system in accordance with 19.3.4, or each area is arranged and located to allow direct supervision by the facility staff from a nursing station or similar space.
 - (c) The area does not obstruct access to required exits.
- (3)* This requirement shall not apply to spaces for nurses' stations.

CHAPTER 18 • New

A.18.3.6.1(3) A typical nurses' station would normally contain one or more of the following with associated furniture and furnishings:

- (1) Charting area
 - (2) Clerical area
 - (3) Nourishment station
 - (4) Storage of small amounts of medications, medical equipment and supplies, clerical supplies, and linens
 - (5) Patient monitoring and communication equipment
- (4) Gift shops not exceeding 46.4 m² (500 ft²) shall be permitted to be open to the corridor or lobby, provided the building is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.
- (5) In a limited care facility, group meeting or multipurpose therapeutic spaces shall be permitted to open to the corridor, provided that the following criteria are met:
- (a) The space is not a hazardous area.
 - (b) The space is protected by an electrically supervised automatic smoke detection system in accordance with 18.3.4, or the space is arranged and located to allow direct supervision by the facility staff from the nurses' station or similar location.
 - (c) The space does not obstruct access to required exits.

CHAPTER 19 • Existing

A.19.3.6.1(3) A typical nurses' station would normally contain one or more of the following with associated furniture and furnishings:

- (1) Charting area
 - (2) Clerical area
 - (3) Nourishment station
 - (4) Storage of small amounts of medications, medical equipment and supplies, clerical supplies, and linens
 - (5) Patient monitoring and communication equipment
- (4) Gift shops not exceeding 46.4 m² (500 ft²) shall be permitted to be open to the corridor or lobby, provided that one of the following is met:
- (a) The building is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7
 - (b) The gift shop is protected throughout by an approved automatic sprinkler system in accordance with Section 9.7 and storage is separately protected.
- (5) Limited care facilities in smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3 shall be permitted to have group meeting or multipurpose therapeutic spaces open to the corridor, provided that the following criteria are met:
- (a) The space is not a hazardous area.
 - (b) The space is protected by an electrically supervised automatic smoke detection system in accordance with 19.3.4, or the space is arranged and located to allow direct supervision by the facility staff from the nurses' station or similar location.
 - (c) The space does not obstruct access to required exits.
- (6) Spaces other than patient sleeping rooms, treatment rooms, and hazardous areas shall be permitted to be open to the corridor and unlimited in area, provided that the following criteria are met:
- (a) The space and the corridors onto which it opens, where located in the same smoke compartment, are protected by an electrically supervised automatic smoke detection system in accordance with 19.3.4.
 - (b)* Each space is protected by automatic sprinklers, or the furnishings and furniture, in combination with all other combustibles within the area, are of such minimum quantity and arrangement that a fully developed fire is unlikely to occur.

A.19.3.6.1(6)(b) A fully developed fire (flashover) occurs if the rate of heat release of the burning materials exceeds

the capability of the space to absorb or vent that heat. The ability of common lining (wall, ceiling, and floor) materials to absorb heat is approximately 0.07 kJ per m² (0.75 Btu per ft²) of lining. The venting capability of open doors or windows is in excess of 1.95 kJ per m² (20 Btu per ft²) of opening. In a fire that has not reached flashover conditions, fire will spread from one furniture item to another only if the burning item is close to another furniture item. For example, if individual furniture items have heat release rates of 525 kW per second (500 Btu per second) and are separated by 305 mm (12 in.) or more, the fire is not expected to spread from item to item, and flashover is unlikely to occur. (See also the *NFPA Fire Protection Handbook*.)

- (c) The space does not obstruct access to required exits.
- (7)* Waiting areas shall be permitted to be open to the corridor, provided that the following criteria are met:
 - (a) Each area does not exceed 55.7 m² (600 ft²).
 - (b) The area is equipped with an electrically supervised automatic smoke detection system in accordance with 19.3.4.
 - (c) The area does not obstruct any access to required exits.

A.19.3.6.1(7) This provision permits waiting areas to be located across the corridor from each other, provided that neither area exceeds the 55.7-m² (600-ft²) limitation.

- (8) Group meeting or multipurpose therapeutic spaces, other than hazardous areas, that are under continuous supervision by facility staff shall be permitted to be open to the corridor, provided that the following criteria are met:
 - (a) Each area does not exceed 139 m² (1500 ft²).
 - (b) Not more than one such space is permitted per smoke compartment.
 - (c) The area is equipped with an electrically supervised automatic smoke detection system in accordance with 19.3.4.
 - (d) The area does not obstruct access to required exits.

Paragraph 18/19.3.6.1 requires that all spaces be separated from corridors by partitions. The intent is to limit the risk of exposing the corridor to fire. Exemptions are provided to allow specific areas to be open to the corridor. Paragraphs 18.3.6.1(1) through 18.3.6.1(5) and 19.3.6.1(1) through 19.3.6.1(8) specify those areas that are permitted to be open to corridors.

Paragraph 18/19.3.6.1(1) contains provisions that

allow unlimited size spaces such as recreation/lounge/waiting areas to be open to the corridor. New health care occupancies are offered this exemption because they are sprinklered; existing health care occupancies must be sprinklered in order to use the exemption. The open space must be visually supervised by staff from a permanent staff location, or equivalent early warning of fire must be provided

CHAPTER 18 • New

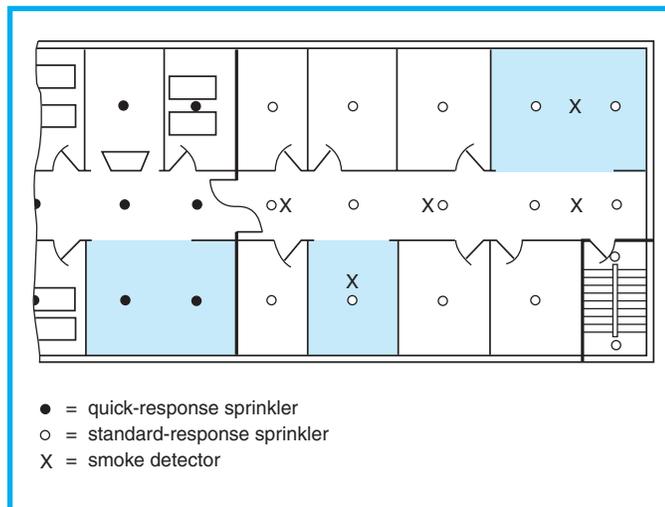

Exhibit 18/19.21 Spaces of unlimited size that are open to the corridor.

by an electrically supervised smoke detection system within the open space. Interconnected corridors that are not separated from the space must be equipped with an electrically supervised smoke detection system, or the smoke compartment must be sprinklered throughout using quick-response sprinklers. Exhibit 18/19.21 illustrates the provisions of 18/19.3.6.1(1). The black-filled circles at the left of the figure depict quick-response sprinklers; the unfilled circles at the right of the figure depict standard response sprinklers. In the smoke compartment at the left, which includes patient sleeping rooms, the open space has direct supervision from the nurses' station located across the corridor. In the smoke compartment at the right, which contains no patient sleeping rooms, neither open space has direct supervision, so each space is equipped with smoke detection (denoted by the X symbols); because the sprinklers in this compartment are standard response sprinklers, the required smoke detection must be extended into the corridor of that compartment.

Waiting areas are permitted to be open to the corridor in accordance with 18/19.3.6.1(2). Waiting areas in any one smoke compartment are not permitted to exceed 55.7 m² (600 ft²) in aggregate area. Each waiting area must be located to permit direct visual supervision by the staff or be equipped with an electrically supervised automatic smoke detection system. In all cases, waiting spaces must be arranged so as not to obstruct access to exits. Exhibit 18/19.22

CHAPTER 19 • Existing

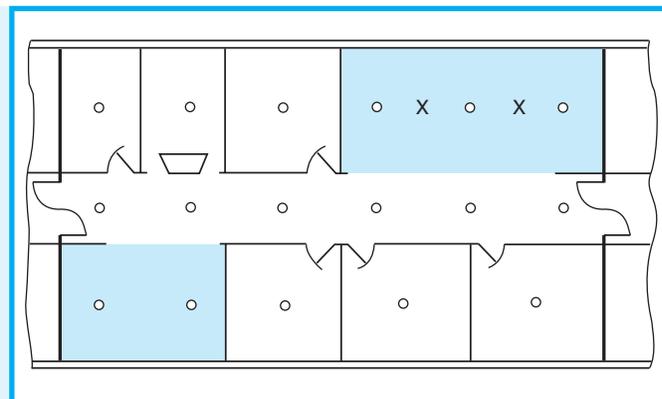

Exhibit 18/19.22 Waiting spaces of limited size that are open to the corridor.

illustrates the provisions of 18/19.3.6.1(2). The waiting space at the left of the compartment receives direct supervision from the nurses' station located across the corridor. The waiting space at the right of the compartment has no direct supervision and therefore must be provided with smoke detection (denoted by the X symbols).

Although 18/19.3.6.1(1) does not permit treatment spaces to be open to corridors, and 18/19.3.6.1(2) limits the open spaces for use as waiting areas, 18/19.3.6.1(5) permits multipurpose therapeutic spaces to be open to corridors in limited care facilities. These spaces are not permitted to be used for hazardous operations, such as woodworking, involving occupational therapy.

Paragraphs 18/19.3.6.1(1), 18/19.3.6.1(2), and 18/19.3.6.1(5) require that the open space be supervised by the staff or protected by a smoke detection system. Staff supervision is important; it allows the staff to see, hear, or smell a developing fire or to prevent the ignition of a fire by virtue of their presence. The use of closed-circuit television or mirrors does not offer all the protection provided by staff and should not be relied on as a substitute for direct supervision. Adequate supervision is not provided if the staff cannot readily supervise the space without special effort (for example, by looking around a corner).

Areas used for charting and communication by staff are permitted to be open to the corridor, as are nurses' stations. See 18/19.3.6.1(3).

Gift shops are addressed in 18/19.3.6.1(4). Many gift shops, particularly those containing combustible storage and having sizable retail areas, pose a hazard

well beyond what is considered normal to patient-occupied spaces and thus merit special protection. However, it is recognized that many small retail areas [less than 46.4 m² (500 ft²), for example] constitute a relatively minor hazard that is mitigated adequately by automatic sprinkler protection. This paragraph

18.3.6.2* Construction of Corridor Walls.

A.18.3.6.2 It is the *Code's* intent that there be no required fire resistance or area limitations for vision panels in corridor walls and doors.

An architectural, exposed, suspended-grid acoustical tile ceiling with penetrating items such as sprinkler piping and sprinklers; ducted HVAC supply and return-air diffusers; speakers; and recessed lighting fixtures is capable of limiting the transfer of smoke.

18.3.6.2.1 Corridor walls shall form a barrier to limit the transfer of smoke.

18.3.6.2.2 Corridor walls shall be permitted to terminate at the ceiling where the ceiling is constructed to limit the transfer of smoke.

18.3.6.2.3 No fire resistance rating is required for corridor walls.

provides the facility some flexibility in the design and operation of gift shops. The gift shop must be sprinklered, and for existing facilities that are not sprinklered throughout, any storage associated with the gift shop must be protected in a separate room.

19.3.6.2 Construction of Corridor Walls.

19.3.6.2.1 Corridor walls shall be continuous from the floor to the underside of the floor or roof deck above, through any concealed spaces, such as those above suspended ceilings, and through interstitial structural and mechanical spaces, unless otherwise permitted by 19.3.6.2.3 through 19.3.6.2.5.

19.3.6.2.2* Corridor walls shall have a fire resistance rating of not less than ½ hour.

A.19.3.6.2.2 The intent of the ½-hour fire resistance rating for corridor partitions is to require a nominal fire rating, particularly where the fire rating of existing partitions cannot be documented. Examples of acceptable partition assemblies would include, but are not limited to 1.3-cm (½-in.) gypsum board, wood lath and plaster, gypsum lath, or metal lath and plaster.

19.3.6.2.3* In smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3, a corridor shall be permitted to be separated from all other areas by non-fire-rated partitions and shall be permitted to terminate at the ceiling where the ceiling is constructed to limit the transfer of smoke.

A.19.3.6.2.3 An architectural, exposed, suspended-grid acoustical tile ceiling with penetrating items such as sprinkler piping and sprinklers; ducted HVAC supply and return-air diffusers; speakers; and recessed lighting fixtures is capable of limiting the transfer of smoke.

19.3.6.2.4 Existing corridor partitions shall be permitted to terminate at ceilings that are not an integral part of a floor construction if 1525 mm (5 ft) or more of space exists between the top of the ceiling subsystem and the bottom of the floor or roof above, provided that the following criteria are met:

- (1) The ceiling is part of a fire-rated assembly tested to have a fire resistance rating of not less than 1 hour in compliance with the provisions of Section 8.3.
- (2) The corridor partitions form smoketight joints with the ceilings (joint filler, if used, shall be noncombustible).

- (3) Each compartment of interstitial space that constitutes a separate smoke area is vented, in a smoke emergency, to the outside by mechanical means having the capacity to provide not less than two air changes per hour but, in no case, a capacity less than 2.35 m³/s (5000 ft³/min).
- (4) The interstitial space is not used for storage.
- (5) The space is not used as a plenum for supply, exhaust, or return air, except as noted in 19.3.6.2.4(3).

19.3.6.2.5* Existing corridor partitions shall be permitted to terminate at monolithic ceilings that resist the passage of smoke where there is a smoketight joint between the top of the partition and the bottom of the ceiling.

A.19.3.6.2.5 Monolithic ceilings are continuous horizontal membranes composed of noncombustible or limited-combustible materials, such as plaster or gypsum board, with seams or cracks permanently sealed.

19.3.6.2.6* Corridor walls shall form a barrier to limit the transfer of smoke.

A.19.3.6.2.6 The purpose of extending a corridor wall above a lay-in ceiling or through a concealed space is to provide a barrier to limit the passage of smoke. The intent of 19.3.6.2.6 is not to require light-tight barriers above lay-in ceilings or to require an absolute seal of the room from the corridor. Small holes, penetrations or gaps around items such as ductwork, conduit, or telecommunication lines should not affect the ability of this barrier to limit the passage of smoke.

19.3.6.2.7 Fixed fire window assemblies in accordance with Section 8.3 shall be permitted in corridor walls, unless otherwise permitted in 19.3.6.2.8.

19.3.6.2.8 There shall be no restrictions in area and fire resistance of glass and frames in smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3.

The choice of materials used to construct corridor walls/partitions might be affected by the building construction types addressed by 18/19.1.6.4. For example, corridor construction materials in buildings of Type I or Type II construction must be either noncombustible or limited-combustible as required by 18/19.1.6.6.

In new health care occupancies and sprinklered existing health care occupancies, corridor walls need not be fire rated but must be constructed to resist the passage of smoke. Corridor walls in such buildings are permitted to terminate at ceilings, provided

the wall and ceiling resist the passage of smoke. Where suspended ceilings are provided, partitions are permitted to terminate at the suspended ceiling without any additional special protection if the suspended ceiling will resist the passage of smoke. The ability to resist the passage of smoke must be carefully evaluated. There are no restrictions in terms of area or fire resistance for glazing used in these nonfire-rated corridor partitions. These requirements are illustrated in Exhibit 18/19.23.

Editions of the *Code* prior to 1997 required that corridor walls in nonsprinklered health care occu-

CHAPTER 18 • New

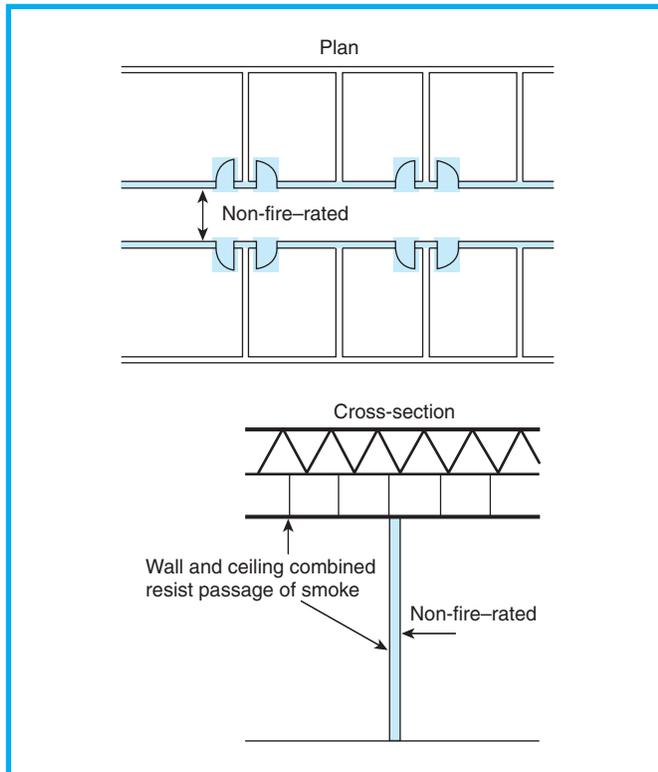

Exhibit 18/19.23 Corridor walls in new health care occupancies and existing, sprinklered health care occupancies.

pancies have a minimum 20-minute fire resistance rating. The change to a minimum ½-hour fire resistance rating was not meant to implement a more stringent requirement. Rather, the intent was to correlate with a change made in Chapter 8 where the range of fire resistance ratings that had previously been 20-minute, ½-hour, and ¾-hour ratings was simplified to the single category of a ½-hour fire resistance rating. See the explanation in A.8.3.1(3) for determining that existing walls in good condition, that previously received credit for providing a 20-minute rating, provide a ½-hour rating. It is not the intent to throw into noncompliance existing walls that were previously judged to meet the former 20-minute rating criterion.

In nonsprinklered existing health care occupancies, corridor walls must be constructed of assemblies having a minimum fire resistance rating of ½ hour. In setting the requirements for ½-hour corridor wall partitions, it was intended to accept the separation provided by existing partitions of any substantial construction that are capable of serving as a barrier for

CHAPTER 19 • Existing

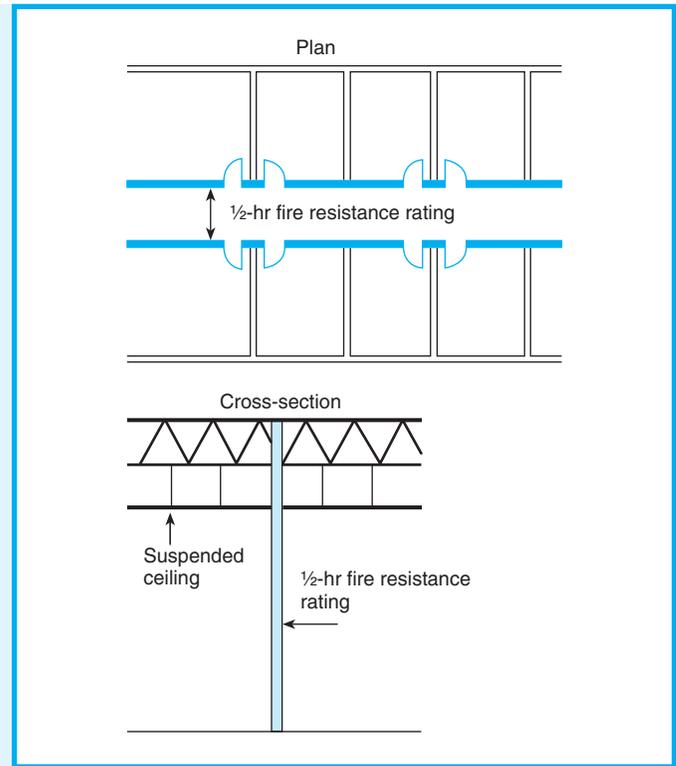

Exhibit 18/19.24 Corridor walls in existing, nonsprinklered health care smoke compartment.

a short period of time—without requiring documentation of a specific fire rating. The ½-hour rating is intended to permit partitions of wood lath and plaster, ½-in. (13-mm) gypsum board, and similar materials. Ordinary glass would not be permitted in corridor walls of nonsprinklered health care occupancies.

Fire-rated existing corridor partitions must be constructed to extend continuously through all concealed spaces—for example, through to the floor or roof deck above a suspended ceiling. This requirement is illustrated in Exhibit 18/19.24. Where a monolithic ceiling composed of noncombustible materials, such as plaster or gypsum board with permanently sealed seams forming a continuous horizontal membrane, is provided, existing partitions are permitted to terminate at the underside of the ceiling in accordance with 19.3.6.2.5.

Openings in corridor partitions in nonsprinklered buildings must be suitably protected to maintain corridor separation. Fire-rated, wired glass 6-mm (¼-in.) thick is limited to a maximum of 0.84 m² (1296 in.²) set in approved metal frames. Each

CHAPTER 18 • New

wired glass panel is limited to a maximum dimension of 1370 mm (54 in.). The glass should be labeled and should be well embedded in putty, with all exposed joints between the metal and the glass struck and pointed (see NFPA 80, *Standard for Fire Doors and Windows*). A number of wired glass panels can be used in a single partition, provided that each 0.84-m² (1296-in.²) section is separated from adjacent panels by a steel or other approved metal mullion. Fire-rated glazing, other than 6-mm (¼-in.) wired glass, should be installed in accordance with the manufacturer's instructions and listing. The use of fire-rated glazing in a partition reduces the fire resistance capability of the partition because of radiant energy transfer through the glass panel. The excessive use of glazing, therefore, should be avoided.

18.3.6.3* Corridor Doors.

A.18.3.6.3 While it is recognized that closed doors serve to maintain tenable conditions in a corridor and adjacent patient rooms, such doors, which under normal or fire conditions are self-closing, might create a special hazard for the personal safety of a room occupant. These closed doors might present a problem of delay in discovery, confining fire products beyond tenable conditions.

Because it is critical for responding staff members to be able to immediately identify the specific room involved, it is suggested that approved automatic smoke detection that is interconnected with the building fire alarm be considered for rooms having doors equipped with closing devices. Such detection is permitted to be located at any approved point within the room. When activated, the detector is required to provide a warning that indicates the specific room of involvement by activation of a fire alarm annunciator, nurse call system, or any other device acceptable to the authority having jurisdiction.

18.3.6.3.1* Doors protecting corridor openings shall be constructed to resist the passage of smoke, and the following also shall apply:

- (1) Compliance with NFPA 80, *Standard for Fire Doors and Fire Windows*, shall not be required.
- (2) Clearance between the bottom of the door and the floor covering not exceeding 25 mm (1 in.) shall be permitted for corridor doors.
- (3) Doors to toilet rooms, bathrooms, shower rooms, sink closets, and similar auxiliary spaces that do not contain flammable or combustible material shall not be required to be constructed to resist the passage of smoke.

CHAPTER 19 • Existing

Paragraph 19.3.6.2.4 specifies criteria for terminating existing corridor partitions at ceilings where the interstitial space above the ceiling meets certain criteria. However, the minimum ½-hour fire resistance rating of the corridor walls still applies. The walls are permitted to terminate at a ceiling that has been tested as a portion of a floor/ceiling or roof/ceiling assembly having a fire resistance rating of 1 hour or more. Each compartment located above such a ceiling must be equipped with an automatic mechanical smoke exhaust system that is capable of providing a minimum of two air changes per hour but exhausting not less than 2.35 m³/s (5000 ft³/min). See the additional criteria in 19.3.6.2.4(1) through 19.3.6.2.4(5).

19.3.6.3 Corridor Doors.

19.3.6.3.1* Doors protecting corridor openings in other than required enclosures of vertical openings, exits, or hazardous areas shall be doors constructed to resist the passage of smoke and shall be constructed of materials such as the following:

- (1) 44-mm (1¾-in.) thick, solid-bonded core wood
- (2) Construction that resists fire for not less than 20 minutes

CHAPTER 18 • New

A.18.3.6.3.1 Gasketing of doors should not be necessary to achieve resistance to the passage of smoke if the door is relatively tight-fitting.

18.3.6.3.2 Reserved.

18.3.6.3.3 Reserved.

18.3.6.3.4 Reserved.

18.3.6.3.5 Doors shall be provided with positive latching hardware.

CHAPTER 19 • Existing

A.19.3.6.3.1 Gasketing of doors should not be necessary to achieve resistance to the passage of smoke if the door is relatively tight-fitting.

19.3.6.3.2 The requirements of 19.3.6.3.1 shall not apply where otherwise permitted by the following:

- (1) Doors to toilet rooms, bathrooms, shower rooms, sink closets, and similar auxiliary spaces that do not contain flammable or combustible materials shall not be required to comply with 19.3.6.3.1.
- (2) In smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3, the door construction requirements of 19.3.6.3.1 shall not be mandatory, but the doors shall be constructed to resist the passage of smoke.

19.3.6.3.3 Compliance with NFPA 80, *Standard for Fire Doors and Fire Windows*, shall not be required.

19.3.6.3.4 Clearance between the bottom of the door and the floor covering not exceeding 25 mm (1 in.) shall be permitted for corridor doors.

19.3.6.3.5* Doors shall be provided with a means for keeping the door closed that is acceptable to the authority having jurisdiction, and the following requirements also shall apply:

- (1) The device used shall be capable of keeping the door fully closed if a force of 22 N (5 lbf) is applied at the latch edge of the door.
- (2) Roller latches shall be prohibited on corridor doors in buildings not fully protected by an approved automatic sprinkler system in accordance with 19.3.5.3.

A.19.3.6.3.5 While it is recognized that closed doors serve to maintain tenable conditions in a corridor and adjacent patient rooms, such doors, which under normal or fire conditions are self-closing, might create a special hazard for the personal safety of a room occupant. These closed doors might present a problem of delay in discovery, confining fire products beyond tenable conditions.

Because it is critical for responding staff members to be able to immediately identify the specific room involved, it is suggested that approved automatic smoke detection that is interconnected with the building fire alarm be considered for rooms having doors equipped with closing devices. Such detection is permitted to be located at any approved point within the room. When activated, the detector is required to provide a warning that indicates the specific room of involvement by activation of a fire alarm annunciator, nurse call system, or any other device acceptable to the authority having jurisdiction.

In existing buildings, use of the following options rea-

CHAPTER 18 • New

18.3.6.3.6 Doors to toilet rooms, bathrooms, shower rooms, sink closets, and similar auxiliary spaces that do not contain flammable or combustible materials shall not be required to be provided with positive latching hardware.

18.3.6.3.7 Roller latches shall be prohibited.

18.3.6.3.8* Doors shall not be held open by devices other than those that release when the door is pushed or pulled.

A.18.3.6.3.8 Doors should not be blocked open by furniture, door stops, chocks, tie-backs, drop-down or plunger-type devices, or other devices that necessitate manual unlatching or releasing action to close. Examples of hold-open devices that release when the door is pushed or pulled are friction catches or magnetic catches.

18.3.6.3.9 Door-closing devices shall not be required on doors in corridor wall openings other than those serving required exits, smoke barriers, or enclosures of vertical openings and hazardous areas.

18.3.6.3.10* Nonrated, factory- or field-applied protective plates extending not more than 1220 mm (48 in.) above the bottom of the door shall be permitted.

A.18.3.6.3.10 It is not the intent of 18.3.6.3.10 to prohibit the application of push-plates, hardware, or other attachments on corridor doors in health care occupancies.

18.3.6.3.11 Dutch doors shall be permitted where they conform to 18.3.6.3 and meet the following criteria:

CHAPTER 19 • Existing

sonably ensures that patient room doors will be closed and remain closed during a fire:

- (1) Doors should have positive latches and a suitable program that trains staff to close the doors in an emergency should be established.
- (2) It is the intent of the *Code* that no new installations of roller latches be permitted; however, repair or replacement of roller latches is not considered a new installation.
- (3) Doors protecting openings to patient sleeping or treatment rooms, or spaces having a similar combustible loading might be held closed using a closer exerting a closing force of not less than 22 N (5 lbf) on the door latch stile.

19.3.6.3.6 The requirements of 19.3.6.3.5 shall not apply where otherwise permitted by the following:

- (1) Doors to toilet rooms, bathrooms, shower rooms, sink closets, and similar auxiliary spaces that do not contain flammable or combustible materials shall not be required to comply with 19.3.6.3.5.
- (2) Existing roller latches demonstrated to keep the door closed against a force of 22 N (5 lbf) shall be permitted to be kept in service.

19.3.6.3.7 Reserved.

19.3.6.3.8* Doors shall not be held open by devices other than those that release when the door is pushed or pulled.

A.19.3.6.3.8 Doors should not be blocked open by furniture, door stops, chocks, tie-backs, drop-down or plunger-type devices, or other devices that necessitate manual unlatching or releasing action to close. Examples of hold-open devices that release when the door is pushed or pulled are friction catches or magnetic catches.

19.3.6.3.9 Door-closing devices shall not be required on doors in corridor wall openings other than those serving required exits, smoke barriers, or enclosures of vertical openings and hazardous areas.

19.3.6.3.10* Nonrated, factory- or field-applied protective plates extending not more than 1220 mm (48 in.) above the bottom of the door shall be permitted.

A.19.3.6.3.10 It is not the intent of 19.3.6.3.10 to prohibit the application of push-plates, hardware, or other attachments on corridor doors in health care occupancies.

19.3.6.3.11 Dutch doors shall be permitted where they conform to 19.3.6.3 and meet the following criteria:

CHAPTER 18 • New

- (1) Both the upper leaf and lower leaf are equipped with a latching device.
- (2) The meeting edges of the upper and lower leaves are equipped with an astragal, a rabbet, or a bevel.
- (3) Where protecting openings in enclosures around hazardous areas, the doors comply with NFPA 80, *Standard for Fire Doors and Fire Windows*.

18.3.6.4 Transfer Grilles.

18.3.6.4.1 Transfer grilles, regardless of whether they are protected by fusible link-operated dampers, shall not be used in corridor walls or doors, unless otherwise permitted by 18.3.6.4.2.

18.3.6.4.2 Doors to toilet rooms, bathrooms, shower rooms, sink closets, and similar auxiliary spaces that do not contain flammable or combustible materials shall be permitted to have ventilating louvers or to be undercut.

18.3.6.5 Openings. In other than smoke compartments containing patient bedrooms, miscellaneous openings such as mail slots, pharmacy pass-through windows, laboratory pass-through windows, and cashier pass-through windows shall be permitted to be installed in vision panels or doors without special protection, provided that both of the following criteria are met:

- (1) The aggregate area of openings per room does not exceed 0.05 m² (0.55 ft²).
- (2) The openings are installed at or below half the distance from the floor to the room ceiling.

CHAPTER 19 • Existing

- (1) Both the upper leaf and lower leaf are equipped with a latching device.
- (2) The meeting edges of the upper and lower leaves are equipped with an astragal, a rabbet, or a bevel.
- (3) Where protecting openings in enclosures around hazardous areas, the doors comply with NFPA 80, *Standard for Fire Doors and Fire Windows*.

19.3.6.3.12 Door frames shall be labeled, shall be of steel construction, or shall be of other materials in compliance with the provisions of Section 8.3, unless otherwise permitted by 19.3.6.3.13.

19.3.6.3.13 Door frames in smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3 shall not be required to comply with 19.3.6.3.12.

19.3.6.3.14 Fixed fire window assemblies in accordance with Section 8.3 shall be permitted in corridor doors.

19.3.6.3.15 Restrictions in area and fire resistance of glass and frames required by Section 8.3 shall not apply in smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3.

19.3.6.4 Transfer Grilles.

19.3.6.4.1 Transfer grilles, regardless of whether they are protected by fusible link-operated dampers, shall not be used in corridor walls or doors.

19.3.6.4.2 Doors to toilet rooms, bathrooms, shower rooms, sink closets, and similar auxiliary spaces that do not contain flammable or combustible materials shall be permitted to have ventilating louvers or to be undercut.

19.3.6.5 Openings.

19.3.6.5.1 Miscellaneous openings such as mail slots, pharmacy pass-through windows, laboratory pass-through windows, and cashier pass-through windows shall be permitted to be installed in vision panels or doors without special protection, provided that both of the following criteria are met:

- (1) The aggregate area of openings per room does not exceed 0.015 m² (0.14 ft²).
- (2) The openings are installed at or below half the distance from the floor to the room ceiling.

19.3.6.5.2 The alternative requirements of 19.3.6.5.1 shall not apply where otherwise modified by the following:

CHAPTER 18 • New

Paragraphs 18.3.6.3.1(2) and 19.3.6.3.4 permit a maximum 25-mm (1-in.) clearance between the bottom of non-fire-rated corridor doors and the upper surface of the floor covering material. The paragraph avoids using the word *undercut* because of the negative connotation that word conjures in many minds. It is not the intent to permit the door to be deliberately undercut for purposes of making the building heating, ventilating, and air conditioning system function. That practice is prohibited by NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*¹³. Also, see 18/19.3.6.4, which addresses the concept by prohibiting transfer grilles in corridor walls.

Paragraph 18.3.6.3.5 requires positive latching hardware on doors in corridor walls in new health care occupancies. The purpose is to ensure that doors, once closed by staff, remain closed. Roller latches are not permitted in new health care occupancies (see 18.3.6.3.7).

Doors protecting openings in non-fire-rated corridor partitions—as permitted in new and existing, sprinklered health care occupancies—must be able to resist the passage of smoke but are not required to have a fire protection rating. Door-closing devices are not required except on doors protecting openings in exit enclosures, vertical openings, or required enclosures of hazardous contents areas. There are no restrictions—in terms of area or fire rating for glazing used in corridor doors—in new and sprinklered existing health care occupancies.

Patient room corridor doors are not required to have a fire protection rating in new and sprinklered existing health care occupancies. In existing, non-sprinklered health care occupancies, the door need not be a true 20-minute fire protection rated assembly; rather, it is permitted to be a substantial door such as those constructed of 44-mm- (1¾-in.-) thick, solid-bonded core wood. Some persons consider these doors to be equivalent to 20-minute fire protection-rated doors for which the self-closer has been omitted. If the doors were truly a 20-minute fire pro-

CHAPTER 19 • Existing

- (1) Openings in smoke compartments containing patient bedrooms shall not be permitted to be installed in vision panels or doors without special protection.
- (2) For rooms protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.3, the aggregate area of openings per room shall not exceed 0.05 m² (0.55 ft²).

tection-rated assembly, field-applied protective plates would be prohibited. Paragraph 18/19.3.6.3.10 reminds the user that factory- or field-applied protective plates are permitted. In issuing that reminder, 18/19.3.6.3.10 sets an arbitrary maximum height of 1220 mm (48 in.) above which the protective plate cannot extend. Paragraph 18/19.3.6.3.10 gives the proponents for protective plates the specific permission they requested, but in doing so, adds a height restriction that did not exist when the *Code* was silent on the subject of protective plates on “nonrated” corridor doors.

Existing corridor doors are not specifically required to be provided with a positive latch. However, they must be capable of being closed and maintained closed during a fire. Where positive latches are used, doors must be equipped with a latch that cannot be held in the retracted position. The latch should be capable of holding the door in a closed position when subjected to stresses imposed by exposure to fire. In nonsprinklered buildings, roller latches are not allowed, unless the existing roller latches meet the performance criterion of being able to keep the door closed against a force of 22 N (5 lbf). See 19.3.6.3.6.

Corridor doors in nonsprinklered smoke compartments in existing health care occupancies are required to be installed in approved metal or “heavy wood” frames. Fixed, wired-glass vision panels installed in these doors are not permitted to exceed an area of 0.84 m² (1296 in.²) [maximum dimension of 1370 mm (54 in.)] and must be set in approved, metal frames. Other fire-rated glazing must be used in accordance with its listing. Labeled door frames and closing devices are not required except on doors protecting openings in exit enclosures, vertical openings, or required enclosures of hazardous areas.

Paragraph 18/19.3.6.4 addresses transfer grilles in corridor walls. The use of an exit access corridor as an exhaust, supply, or return air plenum for the building air-handling system is not permitted. Corridor doors are not permitted to be deliberately undercut

CHAPTER 18 • New

to facilitate transfer of air, but there may be a maximum 25-mm (1-in.) clearance at the bottom of the door in accordance with 18.3.6.3.1(2) and 19.3.6.3.4. Transfer grilles are not allowed in corridor walls (see 18/19.3.6.4.1) or corridor doors. Also see NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*. However, sink closets, bathrooms, and toilets can have doors equipped with a fixed grille or louver to allow exhaust air to be “made up” from the corridor [see 18.3.6.3.1(3) and 19.3.6.3.2(1)], provided the space is not used for the storage of flammable or combustible supplies. When using this exception for sink closets, caution must be exercised because they are often used for storage of combustibles.

18.3.7* Subdivision of Building Spaces.

A.18.3.7 See A.18.2.2.

18.3.7.1 Buildings containing health care facilities shall be subdivided by smoke barriers, unless otherwise permitted by 18.3.7.2, as follows:

- (1) To divide every story used by inpatients for sleeping or treatment into not less than two smoke compartments
- (2) To divide every story having an occupant load of 50 or more persons, regardless of use, into not less than two smoke compartments
- (3) To limit the size of each smoke compartment required by (1) and (2) to an area not exceeding 2100 m² (22,500 ft²), unless the area is an atrium separated in accordance with 8.6.7, in which case no limitation in size is required
- (4) To limit the travel distance from any point to reach a door in the required smoke barrier to a distance not exceeding 61 m (200 ft)

18.3.7.2 The smoke barrier subdivision requirement of 18.3.7.1 shall not apply to the following:

- (1) Stories that do not contain a health care occupancy, located totally above the health care occupancy
- (2) Areas that do not contain a health care occupancy and that are separated from the health care occupancy by a fire barrier complying with 7.2.4.3
- (3) Stories that do not contain a health care occupancy and that are more than one story below the health care occupancy
- (4) Open-air parking structures protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7

CHAPTER 19 • Existing

Paragraph 18/19.3.6.5 establishes restrictions for miscellaneous openings in corridor walls. For practical reasons, many small openings are required in corridor walls for use as mail slots, as cashier windows, and as pass-throughs to laboratory or pharmacy spaces. Paragraph 18/19.3.6.5 allows for such openings. Openings are not allowed in compartments having sleeping rooms. In other sprinklered compartments, the opening must be limited to a maximum of 0.05 m² (0.55 ft²) and must be located in the lower half of the partition. In existing, nonsprinklered, non-sleeping, smoke compartments, the opening size is limited to 0.015 m² (0.14 ft²).

19.3.7 Subdivision of Building Spaces.

19.3.7.1 Smoke barriers shall be provided to divide every story used for sleeping rooms for more than 30 patients into not less than two smoke compartments, and the following also shall apply:

- (1) The size of any such smoke compartment shall not exceed 2100 m² (22,500 ft²), and the travel distance from any point to reach a door in the required smoke barrier shall not exceed 61 m (200 ft).
- (2) Where neither the length nor width of the smoke compartment exceeds 46 m (150 ft), the travel distance to reach the smoke barrier door shall not be limited.
- (3) The area of an atrium separated in accordance with 8.6.7 shall not be limited in size.

19.3.7.2 For purposes of the requirements of 19.3.7, the number of health care occupants shall be determined by actual count of patient bed capacity.

19.3.7.3 Any required smoke barrier shall be constructed in accordance with Section 8.5 and shall have a fire resistance rating of not less than ½ hour, unless otherwise permitted by the following:

- (1) This requirement shall not apply where an atrium is used, provided that both of the following criteria are met:
 - (a) Smoke barriers shall be permitted to terminate at an atrium wall constructed in accordance with 8.6.7(1)(c).
 - (b) Not less than two separate smoke compartments shall be provided on each floor.
- (2)* Smoke dampers shall not be required in duct penetrations of smoke barriers in fully ducted heating, ventilating, and air conditioning systems where an approved,

CHAPTER 18 • New

18.3.7.3 Smoke barriers shall be provided on stories that are usable but unoccupied.

18.3.7.4 Any required smoke barrier shall be constructed in accordance with Section 8.5 and shall have a fire resistance rating of not less than 1 hour, unless otherwise permitted by the following:

- (1) This requirement shall not apply where an atrium is used, provided that both of the following criteria are met:
 - (a) Smoke barriers shall be permitted to terminate at an atrium wall constructed in accordance with 8.6.7(1)(c).
 - (b) Not less than two separate smoke compartments shall be provided on each floor.
- (2)* Smoke dampers shall not be required in duct penetrations of smoke barriers in fully ducted heating, ventilating, and air conditioning systems.

A.18.3.7.4(2) Where the smoke control system design requires dampers so that the system will function effectively, it is not the intent of the provision to permit the damper to be omitted.

This provision is not intended to prevent the use of plenum returns where ducting is used to return air from a ceiling plenum through smoke barrier walls. Short stubs or jumper ducts are not acceptable. Ducting is required to connect at both sides of the opening and to extend into adjacent spaces away from the wall. The intent is to prohibit open-air transfers at or near the smoke barrier walls.

18.3.7.5 Materials and methods of construction used for required smoke barriers shall not reduce the required fire resistance rating.

18.3.7.6 Accumulation space shall be provided in accordance with 18.3.7.6.1 and 18.3.7.6.2.

18.3.7.6.1 Not less than 2.8 net m² (30 net ft²) per patient in a hospital or nursing home, or not less than 1.4 net m² (15 net ft²) per resident in a limited care facility, shall be provided within the aggregate area of corridors, patient rooms, treatment rooms, lounge or dining areas, and other low hazard areas on each side of the smoke barrier.

18.3.7.6.2 On stories not housing bed or litterborne patients, not less than 0.56 net m² (6 net ft²) per occupant shall be provided on each side of the smoke barrier for the total number of occupants in adjoining compartments.

18.3.7.7* Doors in smoke barriers shall be substantial doors, such as 44-mm (1¾-in.) thick, solid-bonded wood core

CHAPTER 19 • Existing

supervised automatic sprinkler system in accordance with 19.3.5.4 has been provided for smoke compartments adjacent to the smoke barrier.

A.19.3.7.3(2) Where the smoke control system design requires dampers in order that the system functions effectively, it is not the intent of the exception to permit the damper to be omitted.

This provision is not intended to prevent the use of plenum returns where ducting is used to return air from a ceiling plenum through smoke barrier walls. Short stubs or jumper ducts are not acceptable. Ducting is required to connect at both sides of the opening and to extend into adjacent spaces away from the wall. The intent is to prohibit open-air transfers at or near the smoke barrier walls.

19.3.7.4 Accumulation space shall be provided in accordance with 19.3.7.4.1 and 19.3.7.4.2.

19.3.7.4.1 Not less than 2.8 net m² (30 net ft²) per patient in a hospital or nursing home, or not less than 1.4 net m² (15 net ft²) per resident in a limited care facility, shall be provided within the aggregate area of corridors, patient rooms, treatment rooms, lounge or dining areas, and other low hazard areas on each side of the smoke barrier.

19.3.7.4.2 On stories not housing bed or litterborne patients, not less than 0.56 net m² (6 net ft²) per occupant shall be provided on each side of the smoke barrier for the total number of occupants in adjoining compartments.

19.3.7.5 Openings in smoke barriers shall be protected using one of the following methods:

- (1) They shall be protected by fire-rated glazing.
- (2) They shall be protected by wired glass panels and steel frames.
- (3) They shall be protected by doors, such as 44-mm (1¾-in.) thick, solid-bonded wood core doors.
- (4) They shall be protected by construction that resists fire for not less than 20 minutes.

19.3.7.5.1* Nonrated factory- or field-applied protective plates extending not more than 1220 mm (48 in.) above the bottom of the door shall be permitted.

A.19.3.7.5.1 It is not the intent of 19.3.7.5.1 to prohibit the application of push-plates, hardware, or other attachments on smoke barrier doors in health care occupancies.

19.3.7.5.2 Doors shall be permitted to have fixed fire window assemblies in accordance with Section 8.3.

19.3.7.6* Doors in smoke barriers shall comply with Section 8.3 and shall be self-closing or automatic-closing in accordance with 19.2.2.2.6. Such doors in smoke barriers shall

CHAPTER 18 • New

doors, or shall be of construction that resists fire for not less than 20 minutes, and shall meet the following requirements:

- (1) Nonrated factory- or field-applied protective plates extending not more than 1220 mm (48 in.) above the bottom of the door shall be permitted.
- (2) Cross-corridor openings in smoke barriers shall be protected by a pair of swinging doors or a horizontal sliding door complying with 7.2.1.14.
- (3) Swinging doors shall be arranged so that each door swings in a direction opposite from the other.
- (4) The minimum clear width for swinging doors shall be as follows:
 - (a) Hospitals and nursing homes—1055 mm (41½ in.)
 - (b) Psychiatric hospitals and limited care facilities—810 mm (32 in.)
- (5) The minimum clear width opening for horizontal sliding doors shall be as follows:
 - (a) Hospitals and nursing homes—2110 mm (83 in.)
 - (b) Psychiatric hospitals and limited care facilities—1625 mm (64 in.)

A.18.3.7.7 Smoke barrier doors are intended to provide access to adjacent zones. The pair of cross-corridor doors are required to be opposite swinging. Access to both zones is required.

It is not the intent of 18.3.7.7 to prohibit the application of push-plates, hardware, or other attachments on some barrier doors in health care occupancies.

18.3.7.8* Doors in smoke barriers shall comply with 8.3.4 and shall be self-closing or automatic-closing in accordance with 18.2.2.2.6.

A.18.3.7.8 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

18.3.7.9* Vision panels consisting of fire-rated glazing or wire glass panels in approved frames shall be provided in each cross-corridor swinging door and at each cross-corridor horizontal sliding door in a smoke barrier.

A.18.3.7.9 It is not the intent to require the frame to be a listed assembly.

18.3.7.10 Rabbits, bevels, or astragals shall be required at the meeting edges, and stops shall be required at the head and sides of door frames in smoke barriers. Positive latching hardware shall not be required. Center mullions shall be prohibited.

CHAPTER 19 • Existing

not be required to swing with egress travel. Positive latching hardware shall not be required.

A.19.3.7.6 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

19.3.7.7 Door openings in smoke barriers shall be protected using one of the following methods:

- (1) A swinging door providing a clear width of not less than 810 mm (32 in.)
- (2) A horizontal sliding door complying with 7.2.1.14 and providing a clear width of not less than 810 mm (32 in.)

19.3.7.8 The requirement of 19.3.7.7 shall not apply to existing 865-mm (34-in.) doors.

CHAPTER 18 • New

CHAPTER 19 • Existing

Paragraph 18.3.7.1 requires that all floors of a building housing a new health care occupancy—other than those meeting one of the four exemptions offered by 18.3.7.2—be subdivided into smoke compartments.

Per 18.3.7.1(1) any floor used by inpatients for sleeping or treatment must be subdivided into at least two smoke compartments, regardless of floor size or number of patients. Also, 18.3.7.1(2) requires any floor with an occupant load of 50 or more persons, regardless of size or use, to be subdivided into two smoke compartments, using smoke barriers. However, 18.3.7.2(1) through 18.3.7.2(4) provide exemptions for some non-health care occupancy floors.

Exhibit 18/19.25 illustrates the use of 18.3.7.1(1) and 18.3.7.1(2) and the four exemptions of 18.3.7.2.

In Exhibit 18/19.25,

- Floors 10 through 12 do not contain a health care occupancy and are located above the health care occupancy—per 18.3.7.2(1), they do not require smoke barriers.
- Floors 6B through 9B are health care occupancy floors used for inpatient sleeping or treatment—

per 18.3.7.1(1), they must be subdivided by smoke barriers.

- Floors 6A through 9A do not contain a health care occupancy and are separated from the health care occupancy by 2-hour fire resistance-rated barriers complying with the provisions of 7.2.4.3 applicable to horizontal exit fire barriers—per 18.3.7.2(2), they do not require smoke barriers.
- Floor 5 does not contain a health care occupancy and does not meet 18.3.7.2(3) because it is not more than one story below the health care occupancy—per 18.3.7.1(2) it must be subdivided by smoke barriers if it has an occupant load of 50 or more persons.
- Floor 4 does not contain a health care occupancy and is more than one story below the health care occupancy—per 18.3.7.2(3), it does not require smoke barriers.
- Floor 3 is a health care occupancy floor used for inpatient sleeping or treatment—per 18.3.7.1(1), it must be subdivided by smoke barriers.
- Floors 1 and 2 are used as an open-air parking structure and are protected by a supervised automatic sprinkler system—even though floor 2 is located immediately below a health care occupancy floor, 18.3.7.2(4) exempts these floors from the smoke barrier requirement.

For existing health care occupancies, the introductory portion of 19.3.7.1 requires smoke barriers only for the purpose of subdividing stories having sleeping rooms for more than 30 patients. Subdivision is not required on treatment floors (provided there are no sleeping rooms) regardless of floor area or number of patients. Patient bed capacity is to be used to determine the number of patients per story (see 19.3.7.2).

Paragraphs 18.3.7.1(3), 18.3.7.1(4), and 19.3.7.1(1) do not present criteria related to whether smoke barriers are required in a building. Rather, they specify dimensional criteria for smoke compartments when their presence is required by 18.3.7.1(1), 18.3.7.1(2), or the introductory portion of 19.3.7.1. The maximum area of any smoke compartment created by subdividing the floor cannot exceed 2100 m² (22,500 ft²). If the compartment were perfectly square, this would involve a 46 m × 46 m (150 ft × 150 ft) area. However, to provide the facility and designer with flexibility in the arrangement of smoke compartments, the arbitrary 46-m (150-ft) length and width limits of earlier

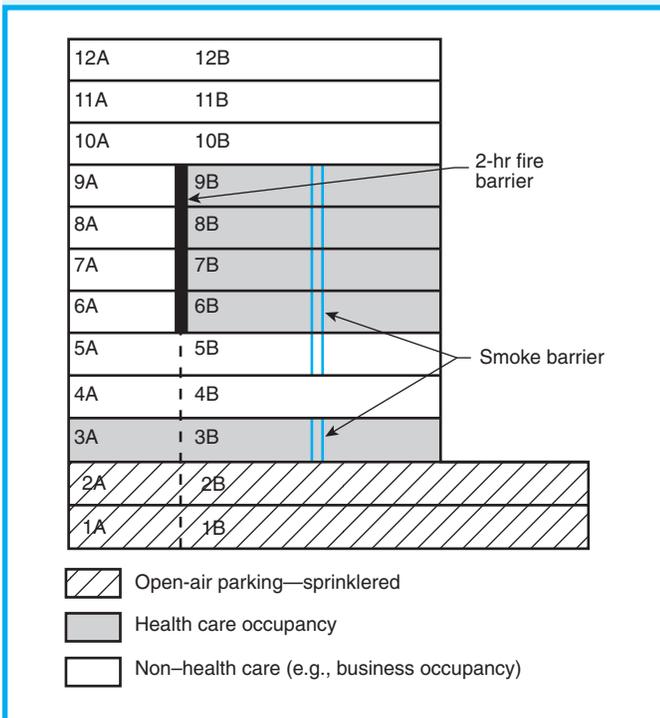

Exhibit 18/19.25 Smoke barriers for new health care occupancy buildings.

CHAPTER 18 • New

CHAPTER 19 • Existing

editions were replaced in 1991 by a 61-m (200-ft) travel limitation to a door in the smoke barrier [see 18.3.7.1(4) and 19.3.7.1(1)]. Smoke compartments must be designed so that a person is able to reach a smoke barrier door within a distance of travel of 61 m (200 ft) from any point in a compartment, measured along the natural path of travel in accordance with 7.6.1. However, the travel limitation is exempted by 19.3.7.1(2) for existing smoke compartments where neither the length nor width exceeds 46 m (150 ft).

In Exhibit 18/19.26, the construction of one smoke barrier divides the floor into two smoke compartments. If either smoke compartment—one consisting of the combination of areas A and B or the other consisting of area C—exceeds 2100 m² (22,500 ft²) or requires occupant travel in excess of 61 m (200 ft) to reach the doors in the smoke barrier, further subdivision using additional smoke barriers is required [unless both are existing smoke compartments and neither the compartment length nor width exceeds 46 m (150 ft)]. Assuming that the smoke compartment consisting of the combination of areas A and B is too large to meet the specified conditions, a second smoke barrier extending from point X to point Y might provide a logical solution.

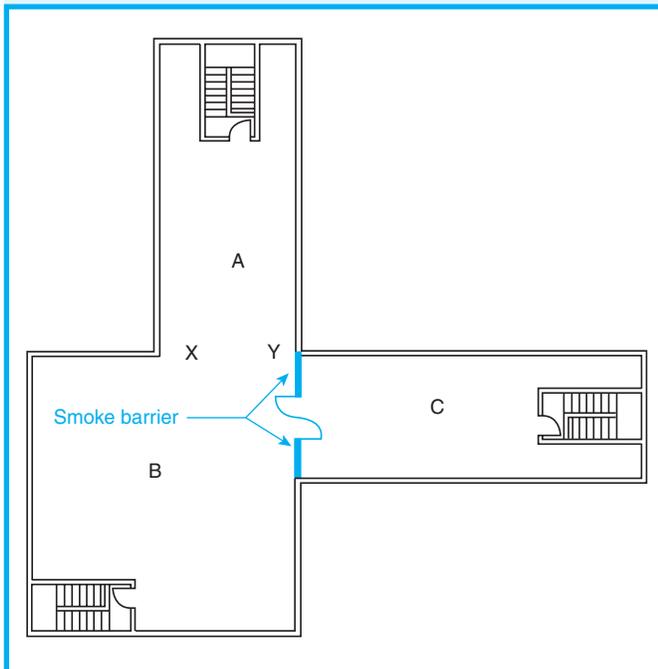

Exhibit 18/19.26 Smoke barrier dividing floor into two smoke compartments.

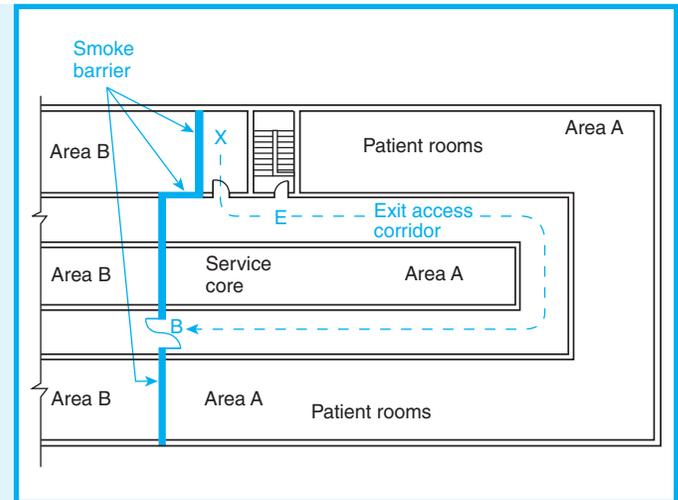

Exhibit 18/19.27 Limited travel distance to door in smoke barrier.

Exhibit 18/19.27 illustrates the travel distance limitation to a door in a smoke barrier. Although the room positioned at the top of exhibit between the smoke barrier and the enclosed exit stair has a short travel distance to an exit (distance X to E), the enclosed exit stair is not usable by those incapable of self-preservation. Therefore, the distance of travel to the doors in the smoke barrier (distance X to E to B) must not exceed 61 m (200 ft). For the existing smoke compartment, the 61-m (200-ft) criterion would be exempted if neither the smoke compartment length nor the width exceeds 46 m (150 ft). For this floor plan, an additional pair of doors in the smoke barrier where it crosses the corridor in the top half of the exhibit might provide a logical solution to a smoke compartment travel distance problem.

Horizontal exits are permitted to be substituted for smoke barriers. In such cases, the horizontal exit would also have to be constructed to comply with smoke barrier requirements. See Section 8.5.

Areas open to atriums are not permitted to be used for patient sleeping or treatment areas (see 18/19.3.1.3). Atrium smoke compartments arranged in accordance with 8.6.7 are not limited in size.

Paragraphs 18.3.7.7 through 18.3.7.10 and 19.3.7.6 through 19.3.7.8 address smoke barrier doors. Although the cross-corridor smoke barrier doors in new health care occupancies are required to resist the penetration of fire for at least 20 minutes, they are not required to have a true fire protection rating.

CHAPTER 18 • New

Similarly, the smoke-barrier doors in existing health care occupancies are not required to have a true fire protection rating. Yet, some persons incorrectly consider these 44-mm (1¾-in.) thick, solid-bonded wood doors to be 20-minute fire protection-rated doors from which the latch has been omitted. If the door were truly a 20-minute fire protection-rated assembly, field-applied protective plates would be prohibited. Paragraphs 18.3.7.7(1) and 19.3.7.5.1 remind the user that factory- or field-applied protective plates are permitted. In issuing that reminder, these paragraphs set an arbitrary maximum height of 1220 mm (48 in.) above which the protective plate cannot extend. Paragraphs 18.3.7.7(1) and 19.3.7.5.1 give the proponents for protective plates the specific permission they requested—but in doing so, adds a height restriction that did not exist when the *Code* was silent on the subject of protective plates on “nonrated” smoke barrier doors.

During a fire, the emergency evacuation of patients in a health care facility is an inefficient, time-consuming process. Realistically, if patients must be moved, sizable numbers of occupants can be relocated only through horizontal travel. Smoke barriers and horizontal exits used to subdivide a building serve three purposes fundamental to the protection of inpatients:

- (1) They limit the spread of fire and smoke.
- (2) They limit the number of occupants exposed to a single fire.
- (3) They provide for the horizontal relocation of patients by creating a safe area on the same floor level.

The smoke barrier requirements result in a floor’s area being divided by a barrier into a minimum of two compartments. Although not stated in the *Code*, it would be desirable to subdivide health care facilities in such a way as to have separate banks of elevators in different smoke zones. Should evacuation of the building become necessary, patients can first be moved horizontally to a temporary area of refuge and then be removed from the floor via elevators.

In new health care occupancies, the openings between the meeting edges of pairs of smoke barrier doors and between the doors and frames must be minimized to retard the transfer of smoke. Because 18.3.7.7(3) requires swinging doors to swing in oppo-

CHAPTER 19 • Existing

site directions from each other, the protection at the meeting edge does not create a coordination problem and, therefore, is simple to provide. An overlapping astragal plate on the leading edge of one of the doors will usually suffice for compliance with 18.3.7.10.

Dampers are not required in ducted penetrations of smoke barriers in new health care occupancies [see 18.3.7.4(2)]. This exemption anticipates that fire size will be limited by automatic sprinklers and that duct systems will also inhibit the transfer of smoke. This exemption does not prohibit the installation of smoke dampers, nor does it permit the omission of the smoke damper if the damper is required for other reasons. For example, if the building has a smoke-control system that needs a smoke damper at the smoke barrier, then such a damper must be installed. An automatic-closing damper, activated by a smoke detector, would be required to protect a transfer grille.

Note that, for existing smoke barriers, the combination fire/smoke dampers required in 8.5.4.2 are allowed to be omitted in engineered smoke control systems if the system design is such that a damper is not required at that point. Paragraph 19.3.7.3(2) also permits deletion of dampers in ducted penetrations of smoke barriers where compartments adjacent to the barrier are protected by automatic sprinklers. This exemption would not be permitted if an engineered smoke control system required a damper at this point. Openings for transfer grilles require automatic-closing dampers.

Exhibits 18/19.28 and 18/19.29 illustrate some of the detailed requirements of 18/19.3.7 for subdividing building spaces through the use of smoke barriers.

In Exhibit 18/19.30, the smoke barrier requirement for a building with an atrium is satisfied by running the smoke barrier partition directly through the building from one outside wall to the opposite outside wall and hugging one edge of the open atrium space. In Exhibit 18/19.31, 18/19.3.7.1(3) is used to permit the smoke compartment containing the atrium to be unlimited in size. The patient floor is divided into three smoke compartments by locating two smoke barriers away from the atrium opening and thus preserving the visual impact of the atrium. The center smoke compartment, which includes the atrium, is not limited in size, but the distance of travel from any point to a smoke barrier door is limited to 61 m (200 ft).

CHAPTER 18 • New

18.3.8* Special Protection Features—Outside Window or Door.

A.18.3.8 Individual sleeping cubicles within sleeping suites, as permitted by 18.2.5.4, are not required to have an outside window or outside door in each cubicle, provided that not less than one outside window or outside door is provided in the suite or that the requirements of 18.3.8.1(2) are met.

18.3.8.1 Every patient sleeping room shall have an outside window or outside door.

- (1) This requirement shall not apply to newborn nurseries and rooms intended for occupancy for less than 24 hours, such as those housing obstetrical labor beds, recovery beds, and observation beds in the emergency department.
- (2) Windows in atrium walls shall be considered outside windows for the purposes of this requirement.

18.3.8.2 Where windows are required by 18.3.8.1, the allowable sill height shall not exceed 915 mm (36 in.) above the floor, unless otherwise permitted by the following:

- (1) The window sill in special nursing care areas, such as those housing ICU, CCU, hemodialysis, and neonatal patients, shall not exceed 1525 mm (60 in.) above the floor.
- (2) The window sill in limited care facilities shall not exceed 1120 mm (44 in.) above the floor.

Paragraphs 18.3.8.1 and 19.3.8 require an outside door or outside window in each room where patients sleep. The window is not required to be operable. Sill height is limited in new construction to ensure access to the window should it ever need to be used for ventilation purposes. A maximum allowable sill height of 915 mm (36 in.) is specified for new health care occupancies, except in special nursing care areas (for example, recovery rooms, intensive care units, coronary care units, and dialysis units) where the sill height is permitted to be not more than 1525 mm (60 in.) above the floor. Sill height in limited care facilities, frequently similar in design to residential-type buildings, has been set at a maximum of 1120 mm (44 in.) above the

Section 18.4 Special Provisions**18.4.1 Limited Access Buildings.**

Limited access buildings or limited access portions of buildings shall not be used for patient sleeping rooms and shall comply with Section 11.7.

CHAPTER 19 • Existing

19.3.8 Special Protection Features—Outside Window or Door.

Every patient sleeping room shall have an outside window or outside door, unless otherwise permitted by the following:

- (1) This requirement shall not apply to newborn nurseries and rooms intended for occupancy for less than 24 hours, such as those housing obstetrical labor beds, recovery beds, and observation beds in the emergency department.
- (2) Windows in atrium walls shall be considered outside windows for the purposes of this requirement.

floor, consistent with residential construction practices.

Rooms that are occupied for less than 24 hours, such as those used for recovery, child delivery, or emergency care, and those used as newborn nurseries need not be provided with a window, because the high incidence of direct nursing supervision of all patients in these areas reduces the likelihood that patients will be trapped in a smoky fire. However, where it is not possible to provide windows, a conservative design should provide some added protection, such as early warning by smoke detectors, or high-volume exhaust ventilation.

Section 19.4 Special Provisions**19.4.1 Limited Access Buildings.**

See Section 11.7 for requirements for limited access buildings.

CHAPTER 18 • New

CHAPTER 19 • Existing

18.4.2 High-Rise Buildings.

High-rise buildings shall comply with Section 11.8.

18.4.3 Nonsprinklered Existing Smoke Compartment Rehabilitation.

18.4.3.1* General. Where a modification in a nonsprinklered smoke compartment is exempted by the provisions of 18.1.1.4.6.4 from the sprinkler requirement of 18.3.5.1, the requirements of 18.4.3.2 through 18.4.3.8 shall apply.

A.18.4.3.1 For example, the provisions of 18.1.1.4.6.1(2) and 18.1.1.4.6.4 do not require the installation of sprinklers if the modification involves less than 50 percent of the area of the smoke compartment and less than 420 m² (4500 ft²) of the area of the smoke compartment.

18.4.3.2 Minimum Construction Requirements (Nonsprinklered Smoke Compartment Rehabilitation). Health care occupancies in buildings not protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.2 shall be limited to the types of construction permitted by Table 18.4.3.2.

Table 18.4.3.2 Construction Type Limitations (Nonsprinklered Buildings)

Construction Type	Stories			
	1	2	3	4 or more
I(443)	X	X	X	X

V(111)	NP	NP	NP	NP
V(000)	NP	NP	NP	NP

X: Permitted type of construction.
NP: Not permitted.

18.4.3.3 Capacity of Means of Egress (Nonsprinklered Smoke Compartment Rehabilitation). The capacity of the means of egress serving the modification area shall be as follows:

- (1) 13 mm (½ in.) per person for horizontal travel, without stairs, by means such as doors, ramps, or level floor surfaces
- (2) 15 mm (0.6 in.) per person for travel by means of stairs

19.4.2 High-Rise Buildings.

(Reserved)

18.4.3.4 Travel Distance (Nonsprinklered Smoke Compartment Rehabilitation).

18.4.3.4.1 The travel distance between any room door required as an exit access and an exit shall not exceed the following:

- (1) 46 m (150 ft) where the travel is wholly within smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.2
- (2) 30 m (100 ft) where the travel is not wholly within smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.2

18.4.3.4.2 The travel distance between any point in a room and an exit shall not exceed the following:

- (1) 61 m (200 ft) where the travel is wholly within smoke compartments protected throughout by an approved, supervised sprinkler system in accordance with 19.3.5.2
- (2) 46 m (150 ft) where the travel is not wholly within smoke compartments protected throughout by an approved, supervised sprinkler system in accordance with 19.3.5.2

18.4.3.5 Hazardous Area Protection (Nonsprinklered Smoke Compartment Rehabilitation). Where a new hazardous area is formed in an existing nonsprinklered smoke compartment, the hazardous area itself shall be protected as indicated in Table 18.4.3.5.

Table 18.4.3.5 Hazardous Area Protection (Nonsprinklered Buildings)

Hazardous Area Description	Separation/Protection
Boiler and fuel-fired heater rooms	1 hour and sprinklers
Central/bulk laundries larger than 9.3 m ² (100 ft ²)	1 hour and sprinklers
Laboratories employing flammable or combustible materials in quantities less than those that would be considered a severe hazard	1 hour or sprinklers (Also see 18.4.3.7.2.2)
Laboratories that use hazardous materials that would be classified as a severe hazard in accordance with NFPA 99, <i>Standard for Health Care Facilities</i>	1 hour and sprinklers
Paint shops employing hazardous substances and materials in quantities less than those that would be classified as a severe hazard	1 hour and sprinklers
Physical plant maintenance shops	1 hour and sprinklers
Soiled linen rooms	1 hour and sprinklers
Storage rooms larger than 4.6 m ² (50 ft ²) but not exceeding 9.3 m ² (100 ft ²) and storing combustible material	1 hour or sprinklers (Also see 18.4.3.7.2.2)
Storage rooms larger than 9.3 m ² (100 ft ²) and storing combustible material	1 hour and sprinklers
Trash collection rooms	1 hour and sprinklers

CHAPTER 18 • New

CHAPTER 19 • Existing

18.4.3.6 Interior Finish (Nonsprinklered Smoke Compartment Rehabilitation).

18.4.3.6.1 General. Interior finish within the modification area shall be in accordance with Section 10.2.

18.4.3.6.2 Interior Wall and Ceiling Finish. Newly installed interior wall and ceiling finish materials complying with Section 10.2 shall be permitted throughout nonsprinklered smoke compartments if the materials are Class A, except as otherwise permitted in 18.4.3.6.2.1 or 18.4.3.6.2.2.

18.4.3.6.2.1 Walls and ceilings shall be permitted to have Class A or Class B interior finish in individual rooms having a capacity not exceeding four persons.

18.4.3.6.2.2 Corridor wall finish not exceeding 1220 mm (48 in.) in height and restricted to the lower half of the wall shall be permitted to be Class A or Class B.

18.4.3.6.3 Interior Floor Finish.

18.4.3.6.3.1 Newly installed interior floor finish shall comply with Section 10.2.

18.4.3.6.3.2 The requirements for newly installed interior floor finish in exit enclosures and corridors not separated from them by walls complying with 19.3.6 shall be as follows:

- (1) Be unrestricted in smoke compartments protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.2
- (2) Be not less than Class I in smoke compartments not protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.2

18.4.3.7 Corridors (Nonsprinklered Smoke Compartment Rehabilitation).**18.4.3.7.1 Construction of Corridor Walls.**

18.4.3.7.1.1 Where the smoke compartment being modified is not protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.2, corridor walls shall comply with the following, as modified by 18.4.3.7.1.2:

- (1) Have a fire resistance rating of not less than ½ hour
- (2) Be continuous from the floor to the underside of the floor or roof deck above
- (3) Resist the passage of smoke

18.4.3.7.1.2 The requirements of 18.4.3.7.1.1 shall be permitted to be modified for conditions permitted by 19.3.6.1(3), 19.3.6.1(4), 19.3.6.1(6), 19.3.6.1(7), and 19.3.6.1(8).

CHAPTER 18 • New

CHAPTER 19 • Existing

18.4.3.7.2 Corridor Doors.

18.4.3.7.2.1 Where the smoke compartment being modified is not protected throughout by an approved, supervised automatic sprinkler system in accordance with 19.3.5.2, the following shall apply:

- (1) Doors protecting corridor openings shall be constructed of 44-mm (1¾-in.) thick, solid-bonded core wood or of construction that resists the passage of fire for not less than 20 minutes.
- (2) Door frames shall be labeled or of steel construction.
- (3) Existing roller latches demonstrated to keep the door closed against a force of 22 N (5 lbf) shall be permitted.

18.4.3.7.2.2 Door-closing devices shall be required on doors in corridor wall openings serving smoke barriers or enclosures of exits, hazardous contents areas, or vertical openings.

18.4.3.8 Subdivision of Building Space (Nonsprinklered Smoke Compartment Rehabilitation). Subparagraph 18.3.7.4(2) shall be permitted only where adjacent smoke compartments are protected throughout by an approved, supervised automatic sprinkler system in accordance with 18.3.5.1 and 18.3.5.2.

Section 18.5 Building Services**18.5.1 Utilities.**

18.5.1.1 Utilities shall comply with the provisions of Section 9.1.

18.5.1.2 Power for alarms, emergency communications systems, and illumination of generator set locations shall be in accordance with the essential electrical system requirements of NFPA 99, *Standard for Health Care Facilities*.

18.5.1.3 Any health care occupancy, as indicated in 18.1.1.1.2, that normally uses life-support devices shall have electrical systems designed and installed in accordance with NFPA 99, *Standard for Health Care Facilities*, unless the facility uses life-support equipment for emergency purposes only.

18.5.2 Heating, Ventilating, and Air Conditioning.

18.5.2.1 Heating, ventilating, and air conditioning shall comply with the provisions of Section 9.2 and shall be installed in accordance with the manufacturer's specifications, unless otherwise modified by 18.5.2.2.

18.5.2.2* Any heating device other than a central heating plant shall be designed and installed so that combustible

Section 19.5 Building Services**19.5.1 Utilities.**

19.5.1.1 Utilities shall comply with the provisions of Section 9.1.

19.5.1.2 Existing installations shall be permitted to be continued in service, provided that the systems do not present a serious hazard to life.

19.5.2 Heating, Ventilating, and Air Conditioning.

19.5.2.1 Heating, ventilating, and air conditioning shall comply with the provisions of Section 9.2 and shall be installed in accordance with the manufacturer's specifications, unless otherwise modified by 19.5.2.2.

19.5.2.2* Any heating device other than a central heating plant shall be designed and installed so that combustible

CHAPTER 18 • New

material cannot be ignited by the device or its appurtenances, and the following requirements shall also apply:

- (1) If fuel-fired, such heating devices shall comply with the following:
 - (a) They shall be chimney connected or vent connected.
 - (b) They shall take air for combustion directly from outside.
 - (c) They shall be designed and installed to provide for complete separation of the combustion system from the atmosphere of the occupied area.
- (2) Any heating device shall have safety features to immediately stop the flow of fuel and shut down the equipment in case of either excessive temperatures or ignition failure.

A.18.5.2.2 For both new and existing buildings, it is the intent to permit the installation and use of fireplace stoves and room heaters utilizing solid fuel as defined in NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel-Burning Appliances*, provided that all such devices are installed, maintained, and used in accordance with the appropriate provisions of that standard and all manufacturers' specifications. These requirements are not intended to permit freestanding solid fuel-burning appliances such as freestanding wood-burning stoves.

18.5.2.3 The requirements of 18.5.2.2 shall not apply where otherwise permitted by the following:

- (1) Approved, suspended unit heaters shall be permitted in locations other than means of egress and patient sleeping areas, provided that both of the following criteria are met:
 - (a) Such heaters are located high enough to be out of the reach of persons using the area.
 - (b) Such heaters are equipped with the safety features required by 18.5.2.2.
- (2) Fireplaces shall be permitted and used only in areas other than patient sleeping areas, provided that all of the following criteria are met:
 - (a) Such areas are separated from patient sleeping spaces by construction having not less than a 1-hour fire resistance rating.
 - (b) Such fireplaces comply with the provisions of 9.2.2.
 - (c) The fireplace is equipped with the following:
 - i. A hearth that is raised not less than 100 mm (4 in.)
 - ii. A fireplace enclosure guaranteed against breakage up to a temperature of 343°C (650°F) and constructed of heat-tempered glass or other approved material
- (3) If, in the opinion of the authority having jurisdiction,

CHAPTER 19 • Existing

material cannot be ignited by the device or its appurtenances, and the following requirements also shall apply:

- (1) If fuel-fired, such heating devices shall comply with the following:
 - (a) They shall be chimney connected or vent connected.
 - (b) They shall take air for combustion directly from the outside.
 - (c) They shall be designed and installed to provide for complete separation of the combustion system from the atmosphere of the occupied area.
- (2) Any heating device shall have safety features to immediately stop the flow of fuel and shut down the equipment in case of either excessive temperature or ignition failure.

A.19.5.2.2 For both new and existing buildings, it is the intent to permit the installation and use of fireplace stoves and room heaters using solid fuel as defined in NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel-Burning Appliances*, provided that all such devices are installed, maintained, and used in accordance with the appropriate provisions of that standard and all manufacturers' specifications. These requirements are not intended to permit freestanding solid fuel-burning appliances such as freestanding wood-burning stoves.

19.5.2.3 The requirements of 19.5.2.2 shall not apply where otherwise permitted by the following:

- (1) Approved, suspended unit heaters shall be permitted in locations other than means of egress and patient sleeping areas, provided that both of the following criteria are met:
 - (a) Such heaters are located high enough to be out of the reach of persons using the area.
 - (b) Such heaters are equipped with the safety features required by 19.5.2.2.
- (2) Fireplaces shall be permitted and used only in areas other than patient sleeping areas, provided that all of the following criteria are met:
 - (a) Such areas are separated from patient sleeping spaces by construction having not less than a 1-hour fire resistance rating.
 - (b) Such fireplaces comply with the provisions of 9.2.2.
 - (c) The fireplace is equipped with a fireplace enclosure guaranteed against breakage up to a temperature of 343°C (650°F) and constructed of heat-tempered glass or other approved material.
- (3) If, in the opinion of the authority having jurisdiction,

CHAPTER 18 • New

special hazards are present, a lock on the enclosure specified in 18.5.2.3(2)(c)(ii) and other safety precautions shall be permitted to be required.

18.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

Paragraphs 18/19.5.2.1 through 18/19.5.2.3 specify safeguards for air conditioning, ventilating, heating, and other service equipment to minimize the possibility of such devices serving as a source of ignition. Fuel-fired heating devices, except central heating systems, must be designed to provide complete separation of the combustion system from the occupied spaces. Air for combustion must be taken directly from the outside.

A major concern is preventing the ignition of clothing, bedclothes, furniture, and other furnishings by a heating device. Therefore, 18/19.7.8 prohibits portable heating devices in areas used by patients.

Paragraph 18/19.5.3 addresses elevators. Although not counted as required exits for the general populace, elevators might constitute a valuable, supplemental facility for evacuating patients from health care occupancies. In some cases, using an elevator might be the only feasible way to move critically ill patients or patients in restraining devices.

Elevators, however, have many inherent weaknesses that tend to limit reliability. Elevator access doors are designed with operating tolerances that permit smoke transfer into the shaft. During a fire, a

18.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

18.5.4.1 Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

18.5.4.2 Any rubbish chute or linen chute, including pneumatic rubbish and linen systems, shall be provided with automatic extinguishing protection in accordance with Section 9.7. (*See Section 9.5.*)

18.5.4.3 Any trash chute shall discharge into a trash collection room used for no other purpose and protected in accordance with Section 8.7.

CHAPTER 19 • Existing

special hazards are present, a lock on the enclosure specified in 19.5.2.3(2)(c) and other safety precautions shall be permitted to be required.

19.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

power failure might cause an elevator to stop between floors, trapping its passengers. Elevators might, during their descent from upper floors, stop automatically at the floor where the fire is burning, allow the doors to open, and expose the occupants to the fire.

Many of these weaknesses can be minimized by providing emergency power, separating the elevator lobby from other building spaces using rated construction, designing detection and alarm equipment to prevent elevators from stopping at a floor exposed to a fire, providing an emergency smoke control system, and pressurizing the elevator shaft and adjacent lobbies. These countermeasures represent good fire protection judgment but are not requirements of this *Code*.

Through emergency planning and staff training, the potential problem of crowded elevators might be avoided. Emergency plans can make effective use of elevators by transferring patients through a horizontal exit, for example, to a separate fire area. Within the separate fire area, a staged evacuation program could be instituted, with the elevators taking patients to the ground level, permitting horizontal movement to the outside.

19.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

19.5.4.1 Any existing linen and trash chute, including pneumatic rubbish and linen systems, that opens directly onto any corridor shall be sealed by fire-resistive construction to prevent further use or shall be provided with a fire door assembly having a fire protection rating of 1 hour. All new chutes shall comply with Section 9.5.

19.5.4.2 Any rubbish chute or linen chute, including pneumatic rubbish and linen systems, shall be provided with automatic extinguishing protection in accordance with Section 9.7. (*See Section 9.5.*)

19.5.4.3 Any trash chute shall discharge into a trash collection room used for no other purpose and protected in accordance with Section 8.7.

CHAPTER 18 • New

18.5.4.4 Incinerators shall not be directly flue-fed, nor shall any floor-charging chute directly connect with the combustion chamber.

Section 18.6 Reserved

Section 18.7* Operating Features

A.18.7 Health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside or even their disturbance caused by moving is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable.

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification need to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum.

18.7.1 Evacuation and Relocation Plan and Fire Drills.

18.7.1.1 The administration of every health care occupancy shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons in the event of fire, for their evacuation to areas of refuge, and for their evacuation from the building when necessary.

18.7.1.2 All employees shall be periodically instructed and kept informed with respect to their duties under the plan required by 18.7.1.1.

18.7.1.3 A copy of the plan required by 18.7.1.1 shall be readily available at all times in the telephone operator's location or at the security center.

18.7.1.4* Fire drills in health care occupancies shall include the transmission of a fire alarm signal and simulation of emergency fire conditions.

A.18.7.1.4 Many health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors to patients' rooms or wards in the vicinity prior to initiation of the drill. The purpose of a fire drill is to test and evaluate

CHAPTER 19 • Existing

19.5.4.4 Existing flue-fed incinerators shall be sealed by fire-resistive construction to prevent further use.

Section 19.6 Reserved

Section 19.7* Operating Features

A.19.7 Health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside or even their disturbance caused by moving is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable.

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification needs to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum.

19.7.1 Evacuation and Relocation Plan and Fire Drills.

19.7.1.1 The administration of every health care occupancy shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons in the event of fire, for their evacuation to areas of refuge, and for their evacuation from the building when necessary.

19.7.1.2 All employees shall be periodically instructed and kept informed with respect to their duties under the plan required by 19.7.1.1.

19.7.1.3 A copy of the plan required by 19.7.1.1 shall be readily available at all times in the telephone operator's location or at the security center.

19.7.1.4* Fire drills in health care occupancies shall include the transmission of a fire alarm signal and simulation of emergency fire conditions.

A.19.7.1.4 Many health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors to patients' rooms or wards in the vicinity prior to initiation of the drill. The purpose of a fire drill is to test and evaluate

CHAPTER 18 • New

the efficiency, knowledge, and response of institutional personnel in implementing the facility fire emergency plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in health care facilities are drilled not less than once in each 3-month period.

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs.

18.7.1.5 Infirm or bedridden patients shall not be required to be moved during drills to safe areas or to the exterior of the building.

18.7.1.6 Drills shall be conducted quarterly on each shift to familiarize facility personnel (nurses, interns, maintenance engineers, and administrative staff) with the signals and emergency action required under varied conditions.

18.7.1.7 When drills are conducted between 9:00 p.m. (2100 hours) and 6:00 a.m. (0600 hours), a coded announcement shall be permitted to be used instead of audible alarms.

18.7.1.8 Employees of health care occupancies shall be instructed in life safety procedures and devices.

The former requirement for patient beds to be on wheels or casters was deleted from the *Code* in 1991. Ordinary practice in health care occupancies is to move patients through the hospital on narrow beds, on gurneys, on carts, or in wheelchairs. Thus, hospitals have little experience in moving patients in large beds. In addition, the furniture in patient rooms—chairs, nightstands, food trays/tables, and medical equipment—must be moved out of the way to allow

18.7.2 Procedure in Case of Fire.

18.7.2.1* Protection of Patients.

A.18.7.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The following recommendations, however, contain many of the elements that should be considered and adapted as appropriate to the individual facility.

Upon discovery of fire, personnel should immediately take the following action:

- (1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase. The use of a code provides for

CHAPTER 19 • Existing

the efficiency, knowledge, and response of institutional personnel in implementing the facility fire emergency plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in health care facilities are drilled not less than once in each 3-month period.

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs.

19.7.1.5 Infirm or bedridden patients shall not be required to be moved during drills to safe areas or to the exterior of the building.

19.7.1.6 Drills shall be conducted quarterly on each shift to familiarize facility personnel (nurses, interns, maintenance engineers, and administrative staff) with the signals and emergency action required under varied conditions.

19.7.1.7 When drills are conducted between 9:00 p.m. (2100 hours) and 6:00 a.m. (0600 hours), a coded announcement shall be permitted to be used instead of audible alarms.

19.7.1.8 Employees of health care occupancies shall be instructed in life safety procedures and devices.

patient beds to be turned and moved out of the room. Moving patients in this way requires extra staff time that is usually unavailable during a fire. Emphasis should be placed on the quick movement of patients who are in the room of fire origin, as well as others who are directly exposed to the fire. Patient movement in fire emergencies is often achieved by dragging occupants on bedding, as opposed to moving beds.

19.7.2 Procedure in Case of Fire.

19.7.2.1* Protection of Patients.

A.19.7.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The following recommendations, however, contain many of the elements that should be considered and adapted as appropriate to the individual facility.

Upon discovery of fire, personnel should immediately take the following action:

- (1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase. The use of a code provides for

CHAPTER 18 • New

both the immediate aid of any endangered person and the transmission of an alarm. Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.

- (2) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
- (3) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
- (4) The telephone operator should determine the location of the fire as indicated by the audible signal. In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
- (5) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system. The operator should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
- (6) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone. The operator should then transmit this information to the fire department and alert the building occupants.

18.7.2.1.1 For health care occupancies, the proper protection of patients shall require the prompt and effective response of health care personnel.

18.7.2.1.2 The basic response required of staff shall include the following:

- (1) Removal of all occupants directly involved with the fire emergency
- (2) Transmission of an appropriate fire alarm signal to warn other building occupants and summon staff
- (3) Confinement of the effects of the fire by closing doors to isolate the fire area
- (4) Relocation of patients as detailed in the health care occupancy's fire safety plan

18.7.2.2 Fire Safety Plan. A written health care occupancy fire safety plan shall provide for the following:

- (1) Use of alarms
- (2) Transmission of alarm to fire department
- (3) Emergency phone call to fire department
- (4) Response to alarms
- (5) Isolation of fire

CHAPTER 19 • Existing

both the immediate aid of any endangered person and the transmission of an alarm. Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.

- (2) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
- (3) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
- (4) The telephone operator should determine the location of the fire as indicated by the audible signal. In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
- (5) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system. The operator should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
- (6) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone. The operator should then transmit this information to the fire department and alert the building occupants.

19.7.2.1.1 For health care occupancies, the proper protection of patients shall require the prompt and effective response of health care personnel.

19.7.2.1.2 The basic response required of staff shall include the following:

- (1) Removal of all occupants directly involved with the fire emergency
- (2) Transmission of an appropriate fire alarm signal to warn other building occupants and summon staff
- (3) Confinement of the effects of the fire by closing doors to isolate the fire area
- (4) Relocation of patients as detailed in the health care occupancy's fire safety plan

19.7.2.2 Fire Safety Plan. A written health care occupancy fire safety plan shall provide for the following:

- (1) Use of alarms
- (2) Transmission of alarm to fire department
- (3) Emergency phone call to fire department
- (4) Response to alarms
- (5) Isolation of fire

CHAPTER 18 • New

- (6) Evacuation of immediate area
- (7) Evacuation of smoke compartment
- (8) Preparation of floors and building for evacuation
- (9) Extinguishment of fire

18.7.2.3 Staff Response.

18.7.2.3.1 All health care occupancy personnel shall be instructed in the use of and response to fire alarms.

18.7.2.3.2 All health care occupancy personnel shall be instructed in the use of the code phrase to ensure transmission of an alarm under the following conditions:

- (1) When the individual who discovers a fire must immediately go to the aid of an endangered person
- (2) During a malfunction of the building fire alarm system

18.7.2.3.3 Personnel hearing the code announced shall first activate the building fire alarm using the nearest manual fire alarm box, then shall execute immediately their duties as outlined in the fire safety plan.

In addition to the requirements of 18/19.7.2, evacuation plans should stress that the doors of as many patient rooms as possible be closed to block smoke spreading from a fire and, if possible, to confine the fire in a room. This single action taken by the staff (that is, manually closing the doors) achieves the level of safety to life mandated by the *Code* in Chapters 18 and 19. In studies of fires in health care institutions in which the staff closed doors and subsequent responders left the doors closed, the fire spread was

18.7.3 Maintenance of Exits.

18.7.3.1 Proper maintenance shall be provided to ensure the dependability of the method of evacuation selected.

18.7.3.2 Health care occupancies that find it necessary to lock exits shall, at all times, maintain an adequate staff qualified to release locks and direct occupants from the immediate danger area to a place of safety in case of fire or other emergency.

18.7.4* Smoking.

Smoking regulations shall be adopted and shall include not less than the following provisions:

- (1) Smoking shall be prohibited in any room, ward, or compartment where flammable liquids, combustible gases, or oxygen is used or stored and in any other hazardous

CHAPTER 19 • Existing

- (6) Evacuation of immediate area
- (7) Evacuation of smoke compartment
- (8) Preparation of floors and building for evacuation
- (9) Extinguishment of fire

19.7.2.3 Staff Response.

19.7.2.3.1 All health care occupancy personnel shall be instructed in the use of and response to fire alarms.

19.7.2.3.2 All health care occupancy personnel shall be instructed in the use of the code phrase to ensure transmission of an alarm under the following conditions:

- (1) When the individual who discovers a fire must immediately go to the aid of an endangered person
- (2) During a malfunction of the building fire alarm system

19.7.2.3.3 Personnel hearing the code announced shall first activate the building fire alarm using the nearest manual fire alarm box, then shall execute immediately their duties as outlined in the fire safety plan.

readily confined, and there was little or no loss of life.

In many fatal fires in health care facilities, staff either did not close doors or someone reopened them; the fire spread was sizable, and the loss of life was high. Emphasis must be placed on training staff to sound an alarm, rescue patients (as needed), and then close all doors. The closing of doors historically has had the most significant effect on limiting the spread of fire and smoke.

19.7.3 Maintenance of Exits.

19.7.3.1 Proper maintenance shall be provided to ensure the dependability of the method of evacuation selected.

19.7.3.2 Health care occupancies that find it necessary to lock exits shall, at all times, maintain an adequate staff qualified to release locks and direct occupants from the immediate danger area to a place of safety in case of fire or other emergency.

19.7.4* Smoking.

Smoking regulations shall be adopted and shall include not less than the following provisions:

- (1) Smoking shall be prohibited in any room, ward, or compartment where flammable liquids, combustible gases, or oxygen is used or stored and in any other hazardous

CHAPTER 18 • New

location, and such areas shall be posted with signs that read NO SMOKING or shall be posted with the international symbol for no smoking.

- (2) In health care occupancies where smoking is prohibited and signs are prominently placed at all major entrances, secondary signs with language that prohibits smoking shall not be required.
- (3) Smoking by patients classified as not responsible shall be prohibited.
- (4) The requirement of 18.7.4(3) shall not apply where the patient is under direct supervision.
- (5) Ashtrays of noncombustible material and safe design shall be provided in all areas where smoking is permitted.
- (6) Metal containers with self-closing cover devices into which ashtrays can be emptied shall be readily available to all areas where smoking is permitted.

A.18.7.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management.

18.7.5 Furnishings, Bedding, and Decorations.

18.7.5.1* Draperies, curtains, and other loosely hanging fabrics and films serving as furnishings or decorations in health care occupancies shall be in accordance with the provisions of 10.3.1 (*see 18.3.5.6*), and the following also shall apply:

- (1) Such curtains shall include cubicle curtains.
- (2) Such curtains shall not include curtains at showers.

A.18.7.5.1 In addition to the provisions of 10.3.1, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

18.7.5.2 Newly introduced upholstered furniture within health care occupancies shall meet the criteria specified when tested in accordance with the methods cited in 10.3.2(2) and 10.3.3.

18.7.5.3 Reserved.

CHAPTER 19 • Existing

location, and such areas shall be posted with signs that read NO SMOKING or shall be posted with the international symbol for no smoking.

- (2) In health care occupancies where smoking is prohibited and signs are prominently placed at all major entrances, secondary signs with language that prohibits smoking shall not be required.
- (3) Smoking by patients classified as not responsible shall be prohibited.
- (4) The requirement of 19.7.4(3) shall not apply where the patient is under direct supervision.
- (5) Ashtrays of noncombustible material and safe design shall be provided in all areas where smoking is permitted.
- (6) Metal containers with self-closing cover devices into which ashtrays can be emptied shall be readily available to all areas where smoking is permitted.

A.19.7.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management.

19.7.5 Furnishings, Bedding, and Decorations.

19.7.5.1* Draperies, curtains, and other loosely hanging fabrics and films serving as furnishings or decorations in health care occupancies shall be in accordance with the provisions of 10.3.1 (*see 19.3.5.6*), and the following also shall apply:

- (1) Such curtains shall include cubicle curtains.
- (2) Such curtains shall not include curtains at showers.

A.19.7.5.1 In addition to the provisions of 10.3.1, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

19.7.5.2 Newly introduced upholstered furniture within health care occupancies shall meet the criteria specified when tested in accordance with the methods cited in 10.3.2(2) and 10.3.3.

19.7.5.3 The requirement of 19.7.5.2 shall not apply to upholstered furniture belonging to the patient in sleeping rooms of nursing homes where the following criteria are met:

CHAPTER 18 • New

18.7.5.4 Newly introduced mattresses within health care occupancies shall meet the criteria specified when tested in accordance with the methods cited in 10.3.2(3) and 10.3.4.

18.7.5.5 Reserved.

18.7.5.6 Combustible decorations shall be prohibited in any health care occupancy unless one of the following criteria is met:

- (1) They are flame-retardant.
- (2) They are decorations, such as photographs and paintings, in such limited quantities that a hazard of fire development or spread is not present.

18.7.5.7 Soiled linen or trash collection receptacles shall not exceed 121 L (32 gal) in capacity and shall meet the following requirements:

- (1) The average density of container capacity in a room or space shall not exceed 20.4 L/m² (0.5 gal/ft²).
- (2) A capacity of 121 L (32 gal) shall not be exceeded within any 16-m² (64-ft²) area.
- (3) Mobile soiled linen or trash collection receptacles with capacities greater than 121 L (32 gal) shall be located in a room protected as a hazardous area when not attended.
- (4) Container size and density shall not be limited in hazardous areas.

Cigarette ignition-resistance testing—as detailed in 10.3.2—and rate of heat release testing—as detailed in 10.3.3 and 10.3.4—are required by 18/19.7.5.2 and 18/19.7.5.4 for newly introduced upholstered furniture and newly introduced mattresses in health care occupancies, unless the room or space is sprinklered. However, these requirements would seldom apply in new health care occupancies because 18.3.5.1 requires new health care occupancies to be sprinklered. Unlike new health care occupancies—which are required to be sprinklered—many existing facilities are not sprinklered. Yet government regulations require that patients be permitted to bring their own furniture with them to a nursing home. Paragraphs

CHAPTER 19 • Existing

- (1) A smoke detector shall be installed in such rooms.
- (2) Battery-powered single-station smoke detectors shall be permitted.

19.7.5.4 Newly introduced mattresses within health care occupancies shall meet the criteria specified when tested in accordance with the methods cited in 10.3.2(3) and 10.3.4.

19.7.5.5 The requirement of 19.7.5.4 shall not apply to mattresses belonging to the patient in sleeping rooms of nursing homes where the following criteria are met:

- (1) A smoke detector shall be installed in such rooms.
- (2) Battery-powered, single-station smoke detectors shall be permitted.

19.7.5.6 Combustible decorations shall be prohibited in any health care occupancy unless one of the following criteria is met:

- (1) They are flame-retardant.
- (2) They are decorations such as photographs and paintings in such limited quantities that a hazard of fire development or spread is not present.

19.7.5.7 Soiled linen or trash collection receptacles shall not exceed 121 L (32 gal) in capacity, and the following also shall apply:

- (1) The average density of container capacity in a room or space shall not exceed 20.4 L/m² (0.5 gal/ft²).
- (2) A capacity of 121 L (32 gal) shall not be exceeded within any 6-m² (64-ft²) area.
- (3) Mobile soiled linen or trash collection receptacles with capacities greater than 121 L (32 gal) shall be located in a room protected as a hazardous area when not attended.
- (4) Container size and density shall not be limited in hazardous areas.

19.7.5.3 and 19.7.5.5 offer nonsprinklered existing health care facilities another option—providing smoke detection within the patient room. If early warning is provided to staff, then an incipient stage fire might be able to be extinguished manually almost as quickly as would occur automatically in a room that is sprinklered.

Paragraph 18/19.7.5.7 establishes maximum trash container sizes and placement densities permitted within a room. Containers larger than that specified, or grouped containers exceeding the density-per-room criterion, present a hazard greater than that associated with the normal furnishing of a health care occupancy room.

CHAPTER 18 • New

Large, mobile soiled linen or trash receptacles can be moved along the corridor as collections occur but must be attended by staff. If housekeeping staff, for example, must leave the area, the container must be stored in a room designed and maintained as a hazardous area in accordance with 18/19.3.2.1.

Exhibit 18/19.32 illustrates the requirements of 18/19.7.5.5.

CHAPTER 19 • Existing

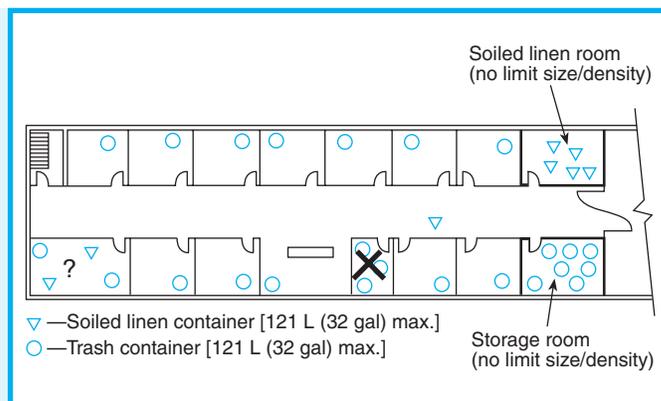

Exhibit 18/19.32 Allowable soiled linen or trash collection receptacles.

18.7.6 Maintenance and Testing.

See 4.6.13.

18.7.7* Engineered Smoke Control Systems.

A.18.7.7 Two documents that provide recognized engineering principles for the testing of smoke control systems are NFPA 92A, *Recommended Practice for Smoke-Control Systems*, and NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*.

18.7.7.1 New engineered smoke control systems shall be tested in accordance with established engineering principles and shall meet the performance requirements of such testing prior to acceptance.

18.7.7.2 Following acceptance, all engineered smoke control systems shall be tested periodically in accordance with recognized engineering principles.

18.7.7.3 Test documentation shall be maintained on the premises at all times.

18.7.8 Portable Space-Heating Devices.

Portable space-heating devices shall be prohibited in all health care occupancies, unless both of the following criteria are met:

- (1) Such devices are permitted to be used only in nonsleeping staff and employee areas.
- (2) The heating elements of such devices do not exceed 100°C (212°F).

19.7.6 Maintenance and Testing.

(See 4.6.13.)

19.7.7* Engineered Smoke Control Systems.

A.19.7.7 Two documents that provide recognized engineering principles for the testing of smoke control systems are NFPA 92A, *Recommended Practice for Smoke-Control Systems*, and NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*.

19.7.7.1 Existing engineered smoke control systems, unless specifically exempted by the authority having jurisdiction, shall be tested in accordance with established engineering principles.

19.7.7.2 Systems not meeting the performance requirements of such testing shall be continued in operation only with the specific approval of the authority having jurisdiction.

19.7.8 Portable Space-Heating Devices.

Portable space-heating devices shall be prohibited in all health care occupancies, unless both of the following criteria are met:

- (1) Such devices are used only in nonsleeping staff and employee areas.
- (2) The heating elements of such devices do not exceed 100°C (212°F).

CHAPTER 18 • New

18.7.9 Construction, Repair, and Improvement Operations.

18.7.9.1 Construction, repair, and improvement operations shall comply with 4.6.11.

18.7.9.2 The means of egress in any area undergoing construction, repair, or improvements shall be inspected daily for compliance with 7.1.10.1 and shall also comply with NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*.

CHAPTER 19 • Existing

19.7.9 Construction, Repair, and Improvement Operations.

19.7.9.1 Construction, repair, and improvement operations shall comply with 4.6.11.

19.7.9.2 The means of egress in any area undergoing construction, repair, or improvements shall be inspected daily for compliance with 7.1.10.1 and shall also comply with NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*.

CHAPTERS 20 and 21

New and Existing Ambulatory Health Care Occupancies

Chapters 20 and 21 address the needs of occupants of facilities that provide medical treatment on an out-patient basis. This treatment is not merely a routine medical visit such as to a doctor's office, but rather a procedure that renders the patient incapable of self-preservation. Although this description might sound similar to what one would expect of a hospital, the major difference is that an ambulatory health care facility does not provide care for any individual for an elapsed time of 24 hours or more. Rather, a patient receives treatment and then leaves the facility. Patients suffering complications that would prevent their leaving the ambulatory health care facility would typically be transported and admitted to a hospital that provides care on a 24-hour basis.

There is also an important distinction concerning the number of occupants required to constitute classification as an ambulatory health care occupancy—that number being four or more (see the definition of *ambulatory health care occupancy* in 3.3.152.1). The requirements for ambulatory health care occupancies

are based on a combination of requirements—some from those that are applicable to hospitals and some that come from directly referencing the provisions of Chapters 38 and 39 for business occupancies. If a facility does not meet the definition of *ambulatory health care occupancy*, it generally needs to comply only with the requirements for a business occupancy.

Commentary Table 20/21.1 differentiates among health care, ambulatory health care, and business occupancies on the basis of patient load and care provided. Incapability of self-preservation might be the result of the use of general anesthesia, a treatment such as dialysis, or an injury or illness that brings the patient to the ambulatory health facility for treatment. Based on the information in the table, a dentist could administer general anesthesia to not more than three patients simultaneously and be classified as a business occupancy. If the dentist expands the simultaneous administration of general anesthesia to a fourth patient, then the more stringent requirements for ambulatory health care occupancies would apply.

Commentary Table 20/21.1 Occupancy Classification Comparison

Factor	Chapters 18/19 Health Care Occupancies	Chapters 20/21 Ambulatory Health Care Occupancies	Chapters 38/39 Business Occupancies
Number of patients rendered incapable of self-preservation	4 or more†	4 or more††	3 or fewer
Care provided on a 24-hour basis?	Yes	No	No

†Incapability of self-preservation might exist prior to admission and be unrelated to the treatment provided (see 18/19.1.1.1.3).

††Incapability of self-preservation might exist prior to admission but be related to the treatment provided [see 3.3.152.1(3)].

CHAPTER 20 • New

Section 20.1 General Requirements**20.1.1 Application.****20.1.1.1 General.**

20.1.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as ambulatory health care occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, an ambulatory health care occupancy (*see 4.6.7 and 20.1.1.4*), unless all of the following criteria are met:
 - (a) The addition is classified as an occupancy other than an ambulatory health care occupancy.
 - (b) The addition is separated from the ambulatory health care occupancy in accordance with 20.1.2.2.
 - (c) The addition conforms to the requirements for the specific occupancy.
- (3) Alterations, modernizations, or renovations of existing ambulatory health care occupancies (*see 4.6.8 and 20.1.1.4*)
- (4) Existing buildings or portions thereof upon change of occupancy to an ambulatory health care occupancy (*see 4.6.12*)

20.1.1.1.2 Ambulatory health care facilities shall comply with the provisions of Chapter 38 and this chapter, whichever is more stringent.

Ambulatory health care facilities exhibit some of the occupancy characteristics of business occupancies and some of the characteristics of health care occupancies. Chapters 20 and 21 prescribe a level of life safety from fire that is greater than that typically specified for business occupancies but less than that typically found in hospitals, nursing homes, and limited care facilities. See the commentary for 18/19.1.3.

Ambulatory health care facilities are required to comply with the provisions of Chapters 38 and 39 pertaining to business occupancies and those contained within Chapters 20 and 21. Where Chapter 38 or 39 and Chapter 20 or 21 address a feature in different ways, the stricter application (typically that addressed by Chapter 20 or 21) governs. Chapters 20 and 21 also address features not covered by Chapters 38 and 39 (for example, subdivision of building space via smoke barriers) but similar to those required for health care occupancies by Chapters 18 and 19.

As an example, Exhibit 20/21.1 is a plan of a

CHAPTER 21 • Existing

Section 21.1 General Requirements**21.1.1 Application.****21.1.1.1 General.**

21.1.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as an ambulatory health care occupancy. (*See also 20.1.1.1.1.*)

21.1.1.1.2 Ambulatory health care facilities shall comply with the provisions of Chapter 39 and this chapter, whichever is more stringent.

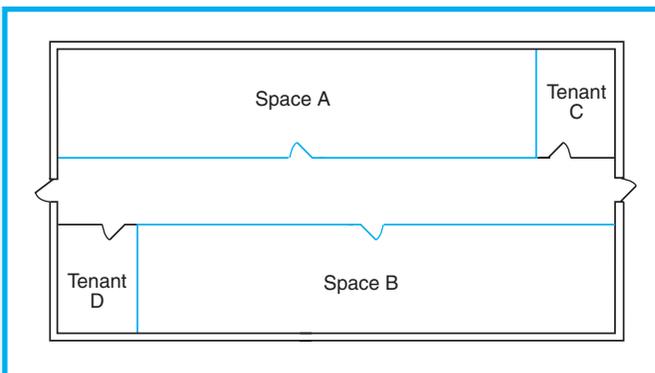

Exhibit 20/21.1 Occupancy classification dependent on tenant use.

single-story, nonsprinklered, existing office building. Tenants C and D occupy a small portion of the floor. Most of the first floor area (spaces A and B located on opposite sides of the corridor) is available for lease-

CHAPTER 20 • New

CHAPTER 21 • Existing

ing to one or more tenants. A kidney dialysis center (an ambulatory health care occupancy) plans to take space A; a multi-lawyer law practice (a business occupancy) plans to take space B. The previous tenants of both space A and space B used their leased space as offices (business occupancies).

The lawyers' office is classified as a business occupancy; and because its occupancy classification represents no change from that of the previous tenant, it is further classified as an existing business occupancy. The lawyers' office must, therefore, meet the requirements of Chapter 39, which apply to existing business occupancies. The kidney dialysis center will render four or more patients simultaneously

incapable of self-preservation [see 3.3.152.1(1)]; it is classified as an ambulatory health care occupancy. Because that occupancy classification represents a change from that of the previous tenant, the dialysis center is further classified as a new ambulatory health care occupancy. The kidney dialysis center must, therefore, meet the requirements of Chapter 20, which apply to new ambulatory health care occupancies, and those of Chapter 38, which apply to new business occupancies.

Commentary Table 20/21.2 contrasts some of the Code provisions that apply to the kidney dialysis center and the lawyers' office addressed in the preceding paragraph.

Commentary Table 20/21.2 Comparison of Applicable Requirements for Occupancy

Building Feature	Kidney Dialysis Center (new ambulatory health care occupancy)	Lawyers' Office (existing business occupancy)
Egress door locking	Addressed by 20.1.1.1.5; doors permitted to be locked to confine and protect patients, but AHJ must make modifications to allow for locked doors.	Doors not permitted to be locked while space is occupied in accordance with 7.2.1.5.1.
Minimum construction	Regulated by 20.1.6, but because building is single story, any NFPA 220 construction type is acceptable. (see 20.1.6.3)	No regulation.
Automatic door closing	In addition to release via methods of 7.2.1.8 (smoke detection, power failure, manual action), initiation of the required fire alarm must release the hold-open devices in accordance with 20.2.2.3.	Release hold-open devices via methods of 7.2.1.8 (smoke detection, power failure, manual action).
Door width	Minimum 810-mm (32-in.) clear width in accordance with 20.2.3.3 and 7.2.1.2.4.	Minimum 710 mm (28 in.) door leaf width in accordance with 7.2.1.2.4(4).
Number of exits	Minimum of two in accordance with 20.2.4.	Single exit permitted 39.2.4.2.
Number of exit accesses	Minimum of two exit access doors from suite of more than 232 m ² (2500 ft ²) in accordance with 20.2.4.2, or if common path of travel with single door would be excessive (see 38.2.5.3).	Second exit access door required from suite if common path of travel with single door would be excessive (see 39.2.5.3).
Travel distance	Considered in two pieces in accordance with 20.2.6.2; room door to exit travel (typically corridor travel) limited to 30 m (100 ft); total travel limited to 46 m (150 ft).	One consideration of total travel distance, which is limited to 61 m (200 ft) in accordance with 39.2.6.
Emergency lighting	Required within center and its egress paths by 20.2.9.1.	Required by 39.2.9.1 only if the single floor has occupant load of 1000 or more persons.
Alarm system	Required within center by 20.3.4; manual fire alarm boxes; automatic occupant notification; and fire department notification.	Required by 39.3.4 only if the single floor has occupant load of 1000 or more persons; automatic initiation permitted to substitute for manual fire alarm boxes; occupant notification can come from attended location; fire department notification not required.

(continues)

Commentary Table 20/21.2 Continued

Building Feature	Kidney Dialysis Center (new ambulatory health care occupancy)	Lawyers' Office (existing business occupancy)
Smoke compartmentation	Required by 20.3.7; separation required from other tenants; subdivision by smoke barriers within center unless <465 m ² (<5000 ft ²) and smoke detection, or <929 m ² (<10,000 ft ²) and sprinklers.	No regulation.
Evacuation and relocation plan	Required by 20.7.1.	No regulation.
Staff procedures in case of fire	Required by 20.7.2.	No regulation.
Control of furnishings	Required by 20.7.5 for curtains, upholstered furniture, mattresses, trash receptacles.	No regulation.

20.1.1.1.3 This chapter establishes life safety requirements, in addition to those required in Chapter 38, for the design of all ambulatory health care occupancies as defined in 3.3.152.1.

20.1.1.1.4 Buildings, or sections of buildings, that primarily house patients who, in the opinion of the governing body of the facility and the governmental agency having jurisdiction, are capable of exercising judgment and appropriate physical action for self-preservation under emergency conditions shall be permitted to comply with chapters of this *Code* other than Chapter 20.

20.1.1.1.5 It shall be recognized that, in buildings providing treatment for certain types of patients or having detention rooms or a security section, it might be necessary to lock doors and bar windows to confine and protect building inhabitants. In such instances, the authority having jurisdiction shall make appropriate modifications to those sections of this *Code* that would otherwise require means of egress to be kept unlocked.

20.1.1.1.6* The requirements of this chapter are based on the assumption that staff is available in all patient-occupied areas to perform certain fire safety functions as required in other paragraphs of this chapter.

A.20.1.1.1.6 The *Code* recognizes that certain functions necessary for the life safety of building occupants, such as the closing of corridor doors, the operation of manual fire alarm devices, and the removal of patients from the room of fire origin, require the intervention of facility staff. It is not the intent of 20.1.1.1.6 to specify the levels or locations of staff necessary to meet this requirement.

21.1.1.1.3 This chapter establishes life safety requirements, in addition to those required in Chapter 39, for the design of all ambulatory health care occupancies as defined in 3.3.152.1.

21.1.1.1.4 Buildings, or sections of buildings, that primarily house patients who, in the opinion of the governing body of the facility and the governmental agency having jurisdiction, are capable of exercising judgment and appropriate physical action for self-preservation under emergency conditions shall be permitted to comply with chapters of this *Code* other than Chapter 21.

21.1.1.1.5 It shall be recognized that, in buildings providing treatment for certain types of patients or having detention rooms or a security section, it might be necessary to lock doors and bar windows to confine and protect building inhabitants. In such instances, the authority having jurisdiction shall make appropriate modifications to those sections of this *Code* that would otherwise require means of egress to be kept unlocked.

21.1.1.1.6* The requirements of this chapter are based on the assumption that staff is available in all patient-occupied areas to perform certain fire safety functions as required in other paragraphs of this chapter.

A.21.1.1.1.6 The *Code* recognizes that certain functions necessary for the life safety of building occupants, such as the closing of corridor doors, the operation of manual fire alarm devices, and the removal of patients from the room of fire origin, require the intervention of facility staff. It is not the intent of 21.1.1.1.6 to specify the levels or locations of staff necessary to meet this requirement.

CHAPTER 20 • New

20.1.1.2* Goals and Objectives. The goals and objectives of Section 4.1 and Section 4.2 shall be met with due consideration for functional requirements, which are accomplished by limiting the development and spread of a fire emergency to the room of fire origin and reducing the need for occupant evacuation, except from the room of fire origin.

A.20.1.1.2 This objective is accomplished in the context of the physical facilities, the type of activities undertaken, the provisions for the capabilities of staff, and the needs of all occupants through requirements directed at the following:

- (1) Prevention of ignition
- (2) Detection of fire
- (3) Control of fire development
- (4) Confinement of the effects of fire
- (5) Extinguishment of fire
- (6) Provision of refuge or evacuation facilities, or both
- (7) Staff reaction

20.1.1.3 Total Concept.

20.1.1.3.1 All ambulatory health care facilities shall be designed, constructed, maintained, and operated to minimize the possibility of a fire emergency requiring the evacuation of occupants.

20.1.1.3.2 Because the safety of ambulatory health care occupants cannot be ensured adequately by dependence on evacuation of the building, their protection from fire shall be provided by appropriate arrangement of facilities, adequate, trained staff, and development of operating and maintenance procedures composed of the following:

- (1) Design, construction, and compartmentation
- (2) Provision for detection, alarm, and extinguishment
- (3) Fire prevention and the planning, training, and drilling programs for the isolation of fire, transfer of occupants to areas of refuge, or evacuation of the building

20.1.1.4 Additions, Conversions, Modernization, Renovation, and Construction Operations.

20.1.1.4.1 Additions.

20.1.1.4.1.1 Additions shall be separated from any existing structure not conforming to the provisions within Chapter 21 by a fire barrier having not less than a 2-hour fire resistance rating and constructed of materials as required for the addition. (See 4.6.4 and 4.6.7.)

20.1.1.4.1.2 Doors in barriers required by 20.1.1.4.1.1 shall normally be kept closed, unless otherwise permitted by 20.1.1.4.1.3.

CHAPTER 21 • Existing

21.1.1.2* Goals and Objectives. The goals and objectives of Section 4.1 and Section 4.2 shall be met with due consideration for functional requirements, which are accomplished by limiting the development and spread of a fire emergency to the room of fire origin and reducing the need for occupant evacuation, except from the room of fire origin.

A.21.1.1.2 This objective is accomplished in the context of the physical facilities, the type of activities undertaken, the provisions for the capabilities of staff, and the needs of all occupants through requirements directed at the following:

- (1) Prevention of ignition
- (2) Detection of fire
- (3) Control of fire development
- (4) Confinement of the effects of fire
- (5) Extinguishment of fire
- (6) Provision of refuge or evacuation facilities, or both
- (7) Staff reaction

21.1.1.3 Total Concept.

21.1.1.3.1 All ambulatory health care facilities shall be designed, constructed, maintained, and operated to minimize the possibility of a fire emergency requiring the evacuation of occupants.

21.1.1.3.2 Because the safety of ambulatory health care occupants cannot be ensured adequately by dependence on evacuation of the building, their protection from fire shall be provided by appropriate arrangement of facilities, adequate, trained staff, and development of operating and maintenance procedures composed of the following:

- (1) Design, construction, and compartmentation
- (2) Provision for detection, alarm, and extinguishment
- (3) Fire prevention and the planning, training, and drilling programs for the isolation of fire, transfer of occupants to areas of refuge, or evacuation of the building

21.1.1.4 Additions, Conversions, Modernization, Renovation, and Construction Operations.

21.1.1.4.1 Additions.

21.1.1.4.1.1 Additions shall be separated from any existing structure not conforming to the provisions within Chapter 21 by a fire barrier having not less than a 2-hour fire resistance rating and constructed of materials as required for the addition. (See 4.6.4 and 4.6.7.)

21.1.1.4.1.2 Doors in barriers required by 21.1.1.4.1.1 shall normally be kept closed, unless otherwise permitted by 21.1.1.4.1.3.

CHAPTER 20 • New

20.1.1.4.1.3 Doors shall be permitted to be held open if they meet the requirements of 20.2.2.3.

20.1.1.4.2 Changes of Occupancy. A change from a hospital or nursing home to an ambulatory health care occupancy shall not be considered a change in occupancy or occupancy subclassification.

20.1.1.4.3 Renovations, Alterations, and Modernizations. (See 4.6.8.)

20.1.1.4.4 Construction, Repair, and Improvement Operations. (See 4.6.11.)

Paragraph 20/21.1.1.4.1 establishes separation criteria for additions to existing structures that do not conform to the provisions of Chapter 21. However, if an existing building meets the provisions of Chapter 21, the new addition that complies with Chapter 20 would not be required to be separated from the existing portion of the newly enlarged building.

20.1.2 Multiple Occupancies.

20.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

Paragraph 20/21.1.2.1 directs the user to the multiple occupancies provisions of 6.1.14, which permit protecting the multiple occupancies either as mixed occupancies or as separated occupancies. Where the multiple occupancy is protected via the provisions of 6.1.14.4 for separated occupancies, the required number of hours of fire-rated separation is specified by Table 6.1.14.4.1. The most common occupancies to abut an ambulatory health care occupancy are health

20.1.2.2* Sections of ambulatory health care facilities shall be permitted to be classified as other occupancies, provided that they meet all of the following conditions:

- (1) They are not intended to serve ambulatory health care occupants for purposes of treatment or customary access by patients incapable of self-preservation.
- (2) They are separated from areas of ambulatory health care occupancies by construction having a fire resistance rating of not less than 1 hour.

CHAPTER 21 • Existing

21.1.1.4.1.3 Doors shall be permitted to be held open if they meet the requirements of 21.2.2.3.

21.1.1.4.2 Changes of Occupancy. A change from a hospital or nursing home to an ambulatory health care occupancy shall not be considered a change in occupancy or occupancy subclassification.

21.1.1.4.3 Renovations, Alterations, and Modernizations. (See 4.6.8.)

21.1.1.4.4 Construction, Repair, and Improvement Operations. (See 4.6.11.)

Where additions are required to be separated from existing portions of buildings, barriers must be constructed of assemblies providing a minimum of 2-hour fire resistance rating.

21.1.2 Multiple Occupancies.

21.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

care occupancies and business occupancies. The required separation between an ambulatory health care occupancy and a health care occupancy is 2 hours; between an ambulatory health care occupancy and a business occupancy, the required separation is 1 hour.

The provisions of 20/21.1.2.2 through 20/21.1.2.7 have the effect of modifying those of 6.1.14 for the very specific situations described.

21.1.2.2* Sections of ambulatory health care facilities shall be permitted to be classified as other occupancies, provided that they meet all of the following conditions:

- (1) They are not intended to serve ambulatory health care occupants for purposes of treatment or customary access by patients incapable of self-preservation.
- (2) They are separated from areas of ambulatory health care occupancies by construction having a fire resistance rating of not less than 1 hour.

CHAPTER 20 • New

A.20.1.2.2 Doctors' offices and treatment and diagnostic facilities that are intended solely for outpatient care that are physically separated from facilities for the treatment or care of inpatients, but are otherwise associated with the management of an institution, might be classified as business occupancies rather than health care occupancies.

20.1.2.3 All means of egress from ambulatory health care occupancies that traverse nonambulatory health care spaces shall conform to requirements of this *Code* for ambulatory health care occupancies, unless otherwise permitted by 20.1.2.4.

20.1.2.4 Exit through a horizontal exit into other contiguous occupancies that do not conform to ambulatory health care egress provisions but that do comply with requirements set forth in the appropriate occupancy chapter of this *Code* shall be permitted, provided that the occupancy does not contain high hazard contents.

20.1.2.5 Egress provisions for areas of ambulatory health care facilities that correspond to other occupancies shall meet the corresponding requirements of this *Code* for such occupancies, and, where the clinical needs of the occupant necessitate the locking of means of egress, staff shall be present for the supervised release of occupants during all times of use.

20.1.2.6 Any area with a hazard of contents classified higher than that of the ambulatory health care occupancy and located in the same building shall be protected as required in 20.3.2.

20.1.2.7 Non-health care-related occupancies classified as containing high hazard contents shall not be permitted in buildings housing ambulatory health care occupancies.

20.1.3 Definition: Ambulatory Health Care Occupancy.

See 3.3.152.1.

Prior to the 1981 edition of the *Code*, occupancies that offered medical services on an outpatient basis would have been regulated within the chapter covering business occupancies. The threat to life in an outpatient facility where four or more patients might be subject to medical procedures requiring general anesthesia, treatments such as hemodialysis, or free-standing emergency or urgent care is significantly greater than that typical of a business occupancy.

CHAPTER 21 • Existing

A.21.1.2.2 Doctors' offices and treatment and diagnostic facilities that are intended solely for outpatient care and are physically separated from facilities for the treatment or care of inpatients, but that are otherwise associated with the management of an institution, might be classified as business occupancies rather than health care occupancies.

21.1.2.3 All means of egress from ambulatory health care occupancies that traverse nonambulatory health care spaces shall conform to the requirements of this *Code* for ambulatory health care occupancies, unless otherwise permitted by 21.1.2.4.

21.1.2.4 Exit through a horizontal exit into other contiguous occupancies that do not conform with ambulatory health care egress provisions but that do comply with requirements set forth in the appropriate occupancy chapter of this *Code* shall be permitted, provided that the occupancy does not contain high hazard contents.

21.1.2.5 Egress provisions for areas of ambulatory health care facilities that correspond to other occupancies shall meet the corresponding requirements of this *Code* for such occupancies, and where the clinical needs of the occupant necessitate the locking of means of egress, staff shall be present for the supervised release of occupants during all times of use.

21.1.2.6 Any area with a hazard of contents classified higher than that of the ambulatory health care occupancy and located in the same building shall be protected as required in 21.3.2.

21.1.2.7 Non-health-care-related occupancies classified as containing high hazard contents shall not be permitted in buildings housing ambulatory health care occupancies.

21.1.3 Definition: Ambulatory Health Care Occupancy.

See 3.3.152.1.

Conversely, application of the requirements for health care facilities that contemplate 24-hour care would be unnecessarily restrictive. In establishing the occupancy classification of an ambulatory health care facility, the intent was to develop requirements that fall between the restrictions applicable to business occupancies and those applicable to health care facilities in terms of the level of life safety provided.

CHAPTER 20 • New

20.1.4 Classification of Occupancy.

(See 20.1.3.)

20.1.5 Classification of Hazard of Contents.

The classification of hazard of contents shall be as defined in Section 6.2.

20.1.6 Minimum Construction Requirements.

20.1.6.1 For the purposes of 20.1.6, the number of stories shall be counted starting with the primary level of exit discharge and ending with the highest occupiable level used as an ambulatory health care facility.

20.1.6.2 For the purposes of 20.1.6.1, the primary level of exit discharge of a building shall be that floor that is level with or above finished grade of the exterior wall line for 50 percent or more of its perimeter.

20.1.6.3 Buildings of one story in height housing ambulatory health care facilities shall be of any construction type in accordance with NFPA 220, *Standard on Types of Building Construction*. (See 8.2.1.)

20.1.6.4 Buildings of two or more stories in height housing ambulatory health care facilities shall be of Type I(443), Type I(332), Type II(222), Type II(111), Type III(211), Type IV(2HH), or Type V(111) construction (see 8.2.1), unless otherwise permitted by 20.1.6.5.

20.1.6.5 Buildings shall be permitted to be constructed of Type II(000), Type III(200), or Type V(000), if protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

20.1.6.6 Any level below the level of exit discharge shall be separated from the level of exit discharge by not less than Type II(111), Type III(211), or Type V(111) construction (see 8.2.1), unless both of the following criteria are met:

- (1) Such levels are under the control of the ambulatory health care facility.
- (2) Any hazardous spaces are protected in accordance with Section 8.4.

20.1.6.7 Where new ambulatory health care facilities are located in existing buildings, the authority having jurisdiction shall be permitted to accept construction systems of lesser fire resistance than that required by 20.1.6.3 through 20.1.6.6, provided that it can be demonstrated to the authority's satisfaction that prompt evacuation of the facility can be achieved in case of fire or that the exposing occupancies

CHAPTER 21 • Existing

21.1.4 Classification of Occupancy.

(See 21.1.3.)

21.1.5 Classification of Hazard of Contents.

The classification of hazard of contents shall be as defined in Section 6.2.

21.1.6 Minimum Construction Requirements.

21.1.6.1 For the purposes of 21.1.6, the number of stories shall be counted starting with the primary level of exit discharge and ending with the highest occupiable level used as an ambulatory health care facility.

21.1.6.2 For the purposes of 21.1.6.1, the primary level of exit discharge of a building shall be that floor that is level with or above finished grade of the exterior wall line for 50 percent or more of its perimeter.

21.1.6.3 Buildings of one story in height housing ambulatory health care facilities shall be of any construction type in accordance with NFPA 220, *Standard on Types of Building Construction*. (See 8.2.1.)

21.1.6.4 Buildings of two or more stories in height housing ambulatory health care facilities shall be of Type I(443), Type I(332), Type II(222), Type II(111), Type III(211), Type IV(2HH), or Type V(111) construction (see 8.2.1), unless otherwise permitted by 21.1.6.5.

21.1.6.5 Buildings shall be permitted to be constructed of Type II(000), Type III(200), or Type V(000), if protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

21.1.6.6 Any level below the level of exit discharge shall be separated from the level of exit discharge by not less than Type II(111), Type III(211), or Type V(111) construction (see 8.2.1), unless both of the following criteria are met:

- (1) Such levels are under the control of the ambulatory health care facility.
- (2) Any hazardous spaces are protected in accordance with Section 8.7.

21.1.6.7 In existing buildings, the authority having jurisdiction shall be permitted to accept construction systems of lesser fire resistance than that required by 21.1.6.3 through 21.1.6.6, provided that it can be demonstrated to the authority's satisfaction that prompt evacuation of the facility can be achieved in case of fire or that the exposing occupancies and materials of construction present no threat of fire pene-

CHAPTER 20 • New

and materials of construction present no threat of fire penetration from such occupancy to the ambulatory health care facility or to the collapse of the structure.

20.1.6.8 All interior walls and partitions in buildings of Type I or Type II construction shall be of noncombustible or limited-combustible materials.

20.1.6.9 All buildings with more than one level below the level of exit discharge shall have all such lower levels separated from the level of exit discharge by not less than Type II(111) construction.

Allowable building construction types are determined as a function of the highest story used as an ambulatory health care facility. In determining the number of stories, the first story is considered to be the primary level of exit discharge.

Determining story height where a building is located on a sloping grade can be difficult. Paragraph 20/21.1.6.2 notes that a story on a sloping site that is partially below grade should be counted as a story if the floor is level with or above grade along 50 percent or more of the perimeter of the building at the exterior wall. Application of the 50 percent perimeter guideline is illustrated in Exhibit 20/21.2. Because of sloping grade, the primary level of exit discharge is not obvi-

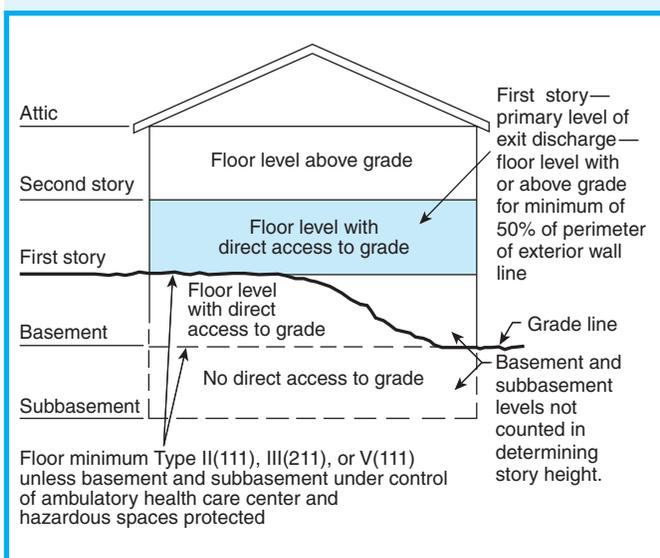

Exhibit 20/21.2 Determining number of stories for application of minimum construction requirements.

CHAPTER 21 • Existing

tration from such occupancy to the ambulatory health care facility or to the collapse of the structure.

21.1.6.8 All interior walls and partitions in buildings of Type I or Type II construction shall be of noncombustible or limited-combustible materials.

21.1.6.9 All buildings with more than one level below the level of exit discharge shall have all such lower levels separated from the level of exit discharge by not less than Type II(111) construction.

ous. The 50 percent perimeter guideline clarifies that for the arrangement illustrated; the first story is the primary level of exit discharge. The number of stories includes primary level of exit, the highest story used as an ambulatory health care facility, and all intervening stories. If the ambulatory health care facility occupies the second story, this is an example of a two-story building.

Construction types permitted for buildings housing ambulatory health care facilities are detailed in 20/21.1.6.3 through 20/21.1.6.5 and summarized in Commentary Table 20/21.3. For additional information on the notations used to designate a particular construction type, see Table A.8.2.1.2 of this Code and

Commentary Table 20/21.3 Construction Types Permitted in Ambulatory Health Care Occupancies

Construction Type	Stories	
	1	2 or More
I(443), I(332), II(222), II(111) (Fire resistive and protected noncombustible)	X	X
II(000) (Unprotected noncombustible)	X	X†
III(211) (Protected ordinary)	X	X
III(200) (Unprotected ordinary)	X	X†
IV(2HH) (Heavy timber)	X	X

V(000) (Unprotected wood frame)	X	X†

X— Construction types allowed.
†—Automatic sprinkler protection required.

CHAPTER 20 • New

NFPA 220, *Standard on Types of Building Construction*¹.

Paragraph 20.1.6.7 permits flexibility in the construction requirements that apply to a new ambulatory health care facility to be placed in an existing

20.1.7 Occupant Load.

(See 38.1.7.)

Section 20.2 Means of Egress Requirements

20.2.1 General.

Every aisle, passageway, corridor, exit discharge, exit location, and access shall be in accordance with Chapter 7, unless otherwise modified by 20.2.2 through 20.2.11.

20.2.2 Means of Egress Components.

20.2.2.1 Components of means of egress shall be limited to the types described in 38.2.2.

20.2.2.2 Special locking arrangements complying with 7.2.1.6 shall be permitted.

20.2.2.3 Any door required to be self-closing shall be permitted to be held open only by an automatic release device that complies with 7.2.1.8.2. The required manual fire alarm system and the systems required by 7.2.1.8.2 shall be arranged to initiate the closing action of all such doors throughout the smoke compartment or throughout the entire facility.

20.2.2.4 Where doors in a stair enclosure are held open by an automatic release device as permitted in 20.2.2.3, initiation of a door-closing action on any level shall cause all doors at all levels in the stair enclosure to close.

It is desirable to keep doors in exit enclosures, stair enclosures, horizontal exits, smoke barriers, and hazardous areas closed at all times to impede the spread of smoke and gases caused by a fire. However, some doors will be kept open for reasons of operating efficiency or comfort. Where doors in required fire or smoke barriers are to be held open, they must be equipped with automatic devices designed to close the doors by the methods described in 20/21.2.2.3 and 7.2.1.8.

CHAPTER 21 • Existing

building. Adequate supporting data must be supplied to the authority having jurisdiction to justify a reduction in fire-rated construction.

21.1.7 Occupant Load.

(See 39.1.7.)

Section 21.2 Means of Egress Requirements

21.2.1 General.

Every aisle, passageway, corridor, exit discharge, exit location, and access shall be in accordance with Chapter 7, unless otherwise modified by 21.2.2 through 21.2.11.

21.2.2 Means of Egress Components.

21.2.2.1 Components of means of egress shall be limited to the types described in 39.2.2.

21.2.2.2 Special locking arrangements complying with 7.2.1.6 shall be permitted.

21.2.2.3 Any door required to be self-closing shall be permitted to be held open only by an automatic release device that complies with 7.2.1.8.2. The required manual fire alarm system and the systems required by 7.2.1.8.2 shall be arranged to initiate the closing action of all such doors throughout the smoke compartment or throughout the entire facility.

21.2.2.4 Where doors in a stair enclosure are held open by an automatic release device as permitted in 21.2.2.3, initiation of a door-closing action on any level shall cause all doors at all levels in the stair enclosure to close.

The automatic device must cause the doors to close by operation of the manual fire alarm system. The doors must also be designed to close by actuation of smoke detectors in the vicinity of the door opening. See 7.2.1.8.2.

It is especially important in facilities providing ambulatory health care to maintain floor-to-floor separation. Doors protecting openings in a stair enclosure can be held open by an automatic device only if arranged to close as specified earlier. Initiation of

CHAPTER 20 • New

CHAPTER 21 • Existing

any action that causes a door to close at one level must cause all doors protecting openings within that stair enclosure to close in accordance with 20/21.2.2.4.

20.2.3 Capacity of Means of Egress.

20.2.3.1 The capacity of any required means of egress shall be determined in accordance with the provisions of 38.2.3.

20.2.3.2 The clear width of any corridor or passageway required for exit access shall be not less than 1120 mm (44 in.).

20.2.3.3 Doors in the means of egress from diagnostic or treatment areas, such as x-ray, surgical, or physical therapy, shall provide a clear width of not less than 810 mm (32 in.).

The capacity of the means of egress in ambulatory health care facilities is determined on the basis of provisions in Chapters 38 and 39 that address business occupancies. Paragraph 38/39.2.3.1 refers to Section 7.3, which requires the capacity of level exit components to be computed on the basis of 5 mm (0.2 in.) per person; stair capacity is computed using 7.6 mm (0.3 in.) per person. These capacities are the same as permitted within sprinklered hospitals, nursing homes, and limited care facilities. Even if the ambulatory health care facility is not sprinklered, these capacity factors are considered reasonable based on the assumption that the majority of occupants will be ambulatory.

Although greater corridor widths might be required for functional purposes, the minimum width for corridors used as common exit access in ambulatory health care facilities is 1120 mm (44 in.), in accordance with 20/21.2.3.2. That width, which is significantly less than required in new hospitals,

20.2.4 Number of Exits.

20.2.4.1 Not less than two exits of the types described in 38.2.2 that are remotely located from each other shall be provided for each floor or fire section of the building.

20.2.4.2 Any room and any suite of rooms of more than 232 m² (2500 ft²) shall have not less than two exit access doors remotely located from each other.

Because the doors in the exit stair enclosure are rated fire door assemblies, they will latch when the closing device brings each door to its closed position.

21.2.3 Capacity of Means of Egress.

21.2.3.1 The capacity of any required means of egress shall be determined in accordance with the provisions of 39.2.3.

21.2.3.2 The clear width of any corridor or passageway required for exit access shall be not less than 1120 mm (44 in.).

21.2.3.3 Doors in the means of egress from diagnostic or treatment areas, such as x-ray, surgical, or physical therapy, shall provide a clear width of not less than 810 mm (32 in.), unless such doors are existing 865-mm (34-in.) doors.

nursing homes, and limited care facilities, is specified on the assumption that most occupants will be ambulatory.

In many instances, doors wider than 810-mm (32-in.) clear width will be required for functional purposes. Paragraph 20/21.2.3.3 addresses doors that provide access to common hallways and corridors. The 810-mm (32-in.) minimum clear width, which is significantly less than what is required in new hospitals and nursing homes, is specified on the assumption that most occupants will be ambulatory or moving in wheelchairs. An 810-mm (32-in.) clear width door opening is sufficiently wide to accommodate a wheelchair user. Per 21.2.3.3, an existing 865-mm (34-in.) door [that is, the door leaf width is 865 mm (34 in.)] is considered as providing the required 810-mm (32-in.) opening width, although there is no assurance that the existing door can be opened a full 90 degrees.

21.2.4 Number of Exits.

21.2.4.1 Not less than two exits of the types described in 39.2.2 that are remotely located from each other shall be provided for each floor or fire section of the building.

21.2.4.2 Any room and any suite of rooms of more than 232 m² (2500 ft²) shall have not less than two exit access doors remotely located from each other.

CHAPTER 20 • New

20.2.4.3 Not less than two exits of the types described in 38.2.2 shall be accessible from each smoke compartment.

20.2.4.4 Egress from smoke compartments addressed in 20.2.4.3 shall be permitted through adjacent compartments but shall not require return through the compartment of fire origin.

20.2.5 Arrangement of Means of Egress.

(See 38.2.5.)

20.2.6 Travel Distance to Exits.

20.2.6.1 Travel distance shall be measured in accordance with Section 7.6.

20.2.6.2 Travel distance shall be as follows:

- (1) The travel distance between any room door required as an exit access and an exit shall not exceed 30 m (100 ft).
- (2) The travel distance between any point in a room and an exit shall not exceed 46 m (150 ft).
- (3) The maximum travel distance in 20.2.6.2(1) or 20.2.6.2(2) shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

Travel distance is measured only to the nearest exit, not to both exits. The requirements of 20/21.2.6.2 are illustrated in Exhibit 20/21.3.

20.2.7 Discharge from Exits.

(See 38.2.7.)

20.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

CHAPTER 21 • Existing

21.2.4.3 Not less than two exits of the types described in 39.2.2 shall be accessible from each smoke compartment.

21.2.4.4 Egress from smoke compartments addressed in 21.2.4.3 shall be permitted through adjacent compartments but shall not require return through the compartment of fire origin.

21.2.5 Arrangement of Means of Egress.

(See 39.2.5.)

21.2.6 Travel Distance to Exits.

21.2.6.1 Travel distance shall be measured in accordance with Section 7.6.

21.2.6.2 Travel distance shall be as follows:

- (1) The travel distance between any room door required as an exit access and an exit shall not exceed 30 m (100 ft).
- (2) The travel distance between any point in a room and an exit shall not exceed 46 m (150 ft).
- (3) The maximum travel distance in 21.2.6.2(1) or 21.2.6.2(2) shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved automatic sprinkler system in accordance with Section 9.7.

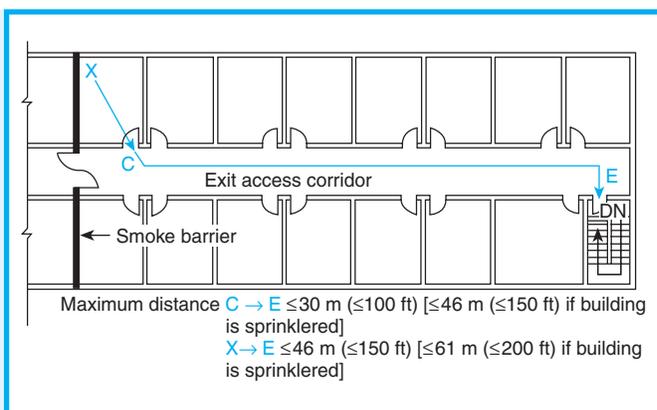

Exhibit 20/21.3 Travel distance limitations for an ambulatory health care facility.

21.2.7 Discharge from Exits.

(See 39.2.7.)

21.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

CHAPTER 20 • New

20.2.9 Emergency Lighting and Essential Electrical Systems.

20.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9.

20.2.9.2 Where general anesthesia or life-support equipment is used, each ambulatory health care facility shall be provided with an essential electrical system in accordance with NFPA 99, *Standard for Health Care Facilities*, unless otherwise permitted by the following:

- (1) Where battery-operated equipment is provided and acceptable to the authority having jurisdiction
- (2) Where a facility uses life-support equipment for emergency purposes only

All ambulatory health care facilities are required to be equipped with emergency lighting. If medical procedures requiring general anesthesia are practiced, or if life-support equipment is used for other than emergency purposes only, ambulatory health care facilities are required to be served by electrical systems meeting the criteria for essential electrical systems as detailed in NFPA 99, *Standard for Health Care Facilities*².

A facility would not be required to have an emergency generator if the building is a freestanding unit and if, as a normal practice, the following conditions apply:

20.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

20.2.11 Special Means of Egress Features.

(Reserved)

Section 20.3 Protection**20.3.1 Protection of Vertical Openings.**

(See 38.3.1.)

20.3.2 Protection from Hazards.

(See 38.3.2.)

20.3.2.1 Doors. Doors to hazardous areas shall be self-closing or automatic-closing in accordance with 20.2.2.3.

CHAPTER 21 • Existing

21.2.9 Emergency Lighting and Essential Electrical Systems.

21.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9.

21.2.9.2 Where general anesthesia or life-support equipment is used, each ambulatory health care facility shall be provided with an essential electrical system in accordance with NFPA 99, *Standard for Health Care Facilities*, unless otherwise permitted by the following:

- (1) Where battery-operated equipment is provided and acceptable to the authority having jurisdiction
- (2) Where a facility uses life-support equipment for emergency purposes only

- (1) Management maintains policies that preclude the provision of care for any patient who might need to be sustained by electrical life-support equipment, such as respirators or suction apparatus.
- (2) No surgical treatment requiring general anesthesia is offered.
- (3) Battery-operated systems or equipment are provided that would maintain power to exit lights and illumination for egress corridors, stairways, medical preparation areas, and the like, for a minimum of 1½ hours. Additionally, battery power would be required to be supplied to all alarm systems.

21.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

21.2.11 Special Means of Egress Features.

(Reserved)

Section 21.3 Protection**21.3.1 Protection of Vertical Openings.**

(See 39.3.1.)

21.3.2 Protection from Hazards.

(See 39.3.2.)

21.3.2.1 Doors. Doors to hazardous areas shall be self-closing or automatic-closing in accordance with 21.2.2.3.

CHAPTER 20 • New

20.3.2.2 Laboratories. Laboratories employing quantities of flammable, combustible, or hazardous materials that are considered as a severe hazard shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

20.3.2.3 Anesthetizing Locations. Anesthetizing locations shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

20.3.2.4 Cooking Facilities. Cooking facilities shall be protected in accordance with 9.2.3 unless otherwise permitted by 20.3.2.5.

20.3.2.5 Domestic Cooking Equipment. Where domestic cooking equipment is used for food-warming or limited cooking, protection or separation of food preparation facilities shall not be required.

Laboratories that contain ordinary combustibles and flammable liquids in sufficient quantity to threaten a 1-hour fire separation [for example, wood-equivalent fuel loads in the range of 25 kg/m² to 50 kg/m² (5 lb/ft² to 10 lb/ft²)] are considered to be a severe hazard. Laboratories representing a severe hazard must be protected in accordance with NFPA 99, *Standard for Health Care Facilities*. Protection would include

20.3.3 Interior Finish.

(See 38.3.3.)

20.3.4 Detection, Alarm, and Communications Systems.

20.3.4.1 General. Ambulatory health care facilities shall be provided with fire alarm systems in accordance with Section 9.6, except as modified by 20.3.4.2 through 20.3.4.5.

20.3.4.2 Initiation. Initiation of the required fire alarm systems shall be by manual means in accordance with 9.6.2 and by means of any detection devices or detection systems required.

20.3.4.3 Occupant Notification. Occupant notification shall be accomplished automatically, without delay, in accordance with 9.6.3 upon operation of any fire alarm activating device.

20.3.4.4 Emergency Forces Notification.

20.3.4.4.1 Fire department notification shall be accomplished in accordance with 9.6.4.

CHAPTER 21 • Existing

21.3.2.2 Laboratories. Laboratories employing quantities of flammable, combustible, or hazardous materials that are considered as a severe hazard shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

21.3.2.3 Anesthetizing Locations. Anesthetizing locations shall be protected in accordance with NFPA 99, *Standard for Health Care Facilities*.

21.3.2.4 Cooking Facilities. Cooking facilities shall be protected in accordance with 9.2.3 unless otherwise permitted by 21.3.2.5.

21.3.2.5 Domestic Cooking Equipment. Where domestic cooking equipment is used for food-warming or limited cooking, protection or separation of food preparation facilities shall not be required.

1-hour fire resistance separation and automatic sprinkler protection.

Where fuel loads of lesser amounts are involved and quantities of flammable liquids are limited, laboratories would simply be considered hazardous contents areas and would require either 1-hour separation or automatic sprinkler protection.

21.3.3 Interior Finish.

(See 39.3.3.)

21.3.4 Detection, Alarm, and Communications Systems.

21.3.4.1 General. Ambulatory health care facilities shall be provided with fire alarm systems in accordance with Section 9.6, except as modified by 21.3.4.2 through 21.3.4.5.

21.3.4.2 Initiation. Initiation of the required fire alarm systems shall be by manual means in accordance with 9.6.2 and by means of any detection devices or detection systems required.

21.3.4.3 Occupant Notification. Occupant notification shall be accomplished automatically, without delay, in accordance with 9.6.3, upon operation of any fire alarm activating device.

21.3.4.4 Emergency Forces Notification.

21.3.4.4.1 Fire department notification shall be accomplished in accordance with 9.6.4.

CHAPTER 20 • New

20.3.4.4.2 Smoke detection devices or smoke detection systems equipped with reconfirmation features shall not be required to automatically notify the fire department unless the alarm condition is reconfirmed after a period not exceeding 120 seconds.

20.3.4.5 Emergency Control. Operation of any activating device in the required fire alarm system shall be arranged to accomplish automatically, without delay, any control functions required to be performed by that device. (*See 9.6.5.*)

Paragraphs 20/21.3.4.1 through 20/21.3.4.5 address required fire alarm equipment. Reliability is of prime importance; therefore, electrical supervision of the system and system components is specified via the reference to Section 9.6. In the event of circuit fault, component failure, or other trouble, a continuous trouble indication signal is required and should be provided at a constantly attended location.

A manual fire alarm system is required by 20/21.3.4.1 and 20/21.3.4.2. Manual fire alarm boxes should be located along the natural routes of egress and cover all portions of the building; they should be located so that those qualified to send an alarm can summon aid without having to leave their zone of ordinary activities or pass beyond the view and hearing of people immediately exposed to, or in direct view of, a fire. The operation of a manual fire alarm box should automatically summon attendants to assist in removing physically helpless occupants.

Actuation of any required fire or smoke detector, activation of a required sprinkler system, or operation of a manual fire alarm box must automatically, with-

20.3.5 Extinguishment Requirements.

(*See 38.3.5.*)

20.3.5.1 Isolated hazardous areas shall be permitted to be protected in accordance with 9.7.1.2.

20.3.5.2 Where more than two sprinklers are installed in a single area for protection in accordance with 9.7.1.2, waterflow detection shall be provided to sound the building fire alarm or to notify, by a signal, any constantly attended location, such as PBX, security, or emergency room, at which the necessary corrective action shall be taken.

20.3.5.3 Portable fire extinguishers shall be provided in ambulatory health care facilities in accordance with 9.7.4.1.

CHAPTER 21 • Existing

21.3.4.4.2 Smoke detection devices or smoke detection systems equipped with reconfirmation features shall not be required to automatically notify the fire department unless the alarm condition is reconfirmed after a period not exceeding 120 seconds.

21.3.4.5 Emergency Control. Operation of any activating device in the required fire alarm system shall be arranged to accomplish automatically, without delay, any control functions required to be performed by that device. (*See 9.6.5.*)

out delay, initiate the alarm system and sound audible alarm devices within the building. Neither pre-signal systems nor positive alarm sequence is permitted (see 9.6.3.3 and 9.6.3.4).

The alarm must automatically transmit to a point outside the facility. If automatic transmission of the alarm to the fire department legally committed to serve the facility is not permitted, arrangements need to be made for the prompt notification of the fire department or such other assistance as is available in the case of fire or other emergency. Paragraph 9.6.4.2 lists various methods acceptable for automatically notifying the fire department. The fire department should also be called manually to verify and confirm the automatic transmission of the alarm. In larger facilities, this may be the responsibility of the facility telephone operator. In smaller facilities, it might be the responsibility of the nursing staff. Actuation of the fire alarm must initiate the operation of audible alerting devices that sound throughout the affected zone or building.

21.3.5 Extinguishment Requirements.

(*See 39.3.5.*)

21.3.5.1 Isolated hazardous areas shall be permitted to be protected in accordance with 9.7.1.2.

21.3.5.2 For new installations in existing ambulatory health care facilities, where more than two sprinklers are installed in a single area for protection in accordance with 9.7.1.2, waterflow detection shall be provided to sound the building fire alarm or to notify, by a signal, any constantly attended location, such as PBX, security, or emergency room, at which the necessary corrective action shall be taken.

21.3.5.3 Portable fire extinguishers shall be provided in ambulatory health care facilities in accordance with 9.7.4.1.

CHAPTER 20 • New

20.3.6 Corridors.

20.3.6.1 General. (See 38.3.6.)

20.3.6.2 Openings.

20.3.6.2.1 Miscellaneous openings such as mail slots, pharmacy pass-through windows, laboratory pass-through windows, and cashier pass-through windows shall be permitted to be installed in vision panels or doors without special protection, provided that both of the following criteria are met:

- (1) The aggregate area of openings per room does not exceed 0.015 m² (0.14 ft²).
- (2) The openings are installed at or below half the distance from the floor to the room ceiling.

20.3.6.2.2 For rooms protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7, the aggregate area of openings per room shall not exceed 0.05 m² (0.55 ft²).

20.3.7 Subdivision of Building Space.

20.3.7.1 Ambulatory health care facilities shall be separated from other tenants and occupancies and shall meet the following requirements:

- (1) Walls shall have not less than a 1-hour fire resistance rating and shall extend from the floor slab below to the floor or roof slab above.
- (2) Doors shall be constructed of not less than 44-mm (1¾-in.) thick, solid-bonded wood core or the equivalent and shall be equipped with positive latches.
- (3) Doors shall be self-closing and shall be kept in the closed position except when in use.
- (4) Any windows in these barriers shall be of fixed fire window assemblies in accordance with Section 8.3.

20.3.7.2 Every story of an ambulatory health care facility shall be divided into not less than two smoke compartments, unless otherwise permitted by the following:

- (1) This requirement shall not apply to facilities of less than 465 m² (5000 ft²) that are protected by an approved automatic smoke detection system.
- (2) This requirement shall not apply to facilities of less than 929 m² (10,000 ft²) that are protected throughout by an approved, supervised automatic sprinkler system installed in accordance with Section 9.7.
- (3) An area in an adjoining occupancy shall be permitted to serve as a smoke compartment for an ambulatory health care facility if the following criteria are met:

CHAPTER 21 • Existing

21.3.6 Corridors.

(No requirements.)

21.3.7 Subdivision of Building Space.

21.3.7.1 Ambulatory health care facilities shall be separated from other tenants and occupancies and shall meet the following requirements:

- (1) Walls shall have not less than a 1-hour fire resistance rating and shall extend from the floor slab below to the floor or roof slab above.
- (2) Doors shall be constructed of not less than 44-mm (1¾-in.) thick, solid-bonded wood core or the equivalent and shall be equipped with positive latches.
- (3) Doors shall be self-closing and shall be kept in the closed position except when in use.
- (4) Any windows in these barriers shall be of fixed fire window assemblies in accordance with Section 8.3.

21.3.7.2 Every story of an ambulatory health care facility shall be divided into not less than two smoke compartments, unless otherwise permitted by the following:

- (1) This requirement shall not apply to facilities of less than 465 m² (5000 ft²) that are protected by an approved automatic smoke detection system.
- (2) This requirement shall not apply to facilities of less than 929 m² (10,000 ft²) that are protected throughout by an approved, supervised automatic sprinkler system installed in accordance with Section 9.7.
- (3) An area in an adjoining occupancy shall be permitted to serve as a smoke compartment for an ambulatory health care facility if the following criteria are met:

CHAPTER 20 • New

- (a) The separating wall and both compartments meet the requirements of 20.3.7.
- (b) The ambulatory health care facility is less than 2100 m² (22,500 ft²).
- (c) Access from the ambulatory health care facility to the other occupancy is unrestricted.

20.3.7.3 Smoke compartments shall not exceed an area of 2100 m² (22,500 ft²) and the travel distance from any point to reach a door in a smoke barrier shall not exceed 61 m (200 ft).

20.3.7.4 The area of an atrium separated in accordance with 8.6.7 shall not be limited in size.

20.3.7.5 Any required smoke barrier shall be constructed in accordance with Section 8.5 and shall have a fire resistance rating of not less than 1 hour, unless otherwise permitted by 20.3.7.6.

20.3.7.6 Smoke dampers shall not be required in duct penetrations of smoke barriers in fully ducted heating, ventilating, and air conditioning systems for buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

20.3.7.7 Windows in the smoke barrier shall be of fixed fire window assemblies in accordance with Section 8.3.

20.3.7.8 Not less than 1.4 net m² (15 net ft²) per ambulatory health care facility occupant shall be provided within the aggregate area of corridors, patient rooms, treatment rooms, lounges, and other low hazard areas on each side of the smoke compartment for the total number of occupants in adjoining compartments.

20.3.7.9* Doors in smoke barriers shall be not less than 44-mm (1¾-in.) thick, solid-bonded wood core or the equivalent and shall be self-closing or automatic-closing in accordance with 20.2.2.3.

A.20.3.7.9 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

20.3.7.10 Positive latching hardware shall not be required on smoke barrier cross-corridor doors.

20.3.7.11 A vision panel of fire-rated glazing or wire glass panels shall be required in smoke barrier cross-corridor doors.

CHAPTER 21 • Existing

- (a) The separating wall and both compartments meet the requirements of 21.3.7.
- (b) The ambulatory health care facility is less than 2100 m² (22,500 ft²).
- (c) Access from the ambulatory health care facility to the other occupancy is unrestricted.

21.3.7.3 Reserved.

21.3.7.4 Reserved.

21.3.7.5 Any required smoke barrier shall be constructed in accordance with Section 8.5 and shall have a fire resistance rating of not less than 1 hour, unless otherwise permitted by 21.3.7.6.

21.3.7.6 Smoke dampers shall not be required in duct penetrations of smoke barriers in fully ducted heating, ventilating, and air conditioning systems for buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.

21.3.7.7 Windows in the smoke barrier shall be of fixed fire window assemblies in accordance with Section 8.3.

21.3.7.8 Reserved.

21.3.7.9* Doors in smoke barriers shall be not less than 44-mm (1¾-in.) thick, solid-bonded wood core or the equivalent and shall be self-closing or automatic-closing in accordance with 20.2.2.3.

A.21.3.7.9 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

21.3.7.10 Positive latching hardware shall not be required on smoke barrier cross-corridor doors.

21.3.7.11 A vision panel of fire-rated glazing or wire glass panels shall be required in smoke barrier cross-corridor doors.

CHAPTER 20 • New

20.3.7.12 Rabbits, bevels, or astragals shall be required at the meeting edges, and stops shall be required at the head and sides of door frames in smoke barriers.

20.3.7.13 Center mullions shall be prohibited in smoke barrier door openings.

Ambulatory health care facilities are frequently located within buildings used for a variety of purposes. Placing these facilities within buildings containing hazardous occupancies should be avoided. If located within a building of mixed use, the ambulatory health care facility must be separated from adjacent tenants and occupancies by minimum 1-hour fire resistance-rated partitions in accordance with 20/21.3.7.1. Doors protecting openings in such partitions must be of at least 44-mm- (1 $\frac{3}{4}$ -in.-) thick, solid-bonded wood core or of equivalent construction that will resist fire for a minimum of 20 minutes. The doors must be equipped with positive latching hardware of a type that cannot be held in the retracted position. Roller latches cannot be used. These doors must be self-closing and normally maintained in the closed position, or, if the doors are to be held open, an automatic device must be used as specified in 20/21.2.2.3.

Glazing within doors and partitions will generally involve a maximum area of 0.84 m² (1296 in.²) of wired glass, set in approved metal frames. Each wired-glass panel should be limited to a maximum dimension of 1370 mm (54 in.). The glass should be labeled, be 6 mm ($\frac{1}{4}$ in.) thick, and be well embedded in putty, with all exposed joints between the metal and the glass struck and pointed (see NFPA 80, *Standard for Fire Doors and Fire Windows*³). A number of wired glass panels can be used in a single partition, provided that each 0.84-m² (1296 in.²) section is separated from adjacent panels by a metal mullion. The excessive use of wired-glass panels should be avoided. The use of wired-glass panels in a partition reduces the effectiveness of the partition because radiant energy transfer readily occurs through the glass panel. Other fire-rated glazing is available and, where used, should be installed in accordance with the manufacturer's instructions and listing.

Partitions separating ambulatory health care facilities from other occupancies must extend from the floor to the floor or roof deck above, extending completely through concealed spaces above suspended ceilings, for example. The partition must form a continuous barrier. Openings around penetrations involving building services should be ade-

CHAPTER 21 • Existing

21.3.7.12 Reserved.

21.3.7.13 Reserved.

quately protected to maintain the 1-hour separation. Special attention should be paid to penetrations involving air-handling ducts. In general, steel ducts will not require a fire damper. Penetrations involving nonmetallic ducts or aluminum ducts should be carefully evaluated. Fire dampers should be provided to protect duct penetrations where the projected fire exposure is judged sufficient to jeopardize the required separation because of the duct penetration. The possible movement of air from space to space under conditions of system operation and conditions of system shutdown should be evaluated for both conditions. If there is a significant potential for the transfer of smoke from an adjacent space to the ambulatory health care facility or from the ambulatory health care facility to a corridor, fire dampers should be provided for duct penetrations, even though the *Code* does not specifically require such protection. See Exhibit 20/21.4.

The requirements of 20/21.3.7.2 through 20/21.3.7.13 for subdividing building spaces through the

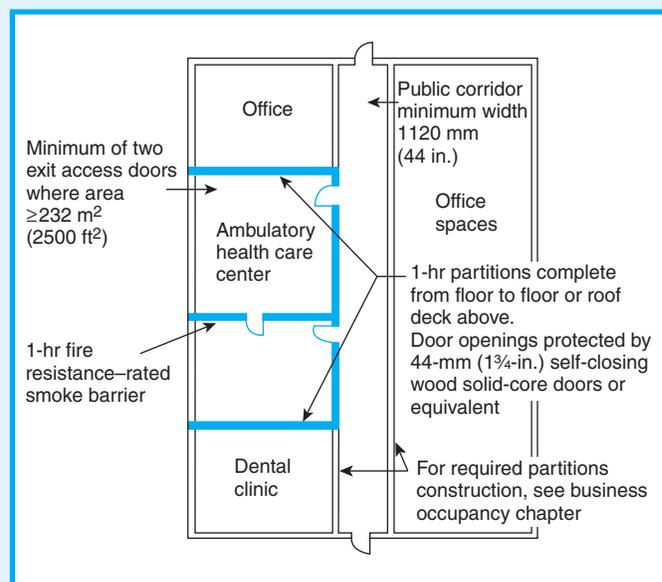

Exhibit 20/21.4 Separation and subdivision requirements for an ambulatory health care facility.

CHAPTER 20 • New

CHAPTER 21 • Existing

use of smoke barriers are illustrated in Exhibit 20/21.4 and Exhibit 20/21.5. Smoke barriers are not required if the ambulatory health care center meets either of the following conditions:

- (1) Its area is less than 465 m² (5000 ft²) and it is protected by an automatic smoke detection system.
- (2) Its area is less than 929 m² (10,000 ft²) and it is protected by an automatic sprinkler system.

Further, 20/21.3.7.2(3) permits the smoke barrier to be located—under specific criteria—at the wall that separates the ambulatory health care center from a neighboring tenant space of some other occupancy classification.

During a fire, the emergency evacuation of patients in an ambulatory health care facility can be an inefficient, time-consuming process. Realistically, if nonambulatory patients must be moved, any number of occupants can be relocated but only readily through horizontal travel. Smoke barriers used to subdivide a building serve three purposes fundamental to the protection of patients:

- (1) They limit the spread of fire and fire-produced contaminants.
- (2) They limit the number of occupants exposed to a single fire.
- (3) They provide for horizontal relocation of patients by creating an area of refuge on the same floor level.

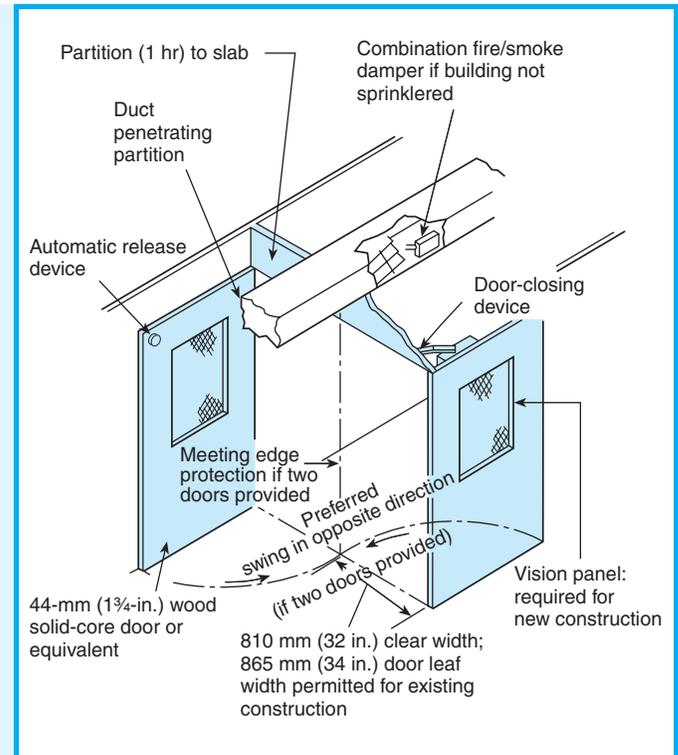

Exhibit 20/21.5 Smoke barrier and associated openings protection for an ambulatory health care facility.

Section 20.4 Special Provisions

(See Section 38.4.)

Section 20.5 Building Services

20.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

Section 21.4 Special Provisions

(See Section 39.4.)

Section 21.5 Building Services

21.5.1 Utilities.

21.5.1.1 Utilities shall comply with the provisions of Section 9.1.

21.5.1.2 Existing installations shall be permitted to be continued in service, provided that the systems do not present a serious hazard to life.

CHAPTER 20 • New

20.5.2 Heating, Ventilating, and Air Conditioning.

20.5.2.1 Heating, ventilating, and air conditioning shall comply with the provisions of Section 9.2 and shall be installed in accordance with the manufacturer's specifications, unless otherwise modified by 20.5.2.2.

20.5.2.2 If fuel-fired, such heating devices shall comply with the following:

- (1) They shall be chimney connected or vent connected.
- (2) They shall take air for combustion directly from the outside.
- (3) They shall be designed and installed to provide for complete separation of the combustion system from the atmosphere of the occupied area.

20.5.2.2.1 Any heating device shall have safety features to immediately stop the flow of fuel and shut down the equipment in case of either excessive temperature or ignition failure.

20.5.2.2.2 Approved, suspended unit heaters shall be permitted in locations other than means of egress and patient treatment areas, provided that both of the following criteria are met:

- (1) Such heaters are located high enough to be out of the reach of persons using the area.
- (2) Such heaters are equipped with the safety features required by 20.5.2.2.1.

20.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

20.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Paragraphs 20/21.5.2.1 and 20/21.5.2.2 specify safeguards for air conditioning, ventilating, heating, and other service equipment in order to minimize the possibility of such devices serving as a source of ignition. Fuel-fired heating devices, except central heating systems, must be designed to provide complete separation of the combustion system from the occupied spaces. Air for combustion must be taken directly from the outside.

A major concern is preventing the ignition of

CHAPTER 21 • Existing

21.5.2 Heating, Ventilating, and Air Conditioning.

21.5.2.1 Heating, ventilating, and air conditioning shall comply with the provisions of Section 9.2 and shall be in accordance with the manufacturer's specifications, unless otherwise modified by 21.5.2.2.

21.5.2.2 If fuel-fired, heating devices shall comply with the following:

- (1) They shall be chimney connected or vent connected.
- (2) They shall take air for combustion directly from the outside.
- (3) They shall be designed and installed to provide for complete separation of the combustion system from the atmosphere of the occupied area.

21.5.2.2.1 Any heating device shall have safety features to immediately stop the flow of fuel and shut down the equipment in case of either excessive temperature or ignition failure.

21.5.2.2.2 Approved, suspended unit heaters shall be permitted in locations other than means of egress and patient treatment areas, provided that both of the following criteria are met:

- (1) Such heaters are located high enough to be out of the reach of persons using the area.
- (2) Such heaters are equipped with the safety features required by 21.5.2.2.1.

21.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

21.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

clothing, bedclothes, furniture, and other furnishings by a heating device. Therefore, 20/21.7.8 prohibits portable heating devices in areas used by patients.

Paragraph 20/21.5.3 addresses elevators. Although not counted as required exits for the general populace, elevators might constitute a valuable, supplemental facility for evacuating ambulatory health care patients from buildings. In some cases, using an elevator might be the only feasible way to move patients who are unable to use the exit stairs.

Elevators, however, have many inherent weaknesses that tend to limit their reliability. Elevator access doors are designed with operating tolerances that permit smoke transfer into the shaft. During a fire, a power failure might cause an elevator to stop between floors, trapping its passengers. Elevators might, during their descent from upper floors, stop automatically at the floor where the fire is burning, allow the doors to open, and expose the occupants to the fire.

Many of these weaknesses can be minimized by providing emergency power, separating the elevator lobby from other building spaces using rated construction, designing detection and alarm equipment

to prevent elevators from stopping at a floor exposed to a fire, providing an emergency smoke control system, and pressurizing the elevator shaft and adjacent lobbies. These measures represent good fire protection judgment but are not required by the *Code*.

Through emergency planning and staff training, the potential problem of crowding elevators might be avoided. Emergency plans can make effective use of elevators by transferring patients through a horizontal exit, for example, to a separate fire area. Within the separate fire area, a staged evacuation program could be instituted, with the elevators taking patients to the ground level, thereby permitting horizontal travel to the outside.

Section 20.6 Reserved

Section 20.7* Operating Features

A.20.7 Health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside or even their disturbance caused by moving is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable.

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification need to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum.

20.7.1 Evacuation and Relocation Plan and Fire Drills.

20.7.1.1 The administration of every ambulatory health care facility shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons in the event of fire, for their evacuation to areas of refuge, and for their evacuation from the building when necessary.

20.7.1.2 All employees shall be periodically instructed and kept informed with respect to their duties under the plan required by 20.7.1.1.

Section 21.6 Reserved

Section 21.7* Operating Features

A.21.7 Health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside or even their disturbance caused by moving is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable.

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification needs to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum.

21.7.1 Evacuation and Relocation Plan and Fire Drills.

21.7.1.1 The administration of every ambulatory health care facility shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons in the event of fire, for their evacuation to areas of refuge, and for their evacuation from the building when necessary.

21.7.1.2 All employees shall be periodically instructed and kept informed with respect to their duties under the plan required by 21.7.1.1.

CHAPTER 20 • New

20.7.1.3 A copy of the plan required by 20.7.1.1 shall be readily available at all times in the telephone operator's location or at the security center.

20.7.1.4* Fire drills in ambulatory health care facilities shall include the transmission of a fire alarm signal and simulation of emergency fire conditions.

A.20.7.1.4 Many health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors to patients' rooms or wards in the vicinity prior to the initiation of the drill. The purpose of a fire drill is to test and evaluate the efficiency, knowledge, and response of institutional personnel in implementing the facility fire emergency plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in health care facilities are drilled not less than once in each 3-month period.

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs.

20.7.1.5 Patients shall not be required to be moved during drills to safe areas or to the exterior of the building.

20.7.1.6 Drills shall be conducted quarterly on each shift to familiarize facility personnel (nurses, interns, maintenance engineers, and administrative staff) with the signals and emergency action required under varied conditions.

20.7.1.7 When drills are conducted between 9:00 p.m. (2100 hours) and 6:00 a.m. (0600 hours), a coded announcement shall be permitted to be used instead of audible alarms.

20.7.1.8 Employees of ambulatory health care facilities shall be instructed in life safety procedures and devices.

20.7.2 Procedure in Case of Fire.

20.7.2.1* Protection of Patients.

A.20.7.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The following recommendations, however, contain many of the elements that should be considered and adapted as appropriate to the individual facility.

Upon discovery of fire, personnel should immediately take the following action:

- (1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase. The use of a code provides for

CHAPTER 21 • Existing

21.7.1.3 A copy of the plan required by 21.7.1.1 shall be readily available at all times in the telephone operator's location or at the security center.

21.7.1.4* Fire drills in ambulatory health care facilities shall include the transmission of a fire alarm signal and simulation of emergency fire conditions.

A.21.7.1.4 Many health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors to patients' rooms or wards in the vicinity prior to initiation of the drill. The purpose of a fire drill is to test and evaluate the efficiency, knowledge, and response of institutional personnel in implementing the facility fire emergency plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in health care facilities are drilled not less than once in each 3-month period.

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs.

21.7.1.5 Patients shall not be required to be moved during drills to safe areas or to the exterior of the building.

21.7.1.6 Drills shall be conducted quarterly on each shift to familiarize facility personnel (nurses, interns, maintenance engineers, and administrative staff) with the signals and emergency action required under varied conditions.

21.7.1.7 When drills are conducted between 9:00 p.m. (2100 hours) and 6:00 a.m. (0600 hours), a coded announcement shall be permitted to be used instead of audible alarms.

21.7.1.8 Employees of ambulatory health care facilities shall be instructed in life safety procedures and devices.

21.7.2 Procedure in Case of Fire.

21.7.2.1* Protection of Patients.

A.21.7.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The following recommendations, however, contain many of the elements that should be considered and adapted as appropriate to the individual facility.

Upon discovery of fire, personnel should immediately take the following action:

- (1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase. The use of a code provides for

CHAPTER 20 • New

both the immediate aid of any endangered person and the transmission of an alarm. Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.

- (2) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
- (3) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
- (4) The telephone operator should determine the location of the fire as indicated by the audible signal. In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
- (5) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system. The operator should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
- (6) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone. The operator should then transmit this information to the fire department and alert the building occupants.

20.7.2.1.1 For ambulatory health care facilities, the proper protection of patients shall require the prompt and effective response of ambulatory health care personnel.

20.7.2.1.2 The basic response required of staff shall include the following:

- (1) Removal of all occupants directly involved with the fire emergency
- (2) Transmission of an appropriate fire alarm signal to warn other building occupants and summon staff
- (3) Confinement of the effects of the fire by closing doors to isolate the fire area
- (4) Relocation of patients as detailed in the facility's fire safety plan

20.7.2.2 Fire Safety Plan. A written fire safety plan shall provide for the following:

- (1) Use of alarms
- (2) Transmission of alarm to fire department
- (3) Response to alarms
- (4) Isolation of fire
- (5) Evacuation of immediate area

CHAPTER 21 • Existing

both the immediate aid of any endangered person and the transmission of an alarm. Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.

- (2) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
- (3) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
- (4) The telephone operator should determine the location of the fire as indicated by the audible signal. In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
- (5) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system. The operator should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
- (6) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone. The operator should then transmit this information to the fire department and alert the building occupants.

21.7.2.1.1 For ambulatory health care facilities, the proper protection of patients shall require the prompt and effective response of ambulatory health care personnel.

21.7.2.1.2 The basic response required of staff shall include the following:

- (1) Removal of all occupants directly involved with the fire emergency
- (2) Transmission of an appropriate fire alarm signal to warn other building occupants and summon staff
- (3) Confinement of the effects of the fire by closing doors to isolate the fire area
- (4) Relocation of patients as detailed in the facility's fire safety plan

21.7.2.2 Fire Safety Plan. A written fire safety plan shall provide for the following:

- (1) Use of alarms
- (2) Transmission of alarm to fire department
- (3) Response to alarms
- (4) Isolation of fire
- (5) Evacuation of immediate area

CHAPTER 20 • New

- (6) Evacuation of smoke compartment
- (7) Preparation of floors and building for evacuation
- (8) Extinguishment of fire

20.7.2.3 Staff Response.

20.7.2.3.1 All personnel shall be instructed in the use of and response to fire alarms.

20.7.2.3.2 All health care personnel shall be instructed in the use of the code phrase to ensure transmission of an alarm under the following conditions:

- (1) When the individual who discovers a fire must immediately go to the aid of an endangered person
- (2) During a malfunction of the building fire alarm system

20.7.2.3.3 Personnel hearing the code announced shall first activate the building fire alarm using the nearest fire alarm box, then shall execute immediately their duties as outlined in the fire safety plan.

20.7.3 Maintenance of Exits.

20.7.3.1 Proper maintenance shall be provided to ensure the dependability of the method of evacuation selected.

20.7.3.2 Ambulatory health care occupancies that find it necessary to lock exits shall, at all times, maintain an adequate staff qualified to release locks and direct occupants from the immediate danger area to a place of safety in case of fire or other emergency.

20.7.4* Smoking.

Smoking regulations shall be adopted and shall include not less than the following provisions:

- (1) Smoking shall be prohibited in any room, ward, or compartment where flammable liquids, combustible gases, or oxygen is used or stored and in any other hazardous location, and such areas shall be posted with signs that read NO SMOKING or shall be posted with the international symbol for no smoking.
- (2) In ambulatory health care facilities where smoking is prohibited and signs are placed at all major entrances, secondary signs with language that prohibits smoking shall not be required.
- (3) Smoking by patients classified as not responsible shall be prohibited.
- (4) The requirement of 20.7.4(3) shall not apply where the patient is under direct supervision.
- (5) Ashtrays of noncombustible material and safe design shall be provided in all areas where smoking is permitted.

CHAPTER 21 • Existing

- (6) Evacuation of smoke compartment
- (7) Preparation of floors and building for evacuation
- (8) Extinguishment of fire

21.7.2.3 Staff Response.

21.7.2.3.1 All personnel shall be instructed in the use of and response to fire alarms.

21.7.2.3.2 All health care personnel shall be instructed in the use of the code phrase to ensure transmission of an alarm under the following conditions:

- (1) When the individual who discovers a fire must immediately go to the aid of an endangered person
- (2) During a malfunction of the building fire alarm system

21.7.2.3.3 Personnel hearing the code announced shall first activate the building fire alarm using the nearest fire alarm box and then shall execute immediately their duties as outlined in the fire safety plan.

21.7.3 Maintenance of Exits.

21.7.3.1 Proper maintenance shall be provided to ensure the dependability of the method of evacuation selected.

21.7.3.2 Ambulatory health care occupancies that find it necessary to lock exits shall, at all times, maintain an adequate staff qualified to release locks and direct occupants from the immediate danger area to a place of safety in case of fire or other emergency.

21.7.4* Smoking.

Smoking regulations shall be adopted and shall include not less than the following provisions:

- (1) Smoking shall be prohibited in any room, ward, or compartment where flammable liquids, combustible gases, or oxygen is used or stored and in any other hazardous location, and such areas shall be posted with signs that read NO SMOKING or shall be posted with the international symbol for no smoking.
- (2) In ambulatory health care facilities where smoking is prohibited and signs are placed at all major entrances, secondary signs with language that prohibits smoking shall not be required.
- (3) Smoking by patients classified as not responsible shall be prohibited.
- (4) The requirement of 21.7.4(3) shall not apply where the patient is under direct supervision.
- (5) Ashtrays of noncombustible material and safe design shall be provided in all areas where smoking is permitted.

CHAPTER 20 • New

- (6) Metal containers with self-closing cover devices into which ashtrays can be emptied shall be readily available to all areas where smoking is permitted.

A.20.7.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management.

20.7.5 Furnishings, Bedding, and Decorations.

20.7.5.1* Draperies, curtains, and other loosely hanging fabrics and films serving as furnishings or decorations in ambulatory health care occupancies shall be in accordance with the provisions of 10.3.1, and the following also shall apply:

- (1) Such curtains shall include cubicle curtains.
- (2) Such curtains shall not include curtains at showers.

A.20.7.5.1 In addition to the provisions of 10.3.1, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

20.7.5.2 Newly introduced upholstered furniture shall meet the criteria specified when tested in accordance with the methods cited in 10.3.2(2) and 10.3.3.

20.7.5.3 Newly introduced mattresses shall meet the criteria specified when tested in accordance with the methods cited in 10.3.2(3) and 10.3.4.

20.7.5.4 Combustible decorations shall be prohibited unless one of the following criteria is met:

- (1) They are flame-retardant.
- (2) They are decorations, such as photographs and paintings, in such limited quantities that a hazard of fire development or spread is not present.

20.7.5.5 Soiled linen or trash collection receptacles shall not exceed 121 L (32 gal) in capacity, and the following also shall apply:

- (1) The average density of container capacity in a room or space shall not exceed 20.4 L/m² (0.5 gal/ft²).

CHAPTER 21 • Existing

- (6) Metal containers with self-closing cover devices into which ashtrays can be emptied shall be readily available to all areas where smoking is permitted.

A.21.7.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management.

21.7.5 Furnishings, Bedding, and Decorations.

21.7.5.1* Draperies, curtains and other loosely hanging fabrics and films serving as furnishings or decorations in ambulatory health care occupancies shall be in accordance with the provisions of 10.3.1, and the following also shall apply:

- (1) Such curtains shall include cubicle curtains.
- (2) Such curtains shall not include curtains at showers.

A.21.7.5.1 In addition to the provisions of 10.3.1, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

21.7.5.2 Newly introduced upholstered furniture shall meet the criteria specified when tested in accordance with the methods cited in 10.3.2(2) and 10.3.3.

21.7.5.3 Newly introduced mattresses shall meet the criteria specified when tested in accordance with the methods cited in 10.3.2(3) and 10.3.4.

21.7.5.4 Combustible decorations shall be prohibited unless one of the following criteria is met:

- (1) They are flame-retardant.
- (2) They are decorations, such as photographs and paintings, in such limited quantities that a hazard of fire development or spread is not present.

21.7.5.5 Soiled linen or trash collection receptacles shall not exceed 121 L (32 gal) in capacity, and the following also shall apply:

- (1) The average density of container capacity in a room or space shall not exceed 20.4 L/m² (0.5 gal/ft²).

CHAPTER 20 • New

- (2) A capacity of 121 L (32 gal) shall not be exceeded within any 6-m² (64-ft²) area.
- (3) Mobile soiled linen or trash collection receptacles with capacities greater than 121 L (32 gal) shall be located in a room protected as a hazardous area when not attended.
- (4) Container size and density shall not be limited in hazardous areas.

Cigarette ignition-resistance testing—as detailed in 10.3.2—and rate of heat release testing—as detailed in 10.3.3 and 10.3.4—are required by 20/21.7.5.2 and 20/21.7.5.3 for newly introduced upholstered furniture and newly introduced mattresses in ambulatory health care occupancies, unless the room or space is sprinklered. Unlike new hospitals and nursing homes—which are required to be sprinklered—many new and existing ambulatory health care facilities will not be sprinklered. Thus, newly introduced upholstered furniture and mattresses will be subject to cigarette ignition resistance and rate-of-heat-release testing.

Paragraph 20/21.7.5.5 establishes maximum trash container sizes and placement densities permitted within a room. Containers larger than those specified, or grouped containers exceeding the density per room criterion, present a hazard greater than that associated with the normal furnishing of an ambulatory health care center room.

Large, mobile soiled linen or trash receptacles can be moved along the corridor as collections occur

20.7.6 Maintenance and Testing.

(See 4.6.13.)

20.7.7* Engineered Smoke Control Systems.

A.20.7.7 Two documents that provide recognized engineering principles for the testing of smoke control systems are NFPA 92A, *Recommended Practice for Smoke-Control Systems*, and NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*.

20.7.7.1 New engineered smoke control systems shall be tested in accordance with established engineering principles and shall meet the performance requirements of such testing prior to acceptance.

20.7.7.2 Following acceptance, all engineered smoke control systems shall be tested periodically in accordance with recognized engineering principles.

CHAPTER 21 • Existing

- (2) A capacity of 121 L (32 gal) shall not be exceeded within any 6-m² (64-ft²) area.
- (3) Mobile soiled linen or trash collection receptacles with capacities greater than 121 L (32 gal) shall be located in a room protected as a hazardous area when not attended.
- (4) Container size and density shall not be limited in hazardous areas.

but must be attended by staff. If housekeeping staff, for example, must leave the area, the container must be stored in a room designed and maintained as a hazardous area in accordance with 20/21.3.2. Exhibit 20/21.6 illustrates the requirements of 20/21.7.5.5.

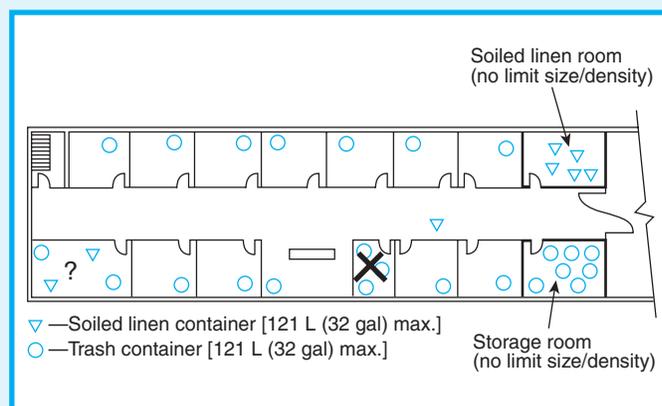

Exhibit 20/21.6 Allowable soiled linen or trash collection receptacles.

21.7.6 Maintenance and Testing.

(See 4.6.13.)

21.7.7* Engineered Smoke Control Systems.

A.21.7.7 Two documents that provide recognized engineering principles for the testing of smoke control systems are NFPA 92A, *Recommended Practice for Smoke-Control Systems*, and NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*.

21.7.7.1 New engineered smoke control systems shall be tested in accordance with established engineering principles and shall meet the performance requirements of such testing prior to acceptance.

21.7.7.2 Following acceptance, all engineered smoke control systems shall be tested periodically in accordance with recognized engineering principles.

CHAPTER 20 • New

20.7.7.3 Test documentation shall be maintained on the premises at all times.

20.7.8 Portable Space-Heating Devices.

Portable space-heating devices shall be prohibited in all ambulatory health care occupancies unless both of the following criteria are met:

- (1) Such devices are used only in nonsleeping staff and employee areas.
- (2) The heating elements of such devices do not exceed 100°C (212°F).

20.7.9 Construction, Repair, and Improvement Operations.

20.7.9.1 Construction, repair, and improvement operations shall comply with 4.6.11.

20.7.9.2 The means of egress in any area undergoing construction, repair, or improvements shall be inspected daily for compliance with 7.1.10.1 and shall also comply with NFPA 241, *Standard for Safeguarding Construction, Alteration, and Demolition Operations*.

CHAPTERS 22 and 23

New and Existing Detention and Correctional Occupancies

Detention and correctional occupancies apply the total concept approach to life safety—complete with a defend-in-place strategy—much as is done for health care occupancies. Unlike people in health care occupancies, whose incapability of self-preservation is due to medical conditions, those in detention and correctional occupancies are incapable of self-preservation because of security restrictions. Security restrictions prevent, to a large extent, free and customary movement and access to other areas of a building. In general, many of the normal features needed in a detention facility are nearly the exact opposite of what the *Code* attempts to provide for other occupancies. The use of locked doors, often with key-operated locks (see 22/23.2.11.2); egress components for which use is restricted or traffic flow is constricted, such as a sally port (see 22/23.2.5.4); and discharge of exits onto other than public ways (see 22/23.2.7.1) are features not usually permitted in other occupancies.

Chapters 22 and 23 impose limitations on the degree of locking that can be used. These limits form a classification scheme based on the appropriate use condition. In general, the amount of restriction (Use Condition I is free egress and Use Condition V is contained; see 22/23.1.4.1) in the detention and correctional facility dictates the use of acceptable locking methods and means of egress features not permitted

in other occupancies. As in a health care facility, those unique features necessary to protect the occupants *in place* include construction, compartmentation, alarm and detection, and staff facilitation to help lead or direct occupants to safe areas within the premises of the detention facility campus.

Section 22/23.7 provides routine operating requirements, such as 24-hour staffing; means for resident notification of staff in an emergency; preparation and maintenance of evacuation plans; staff training in the use of portable fire extinguishers; storage of combustible personal property; presence of heat-producing appliances; control of flammability of draperies, curtains, mattresses, and upholstered furniture; and visual and tactile identification of keys necessary for unlocking doors within the means of egress. Because locking doors—which is necessary for the intended function of the facility—is contrary to the basic *Code* tenet that the means of egress system is under the control of building occupants, the presence of properly trained staff is paramount to providing a level of life safety equivalent to that provided in other occupancies. Section 22/23.7 requires the necessary staffing and training that—where combined with the *Code* requirements of the core chapters and the remainder of Chapter 22 or 23—achieve the necessary level of life safety.

Section 22.1 General Requirements

22.1.1 Application.

22.1.1.1 General.

Section 23.1 General Requirements

23.1.1 Application.

23.1.1.1 General.

CHAPTER 22 • New

22.1.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as detention or correctional occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, a detention or correctional occupancy (*see 4.6.7 and 22.1.1.3*)
- (3) Alterations, modernizations, or renovations of existing detention or correctional occupancies (*see 4.6.8 and 22.1.1.4*)
- (4) Existing buildings or portions thereof upon change of occupancy to a detention or correctional occupancy (*see 4.6.12*)

22.1.1.1.2 This chapter establishes life safety requirements for the design of all new detention and correctional facilities, other than the following:

- (1) Use Condition I facilities protected as residential occupancies in accordance with 22.1.4.3
- (2)* Facilities determined to have equivalent safety provided in accordance with Section 1.4.

A.22.1.1.1.2(2) In determining equivalency for conversions, modernizations, renovations, or unusual design concepts of detention and correctional facilities, the authority having jurisdiction is permitted to accept evaluations based on the detention and correctional occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, utilizing the parameters for new construction.

22.1.1.1.3 Detention and correctional occupancies shall include those used for purposes such as correctional institutions, detention facilities, community residential centers, training schools, work camps, and substance abuse centers where occupants are confined or housed under some degree of restraint or security.

22.1.1.1.4 Detention and correctional occupancies shall include those that provide sleeping facilities for four or more residents and are occupied by persons who are generally prevented from taking self-preservation action because of security measures not under the occupants' control.

22.1.1.2 Total Concept.

22.1.1.2.1 All detention and correctional facilities shall be designed, constructed, maintained, and operated to minimize the possibility of a fire emergency.

22.1.1.2.2 Because the safety of all occupants in detention and correctional facilities cannot be adequately ensured solely by dependence on evacuation of the building, their protection from fire shall be provided by appropriate arrange-

CHAPTER 23 • Existing

23.1.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as detention or correctional occupancies. (*See also 22.1.1.1.*)

23.1.1.1.2 This chapter establishes life safety requirements for all existing detention and correctional facilities, other than the following:

- (1) Use Condition I facilities protected as residential occupancies in accordance with 23.1.4.3
- (2)* Facilities determined to have equivalent safety provided in accordance with Section 1.4

A.23.1.1.1.2(2) In determining equivalency for existing detention and correctional facilities, the authority having jurisdiction is permitted to accept evaluations based on the detention and correctional occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, utilizing the parameters for existing buildings.

23.1.1.1.3 Detention and correctional occupancies shall include those used for purposes such as correctional institutions, detention facilities, community residential centers, training schools, work camps, and substance abuse centers where occupants are confined or housed under some degree of restraint or security.

23.1.1.1.4 Detention and correctional occupancies shall include those that provide sleeping facilities for four or more residents and are occupied by persons who are generally prevented from taking self-preservation action because of security measures not under the occupants' control.

23.1.1.2 Total Concept.

23.1.1.2.1 All detention and correctional facilities shall be designed, constructed, maintained, and operated to minimize the possibility of a fire emergency.

23.1.1.2.2 Because the safety of all occupants in detention and correctional facilities cannot be adequately ensured solely by dependence on evacuation of the building, their protection from fire shall be provided by appropriate arrange-

CHAPTER 22 • New

ment of facilities; adequate, trained staff; and development of operating, security, and maintenance procedures composed of the following:

- (1) Design, construction, and compartmentation
- (2) Provision for detection, alarm, and extinguishment
- (3) Fire prevention and planning, training, and drilling programs for the isolation of fire and the transfer of occupants to areas of refuge, for evacuation of the building, or for protection of the occupants in place
- (4) Provision of security to the degree necessary for the safety of the public and the occupants of the facility

22.1.1.3 Additions. Additions shall be separated from any existing structure not conforming with the provisions of Chapter 23 by a fire barrier having not less than a 2-hour fire resistance rating constructed to the requirements of the addition, and the following also shall apply:

- (1) Doors in such partitions shall normally be kept closed.
- (2) Doors in such partitions shall be permitted to be held open if they meet the requirements of 7.2.1.8.2.

22.1.1.4 Modernizations or Renovations.

22.1.1.4.1 Modernizations and renovations shall be in accordance with 4.6.8, unless otherwise permitted by 22.1.1.4.2.

22.1.1.4.2 In nonsprinklered existing buildings, modernizations or renovations shall be permitted to comply with the nonsprinklered options contained in 22.4.4 in lieu of the sprinkler requirement of 22.3.5.2.

Although 22/23.1.1.1.2 states that Chapters 22 and 23 establish life safety requirements for detention and correctional facilities, the chapters focus primarily on life safety requirements for the residential portions of these occupancies.

Paragraph 22/23.1.1.1.2(1) exempts Use Condition I facilities from the requirements of Chapters 22 and 23 if such facilities are protected as residential occupancies. In accordance with 22/23.1.4.1, which defines the five resident user category groups, Use Condition I provides residents with free movement from sleeping areas and other spaces where access or occupancy is permitted to the exterior, by a means of an egress system that meets the same requirements as would be provided for occupants of hotel, dormitory, apartment, or lodging or rooming house occupancies. Because locked doors have not been imposed on the residents of a Use Condition I detention or correctional occupancy, such a facility does not require the protect-in-place strategy and associated require-

CHAPTER 23 • Existing

ment of facilities; adequate, trained staff; and development of operating, security, and maintenance procedures composed of the following:

- (1) Design, construction, and compartmentation
- (2) Provision for detection, alarm, and extinguishment
- (3) Fire prevention and planning, training, and drilling programs for the isolation of fire and the transfer of occupants to areas of refuge, for evacuation of the building, or for protection of the occupants in place
- (4) Provision of security to the degree necessary for the safety of the public and the occupants of the facility

23.1.1.3 Additions. Additions shall be separated from any existing structure not conforming with the provisions of this chapter by a fire barrier having not less than a 2-hour fire resistance rating constructed to the requirements of the addition, and the following also shall apply:

- (1) Doors in such partitions shall normally be kept closed.
- (2) Doors shall be permitted to be held open if they meet the requirements of 7.2.1.8.2.

23.1.1.4 Modernizations or Renovations.

23.1.1.4.1 Modernizations and renovations shall be in accordance with 4.6.8, unless otherwise permitted by 23.1.1.4.2.

23.1.1.4.2 In nonsprinklered existing buildings, modernizations or renovations shall be permitted to comply with the nonsprinklered options contained in 22.4.4 in lieu of the sprinkler requirement of 22.3.5.2.

ments of Chapters 22 and 23. For information on the protection of Use Condition I facilities, 22/23.1.1.1.2(1) and 22/23.1.4.3(1) refer the user to the residential occupancy chapters of the *Code* in lieu of the provisions of Chapters 22 and 23.

Paragraph 22/23.1.1.1.2(2) permits use of the equivalency provisions of Section 1.4 to comply with the intended level of life safety rather than having to meet the requirements of Chapters 22 and 23. The 2004 edition of NFPA 101A, *Guide on Alternative Approaches to Life Safety*¹, will provide information on one possible equivalency system for use in detention and correctional occupancies. The measurement system of that document, which is to be published early in 2004, will be calibrated against the requirements of the 2003 edition of the *Life Safety Code*; the fire safety evaluation systems contained in the 2001 edition of NFPA 101A were calibrated against the requirements of the 2000 edition of the *Code*.

The fire safety evaluation system (FSSES) for de-

CHAPTER 22 • New

tention and correctional occupancies contained in NFPA 101A provides a method in which the user assigns numerical values to various building parameters. The individual values are totaled and compared with established values. Using this system, alternative designs can be evaluated as options to literal *Code* compliance. The *Code* does not intend to limit acceptable equivalency evaluations solely to those based on the FSES in NFPA 101A. The authority having jurisdiction retains the discretion—in accordance with Section 1.4—to evaluate and approve alternative designs on the basis of appropriate supporting data. Also, Section 4.4 of the *Code* permits the use of the performance-based option for the design of a complete life safety system in accordance with Chapter 5.

Both A.6.1.7.1 and 22/23.1.1.1.3 reflect the current terminology for various forms of detention and correctional occupancies. The terms *adult correctional institutions*, *adult local detention facilities*, *juvenile detention facilities*, *juvenile training schools*, *adult and juvenile community residential centers*, *adult and juvenile work camps*, and *adult and juvenile substance abuse centers* are used in place of terms such as *reformatories* and *houses of correction*.

Residents of detention and correctional occupancies and patients in health care occupancies are judged to be incapable of self-preservation during a fire emergency. In the case of a health care occupancy patient, incapability is due to physical or mental illness or infirmity. The detention and correctional occupancy resident, although most likely ambulatory or able-bodied, is incapable of self-preservation due to security measures imposed and beyond the resident's control. In both cases, the occupants might have to await staff action before moving to an exit, another fire compartment, or another smoke compartment. Impediments to adequate egress are further compounded in detention and correctional occupancies by the reluctance of staff to unlock doors leading to the outside. Thus, horizontal movement within the facility to another fire compartment or smoke compartment might be the only means of

22.1.2* Multiple Occupancies.

A.22.1.2 Detention and correctional facilities are a complex of structures, each serving a definite and usually different purpose. In many institutions, all, or almost all, the occupancy-type classifications found in this *Code* are represented. Means of egress and other features are governed

CHAPTER 23 • Existing

egress system that the resident is allowed to use in a fire emergency, regardless of how many exit doors to the outside are installed. Therefore, use of the “total concept” described in 22/23.1.1.2 is critical.

The total concept as used in 22/23.1.1.2 establishes a protect-in-place or defend-in-place strategy. This strategy mandates requirements that minimize the need for building evacuation by restricting the development and spread of a fire emergency to the room of fire origin. This concept is desirable because safety cannot be ensured by relying on a means of egress system that is predicated on the use of evacuation but for which locks either cannot or will not be unlocked in a timely manner. The requirements (for example, Section 22/23.7) first try to prevent ignition and, when fires do occur, set out to detect them (for example, 22/23.3.4.4). Other requirements aim to control the speed with which a fire will develop (for example, 22/23.3.3), and still others serve to confine the effects of fire. Extinguishment of fire is facilitated by sprinkler, standpipe, and portable fire extinguisher requirements. Provisions are made for refuge areas by encouraging the use of horizontal exits and by requiring smoke barriers. Heavy reliance is placed on staff reaction. All these requirements fit together to minimize the need for evacuation. This is the “total concept.”

Additions to existing facilities are addressed in 22/23.1.1.3. Buildings that comply with the requirements for existing detention and correctional occupancies in accordance with Chapter 23 do not require separation from new additions.

Note that, unlike similar requirements that apply to health care occupancies, the positioning of doors in the separating fire barriers is not restricted to cross-corridor locations. Doors must be kept closed unless they meet the requirements for automatic closing found in 7.2.1.8.2.

Exhibit 22/23.1 illustrates the requirements of 22/23.1.1.3. If the existing portion of the building meets the requirements of Chapter 23, the new addition could be open to the existing building.

23.1.2* Multiple Occupancies.

A.23.1.2 Detention and correctional facilities are a complex of structures, each serving a definite and usually different purpose. In many institutions all, or almost all, of the occupancy-type classifications found in this *Code* are represented. Means of egress and other features are governed

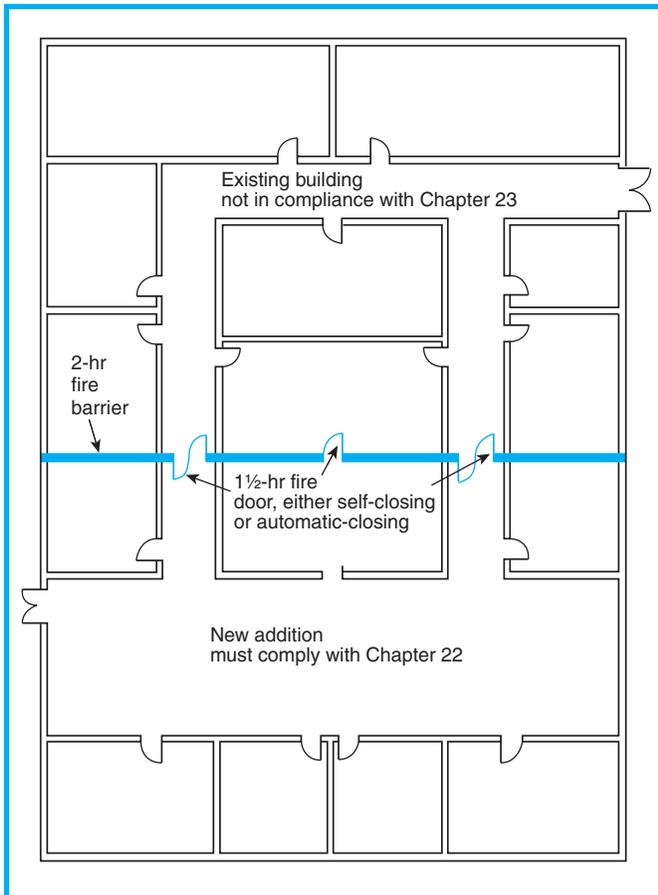

Exhibit 22/23.1 Separation required between new addition, complying with Chapter 22, and existing building not complying with requirements of Chapter 23.

by the type of occupancy classification and the hazard of occupancy, unless specific exemptions are made.

All buildings and structures are to be classified using Chapter 22 and Section 6.1 as a guide, subject to the ruling of the authority having jurisdiction where a question arises concerning the proper classification of any individual building or structure.

Use condition classification of the institution, as well as individual areas within the complex, is always to be considered by the authority having jurisdiction.

22.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

22.1.2.2 Egress provisions for areas of detention and correctional facilities that correspond to other occupancies shall meet the corresponding requirements of this *Code* for such occupancies as modified by 22.1.2.2.1 and 22.1.2.2.2.

by the type of occupancy classification and the hazard of occupancy, unless specific exemptions are made.

All buildings and structures are to be classified using Chapter 23 and Section 6.1 as a guide, subject to the ruling of the authority having jurisdiction where there is a question as to the proper classification of any individual building or structure.

Use condition classification of the institution, as well as individual areas within the complex, is always to be considered by the authority having jurisdiction.

23.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

23.1.2.2 Egress provisions for areas of detention and correctional facilities that correspond to other occupancies shall meet the corresponding requirements of this *Code* for such occupancies as modified by 23.1.2.2.1.

CHAPTER 22 • New

22.1.2.2.1 Where security operations necessitate the locking of required means of egress, staff in the building shall be provided with a means for the supervised release of occupants during all times of use.

22.1.2.2.2* Where security operations necessitate the locking of required means of egress, the following shall apply:

- (1) Detention grade hardware, meeting ASTM F1577, *Standard Test Method for Detention Locks for Swinging Doors*, shall be provided on swinging doors within the required means of egress.
- (2) Sliding doors within the required means of egress shall be designed and engineered for detention and correctional use, and lock cylinders shall meet the cylinder test requirements of ASTM F 1577.

A.22.1.2.2.2 Key-operated locking hardware of a lesser grade than institutional grade hardware might not be suitable for the heavy use that these locks are expected to receive.

22.1.2.3 Sections of detention and correctional facilities shall be permitted to be classified as other occupancies, provided that they meet all of the following conditions:

- (1) They are not intended to serve residents for sleeping purposes.
- (2) They are separated from areas of detention or correctional occupancies by construction having not less than a 2-hour fire resistance rating.

22.1.2.4 All means of egress from detention and correctional occupancies that traverse other use areas shall, as a minimum, conform to the requirements of this *Code* for detention and correctional occupancies, unless otherwise permitted by 22.1.2.5.

22.1.2.5 Egress through a horizontal exit into other contiguous occupancies that do not conform with detention and correctional occupancy egress provisions but that do comply with requirements set forth in the appropriate occupancy chapter of this *Code* shall be permitted, provided that both of the following criteria apply:

- (1) The occupancy shall not contain high hazard contents.
- (2) The horizontal exit shall comply with the requirements of 22.2.2.5.

22.1.2.6 Any area with a hazard of contents classified higher than that of the detention or correctional occupancy and

CHAPTER 23 • Existing

23.1.2.2.1* Where security operations necessitate the locking of required means of egress, staff in the building shall be provided with the means for the supervised release of occupants during all times of use.

A.23.1.2.2.1 Key-operated locking hardware should be of institutional grade. Lesser grade hardware might not be suitable for the heavy use that these locks are expected to receive.

23.1.2.2.2 Reserved.

23.1.2.3 Sections of detention and correctional facilities shall be permitted to be classified as other occupancies, provided that they meet all of the following conditions:

- (1) They are not intended to serve residents for sleeping purposes.
- (2) They are separated from areas of detention or correctional occupancies by construction having not less than a 2-hour fire resistance rating.

23.1.2.4 All means of egress from detention and correctional occupancies that traverse other use areas shall, as a minimum, conform to the requirements of this *Code* for detention and correctional occupancies, unless otherwise permitted by 23.1.2.5.

23.1.2.5 Egress through a horizontal exit into other contiguous occupancies that do not conform to detention and correctional occupancy egress provisions but that do comply with requirements set forth in the appropriate occupancy chapter of this *Code* shall be permitted, provided that both of the following criteria apply:

- (1) The occupancy shall not contain high hazard contents.
- (2) The horizontal exit shall comply with the requirements of 23.2.2.5.

23.1.2.6 Any area with a hazard of contents classified higher than that of the detention or correctional occupancy and

CHAPTER 22 • New

located in the same building shall be protected as required in 22.3.2.

22.1.2.7 Nondetention- or noncorrectional-related occupancies classified as containing high hazard contents shall not be permitted in buildings housing detention or correctional occupancies.

Paragraph 22/23.1.2.1 directs the user to the multiple occupancies provisions of 6.1.14, which permit protecting multiple occupancies either as mixed occupancies or as separated occupancies. Where the multiple occupancy is protected via the provisions of 6.1.14.4 for separated occupancies, the required number of hours of fire-rated separation is specified by Table 6.1.14.4.1. Note that per Table 6.1.14.4.1 the 2-hour separation required between detention/correctional occupancies and other occupancies is not permitted to be reduced to a 1-hour separation due to the presence of sprinklers. The protect-in-place strategy being used needs to help ensure tenable conditions for more than 1 hour under fire conditions.

The provisions of 22/23.1.2.2 through 22/23.1.2.7 have the effect of modifying those of 6.1.14 for the very specific situations described.

Paragraph 22/23.1.2.2 addresses areas of detention and correctional facilities that correspond to other occupancies. Yet, the detailed provisions of Chapters 22 and 23 apply mainly to the sleeping and living areas of the detention and correctional facility. Although the work areas resemble a typical industrial occupancy, the requirements of Chapter 40, Industrial Occupancies, cannot be applied by themselves because doors within the required means of egress of a detention and correctional occupancy are locked for security. Therefore, the concepts of Chapters 22 and 23 should be implemented in locked industrial work areas to ensure that the necessary trained staff who control locks are present to facilitate immediate, supervised release of occupants in the event of fire or a similar emergency.

In addition, some areas of a large facility might correspond to another occupancy classification. For example, a gymnasium would be considered an assembly occupancy (Chapters 12 and 13). If locked doors are required, prompt unlocking and release are critical. Additionally, the requirement of 22.1.2.2.2 for detention grade hardware increases the reliability of the hardware over that which would normally be installed in non-detention occupancies.

CHAPTER 23 • Existing

located in the same building shall be protected as required in 23.3.2.

23.1.2.7 Nondetention- or noncorrectional-related occupancies classified as containing high hazard contents shall not be permitted in buildings housing detention or correctional occupancies.

Release of locked doors is permitted to be achieved by a remotely activated system capable of unlocking all doors in the means of egress or by a sufficient number of attendants who are continuously on duty, provided with keys, and stationed in the immediate area of all locked means of egress doors. Continuous staff supervision is essential.

Paragraph 22/23.1.2.3 permits portions of a detention and correctional occupancy to be classified as some other occupancy provided that certain safeguards are implemented. For example, administrative offices or maintenance areas that are not customarily used by residents as sleeping areas and are separated by 2-hour fire resistance-rated construction could be classified as business or industrial occupancies. In many cases, “trustees” might be employed in these areas. Their presence in these areas would be permitted, provided they have the freedom of egress found in an unlocked environment.

Paragraph 22/23.1.2.3(2) requires that if a detention or correctional occupancy is located in a building of another classification, the detention or correctional occupancy must be separated from the other occupancy by construction having a fire resistance rating of 2 hours. This requirement would apply to a small detention lockup facility (at least four residents, per 22/23.1.1.1.4) located in a combination county courthouse/office/police building. In accordance with 22/23.7.1.1, the detention area must be staffed 24 hours per day. The remainder of the building, especially office areas, might not be occupied at night. A fire that originates and develops in an unoccupied area will not threaten the occupants of the detention facility as readily due to the protection provided by the required 2-hour fire resistance-rated barrier.

Paragraph 22/23.1.2.4 addresses detention and correctional occupancy egress paths that traverse other use areas. The means of egress from detention and correctional occupancies that traverse other types of spaces must conform to the requirements for detention and correctional occupancies. However, if a 2-hour fire barrier and the associated opening

CHAPTER 22 • New

protectives located between a detention or correctional occupancy and another occupancy (for example, business) qualify as a horizontal exit (see 22/23.2.2.5 and 7.2.4), the means of egress system in the business occupancy need comply only with the appropriate requirements contained in Chapters 38 and 39. See 22/23.1.2.5.

Paragraph 22/23.1.2.6 regulates those spaces that have more hazardous contents—in quantity or type—than are usually found in a detention and correctional occupancy. Spaces, such as rooms used for the storage of highly combustible materials, trash collection rooms, and paint shops, must be protected in accordance with 22/23.3.2.

Paragraph 22/23.1.2.7 prohibits another occu-

22.1.3 Definitions.

The following terms are used in this chapter:

- (1) **Detention and Correctional Residential Housing Area.** See 3.3.16.1.
- (2) **Sally Port (Security Vestibule).** See 3.3.187.

22.1.4 Classification of Occupancy.

22.1.4.1* For application of the life safety requirements of this chapter, the resident user category shall be divided into the following five groups:

- (1) *Use Condition I—Free Egress.* Free movement is allowed from sleeping areas and other spaces where access or occupancy is permitted to the exterior via means of egress that meet the requirements of the *Code*.
- (2) *Use Condition II—Zoned Egress.* Free movement is allowed from sleeping areas and any other occupied smoke compartment to one or more other smoke compartments.
- (3) *Use Condition III—Zoned Impeded Egress.* Free movement is allowed within individual smoke compartments, such as within a residential unit comprised of individual sleeping rooms and a group activity space, with egress impeded by remote-controlled release of means of egress from such a smoke compartment to another smoke compartment.
- (4) *Use Condition IV—Impeded Egress.* Free movement is restricted from an occupied space. Remote-controlled release is provided to allow movement from all sleeping rooms, activity spaces, and other occupied areas within the smoke compartment to another smoke compartment.
- (5) *Use Condition V—Contained.* Free movement is restricted from an occupied space. Staff-controlled manual

CHAPTER 23 • Existing

pancy with highly hazardous contents—such as flammable liquids storage—from being located in a building housing detention and correctional occupancies. The intent of this paragraph is not to exclude normal storage, but to prevent the conversion of a portion of a detention and correctional facility to a warehouse that contains a larger quantity or a more hazardous type of combustible material than would be normally expected in a detention and correctional occupancy. This requirement applies principally to residential areas. For example, industrial areas that are part of the overall detention and correctional facility but are located in a nonresidential-use building can have flammable liquids as part of the industrial process.

23.1.3 Definitions.

The following terms are used in this chapter:

- (1) **Detention and Correctional Residential Housing Area.** See 3.3.16.1.
- (2) **Sally Port (Security Vestibule).** See 3.3.187.

23.1.4 Classification of Occupancy.

23.1.4.1* For application of the life safety requirements that follow, the resident user category shall be divided into the following five groups:

- (1) *Use Condition I—Free Egress.* Free movement is allowed from sleeping areas and other spaces where access or occupancy is permitted to the exterior via means of egress meeting the requirements of this *Code*.
- (2) *Use Condition II—Zoned Egress.* Free movement is allowed from sleeping areas and any other occupied smoke compartment to one or more other smoke compartments.
- (3) *Use Condition III—Zoned Impeded Egress.* Free movement is allowed within individual smoke compartments, such as within a residential unit comprised of individual sleeping rooms and a group activity space, with egress impeded by remote-controlled release of means of egress from such a smoke compartment to another smoke compartment.
- (4) *Use Condition IV—Impeded Egress.* Free movement is restricted from an occupied space. Remote-controlled release is provided to allow movement from all sleeping rooms, activity spaces, and other occupied areas within the smoke compartment to another smoke compartment.
- (5) *Use Condition V—Contained.* Free movement is restricted from an occupied space. Staff-controlled manual

release at each door is provided to allow movement from all sleeping rooms, activity spaces, and other occupied areas within the smoke compartment to another smoke compartment.

A.23.1.4.1 Users and occupants of detention and correctional facilities at various times can be expected to include staff, visitors, and residents. The extent and nature of facility utilization will vary according to the type of facility, its function, and its programs.

Figure A.23.1.4.1 illustrates the five use conditions.

23.1.4.2* To be classified as Use Condition III or Use Condition IV, the arrangement, accessibility, and security of the release mechanism(s) used for emergency egress shall be

CHAPTER 22 • New

such that the minimum available staff, at any time, can promptly release the locks.

A.22.1.4.2 Prompt operation is intended to be accomplished in the period of time between detection of fire by either the smoke detector(s) required by 22.3.4.4 or by other means, whichever comes first, and the advent of intolerable conditions forcing emergency evacuation. Fire tests have indicated that the time available is a function of the volume and height of the space involved and the rate of fire development. In traditional single-story corridor arrangements, the time between detection by smoke detectors and the advent of lethal conditions down to head height can be as short as approximately 3 minutes. In addition, it should be expected that approximately 1 minute will be required to evacuate all the occupants of a threatened smoke compartment once the locks are released. In such a case, a prompt release time would be 2 minutes.

22.1.4.3 Areas housing occupancies corresponding to Use Condition I shall conform to one of the following:

- (1) The requirements of residential occupancies under this *Code*.
- (2)* The requirements of this chapter for Use Condition II facilities, provided that the staffing requirements of Section 22.7 are met.

A.22.1.4.3(2) If the Use Condition I facility conforms to the requirements of residential occupancies under this *Code*, there are no staffing requirements. If the Use Condition I facility conforms to the requirements of Use Condition II facilities as permitted by this provision, staffing is required in accordance with Section 22.7.1.

Use Condition I facilities have no physical restrictions—such as locks—on the means of egress. The occupants are capable of self-preservation. An example is a work release center in which the doors are not locked. See Figure A.22/A.23.1.4.1. Because the means of egress system is kept unlocked, occupants are as free to escape a fire emergency as occupants of any other residential type of occupancy. Therefore, Use Condition I detention and correctional occupancies are exempted from the requirements of Chapters 22 and 23 and must meet the requirements of some other occupancy chapter, such as Chapter 28 or Chapter 29 for hotels and dormitories. See 22/23.1.4.3 and 22/23.1.1.1.2(1).

The residents of a Use Condition II facility have the freedom to move within the building, including

CHAPTER 23 • Existing

such that the minimum available staff, at any time, can promptly release the locks.

A.23.1.4.2 Prompt operation is intended to be accomplished in the period of time between detection of fire by either the smoke detector(s) required by 23.3.4.4 or by other means, whichever comes first, and the advent of intolerable conditions forcing emergency evacuation. Fire tests have indicated that the time available is a function of the volume and height of the space involved and the rate of fire development. In traditional single-story corridor arrangements, the time between detection by smoke detectors and the advent of lethal conditions down to head height can be as short as approximately 3 minutes. In addition, it should be expected that approximately 1 minute will be required to evacuate all the occupants of a threatened smoke compartment once the locks are released. In such a case, a prompt release time would be 2 minutes.

23.1.4.3 Areas housing occupancies corresponding to Use Condition I shall conform to one of the following:

- (1) The requirements of residential occupancies under this *Code*.
- (2)* The requirements of this chapter for Use Condition II facilities, provided that the staffing requirements of Section 23.7 are met.

A.23.1.4.3(2) If the Use Condition I facility conforms to the requirements of residential occupancies under this *Code*, there are no staffing requirements. If the Use Condition I facility conforms to the requirements of Use Condition II facilities as permitted by this exception, staffing is required in accordance with 23.7.1.

the freedom to move from their rooms, across the smoke barrier, and into a separate smoke compartment. Movement through the exit door in the exterior wall to the outside is impeded by locked doors that are permitted to be unlocked manually at the door. See Figure A.22/A.23.1.4.1.

The residents of a Use Condition III facility are free to move outside their rooms but are confined to the smoke compartment that contains their rooms. Movement to an adjoining smoke compartment is impeded by locked doors within the smoke barrier that must be equipped with remote-control release. Movement through the exit door in the exterior wall to the outside is impeded by locked doors that are permitted to be unlocked manually at the door. See Figure A.22/A.23.1.4.1.

CHAPTER 22 • New

The residents of Use Condition IV facilities are locked in their sleeping rooms. Locks on sleeping room doors must be equipped with remote control release. Movement to an adjoining smoke compartment is impeded by locked doors within the smoke barrier that must be equipped with remote-control release. Movement through the exit door in the exterior wall to the outside is impeded by locked doors that are permitted to be unlocked manually at the door. See Figure A.22/A.23.1.4.1.

In Use Condition V facilities, all locks are manually operated at the individual door. See Figure A.22/A.23.1.4.1. The unlocking process places a heavy demand on staff to open doors in an emergency and severely restricts the movement of residents of Use Condition V facilities. Therefore, the most stringent requirements of Chapters 22 and 23 are applied to such facilities.

As part of the definitions of Use Condition II through Use Condition V, reference is made to smoke compartments and the type of locking (none, remote release, or manual operation) used for smoke barrier doors. A facility without a smoke barrier can still qualify as meeting the requirements for one of these use conditions by providing for movement to a location judged to be equivalent to a smoke compartment, such as (1) a public way, (2) a building separated from the space in question by either adequate fire resistance-rated construction or distance, or (3) an adequately sized outside holding area located at a safe distance. The locking operation of the door to this alternative location cannot be more stringent than that allowed for the smoke barrier door of the corresponding use condition—no locking for Use Condition II, remote release for Use Condition III and Use Condition IV, and manual operation for Use Condition V. See also 22/23.3.7.

Note that in Figure A.22/A.23.1.4.1, “Locked” designates manual unlocking operation at the door.

The major requirements of 22/23.1.4.2 are that the area must be under continuous supervision and a sufficient number of staff must be present and have

CHAPTER 23 • Existing

the necessary keys readily available to release the locks.

The intent of 22/23.1.4.3 is that detention and correctional occupancies in which the occupants are not locked in at any time are to be classified as residential occupancies and thus meet the requirements of Chapter 26, 28, 29, 30, or 31, as appropriate. Those buildings that permit free egress, although used as correctional occupancies, are not classified as detention and correctional occupancies under this *Code*. A facility equipped with locking devices on its doors cannot be classified as Use Condition I because the locks could be used in the future. Instead, depending on the locks’ mode of operation—remote or manual—the corresponding use condition should be assigned and the requirements of Chapter 22 or Chapter 23 followed. A facility should be classified as Use Condition I only if the locking devices are physically removed.

In lieu of following the requirements for a normal residential occupancy—as detailed in Chapter 26, 28, 29, 30, or 31—a Use Condition I facility is permitted to comply with the Chapter 22 or 23 provisions applicable to a Use Condition II facility. This exemption permits the entire facility—which might have a variety of use conditions—to be measured against the requirements of Chapter 22 or Chapter 23 without having to make special use of other occupancy chapters. However—as A.22/A.23.1.4.3(2) advises—if the requirements applicable to Use Condition II are used, staffing is required. Proper protection would not be ensured by mixing the provisions of a residential occupancy chapter—Chapters 28 and 29, for example, for which the hotel provisions do not rely on staff action—with those of Chapters 22 and 23 applicable to Use Condition II facilities, for which heavy reliance is placed on staff action. In other words, the *Code* requires full compliance with either the requirements applicable to a residential occupancy or those applicable to a detention and correctional occupancy—not a self-prescribed mixing of options.

22.1.5 Classification of Hazard of Contents.

The classification of hazard of contents shall be as defined in Section 6.2.

23.1.5 Classification of Hazard of Contents.

The classification of hazard of contents shall be as defined in Section 6.2.

CHAPTER 22 • New

22.1.6 Minimum Construction Requirements.

22.1.6.1 For the purposes of 22.1.6, the number of stories shall be counted starting with the primary level of exit discharge.

22.1.6.2 For the purposes of 22.1.6.1, the primary level of exit discharge of a building shall be that floor that is level with or above finished grade on the exterior wall line for 50 percent or more of its perimeter.

22.1.6.3 For the purposes of 22.1.6.2, building levels below the primary level shall not be counted as a story in determining the height of the building.

22.1.6.4 Reserved.

22.1.6.5 Detention and correctional occupancies shall be limited to the types of building construction permitted by Table 22.1.6.5. (See 8.2.1.)

22.1.6.6 All interior walls and partitions in Type I or Type II construction shall be of noncombustible or limited-combustible materials.

Exhibit 22/23.2 illustrates the method for counting stories in accordance with 22/23.1.6.1 through 22/23.1.6.3 for use with Table 22/23.1.6.5. If the attic were judged occupiable, the exhibit would depict a four-

CHAPTER 23 • Existing

23.1.6 Minimum Construction Requirements.

23.1.6.1 For the purposes of 23.1.6, the number of stories shall be counted starting with the primary level of exit discharge.

23.1.6.2 For the purposes of 23.1.6.1, the primary level of exit discharge of a building shall be that floor that is level with or above finished grade on the exterior wall line for 50 percent or more of its perimeter.

23.1.6.3 For the purposes of 23.1.6.2 building levels below the primary level shall not be counted as a story in determining the height of the building.

23.1.6.4 A residential housing area complying with 23.3.1.2 shall be considered as a one-story building for purposes of applying 23.1.6.5.

23.1.6.5 Detention and correctional occupancies shall be limited to the types of building construction permitted by Table 23.1.6.5 (see 8.2.1), unless otherwise permitted by the following:

- (1) Any building of Type I, Type II(222), or Type II(111) construction shall be permitted to include roofing systems involving combustible or steel supports, decking, or roofing, provided that the following criteria are met:
 - (a) The roof covering shall meet not less than Class C requirements in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.
 - (b) The roof shall be separated from all occupied portions of the building by a noncombustible floor assembly that includes not less than 63 mm (2½ in.) of concrete or gypsum fill and the attic or other space so developed shall meet one of the following requirements:
 - i. It shall be unoccupied.
 - ii. It shall be protected throughout by an approved automatic sprinkler system.
- (2) In determining building construction type, exposed steel roof members located 4875 mm (192 in.) or more above the floor of the highest cell shall be permitted to be disregarded.

story building; otherwise the exhibit illustrates a three-story building.

The provisions of 22.4.4.6 and 23.3.1.2 address multilevel housing areas for which the vertical sepa-

X: Permitted types of construction.

¹Permitted if the entire building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 23.3.5.3.

²Where Use Condition V is used, permitted if the entire building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 23.3.5.3.

ration between the lowest floor level and the uppermost floor level does not exceed 3960 mm (156 in.), without limiting the number of levels. See Figure A.22.4.4.6.4 and Figure A.23.3.1.2.3. A multilevel housing area meeting all the requirements of 22.4.4.6 and 23.3.1.2 is treated as a single story in determining required building construction type in accordance with 22/23.1.6.5.

The Code recognizes that locked doors to the outside will be reluctantly unlocked, slowly unlocked,

or never unlocked. Therefore, the Code relies on the defend-in-place or protect-in-place strategy addressed in the commentary on 22/23.1.1.2. Paragraph 22/23.1.6.5 establishes minimum construction requirements to help ensure the structural integrity of the building for the time required to release residents to the outside or hold them in a safe fire compartment or smoke compartment.

Table 22/23.1.6.5 establishes minimum construction types for detention and correctional occupancies.

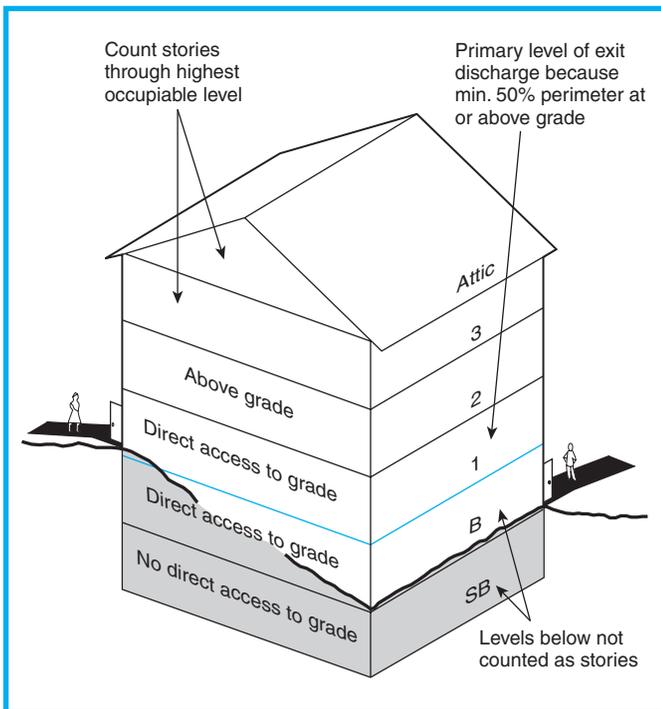

Exhibit 22/23.2 Method for counting stories.

Under some conditions, certain building construction types are prohibited from being constructed and occupied for detention and correctional occupancy use, even if protected by automatic sprinklers. The automatic sprinkler requirements contained in this table are based on construction type. Automatic sprinkler protection also is required for new construction by 22.3.5.2. See NFPA 220, *Standard on Types of Building Construction*², for definitions of types of construction. Also see 8.2.1.2 and Table A.8.2.1.2.

Maintaining the integrity of building construction under fire conditions is mandated because detention and correctional facility residents are incapable of self-preservation due to security requirements imposed by the facility. Thus, although NFPA 220 does not regulate the combustibility of interior nonbearing walls and partitions, 22.1.6.6 allows for credit to be taken for Type I or Type II construction in new detention and correctional occupancies only if such interior walls and partitions are of noncombustible or limited-combustible construction. The terms *noncombustible* and *limited-combustible* are defined in 3.3.135.3 and 3.3.135.2, respectively.

22.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, either shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

Paragraph 22/23.1.7 references the use of the occupant load factors of Table 7.3.1.2 from which an occupant load can be determined. The means of egress system must be sized to handle whichever is larger: the number of persons intended to occupy the space or the number of persons calculated by using the occupant load factor.

The *Code* intends that the occupant load factor be used only for sizing the means of egress, not for

23.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, either shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

limiting the number of persons within a space. If a means of egress can accommodate an occupant load larger than that calculated using the occupant load factor characteristic of the use of the space, the *Code* does not prohibit such a load. In a facility with excess means of egress capacity, other considerations such as plumbing codes or sanitary codes, sociological factors, and common sense will help determine the maximum occupant load.

CHAPTER 22 • New

Section 22.2 Means of Egress Requirements

22.2.1 General.

Means of egress shall comply with Chapter 7, unless otherwise provided or modified by Section 22.2.

22.2.2 Means of Egress Components.

22.2.2.1 General. Components of means of egress shall be limited to the types described in 22.2.2.2 through 22.2.2.11.

22.2.2.2 Doors. Doors complying with 7.2.1 shall be permitted, unless otherwise provided by 22.2.11.

22.2.2.3 Stairs.

22.2.2.3.1 Stairs shall be permitted as follows:

- (1) Stairs complying with 7.2.2 shall be permitted.
- (2) Noncombustible grated stair treads and landing floors shall be permitted.

22.2.2.3.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted for access to and between staff locations.

22.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

22.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 and the modifications of 22.2.2.5.1 and 22.2.2.5.2 shall be permitted.

22.2.2.5.1 Not less than 0.55 m² (6 ft²) of accessible space per occupant shall be provided on each side of the horizontal exit for the total number of people in adjoining compartments.

22.2.2.5.2* Horizontal exits shall be permitted to comprise 100 percent of the exits required, provided that an exit, other than a horizontal exit, located in another (not necessarily adjacent) fire compartment is accessible without returning through the compartment of fire origin.

A.22.2.2.5.2 An exit is not necessary from each individual fire compartment or smoke compartment if there is access to an exit through other fire compartments or smoke compartments without passing through the fire compartment or smoke compartment of fire origin.

CHAPTER 23 • Existing

Section 23.2 Means of Egress Requirements

23.2.1 General.

Means of egress shall comply with Chapter 7, unless otherwise provided or modified by Section 23.2.

23.2.2 Means of Egress Components.

23.2.2.1 General. Components of means of egress shall be limited to the types described in 23.2.2.2 through 23.2.2.11.

23.2.2.2 Doors. Doors complying with 7.2.1 shall be permitted, unless otherwise provided in 23.2.11.

23.2.2.3 Stairs.

23.2.2.3.1 Stairs shall be permitted as follows:

- (1) Stairs complying with 7.2.2 shall be permitted.
- (2) Noncombustible grated stair treads and landing floors shall be permitted.

23.2.2.3.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted for access to and between staff locations.

23.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

23.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 and the modifications of 23.2.2.5.1 through 23.2.2.5.4 shall be permitted.

23.2.2.5.1 Not less than 0.55 m² (6 ft²) of accessible space per occupant shall be provided on each side of the horizontal exit for the total number of people in adjoining compartments.

23.2.2.5.2* Horizontal exits shall be permitted to comprise 100 percent of the exits required, provided that an exit, other than a horizontal exit, located in another (not necessarily adjacent) fire compartment is accessible without returning through the compartment of fire origin.

A.23.2.2.5.2 An exit is not necessary from each individual fire compartment if there is access to an exit through other fire compartments without passing through the fire compartment of fire origin.

23.2.2.5.3* Ducts shall be permitted to penetrate horizontal exits in accordance with 7.2.4.3.4(3) if protected by combination fire dampers/smoke leakage-rated dampers that meet the smoke damper actuation requirements of 8.5.4.

CHAPTER 22 • New

22.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

22.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

22.2.2.8 Reserved.

22.2.2.9 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

22.2.2.10 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

22.2.2.11 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

Chapters 22 and 23 recognize the following means of egress components as described in Chapter 7: doors (7.2.1), stairs (7.2.2), smokeproof enclosures (7.2.3), horizontal exits (7.2.4), ramps (7.2.5), exit passageways (7.2.6), fire escape ladders (7.2.9), alternating tread devices (7.2.11), and areas of refuge (7.2.12). Also, Chapter 23 recognizes existing fire escape stairs (7.2.8). However, Chapters 22 and 23 often modify the provisions of Chapter 7 applicable to those means of egress components. For example, although the Chapter 7 provisions that apply to horizontal exits would limit a horizontal exit to providing a maximum of 50 percent of the number of exits or 50 percent of the total egress capacity, Chapters 22 and 23 encourage the voluntary use of horizontal exits by permitting up to 100 percent of the exits to be reached

CHAPTER 23 • Existing

A.23.2.2.5.3 This provision is intended to promote the use of horizontal exits in detention and correctional occupancies. Horizontal exits provide an especially effective egress system for an occupancy in which the occupants, due to security concerns, are not commonly released to the outside. This provision offers a *Code*-specified equivalent alternative to the requirement of 7.2.4.3.4 that horizontal exits are not to be penetrated by ducts. The intended continuity of the fire resistance-rated and smoke-resisting barrier is maintained by requiring that duct penetrations of horizontal exits be protected by combination fire damper/smoke leakage-rated dampers that close upon activation of a smoke detector and a heat-actuated mechanism before the barrier's ability to resist the passage of smoke and fire is compromised.

23.2.2.5.4 A door in a horizontal exit shall not be required to swing with egress travel as specified in 7.2.4.3.7(1).

23.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

23.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

23.2.2.8 Fire Escape Stairs. Fire escape stairs complying with 7.2.8 shall be permitted.

23.2.2.9 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

23.2.2.10 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

23.2.2.11 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

by way of horizontal exits if additional criteria can be met.

Chapter 7 considers escalators and moving walks as acceptable means of egress only if they are part of an existing occupancy and are specifically recognized by an occupancy chapter. They are not permitted in the means of egress system of a detention and correctional occupancy. Chapters 22 and 23 do not recognize slide escapes as part of an egress system. Areas of refuge (see 7.2.12) might be used to provide accessible means of egress as required for new facilities in accordance with the provisions of 7.5.4.

Older editions of the *Code* contained a provision in Chapters 22 and 23 that exempted handrails and guards from the requirement for intermediate rails designed to keep children from falling through the

CHAPTER 22 • New

spaces between rails. The exemption still applies to detention and correctional occupancies—see 7.2.2.4.5.3(2). The rationale for this exemption is that only adults or older juveniles use these facilities, and intermediate railings might impact functional requirements by interfering with visual observation by staff.

Grated stair treads and grated landing floors are recognized as usable in this occupancy because occupant reluctance to walk on such surfaces is not expected. Similarly, the potential for small shoe heels getting caught in the grated surfaces is greatly reduced in this occupancy.

Paragraph 22/23.2.2.3.2 permits spiral stairs conforming to 7.2.2.2.3 for staff use only. These provisions prohibit a spiral stair from being part of the required means of egress system within areas occupied by residents.

Paragraph 22/23.2.2.4 permits a smokeproof enclosure to serve as part of the means of egress system in detention and correctional occupancies if that enclosure meets the requirements of 7.2.3. However, the smokeproof enclosure is not required. An example of an occupancy requiring a smokeproof enclosure can be found in 31.2.11, in which nonsprinklered, existing, high-rise apartment buildings are required to be provided with smokeproof enclosures in accordance with 7.2.3.

Horizontal exits are addressed in 22/23.2.2.5. Although 7.2.4 requires only 0.28 m² (3 ft²) of accessible space per occupant on each side of the horizontal exit, 22/23.2.2.5.1 requires 0.55 m² (6 ft²) per occupant. The reasons for this requirement include possible conflicts among the residents, the anticipated extended time spent in the refuge area, and the fact that horizontal exits are permitted to comprise 100 percent of required exits in detention and correctional occupancies in accordance with 22/23.2.2.5.2.

Paragraph 22/23.2.2.5.2 permits horizontal exits to comprise 100 percent of the exits from any fire compartment as long as it is not necessary to travel through the compartment of fire origin to reach a door to the outside—that is, the compartment is not “dead-ended.”

In Exhibit 22/23.3, horizontal exits correctly comprise 100 percent of total exits from fire compartments B, C, and D. Compartment F would require the addition of an exit door that opens directly to the outside in order to reach the outside of the building without

CHAPTER 23 • Existing

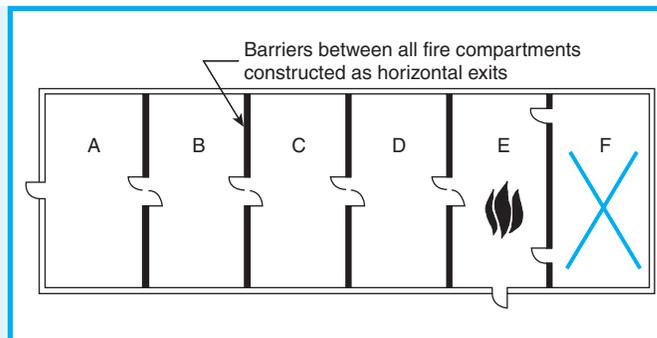

Exhibit 22/23.3 Horizontal exit fire compartment arrangement.

traveling through fire compartment E. Compartments A and E comply with the *Code*, using one horizontal exit and one exit door directly to the exterior of the building.

Due to the practical difficulties of using vertical exit travel to the outside in detention and correctional occupancies, including the reluctance of staff to unlock doors, special recognition is given to horizontal travel and the use of horizontal exits. As previously explained, 100 percent of the total required egress capacity for a given fire area is permitted to be provided by horizontal exits. In the event a horizontal exit also serves as a smoke barrier, refer to 22/23.2.4.2 and 22/23.3.7.

Paragraph 7.2.4.3.4 states that fire barriers used in creating a horizontal exit are prohibited from penetration by ducts. To promote the use of horizontal exits in detention and correctional occupancies—without burdening a facility with regard to duct penetrations—22.4.4.3 and 23.2.2.5.3 and the corresponding exemption in 7.2.4.3.4(3) were developed. If smoke detection is used to shut a combination fire damper/smoke leakage-rated damper early in a fire, the fire- and smoke-resisting features of the horizontal exit can be reestablished at points where ducts penetrate the barrier.

Paragraphs 22/23.2.2.6, 22/23.2.2.7, 22/23.2.2.9, and 22/23.2.2.10 do not mandate the use of ramps, exit passageways, fire escape ladders, or alternating tread devices. Rather, these paragraphs recognize ramps, exit passageways, fire escape ladders, or alternating tread devices as part of the means of egress system only if they meet the applicable requirements of 7.2.5 through 7.2.11. Further, 23.2.2.8 recognizes the use of existing fire escape stairs in accordance with

CHAPTER 22 • New

7.2.8. Note that 7.2.9 and 7.2.11 restrict the use of fire escape ladders and alternative tread devices, respectively, to spaces such as normally unoccupied roofs and equipment platforms. Further, use is restricted to a maximum of three persons—all capable of using the ladder or device.

Paragraph 22/23.2.2.11 does not mandate the use

22.2.3 Capacity of Means of Egress.

22.2.3.1 The capacity of any required means of egress shall be in accordance with Section 7.3.

22.2.3.2 Aisles, corridors, and ramps required for egress shall be not less than 1220 mm (48 in.) in width.

22.2.3.3 For residents' sleeping room door widths, see 22.2.11.3.

22.2.4 Number of Exits.

(See also Section 7.4.)

22.2.4.1 Not less than two separate exits shall meet the following criteria:

- (1) They shall be provided on every story.
- (2) They shall be accessible from every part of every story, fire compartment, or smoke compartment; however, exit access travel shall be permitted to be common for the distances permitted as common path of travel by 22.2.5.3.

22.2.4.2 Not less than one approved exit shall be accessible from each fire compartment and each required smoke compartment into which residents are potentially moved in a fire emergency, with the exits arranged so that egress is possible without returning through the zone of fire origin.

22.2.5 Arrangement of Means of Egress.

(See also Section 7.5.)

CHAPTER 23 • Existing

of areas of refuge but does recognize an area of refuge as part of the means of egress system only if it meets the requirements of 7.2.12. Areas of refuge will often be used to meet the requirements for accessible means of egress mandated for new facilities by 7.5.4 in areas accessible to persons with severe mobility impairments.

23.2.3 Capacity of Means of Egress.

23.2.3.1 The capacity of any required means of egress shall be in accordance with Section 7.3.

23.2.3.2 Aisles, corridors, and ramps required for egress shall be not less than 915 mm (36 in.) in width.

23.2.3.3 For residents' sleeping room door widths, see 23.2.11.3.

23.2.4 Number of Exits.

See also Section 7.4.

23.2.4.1* Not less than two separate exits shall meet the following criteria:

- (1) They shall be provided on every story.
- (2) They shall be accessible from every part of every story, fire compartment, or smoke compartment; however, exit access travel shall be permitted to be common for the distances permitted as common path of travel by 23.2.5.3.

A.23.2.4.1 Multilevel and multitiered residential housing areas meeting the requirements of 23.3.1.2 and 23.3.1.3 are considered single story. Therefore, two exits are not required from each level; only access to two exits is required.

23.2.4.2* Not less than one approved exit shall be accessible from each fire compartment and each required smoke compartment into which residents are potentially moved in a fire emergency, with the exits arranged so that egress is possible without returning through the zone of fire origin.

A.23.2.4.2 An exit is not necessary from each individual fire compartment and smoke compartment if there is access to an exit through other fire compartments or smoke compartments without passing through the fire compartment or smoke compartment of fire origin.

23.2.5 Arrangement of Means of Egress.

See also Section 7.5.

CHAPTER 22 • New

22.2.5.1 Every sleeping room shall have a door leading directly to an exit access corridor, unless otherwise permitted by the following:

- (1) The requirement of 22.2.5.1 shall not apply if there is an exit door opening directly to the outside from the room at ground level.
- (2) One adjacent room, such as a day room, group activity space, or other common space shall be permitted to intervene, and the following also shall apply:
 - (a) Where sleeping rooms directly adjoin a day room or group activity space that is used for access to an exit, such sleeping rooms shall be permitted to open directly to the day room or space.
 - (b) Sleeping rooms permitted to open directly to the day room or space shall be permitted to be separated in elevation by a one-half or full story height. (*See 22.4.4.6.*)

22.2.5.2 No exit or exit access shall contain a corridor, hallway, or aisle having a pocket or dead end exceeding 15 m (50 ft) for Use Condition II, Use Condition III, or Use Condition IV and 6100 mm (240 in.) for Use Condition V.

22.2.5.3 A common path of travel shall not exceed 30 m (100 ft).

22.2.5.4 A sally port shall be permitted in a means of egress where there are provisions for continuous and unobstructed

CHAPTER 23 • Existing

23.2.5.1 Every sleeping room shall have a door leading directly to an exit access corridor, unless otherwise permitted by the following:

- (1) The requirement of 23.2.5.1 shall not apply if there is an exit door opening directly to the outside from the room at the ground level.
- (2) One adjacent room, such as a day room, group activity space, or other common space, shall be permitted to intervene, and the following also shall apply:
 - (a) Where sleeping rooms directly adjoin a day room or group activity space that is used for access to an exit, such sleeping rooms shall be permitted to open directly to the day room or space.
 - (b) Sleeping rooms permitted to open directly to the day room or space shall be permitted to be separated in elevation by a one-half or full story height. (*See 23.3.1.1.*)

23.2.5.2* Existing dead-end corridors are undesirable and shall be altered wherever possible so that exits are accessible in not less than two different directions from all points in aisles, passageways, and corridors.

A.23.2.5.2 Every exit or exit access should be arranged, if feasible, so that no corridor or aisle has a pocket or dead end exceeding 15 m (50 ft) for Use Conditions II, III, and IV and 6100 mm (240 in.) for Use Condition V.

23.2.5.3 A common path of travel shall not exceed 15 m (50 ft), unless otherwise permitted by the following:

- (1) A common path of travel shall be permitted for the first 30 m (100 ft) in smoke compartments protected throughout by an approved automatic sprinkler system in accordance with 23.3.5.3.
- (2) A common path of travel shall be permitted to exceed 15 m (50 ft) in multilevel residential housing units in which each floor level, considered separately, has not less than one-half of its individual required egress capacity accessible by exit access leading directly out of that level without traversing another communicating floor level.
- (3)* Approved existing common paths of travel that exceed 15 m (50 ft) shall be permitted to continue to be used.

A.23.2.5.3(3) In determining whether to approve the existing common path of travel that exceeds 15 m (50 ft), the authority having jurisdiction should assure that the common path is not in excess of the travel distance permitted by 23.2.6.

23.2.5.4 A sally port shall be permitted in a means of egress where there are provisions for continuous and unobstructed

CHAPTER 22 • New

travel through the sally port during an emergency egress condition.

Exhibit 22/23.4 illustrates the use of 22/23.2.5.1(2), which permits one adjacent room to intervene between a sleeping room and the exit access corridor. Sleeping rooms are permitted to be separated in elevation from the day room by one-half to one story. See 22/23.2.5.1(2)(b).

Exhibit 22/23.5 illustrates the dead-end corridor requirements of 22.2.5.2 applicable to new detention and correctional facilities. In Use Condition V, resident room doors are individually key-locked and the allowable dead-end corridor length is reduced from 15 m (50 ft) to 6100 mm (240 in.). For existing facilities, 23.2.5.2 advises that dead-end corridors are undesirable but sets no maximum depth for existing dead ends.

Exhibit 22/23.6 illustrates a common path of travel. If distance X to C exceeds 15 m (50 ft) [30 m (100 ft), if the smoke compartment is sprinklered as is required of new construction], a second exit access is required for the upper level per 22/23.2.5.3. If the multilevel housing area is large, the common path of travel limitation might require a remote, second exit access door to the corridor.

Paragraphs 23.2.5.3(2) and 23.2.5.3(3) introduce

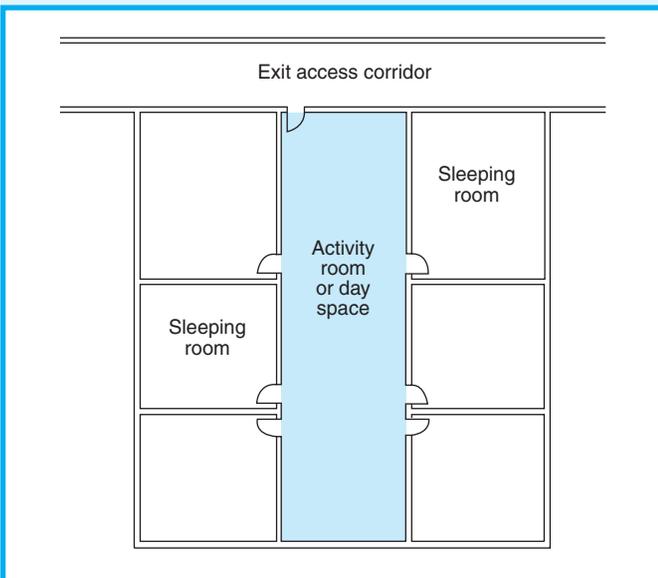

Exhibit 22/23.4 One intervening room between sleeping room and exit access corridor.

CHAPTER 23 • Existing

travel through the sally port during an emergency egress condition.

criteria that recognize existing common paths of travel that exceed the 15-m (50-ft) limitation contained in the base paragraph and the 30-m (100-ft)

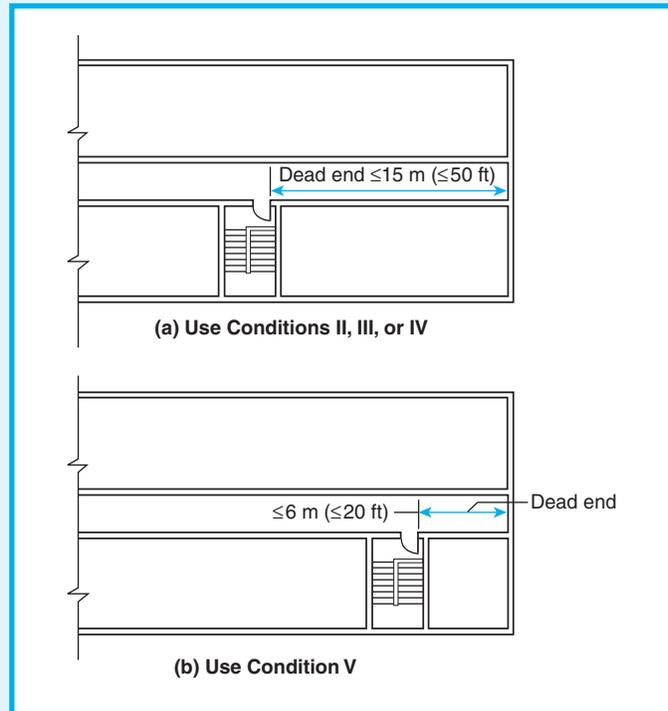

Exhibit 22/23.5 Maximum dead-end corridor for new construction.

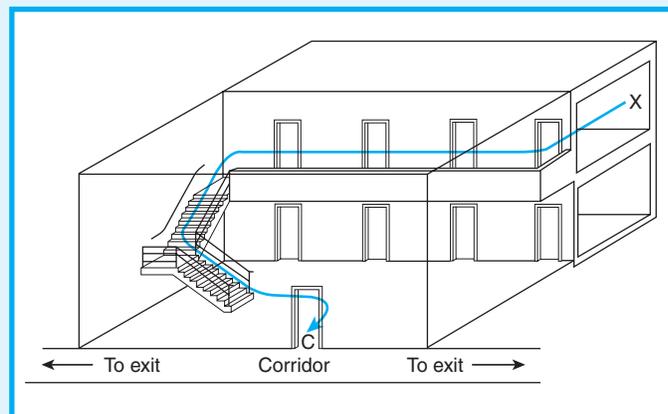

Exhibit 22/23.6 Common path of travel.

CHAPTER 22 • New

limitation allowed in sprinklered smoke compartments by 23.2.5.3(1). Paragraph 23.2.5.3(2) offers some relief to existing facilities with lengthy common paths of travel on individual levels of multilevel residential housing units, provided that at least half the occupant load of any level can be accommodated by exit access leading directly from that level without traveling on any other level that is open to that housing unit. This affords the residents of any level with an exit access that leads to an exit without being exposed to the fire on another level of the housing unit. Paragraph 23.2.5.3(3) permits existing, excessively long common paths of travel to continue to be used only if specifically approved by the authority having jurisdiction.

A security vestibule, called a *sally port*, is addressed in 22/23.2.5.4. A sally port is designed so that during routine and non-fire emergency conditions the door at one end of the vestibule is securely locked whenever the door at the opposite end is open. When one door is opened, the door through which entrance is made is closed and locked; the door at the opposite end is then unlocked and opened to provide egress from the vestibule. The sally port acts as a security device that prevents a continuous flow of people from

CHAPTER 23 • Existing

“storming” the exits. Under fire conditions, it would severely restrict the egress flow of occupants and prevent hose lines from being run through the openings. Therefore, if a sally port is to be permitted as part of a required means of egress, the door controls must be capable of being overridden to allow continuous and unobstructed passage in accordance with 22/23.2.5.4. Exhibit 22/23.7 depicts a sally port.

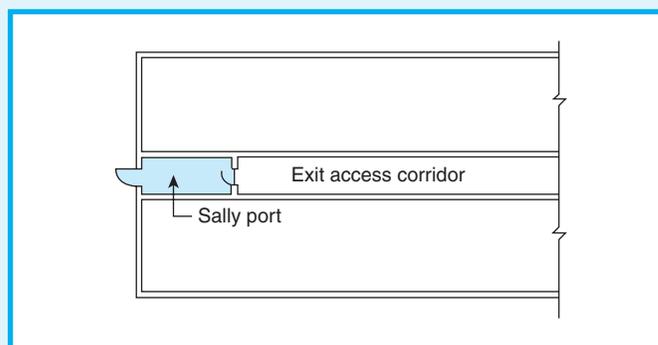

Exhibit 22/23.7 A sally port or security vestibule.

22.2.6 Travel Distance to Exits.

Travel distance shall comply with 22.2.6.1 through 22.2.6.6.

22.2.6.1 The travel distance between any room door required as an exit access and an exit shall not exceed 46 m (150 ft).

22.2.6.2 Reserved.

22.2.6.3 The travel distance between any point in a room and an exit shall not exceed 61 m (200 ft).

22.2.6.4 Reserved.

23.2.6 Travel Distance to Exits.

Travel distance shall comply with 23.2.6.1 through 23.2.6.6.

23.2.6.1 The travel distance between any room door required as an exit access and an exit or smoke barrier shall not exceed 30 m (100 ft), unless otherwise permitted by 23.2.6.2.

23.2.6.2 The maximum travel distance limitations of 23.2.6.1 shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved automatic sprinkler system in accordance with 23.3.5.3 or a smoke control system.

23.2.6.3 The travel distance between any point in a room and an exit or smoke barrier shall not exceed 46 m (150 ft), unless otherwise permitted by 23.2.6.4.

23.2.6.4 The maximum travel distance limitations of 23.2.6.3 shall be permitted to be increased by 15 m (50 ft) in buildings protected throughout by an approved automatic sprinkler system in accordance with 23.3.5.3 or a smoke control system.

CHAPTER 22 • New

22.2.6.5 The travel distance between any point in a sleeping room to the door in that room shall not exceed 15 m (50 ft), unless otherwise permitted by 22.2.6.6.

22.2.6.6 The maximum travel distance limitation of 22.2.6.5 shall be permitted to be increased to 30 m (100 ft) in open dormitories, provided the following criteria are met:

- (1) The enclosing walls of the dormitory space shall be of smoketight construction.
- (2) Not less than two exit access doors remotely located from each other shall be provided where travel distance to the exit access door from any point within the dormitory exceeds 15 m (50 ft).

Exhibit 22/23.8 illustrates the travel distance requirements of 22/23.2.6. Travel distance is measured to the closest exit only, not to both of the exits required by 22/23.2.4. Travel distance is measured along the natural path of travel (see 7.6.2). The term *sprinklered*, as used in the exhibit, means that the entire building is protected by a complete, approved automatic extinguishing system. New detention and correctional occupancies are required to be sprinklered; thus, they are permitted the longer travel distances. The term *smoke control*, as used in the exhibit, means that the entire building is equipped with a system to control the movement of smoke in accordance with Section 9.3.

CHAPTER 23 • Existing

23.2.6.5 The travel distance between any point in a sleeping room to the door of that room shall not exceed 15 m (50 ft), unless otherwise permitted by 23.2.6.6.

23.2.6.6 The maximum travel distance limitations of 23.2.6.5 shall be permitted to be increased to 30 m (100 ft) in open dormitories, provided the following criteria are met:

- (1) The enclosing walls of the dormitory space shall be of smoketight construction.
- (2) Not less than two exit access doors remotely located from each other shall be provided where travel distance to the exit access door from any point within the dormitory exceeds 15 m (50 ft).

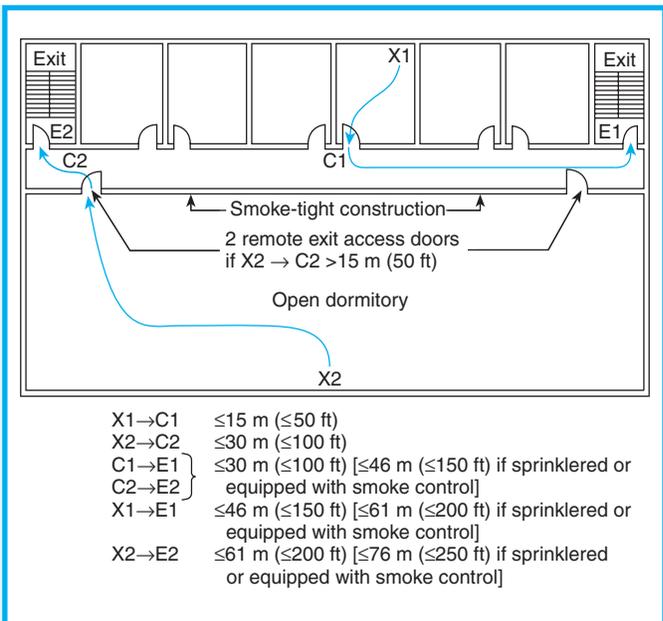

Exhibit 22/23.8 Travel distance to exits in detention and correctional occupancies.

22.2.7 Discharge from Exits.

22.2.7.1 Exits shall be permitted to discharge into a fenced or walled courtyard, provided that not more than two walls of the courtyard are the building walls from which egress is being made.

22.2.7.2 Enclosed yards or courts used for exit discharge in accordance with 22.2.7.1 shall be of sufficient size to accommodate all occupants at a distance of not less than 15 m (50 ft) from the building while providing a net area of 1.4 m² (15 ft²) per person.

23.2.7 Discharge from Exits.

23.2.7.1 Exits shall be permitted to discharge into a fenced or walled courtyard, provided that not more than two walls of the courtyard are the building walls from which egress is being made.

23.2.7.2 Enclosed yards or courts used for exit discharge in accordance with 23.2.7.1 shall be of sufficient size to accommodate all occupants at a distance of not less than 15 m (50 ft) from the building while providing a net area of 1.4 m² (15 ft²) per person.

CHAPTER 22 • New

22.2.7.3 All exits shall be permitted to discharge through the level of exit discharge.

22.2.7.4 The requirements of 7.7.2 shall be waived, provided that not more than 50 percent of the exits discharge into a single fire compartment separated from other compartments by construction having not less than a 1-hour fire resistance rating.

CHAPTER 23 • Existing

23.2.7.3 All exits shall be permitted to discharge through the level of exit discharge.

23.2.7.4 The requirements of 7.7.2 shall be waived, provided that not more than 50 percent of the exits discharge into a single fire compartment separated from other compartments by construction having not less than a 1-hour fire resistance rating.

23.2.7.5 Where all exits are permitted to discharge through areas on the level of discharge, the following criteria shall be met:

- (1) A smoke barrier shall be provided to divide that level into not less than two compartments with not less than one exit discharging into each compartment
- (2) Each smoke compartment shall have an exit discharge to the building exterior.
- (3) The level of discharge shall be provided with automatic sprinkler protection.
- (4) Any other portion of the level of discharge with access to the discharge area shall be provided with automatic sprinkler protection or shall be separated from the discharge area in accordance with the requirements for the enclosure of exits. (See 7.1.3.2.1.)

Exhibits 22/23.9 and 22/23.10 illustrate the requirements of 22/23.2.7.1 and 22/23.2.7.2.

The provisions of 7.7.2 establish criteria under which up to 50 percent of the required exits, in either number or capacity, are permitted to discharge

through the level of exit discharge, with the other 50 percent required to discharge directly to the outside. Because of security concerns and the belief that doors

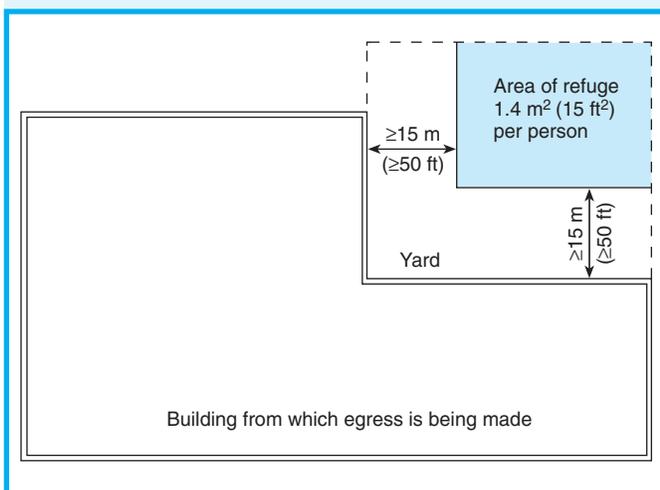

Exhibit 22/23.9 Exit discharge into fenced yard with minimum separation distance from building.

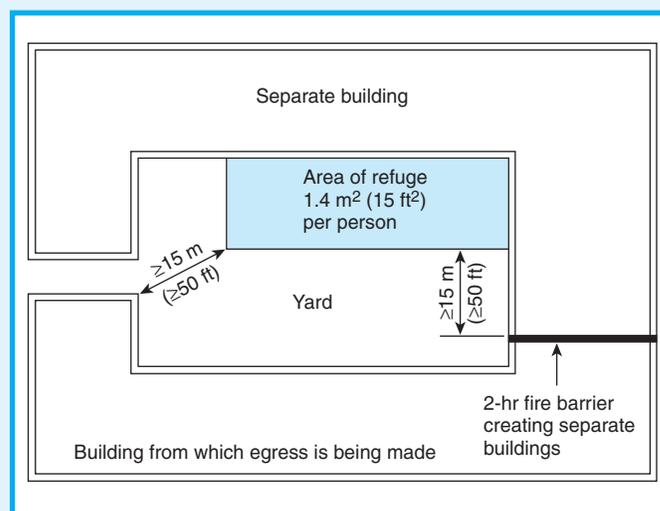

Exhibit 22/23.10 Exit discharge into an enclosed yard with minimum separation distance from "building" from which egress is being made.

CHAPTER 22 • New

to the exterior will not be readily unlocked in detention and correctional occupancies, 22/23.2.7.3 and 22/23.2.7.4 allow 100 percent of the exits to discharge through the level of exit discharge. This exemption is permitted if a minimum 1-hour fire resistance-rated separation that creates at least two fire compartments is provided on the level of exit discharge. Not more than one-half of the exits are permitted to discharge into any one fire compartment.

22.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

22.2.9 Emergency Lighting.

Emergency lighting shall be provided in accordance with Section 7.9.

22.2.10 Marking of Means of Egress.

Exit marking shall be provided as follows:

- (1) Exit signs shall be provided in areas accessible to the public in accordance with Section 7.10.
- (2) Exit signs shall not be required in detention and correctional residential housing areas. (*See Detention and Correctional Residential Housing Area in 3.3.16.1.*)

The exemption of exit signs in sleeping areas of detention and correctional occupancies recognizes that persons occupying such areas are familiar with those portions of the facility and know the location of exits.

22.2.11 Special Features.

22.2.11.1 Doors within means of egress shall be in accordance with Chapter 7, unless otherwise provided in 22.2.11.2 through 22.2.11.11.

22.2.11.2 Doors shall be permitted to be locked in accordance with the applicable use condition.

22.2.11.3* Doors to resident sleeping rooms shall be not less than 710 mm (28 in.) in clear width.

CHAPTER 23 • Existing

Paragraph 23.2.7.5 allows a smoke barrier to be substituted for a fire barrier in an existing facility if certain conditions can be met. The travel route along the level of exit discharge must be sprinklered, and the route must be separated from nonsprinklered portions of the level of exit discharge by fire barriers meeting the fire resistance rating requirements applicable to exit enclosures.

23.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

23.2.9 Emergency Lighting.

23.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9, unless otherwise permitted by 23.2.9.2.

23.2.9.2 Emergency lighting of not less than a 1-hour duration shall be permitted to be provided.

23.2.10 Marking of Means of Egress.

Exit marking shall be provided as follows:

- (1) Exit signs shall be provided in areas accessible to the public in accordance with Section 7.10.
- (2) Exit signs shall not be required in detention and correctional residential housing areas. (*See Detention and Correctional Residential Housing Area in 3.3.16.1.*)

Other portions of the facility might not be as familiar to residents and visitors and thus must have proper exit marking in accordance with 22/23.2.10.

23.2.11 Special Features.

23.2.11.1 Doors within means of egress shall be in accordance with Chapter 7, unless otherwise provided in 23.2.11.2 through 23.2.11.9.

23.2.11.2 Doors shall be permitted to be locked in accordance with the applicable use condition.

23.2.11.3* Doors to resident sleeping rooms shall be not less than 710 mm (28 in.) in clear width.

CHAPTER 22 • New

A.22.2.11.3 It might be necessary to provide a certain number of resident sleeping rooms with doors providing a clear width of not less than 810 mm (32 in.) (*see* 7.2.1.2) in order to comply with the requirements for the physically handicapped. Such sleeping rooms should be located where there is a direct accessible route to the exterior or to an area of safe refuge. (*See* 22.3.7.)

22.2.11.4 Reserved.

22.2.11.5 Doors in a means of egress shall be permitted to be of the horizontal sliding type, provided that the force necessary to slide the door to its fully open position does not exceed 222 N (50 lbf) where a force of 222 N (50 lbf) is simultaneously applied perpendicular to the door.

22.2.11.6 Doors from areas of refuge to the exterior shall be permitted to be locked with key locks in lieu of locking methods described in 22.2.11.7, and the keys to unlock such doors shall be maintained and available at the facility at all times, and the locks shall be operable from the outside.

22.2.11.7* Any remote-control release used in a means of egress shall be provided with a reliable means of operation to release locks on all doors and shall be remotely located from the resident living areas, unless otherwise permitted by 22.2.11.7.2.

A.22.2.11.7 A remote position is generally a control point where a number of doors can be unlocked simultaneously, either mechanically or electrically. In areas where there are a number of sleeping rooms, it is impractical for attendants to unlock doors individually. Doors in an exit should be unlocked prior to unlocking sleeping room doors. Sight and sound supervision of resident living areas can be by means of camera and communications systems.

This section of the *Code* does not intend to prohibit Use Condition V facilities, nor does it intend to limit Use Condition V facilities to 10 manually released locks.

22.2.11.7.1 The remote location of a remote-control release used in a means of egress shall provide sight and sound supervision of the resident living areas.

22.2.11.7.2 Remote-control locking and unlocking of occupied rooms in Use Condition IV shall not be required, provided that both of the following criteria are met:

- (1) Not more than 10 locks need to be unlocked to relocate all occupants from one smoke compartment to an area of refuge as promptly as is required where remote-control

CHAPTER 23 • Existing

A.23.2.11.3 It might be necessary to provide a certain number of resident sleeping rooms with doors providing a clear width of not less than 810 mm (32 in.) (*see* 7.2.1.2) in order to comply with the requirements for the physically handicapped. Such sleeping rooms should be located where there is a direct accessible route to the exterior or to an area of safe refuge. (*See* 23.3.7.)

23.2.11.4 Existing doors to resident sleeping rooms housing four or fewer residents shall be permitted to be not less than 485 mm (19 in.) in clear width.

23.2.11.5 Doors in a means of egress shall be permitted to be of the horizontal sliding type, provided that the force necessary to slide the door to its fully open position does not exceed 222 N (50 lbf) where a force of 222 N (50 lbf) is simultaneously applied perpendicular to the door.

23.2.11.6 Doors from areas of refuge to the exterior shall be permitted to be locked with key locks in lieu of locking methods described in 23.2.11.7, and the keys to unlock such doors shall be maintained and available at the facility at all times, and the locks shall be operable from the outside.

23.2.11.7* Any remote-control release used in a means of egress shall be provided with a reliable means of operation to release locks on all doors and shall be remotely located from the resident living area, unless otherwise permitted by 23.2.11.7.2.

A.23.2.11.7 A remote position is generally a control point where a number of doors can be unlocked simultaneously, either mechanically or electrically. In areas where there are a number of sleeping rooms, it is impractical for attendants to unlock doors individually. Doors in an exit should be unlocked prior to unlocking sleeping room doors. Sight and sound supervision of resident living areas can be by means of camera and communications systems.

This section of the *Code* does not intend to prohibit Use Condition V facilities, nor does it intend to limit Use Condition V facilities to 10 manually released locks.

23.2.11.7.1 The remote location of a remote-control release used in a means of egress shall provide sight and sound supervision of the resident living areas.

23.2.11.7.2 Remote-control locking and unlocking of occupied rooms in Use Condition IV shall not be required, provided that both of the following criteria are met:

- (1) Not more than 10 locks need to be unlocked to relocate all occupants from one smoke compartment to an area of refuge as promptly as is required where remote-control

CHAPTER 22 • New

unlocking is used. (See 22.3.7.9 for requirements for smoke barrier doors.)

- (2) Unlocking of all necessary locks shall be accomplished with not more than two separate keys.

22.2.11.8 All remote-control release-operated doors shall be provided with a redundant means of operation as follows:

- (1) Power-operated sliding doors or power-operated locks shall be constructed so that, in the event of power failure, a manual mechanical means to release and open the doors is provided at each door, and either emergency power arranged in accordance with 7.9.2.2 is provided for the power operation or a remote-control manual mechanical release is provided.
- (2) Mechanically operated sliding doors or mechanically operated locks shall be provided with a manual mechanical means at each door to release and open the door.

22.2.11.9 The provisions of 7.2.1.5.7 for stairway re-entry shall not apply.

22.2.11.10 Doors unlocked by means of remote control under emergency conditions shall not automatically relock when closed unless specific action is taken at the remote-control location to enable doors to relock.

22.2.11.11 Emergency power shall be provided for all electrically power-operated sliding doors and power-operated locks, unless otherwise permitted by 22.2.11.11.2.

22.2.11.11.1 The emergency power shall be arranged to automatically operate within 10 seconds upon failure of normal power and to maintain the necessary power source for not less than 1½ hours.

22.2.11.11.2 The emergency power specified in 22.2.11.11 shall not be required in facilities with 10 or fewer locks complying with 22.2.11.7.2.

The provision of 22/23.2.11.2 overrides the Chapter 7 requirement that all doors within the required means of egress be unlocked from the side from which egress is to be made and fully under the control of the building occupants. It recognizes that, to function as intended, a detention and correctional occupancy uses various means of locking. Paragraph 22/23.2.11.2 allows only that degree of locking that is appropriate

CHAPTER 23 • Existing

unlocking is used. (See 23.3.7.9 for requirements for smoke barrier doors.)

- (2) Unlocking of all necessary locks shall be accomplished with not more than two separate keys.

23.2.11.8 All remote-control release-operated doors shall be provided with a redundant means of operation as follows:

- (1) Power-operated sliding doors or power-operated locks shall be constructed so that, in the event of power failure, a manual mechanical means to release and open the doors is provided at each door, and either emergency power arranged in accordance with 7.9.2.2 is provided for the power operation or a remote-control manual mechanical release is provided.
- (2) A combination of the emergency power-operated release of selected individual doors and remote-control manual mechanical ganged release specified in 23.2.11.8(1) shall be permitted without mechanical release means at each door.
- (3) Mechanically operated sliding doors or mechanically operated locks shall be provided with a manual mechanical means at each door to release and open the door.

23.2.11.9 The provisions of 7.2.1.5.7 for stairway re-entry shall not apply.

to a specific use condition. Therefore, a Use Condition II facility, which has more lenient life safety requirements than a Use Condition V facility, cannot contain sleeping rooms that must be individually locked by key. A Use Condition V facility must comply with a more stringent set of requirements than a Use Condition II facility and is permitted to have individual doors manually locked by key.

CHAPTER 22 • New

Paragraph 7.2.1.4.1 requires that all doors in a means of egress be side-hinged or pivoted-swinging. Paragraph 22/23.2.11.5 allows the use of sliding doors if they meet the specified requirements. In addition, 7.2.1.4.1.5 recognizes the limited use of other horizontal sliding doors in accordance with the provisions of 7.2.1.14.

Paragraph 22/23.2.11.6 requires that keys be maintained and available. The term *available* means that keys are readily accessible to staff for use at any time for evacuation of occupants. The following requirements are important:

- (1) The keys required to evacuate occupants are accessible at all times.
- (2) The staff is trained in the location and use of keys.
- (3) The staff has authorization and standing orders to immediately unlock doors that lead from smoke compartments to the exterior during fire emergency conditions.

Authorizing staff to unlock doors avoids time lost awaiting authorization from administrative authorities before doors are unlocked.

In 22/23.2.11.7, use of the term *remote* means outside the area where occupants are restrained. It is not necessary to have the remote unlocking mechanism in a separate fire area, although doing so might be beneficial. Doors within the exit should be unlocked prior to unlocking sleeping room doors. This precaution prevents jamming of the exit door caused by several persons exerting pressure on it.

Paragraph 22/23.2.11.7.2 serves as an exemption to 22/23.2.11.7. It applies to facilities that are seeking classification as Use Condition IV but that have need for up to 10 locks that must be manually released at the door. Where remote locking is required by Use Condition IV, it must be provided, except as addressed by the exemption. The exemption permits up to 10 manual locks to allow occupants to move to another fire compartment or smoke compartment while permitting the facility to qualify as having provided remote release. The use of a limited number (a maximum of 10) of manual locks, in addition to the possibility of hundreds of remotely released locks within the same facility, does not impose a Use Condition V classification. This exemption might apply in situations involving fewer than 10 doors if a door is secured with more than one lock.

Exhibits 22/23.11 and 22/23.12 depict two typical arrangements that illustrate the exemption of 22/

CHAPTER 23 • Existing

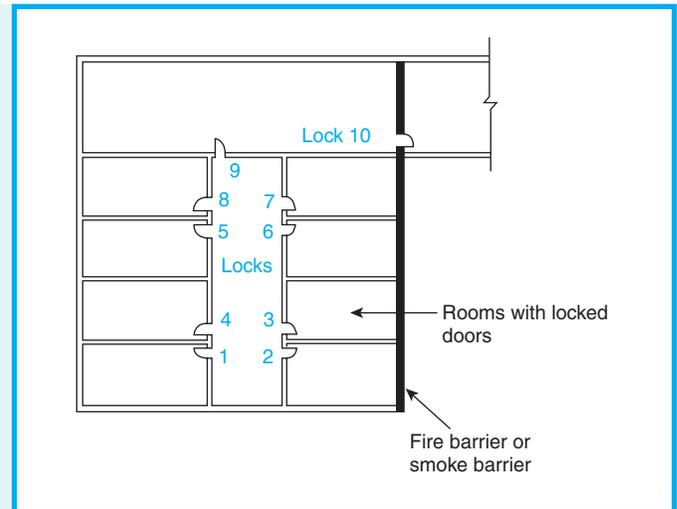

Exhibit 22/23.11 Example of manually unlocked locks permitted within smoke compartment of Use Condition IV facility.

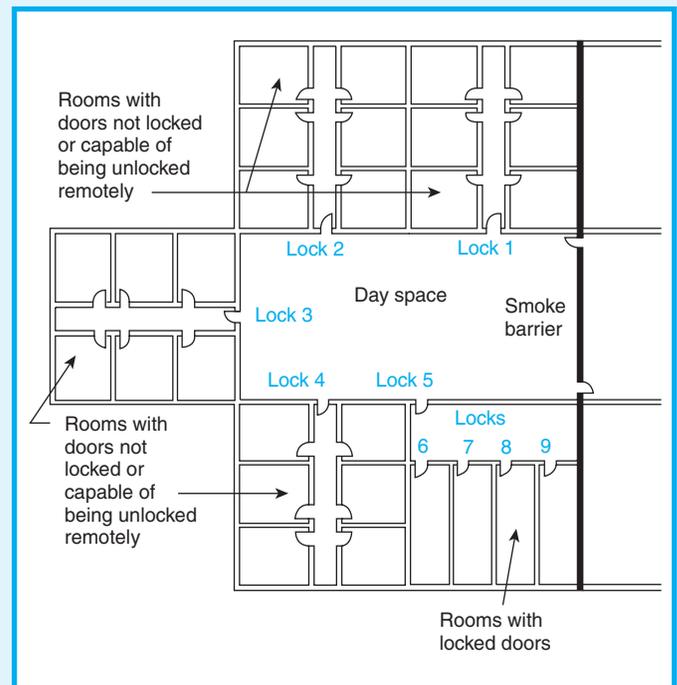

Exhibit 22/23.12 Another example of manually unlocked locks permitted within smoke compartment of Use Condition IV facility.

23.2.11.7.2. In Exhibit 22/23.11 each door is equipped with a single key-operated lock. In Exhibit 22/23.12, a door with a single key-operated lock secures multiple door areas. One manual lock, in addition to the 9

CHAPTER 22 • New

shown in the exhibit, would be permitted but it cannot be on the smoke barrier door if the smoke compartment contains more than 20 persons, in accordance with 22/23.3.7.9.

The provisions of 22/23.2.11.7.2 have been misinterpreted to mean that a Use Condition V detention/correctional facility (which, by definition, permits manual unlocking of each door) is limited to a maximum of 10 such manual locks. A Use Condition V facility is permitted to have an unlimited number of manual locks. In fact, 22/23.2.11.7.2 applies only to Use Condition IV facilities and allows a facility to retain its classification as Use Condition IV (that is, remote release), provided that there are 10 or fewer manually released locks and that unlocking can be achieved with a maximum of two keys.

Section 22.3 Protection

22.3.1 Protection of Vertical Openings.

Any vertical opening shall be enclosed or protected in accordance with Section 8.6, unless otherwise permitted by the following:

- (1) Unprotected vertical openings in accordance with 8.6.8.2 shall be permitted.
- (2)* In residential housing area smoke compartments, unprotected vertical openings shall be permitted in accordance with the conditions of 8.6.6, provided that the height between the lowest and highest finished floor levels does not exceed 7010 mm (276 in.), and the following also shall be permitted:
 - (a) The number of levels shall not be restricted.
 - (b) Residential housing areas subdivided in accordance with 22.3.8 shall be permitted to be considered as part of the communicating space.
 - (c) The separation shall not be required to have a fire resistance rating. *[See 8.6.6(4)(b).]*

A.22.3.1(2) For purposes of providing control valves and waterflow devices, multilevel residential housing areas complying with this provision are considered to be single story.

CHAPTER 23 • Existing

The speed with which the doors can be unlocked and the occupants moved to a safe location is critical. If the 10 locks cannot be rapidly released by manual unlocking due to staffing restrictions or for any other reason, remote unlocking must be used. If doors are equipped with locking devices, it is assumed that the locks will be used, and they must be counted as part of the total number of locks.

Paragraph 22.2.11.10, applicable to new facilities, requires that, once doors are remotely unlocked under emergency conditions, they cannot automatically relock if they reclose unless deliberate action is taken to lock them. This deliberate action can be taken at the individual door or at the remote location. This safety measure prevents occupants from being mistakenly locked into a room during emergency egress.

Section 23.3 Protection

23.3.1 Protection of Vertical Openings.

23.3.1.1 Any vertical opening shall be enclosed or protected in accordance with Section 8.6, unless otherwise permitted by the following:

- (1) Unprotected vertical openings in accordance with 8.6.8.2 shall be permitted.
- (2) In residential housing area smoke compartments protected throughout by an approved automatic sprinkler system in accordance with 23.3.5.3, unprotected vertical openings shall be permitted in accordance with the conditions of 8.6.6, provided that the height between the lowest and highest finished floor levels does not exceed 7010 mm (276 in.) and the following also shall be permitted:
 - (a) The number of levels shall not be restricted.
 - (b) Residential housing areas subdivided in accordance with 23.3.8 shall be permitted to be considered as part of the communicating space.
 - (c) The separation shall not be required to have a fire resistance rating. *[(See 8.6.6(4)(b).)]*
- (3) The requirement of 23.3.1.1 shall not apply to multilevel residential housing areas in accordance with 23.3.1.2.
- (4) Where full enclosure is impractical, the required enclosure shall be permitted to be limited to that necessary to prevent a fire originating in any story from spreading to any other story.
- (5) The fire resistance rating of enclosures in detention and correctional occupancies protected throughout by an ap-

proved automatic sprinkler system in accordance with 23.3.5.3 shall be not less than 1 hour.

23.3.1.2 Multilevel residential housing areas without enclosure protection between levels shall be permitted, provided that the conditions of 23.3.1.2.1 through 23.3.1.2.3 are met.

23.3.1.2.1* The entire normally occupied area, including all communicating floor levels, shall be sufficiently open and unobstructed so that a fire or other dangerous condition in any part is obvious to the occupants or supervisory personnel in the area.

A.23.3.1.2.1 It is not the intent of this requirement to restrict room face separations, which restrict visibility from the common space into individual sleeping rooms.

23.3.1.2.2 Egress capacity shall simultaneously accommodate all occupants of all communicating levels and areas, with all communicating levels in the same fire area considered as a single floor area for purposes of determining required egress capacity.

23.3.1.2.3* The height between the highest and lowest finished floor levels shall not exceed 3960 mm (156 in.). The number of levels shall not be restricted.

A.23.3.1.2.3 The vertical separation between the lowest floor level and the uppermost floor level is not to exceed 3960 mm (156 in.). Figure A.23.3.1.2.3 illustrates how the height is to be determined.

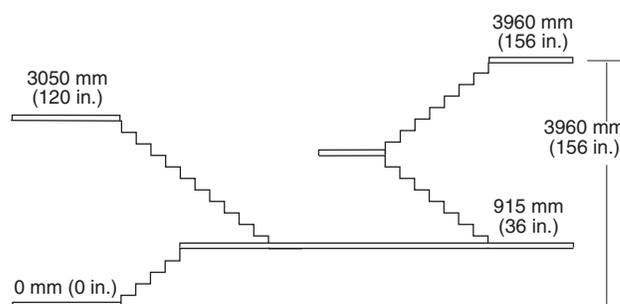

FIGURE A.23.3.1.2.3 Vertical Height Measurement.

23.3.1.3* A multitiered, open cell block shall be considered as a single-story building, where one of the following criteria is met:

- (1) A smoke control system is provided (*see recommended design criteria in A.23.3.1.3*) to maintain the level of smoke from potential cell fires at not less than 1525

- mm (60 in.) above the floor level of any occupied tier involving space that is classified as follows:
- (a) Use Condition IV or Use Condition V
 - (b) Use Condition III, unless all persons housed in such space can pass through a free access smoke barrier or freely pass below the calculated smoke level with not more than 15 m (50 ft) of travel from their cells
- (2) The entire building, including cells, is provided with complete automatic sprinkler protection in accordance with 23.3.5.3.

A.23.3.1.3 A recommended method of calculating the expected level of smoke in a smoke removal-equipped cell block follows.

This method for calculating the expected level of smoke has been developed from data experimentally produced in full-scale burnouts of test cells. The test cells were sized, loaded with fuel, and constructed to represent severe conditions of heavily fuel-loaded [approximately 29 kg/m² (6 lb/ft²)] cells as found in prison locations. The filling rate and temperature of the effluent gas and smoke have been calculated using the data from these tests and established formulae from plume dynamics.

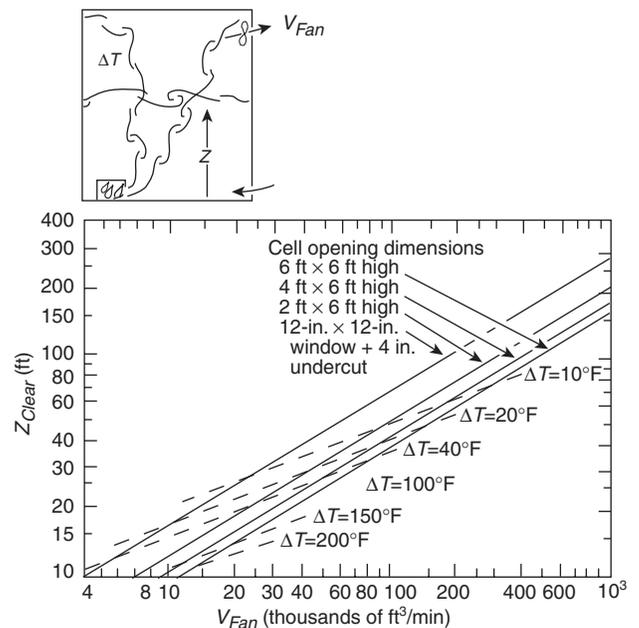

The application of the method described in A.23.3.1.3 should be limited to situations where there is not less than 3050 mm (120 in.) from the floor level to the lowest acceptable level of smoke accumulation (*Z*); the reservoir above the lowest acceptable level for *Z* is at least 20 percent of the *Z* dimension, the length of the cell block is not less than *Z*, and the fan is not less than 3050 mm (120 in.) higher than the floor of the highest cell.

The determination of smoke removal requirements is based on the dimensions of the cell opening. Where more than one cell opening is involved, the larger size on the level being calculated should be used.

The fan size, temperature rating, and operations means can be determined by the following procedure:

- (1) *Acceptable Smoke Level*. Determine the lowest acceptable level of smoke accumulation in accordance with 23.3.1.3. The vertical distance between that level and the floor level of the lowest open cell is the value of *Z* to be used in connection with Figure A.23.3.1.3(a).
- (2) *Characteristic Cell Opening*. Determine the opening of the cell face. Where there is more than one size of cell opening, use the largest. Match the actual opening to those shown in Figure A.23.3.1.3(b), and use the corresponding curve from Figure A.23.3.1.3(a). If there is no match between the size and shape of the opening and Figure A.23.3.1.3(a), interpolate between the curves. If the opening exceeds 1830 mm × 1830 mm (72 in. × 72 in.), use the curve for a 1830 mm × 1830 mm

- (72 in. × 72 in.) opening. This curve represents the maximum burning situation, and increasing the size of the opening will not increase the actual burning rate.
- (3) *Exhaust Fan Rate.* Determine the exhaust fan capacity needed to extract smoke at a rate that will maintain the smoke level at a point higher than Z. This is the rate shown on the baseline of Figure A.23.3.1.3(a) corresponding to the level of Z on the vertical axis for the solid line (ventilation rate) curve appropriate to the cell door size. This exhaust capability needs to be provided at a point higher than Z.
 - (4) *Intake Air.* Provide intake air openings that either exist or are automatically provided at times of emergency smoke removal. These openings are to be located at or near the baseline of the cell block to allow for intake air at the rate to be vented by the fan. The openings provided shall be sufficient to avoid a friction load that can reduce the exhaust efficiency. Standard air-handling design criteria are used in making this calculation.

ΔT = Temperature of upper layer gases above ambient
 V_{Fan} = Fan discharge capacity (as installed)
 Z_{Clear} = Distance from cell floor to smoke layer

Solid line: Ventilation rate curves
 Dashed line: Constant temperature rise curves

For SI units, ft × 0.3048 = m; ft³/min × 0.00047 = m³/s;
 (°F - 32) ÷ 1.8 = °C; 1 in. = 2.54 cm.

FIGURE A.23.3.1.3(a) Cell Block Smoke Control Ventilation Curves.

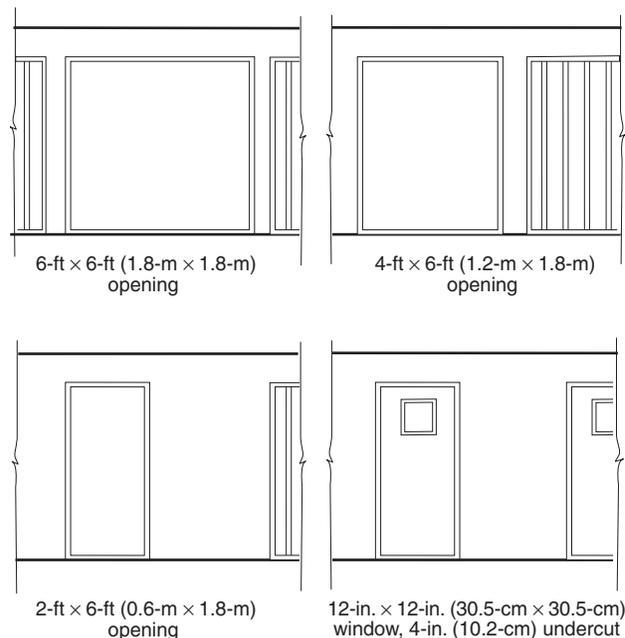

FIGURE A.23.3.1.3(b) Typical Cell Openings.

- (5) *Fan Temperature Rating.* Determine the potential temperature of gases that the fan might be required to handle by measuring the distance from the floor of the highest cell to the centerline of the fan, or fan ports if the fan is in a duct or similar arrangement. Determine the intersection of the new Z value with the appropriate ventilation rate curve (solid line) from Figure A.23.3.1.3(a). Estimate the temperature rise by interpolating along the appropriate ventilation rate curve and between the constant temperature rise curves (dashed lines) from Figure A.23.3.1.3(a). Provide all elements of the exhaust system that are to be above the acceptable smoke level with the capability to effectively operate with the indicated increase in temperature.
- (6) *Operation of Exhaust System.* The emergency exhaust system should be arranged to initiate automatically on detection of smoke, on operation of a manual fire alarm system, or by direct manual operation. The capability to manually start the automatic exhaust system should be provided in a guard post in the cell block, at another control location, or both. Where appropriate, the emergency exhaust fans are permitted to be used for comfort ventilation as well as serving their emergency purposes.

CHAPTER 22 • New

CHAPTER 23 • Existing

Subsection 22/23.3.1 specifies the protection required to maintain floor-to-floor separation, which helps to prevent the products of combustion from moving vertically through the building.

The convenience stair addressed by 8.6.8.2 and recognized by 22.3.1(1) and 23.3.1.1(1) is illustrated in Exhibits 22/23.13 and 22/23.14.

Paragraph 8.6.6 addresses a vertical opening that is permitted to connect not more than three floor levels. Paragraphs 22.3.1(2) and 23.3.1.1(2) address typical, multilevel housing areas that use staggered, partial levels as depicted in Exhibit 22/23.15. The exemption modifies the three-floor restriction of 8.6.6(1) by allowing a 7010-mm (276-in.) height limitation between the lowest and highest finished floor levels to permit greater flexibility in the design and use of detention and correctional occupancies. The exemption applies only to facilities whose residential housing areas are protected throughout by automatic sprinklers.

Paragraphs 22.3.1(2)(b) and 23.3.1.1(2)(b) clarify that a residential housing unit that complies with the requirements of Table 22/23.3.8 is considered to be part of the communicating space addressed by 8.6.6. This clarification prevents the Code user from needlessly complying with 8.6.6(4), which would require a fully sprinklered residential area to be separated from all rooms abutting a communicating space (for example, a day room with a high ceiling) by means of a smoke barrier. If this clarification were not made, all openings, including doors, from resident sleeping

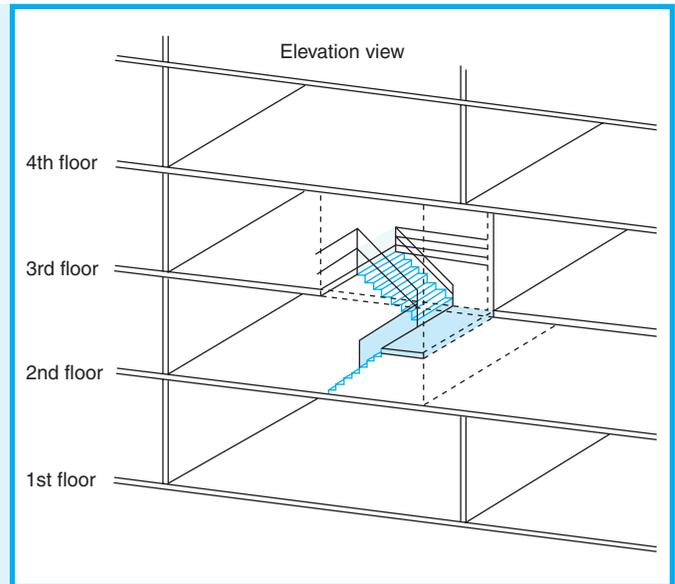

Exhibit 22/23.14 Elevation view of convenience stair.

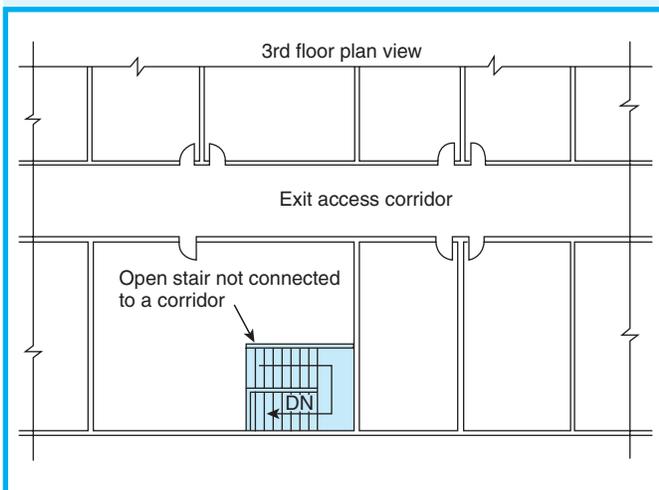

Exhibit 22/23.13 Plan view of unenclosed convenience stair.

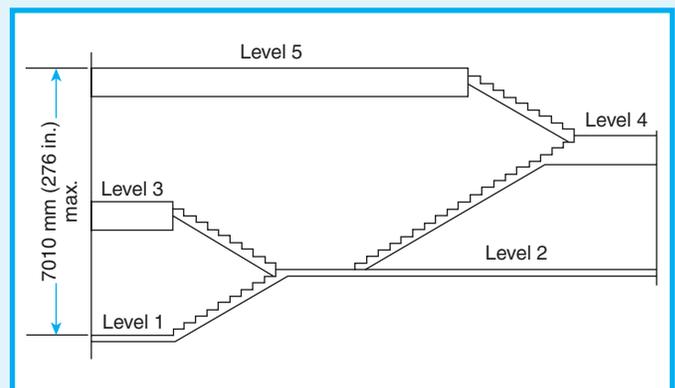

Exhibit 22/23.15 Unprotected vertical openings in sprinklered housing area.

rooms to the day space would be required to have smoke-resistant opening protectives. Such a requirement would place an undue burden on such facilities. Instead of requiring smoke barriers between each resident sleeping room and the day space, the Code judges that adequate life safety is provided if the residential housing unit is subdivided in accordance with the provisions of 22/23.3.8. Also, compliance with 8.6.6(8) would then be impractical. Paragraph 8.6.6(4)(b) prevents this portion of 22.3.1(2) and

CHAPTER 22 • New

23.3.1.1(2) from conflicting with the provisions of 8.6.6(4).

Whereas 22.3.1(2) and 23.3.1.1(2) allow multilevel housing areas with a maximum 7010-mm (276-in.) height between the lowest and the highest finished floor levels if the housing areas are fully sprinklered, 23.3.1.2 allows similar vertical openings in nonsprinklered, existing multilevel housing areas but limits the height of the area served by the openings to 3960 mm (156 in.).

Paragraph 23.3.1.3 addresses an existing multitiered open cell block. A multitiered open cell block in excess of 7010 mm (276 in.) in height, measured between the lowest and highest finished floor

22.3.2 Protection from Hazards.

22.3.2.1* Any hazardous area shall be protected in accordance with Section 8.7. The areas described in Table 22.3.2.1 shall be protected as indicated.

Table 22.3.2.1 Hazardous Area Protection

Hazardous Area Description	Separation/Protection
Areas not incidental to resident housing	2 hours
Boiler and fuel-fired heater rooms	1 hour
Central or bulk laundries >9.3 m ² (>100 ft ²)	1 hour
Commercial cooking equipment	In accordance with 9.2.3
Commissaries	Smoke resistant
Employee locker rooms	Smoke resistant
Hobby/handicraft shops	Smoke resistant
Maintenance shops	Smoke resistant
Padded cells	1 hour
Soiled linen rooms	1 hour
Storage rooms >4.6 m ² (>50 ft ²) in area but ≤9.3 m ² (≤100 ft ²) in area storing combustible material	Smoke resistant
Storage rooms >9.3 m ² (>100 ft ²) storing combustible materials	1 hour
Trash collection rooms	1 hour

A.22.3.2.1 Furnishings are usually the first items ignited in a detention and correctional environment. The type, quantity, and arrangement of furniture and other combustibles are important factors in determining how fast the fire will de-

CHAPTER 23 • Existing

velop [see 23.3.1.1(2)], could not be built in compliance with the *Life Safety Code*. However, the provisions of 23.3.1.3 continue to recognize existing, multitiered open cell blocks if (1) smoke control is provided to deal with the limited amount of smoke that a sprinkler-controlled fire generates or (2) automatic sprinkler protection is provided. In addition to the information on smoke control provided in A.23.3.1.3, see the detailed commentary following 8.6.7(6) on the subject of atrium smoke control. The physics associated with smoke development, spread, and control in a multitiered open cell block are similar to that of an atrium.

23.3.2 Protection from Hazards.

23.3.2.1* Any hazardous area shall be protected in accordance with Section 8.7. The areas described in Table 23.3.2.1 shall be protected as indicated.

Table 23.3.2.1 Hazardous Area Protection

Hazardous Area Description	Separation/Protection
Areas not incidental to resident housing	2 hours
Boiler and fuel-fired heater rooms	1 hour or sprinklers
Central or bulk laundries >9.3 m ² (>100 ft ²)	1 hour or sprinklers
Commercial cooking equipment	In accordance with 9.2.3
Commissaries	1 hour or sprinklers
Employee locker rooms	1 hour or sprinklers
Hobby/handicraft shops	1 hour or sprinklers
Maintenance shops	1 hour or sprinklers
Padded cells	1 hour and sprinklers
Soiled linen rooms	1 hour or sprinklers
Storage rooms >4.6 m ² (>50 ft ²) in area storing combustible material	1 hour or sprinklers
Trash collection rooms	1 hour or sprinklers

A.23.3.2.1 It is strongly recommended that padded cells not be used due to their fire record. However, recognizing that they will be used in some cases, provisions for the protection of padded cells are provided. It is recognized that the 3/4-

CHAPTER 22 • New

velop. Furnishings, including upholstered items and wood items such as wardrobes, desks, and bookshelves, might provide sufficient fuel to result in room flashover, which is the full fire involvement of all combustibles within a room once sufficient heat has been built up within the room.

Combustible loading in any room opening onto a residential housing area should be limited to reduce the potential for room flashover. Rooms in which fuel loads are not controlled, thereby creating a potential for flashover, should be considered hazardous areas. Where fire-rated separation is provided, doors to such rooms, including sleeping rooms, should be self-closing.

It is strongly recommended that padded cells not be used due to their fire record. However, recognizing that they will be used in some cases, provisions for the protection of padded cells are provided. It is recognized that the ¾-hour fire door will be violated with the “plant on” of the padding, but a ¾-hour fire door should be the base of the assembly.

22.3.2.2 Hazardous areas determined by the authority having jurisdiction as not incidental to residents’ housing shall be separated by 2-hour fire resistance-rated barriers in conjunction with automatic sprinkler protection.

22.3.2.3 Where cooking facilities are protected in accordance with 9.2.3, kitchens shall not be required to be provided with roomwide protection.

Hazardous areas in detention and correctional occupancies are spaces with contents that, due to their nature—as in the case of flammable liquids—or because of the quantity of combustible materials involved, represent a significantly higher hazard than would otherwise be typical of detention and correctional occupancies. Paragraph 22/23.3.2.1 requires hazardous areas to be protected. The protection required by Table 22.3.2.1 for hazardous areas in new facilities was specified knowing that new facilities must be sprinklered. Thus, where Table 22.3.2.1 requires smoke-resistant separation—for example, for employee locker rooms—the actual protection is that provided by both the sprinkler system and the smoke-resistant walls. Similarly, where Table 22.3.2.1 requires 1-hour fire resistance-rated separation, the actual protection is that provided by both the sprinkler system and the fire-rated walls. For existing facilities, the areas listed in Table 23.3.2.1 must be protected by the specified fire resistance-rated separation, sprinklering, or combination of separation and sprinklering.

CHAPTER 23 • Existing

hour fire door will be violated with the “plant on” of the padding, but a ¾-hour fire door should be the base of the assembly.

23.3.2.2 Hazardous areas determined by the authority having jurisdiction as not incidental to residents’ housing shall be separated by 2-hour fire resistance-rated barriers in conjunction with automatic sprinkler protection.

23.3.2.3 Where cooking facilities are protected in accordance with 9.2.3, kitchens shall not be required to be provided with roomwide protection.

Padded cells are considered to be severe hazard areas due to high heat release, high rate of combustion, and the quantity of smoke produced by padding materials. Therefore, padded cells must be protected by automatic sprinklers and separated by 1-hour construction.

Where flammable liquids are handled or stored, NFPA 30, *Flammable and Combustible Liquids Code*³, should be consulted to establish the minimum criteria necessary to mitigate this hazard. See also 8.7.3.

Even typical housing area furnishings can provide the combustible loading that will allow room flashover to occur. The potential for flashover should be considered, particularly for nonsprinklered, multi-level housing areas allowed by 23.3.1.2. Flashover on a lower level could rapidly deteriorate the tenability of conditions on upper levels, as the products of combustion bank down from the ceiling of the housing area, affecting residents of the upper levels before they can use the means of egress system.

CHAPTER 22 • New

22.3.3 Interior Finish.

22.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

22.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in corridors, in exits, and in any space not separated from corridors and exits by partitions capable of retarding the passage of smoke; and Class A, Class B, or Class C in all other areas. The provisions of 10.2.8.2 shall not apply.

22.3.3.3 Interior Floor Finish.

22.3.3.3.1 Interior floor finish shall comply with Section 10.2.

22.3.3.3.2 Interior floor finish in exit enclosures and exit access corridors shall be not less than Class II. The provisions of 10.2.8.1 shall not apply.

22.3.3.3.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

Paragraph 22/23.3.3.2 imposes stricter interior wall and ceiling finish requirements in exits, corridors, and spaces not separated from the corridor than it does in other use areas. To apply the less stringent requirements within the use areas, the required separation need be only a partition capable of retarding the passage of smoke. The partition must be of substantial construction but is not required to have a fire resistance rating.

Paragraph 23.3.3.3.2 recognizes existing interior floor finish materials that have been tested in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*⁴, as an

22.3.4 Detection, Alarm, and Communications Systems.**22.3.4.1 General.**

22.3.4.1.1 Detention and correctional occupancies shall be provided with a fire alarm system in accordance with Section 9.6, except as modified by 22.3.4.1.3 through 22.3.4.4.3.

22.3.4.1.2 Reserved.

CHAPTER 23 • Existing

23.3.3 Interior Finish.

23.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

23.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in corridors, in exits, and in any space not separated from corridors and exits by partitions capable of retarding the passage of smoke; and Class A, Class B, or Class C in all other areas.

23.3.3.3 Interior Floor Finish.

23.3.3.3.1 Interior floor finish complying with Section 10.2 shall be Class I or Class II in corridors and exits.

23.3.3.3.2 Existing floor finish material of Class A or Class B in nonsprinklered smoke compartments and Class A, Class B, or Class C in sprinklered smoke compartments shall be permitted to be continued to be used, provided that it has been evaluated based on tests performed in accordance with 10.2.7.

exemption to the requirement of 10.2.7 that testing of floor finish materials be performed per NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*.⁵ NFPA 255 contains the flame spread and smoke development measurement method currently used to evaluate interior wall and ceiling finish materials in accordance with the requirements of Section 10.2. Prior to the 1981 edition of the *Code*, floor finish was tested in accordance with NFPA 255. Paragraph 23.3.3.3.2 allows material that was tested and approved by this method to remain in use.

23.3.4 Detection, Alarm, and Communications Systems.**23.3.4.1 General.**

23.3.4.1.1 Detention and correctional occupancies shall be provided with a fire alarm system in accordance with Section 9.6, except as modified by 23.3.4.1.2 through 23.3.4.4.4.

23.3.4.1.2 Existing systems lacking the monitoring of wiring required by 9.6.1.5 shall be permitted to be continued

CHAPTER 22 • New

22.3.4.1.3 All fire alarm systems and detection systems required in 22.3.4 shall be provided with a secondary power supply, and the installation shall be in accordance with *NFPA 72®*, *National Fire Alarm Code®*.

22.3.4.2 Initiation. Initiation of the required fire alarm system shall be by manual means in accordance with 9.6.2, by means of any required detection devices or detection systems, and by means of waterflow alarm in the sprinkler system required by 22.3.5.2, unless otherwise permitted by the following:

- (1) Manual fire alarm boxes shall be permitted to be locked, provided that staff is present within the area when it is occupied and staff has keys readily available to unlock the boxes.
- (2) Manual fire alarm boxes shall be permitted to be located in a staff location, provided that both of the following criteria are met:
 - (a) The staff location is attended when the building is occupied.
 - (b) The staff attendant has direct supervision of the sleeping area.

22.3.4.3 Notification.

22.3.4.3.1 Occupant Notification. Occupant notification shall be accomplished automatically in accordance with 9.6.3, and the following also shall apply:

- (1) A positive alarm sequence shall be permitted in accordance with 9.6.3.4.
- (2)* Any smoke detectors required by this chapter shall be permitted to be arranged to alarm at a constantly attended location only and shall not be required to accomplish general occupant notification.

A.22.3.4.3.1(2) The staff at the constantly attended location should have the capability to promptly initiate the general alarm function and contact the fire department or have direct communication with a control room or other location that can initiate the general alarm function and contact the fire department.

22.3.4.3.2 Emergency Forces Notification.

22.3.4.3.2.1 Fire department notification shall be accomplished in accordance with 9.6.4, unless otherwise permitted by the following:

- (1) A positive alarm sequence shall be permitted in accordance with 9.6.3.4.

CHAPTER 23 • Existing

in use in buildings protected by a complete automatic extinguishing system.

23.3.4.1.3 All fire alarm systems and detection systems required in 23.3.4 shall be provided with a secondary power supply, and the installation shall be in accordance with *NFPA 72®*, *National Fire Alarm Code®*.

23.3.4.2 Initiation. Initiation of the required fire alarm system shall be by manual means in accordance with 9.6.2 and by means of any required detection devices or detection systems, unless otherwise permitted by the following:

- (1) Manual fire alarm boxes shall be permitted to be locked, provided that staff is present within the area when it is occupied and staff has keys readily available to unlock the boxes.
- (2) Manual fire alarm boxes shall be permitted to be located in a staff location, provided that both of the following criteria are met:
 - (a) The staff location is attended when the building is occupied.
 - (b) The staff attendant has direct supervision of the sleeping area.

23.3.4.3 Notification.

23.3.4.3.1 Occupant Notification. Occupant notification shall be accomplished automatically in accordance with 9.6.3, and the following also shall apply:

- (1) A positive alarm sequence shall be permitted in accordance with 9.6.3.4.
- (2)* Any smoke detectors required by this chapter shall be permitted to be arranged to alarm at a constantly attended location only and shall not be required to accomplish general occupant notification.

A.23.3.4.3.1(2) The staff at the constantly attended location should have the capability to promptly initiate the general alarm function and contact the fire department or have direct communication with a control room or other location that can initiate the general alarm function and contact the fire department.

23.3.4.3.2 Emergency Forces Notification.

23.3.4.3.2.1 Fire department notification shall be accomplished in accordance with 9.6.4, unless otherwise permitted by the following:

- (1) A positive alarm sequence shall be permitted in accordance with 9.6.3.4.

CHAPTER 22 • New

- (2) Any smoke detectors required by this chapter shall not be required to transmit an alarm to the fire department.
- (3) This requirement shall not apply where staff is provided at a constantly attended location that meets one of the following criteria:
 - (a) It has the capability to promptly notify the fire department.
 - (b) It has direct communication with a control room having direct access to the fire department.

22.3.4.3.2.2 Where the provision of 22.3.4.3.2.1(3) is utilized, the fire plan, as required by 22.7.1.3, shall include procedures for logging of alarms and immediate notification of the fire department.

22.3.4.4* Detection. An approved automatic smoke detection system shall be in accordance with Section 9.6, as modified by 22.3.4.4.1 through 22.3.4.4.3, throughout all resident sleeping areas and adjacent day rooms, activity rooms, or contiguous common spaces.

A.22.3.4.4 Examples of contiguous common spaces are galleries and corridors.

22.3.4.4.1 Smoke detectors shall not be required in sleeping rooms with four or fewer occupants.

22.3.4.4.2 Other arrangements and positioning of smoke detectors shall be permitted to prevent damage or tampering, or for other purposes.

22.3.4.4.2.1 Such arrangements shall be capable of detecting any fire, and the placement of detectors shall be such that the speed of detection is equivalent to that provided by the spacing and arrangements required by the installation standards referenced in Section 9.6.

22.3.4.4.2.2 Detectors shall be permitted to be located in exhaust ducts from cells, behind grilles, or in other locations.

22.3.4.4.2.3 The equivalent performance of the design, however, shall be acceptable to the authority having jurisdiction in accordance with the equivalency concepts specified in Section 1.4.

22.3.4.4.3* Smoke detectors shall not be required in Use Condition II open dormitories where staff is present within the dormitory whenever the dormitory is occupied.

A.22.3.4.4.3 An open dormitory is a dormitory that is arranged to allow staff to observe the entire dormitory area at one time.

CHAPTER 23 • Existing

- (2) Any smoke detectors required by this chapter shall not be required to transmit an alarm to the fire department.
- (3) This requirement shall not apply where staff is provided at a constantly attended location that meets one of the following criteria:
 - (a) It has the capability to promptly notify the fire department.
 - (b) It has direct communication with a control room having direct access to the fire department.

23.3.4.3.2.2 Where the provision of 23.3.4.3.2.1(3) is utilized, the fire plan, as required by 23.7.1.3, shall include procedures for logging of alarms and immediate notification of the fire department.

23.3.4.4 Detection. An approved automatic smoke detection system shall be in accordance with Section 9.6, as modified by 23.3.4.4.1 through 23.3.4.4.4, throughout all resident housing areas.

23.3.4.4.1 Smoke detectors shall not be required in sleeping rooms with four or fewer occupants in Use Condition II or Use Condition III.

23.3.4.4.2 Other arrangements and positioning of smoke detectors shall be permitted to prevent damage or tampering, or for other purposes.

23.3.4.4.2.1 Such arrangements shall be capable of detecting any fire, and the placement of detectors shall be such that the speed of detection is equivalent to that provided by the spacing and arrangements required by the installation standards referenced in Section 9.6.

23.3.4.4.2.2 Detectors shall be permitted to be located in exhaust ducts from cells, behind grilles, or in other locations.

23.3.4.4.2.3 The equivalent performance of the design, however, shall be acceptable to the authority having jurisdiction in accordance with the equivalency concepts specified in Section 1.4.

23.3.4.4.3* Smoke detectors shall not be required in Use Condition II open dormitories where staff is present within the dormitory whenever the dormitory is occupied and the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 23.3.5.3.

A.23.3.4.4.3 An open dormitory is a dormitory that is arranged to allow staff to observe the entire dormitory area at one time.

CHAPTER 22 • New

Given that new detention and correctional facilities must be sprinklered, 22.3.4.2 requires waterflow alarm as one of the means for initiating the fire alarm system.

By being silent on the subject, 22/23.3.4.3.1 does not permit presignal systems. Rather, notification must be provided without delay in accordance with 9.6.3, or the more reliable form of presignal—called positive alarm sequence—can be used if complying with 9.6.3.4. However, to avoid numerous nuisance alarms, smoke detectors are exempted from sounding a general alarm.

Where the fire department is not equipped to receive alarms or where direct transmission to the fire department is not permitted, the provisions of 22/23.3.4.3.2 require that arrangements be made for the prompt notification of the fire department. One means of notification is by an approved central station

22.3.5 Extinguishment Requirements.

22.3.5.1 High-rise buildings shall comply with 22.4.3.

22.3.5.2 All buildings classified as Use Condition II, Use Condition III, Use Condition IV, or Use Condition V shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 22.3.5.3.

22.3.5.3 The automatic sprinkler system required by 22.3.5.2 shall be as follows:

- (1) In accordance with Section 7.7
- (2) Installed in accordance with 9.7.1.1(1).
- (3) Electrically connected to the fire alarm system
- (4) Fully supervised

CHAPTER 23 • Existing

23.3.4.4.4 In smoke compartments protected throughout by an approved automatic sprinkler system in accordance with 23.3.5.3, smoke detectors shall not be required, except in corridors, common spaces, and sleeping rooms with more than four occupants.

alarm system. Subsection 9.6.4 provides several options for notifying the fire department automatically. Where smoke detectors are provided, they are not required to sound the fire alarm or to transmit a signal to the fire department but are required to sound an alarm at a constantly attended location, unless otherwise specified.

Paragraph 22/23.3.4.4.3 is an exemption to the smoke detection system requirement. It applies to Use Condition II open dormitories where staff are present within the dormitory whenever the dormitory is occupied. Note that Use Condition II facilities must permit free movement from sleeping areas to another smoke compartment. The concept employed is one of relying on awake and alert staff within the dormitory to act as human fire detectors, provide early warning, and permit residents to move into a safe smoke compartment.

23.3.5 Extinguishment Requirements.

23.3.5.1 High-rise buildings shall comply with 23.4.3.

23.3.5.2* Where required by Table 23.1.6.5, facilities shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 23.3.5.3.

A.23.3.5.2 Where the openings in ceilings or partitions are $\frac{1}{4}$ in. (0.6 cm) or larger in the smallest dimension, where the thickness or depth of the material does not exceed the smallest dimension of the openings, and where such openings constitute not less than 70 percent of the area of the ceiling or partition material, the disruption of sprinkler spray patterns is permitted to be disregarded.

23.3.5.3 Where this *Code* permits exceptions for fully sprinklered detention and correctional occupancies or sprinklered smoke compartments, the sprinkler system shall be as follows:

- (1) In accordance with Section 9.7
- (2) Installed in accordance with 9.7.1.1(1).
- (3) Electrically connected to the fire alarm system
- (4) Fully supervised

CHAPTER 22 • New

22.3.5.4 Portable fire extinguishers shall be provided in accordance with 9.7.4.1, unless otherwise permitted by the following:

- (1)* Access to portable fire extinguishers shall be permitted to be locked.

A.22.3.5.4(1) Where access to portable fire extinguishers is locked, staff should be present on a 24-hour basis and should have keys readily available to unlock access to the extinguishers. Where supervision of sleeping areas is from a 24-hour attended staff location, portable fire extinguishers are permitted to be provided at the staff location in lieu of the sleeping area.

- (2) Portable fire extinguishers shall be permitted to be located at staff locations only.

22.3.5.5 Standpipe and hose systems shall be provided in accordance with 9.7.4.2 as follows, unless otherwise permitted by 22.3.5.6:

- (1) Class I standpipe systems shall be provided for any building over two stories in height.
- (2) Class III standpipe and hose systems shall be provided for all nonsprinklered buildings over two stories in height.

22.3.5.6 The requirements of 22.3.5.5 shall not apply where otherwise permitted by the following:

- (1) Formed hose, 25 mm (1 in.) in diameter, on hose reels shall be permitted to provide Class II service.
- (2) Separate Class I and Class II systems shall be permitted in lieu of a Class III system.

Paragraph 22.3.5.1, applicable to new facilities in high-rise buildings, refers to 22.4.3, which in turn mandatorily references 11.8.2—which addresses those high-rise building provisions applicable to automatic sprinkler systems and standpipes. Paragraph 23.3.5.1, applicable to existing facilities in high-rise buildings, refers to 23.4.3, which in turn mandates an automatic sprinkler system, but not standpipes. For both new and existing facilities, a sprinkler control valve and waterflow device must be provided for each floor.

Paragraph 22.3.5.2 requires that new detention and correctional occupancies be protected throughout by approved, supervised automatic sprinkler systems. However, in establishing the sprinkler requirement, the Technical Committee on Detention and Correctional Occupancies realized that rehabili-

CHAPTER 23 • Existing

23.3.5.4 Portable fire extinguishers shall be provided in accordance with 9.7.4.1, unless otherwise permitted by the following:

- (1)* Access to portable fire extinguishers shall be permitted to be locked.

A.23.3.5.4(1) Where access to portable fire extinguishers is locked, staff should be present on a 24-hour basis and should have keys readily available to unlock access to the extinguishers. Where supervision of sleeping areas is from a 24-hour attended staff location, portable fire extinguishers are permitted to be provided at the staff location in lieu of the sleeping area.

- (2) Portable fire extinguishers shall be permitted to be located at staff locations only.

23.3.5.5 Standpipe and hose systems shall be provided in accordance with 9.7.4.2 as follows, unless otherwise permitted by 23.3.5.6:

- (1) Class I standpipe systems shall be provided for any building over two stories in height.
- (2) Class III standpipe and hose systems shall be provided for all nonsprinklered buildings over two stories in height.

23.3.5.6 The requirements of 23.3.5.5 shall not apply where otherwise permitted by the following:

- (1) Formed hose, 25 mm (1 in.) in diameter, on hose reels shall be permitted to provide Class II service.
- (2) Separate Class I and Class II systems shall be permitted in lieu of a Class III system.

tation, modernizations, and renovations might take place in nonsprinklered existing buildings. Thus, 22.4.4 provides additional criteria needed for the proper protection of nonsprinklered existing building renovations.

Where automatic sprinklers are installed to comply with the *Code*, the system must be a complete, approved automatic sprinkler system installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*⁶. The use of manually operated sprinklers is not recognized by the *Code*. Informal surveys of detention and correctional occupancy staff indicate no significant problems with the installation, maintenance, and use of automatic sprinkler systems in detention and correctional facilities. The system must also be supervised in accordance with the requirements of 9.7.2 to comply with the *Code*.

CHAPTER 22 • New

Exhibit 22/23.16 illustrates a typical institutional sprinkler. The sprinkler body and frame are designed to prevent residents from hanging things or themselves from the sprinkler.

Paragraph 22/23.3.5.4(1) permits fire extinguishers to be locked away. Time is critical when using extinguishers; therefore, keys must be carried by the staff or be readily accessible.

The requirements of 22/23.3.5.5 for standpipes intend that 63-mm (2½-in.) hose connections be available for fire department use in any detention and correctional occupancy more than two stories in height. In addition, if such buildings are nonsprinklered, there should also be 38-mm (1½-in.) connections and hose for staff and resident use.

Paragraph 22/23.3.5.6(1) permits the use of 25-mm (1-in.) formed rubber hose in place of the fabric-jacketed, rubber-lined hose normally required in standpipe systems. The rubber hose is normally stored on reels and is easier to use.

CHAPTER 23 • Existing

Exhibit 22/23.16 Typical institutional sprinkler.

22.3.6 Corridors.

(See 22.3.8.)

22.3.7 Subdivision of Building Spaces.

22.3.7.1 Smoke barriers shall be provided to divide every story used for sleeping by residents, or any other story having an occupant load of 50 or more persons, into not less than two compartments, unless otherwise permitted by the following:

- (1) Protection shall be permitted to be accomplished using horizontal exits. (See 7.2.4.)
- (2)* The requirement for subdivision of building space shall be permitted to be fulfilled by one of the following:
 - (a) Smoke compartments having exit to a public way where such exit serves only one area and has no openings to other areas
 - (b) A building separated from the resident housing area by a 2-hour fire resistance rating or 15 m (50 ft) of open space
 - (c) A secured, open area having a holding space located 15 m (50 ft) from the housing area that provides 1.4 m² (15 ft²) or more of refuge area for each person (resident, staff, visitors) potentially present at the time of a fire

23.3.6 Corridors.

(See 23.3.8.)

23.3.7 Subdivision of Building Spaces.

23.3.7.1* Smoke barriers shall be provided to divide every story used for sleeping by 10 or more residents, or any other story having an occupant load of 50 or more persons, into not less than two compartments, unless otherwise permitted by the following:

- (1) Protection shall be permitted to be accomplished using horizontal exits. (See 7.2.4.)
- (2)* The requirement for subdivision of building space shall be permitted to be fulfilled by one of the following:
 - (a) Smoke compartments having exit to a public way where such exit serves only one area and has no openings to other areas
 - (b) A building separated from the resident housing area by a 2-hour fire resistance rating or 15 m (50 ft) of open space
 - (c) A secured, open area having a holding space located 15 m (50 ft) from the housing area that provides 1.4 m² (15 ft²) or more of refuge area for each person (resident, staff, visitors) potentially present at the time of a fire

CHAPTER 22 • New

A.22.3.7.1(2) A door to the outside, by itself, does not meet the intent of this provision if emergency operating procedures do not provide for the door to be unlocked when needed. In cases where use of the door is not ensured, a true smoke barrier per the base requirement of 22.3.7.1 would be needed.

22.3.7.2 Doors used to access the areas specified in 22.3.7.1(2)(a), 22.3.7.1(2)(b), and 22.3.7.1(2)(c) shall meet the requirements for doors at smoke barriers for the applicable use condition.

22.3.7.3 Where smoke barriers are required by 22.3.7.1, they shall be provided as follows:

- (1) They shall limit the occupant load to not more than 200 residents in any smoke compartment.
- (2) They shall limit the travel distance to a door in a smoke barrier as follows:
 - (a) The distance from any room door required as exit access shall not exceed 46 m (150 ft).
 - (b) The distance from any point in a room shall not exceed 61 m (200 ft).

22.3.7.4 Reserved.

22.3.7.5* Any required smoke barrier shall be constructed in accordance with Section 8.5, shall be of substantial construction, and shall have structural fire resistance.

A.22.3.7.5 Structural fire resistance is defined as the ability of the assembly to stay in place and maintain structural integrity without consideration of heat transmission. Twelve-gauge steel plate suitably framed and stiffened meets this requirement.

CHAPTER 23 • Existing

A.23.3.7.1(2) A door to the outside, by itself, does not meet the intent of this provision if emergency operating procedures do not provide for the door to be unlocked when needed. In cases where use of the door is not ensured, a true smoke barrier per the base requirement of 23.3.7.1 would be needed.

A.23.3.7.1 Consideration can be given for large open areas that might be permitted to function as smoke sinks as an alternative to the installation of more than one smoke barrier as required by 23.3.7.1. Vertical movement downward to an area of refuge might be permitted by the authority having jurisdiction in lieu of horizontal movement.

23.3.7.2 Doors used to access the areas specified in 23.3.7.1(2)(a), 23.3.7.1(2)(b), and 23.3.7.1(2)(c) shall meet the requirements for doors at smoke barriers for the applicable use condition.

23.3.7.3 Where smoke barriers are required by 23.3.7.1, they shall be provided as follows:

- (1) They shall limit the occupant load to not more than 200 residents in any smoke compartment.
- (2)* They shall limit the travel distance to a door in a smoke barrier, unless otherwise permitted by 23.3.7.4, as follows:
 - (a) The distance from any room door required as exit access shall not exceed 30 m (100 ft).
 - (b) The distance from any point in a room shall not exceed 46 m (150 ft).

A.23.3.7.3(2) Consideration should be given to increasing the travel distance to a smoke barrier to coincide with existing range lengths and exits.

23.3.7.4 The maximum travel distance to a door in a smoke barrier shall be permitted to be increased by 15 m (50 ft) in smoke compartments protected throughout by an approved automatic sprinkler system in accordance with 23.3.5.3 or an automatic smoke control system.

23.3.7.5* Any required smoke barrier shall be constructed in accordance with Section 8.5, shall be of substantial construction, and shall have a structural fire resistance.

A.23.3.7.5 Structural fire resistance is defined as the ability of the assembly to stay in place and maintain structural integrity without consideration of heat transmission. Twelve-gauge steel plate suitably framed and stiffened meets this requirement.

CHAPTER 22 • New

22.3.7.6 Openings in smoke barriers shall be protected in accordance with Section 8.5, unless otherwise permitted by the following:

- (1)* The total number of vision panels in any barrier shall not be restricted.

A.22.3.7.6(1) As an example, a smoke barrier is permitted to consist of fire-rated glazing panels mounted in a security grille arrangement.

- (2) Sliding doors in smoke barriers that are designed to normally be kept closed and are remotely operated from a continuously attended location shall not be required to be self-closing.

22.3.7.7 Not less than 0.55 net m² (6 net ft²) per occupant shall be provided on each side of the smoke barrier for the total number of occupants in adjoining compartments, and this space shall be readily available wherever occupants are moved across the smoke barrier in a fire emergency.

22.3.7.8 Doors shall provide resistance to the passage of smoke. Swinging doors shall be self-latching, or the opening resistance of the door shall be not less than 22 N (5 lbf).

22.3.7.9 Doors in smoke barriers shall conform with the requirements for doors in means of egress as specified in Section 22.2 and shall have locking and release arrangements according to the applicable use condition. The provisions of 22.2.11.7.2 shall not be used for smoke barrier doors serving a smoke compartment containing more than 20 persons.

22.3.7.10 Vision panels shall be provided in smoke barriers at points where the barrier crosses an exit access corridor.

22.3.7.11 Smoke dampers shall be provided in accordance with 8.5.4, unless otherwise permitted by 22.3.7.12.

22.3.7.12 Arrangements and positioning of smoke detectors required by 22.3.7.11 shall be permitted to prevent damage or tampering, or for other purposes, provided that the following criteria are met:

- (1) Such arrangements shall be capable of detecting any fire.
- (2) The placement of detectors shall be such that the speed of detection is equivalent to that provided by the spacing and arrangement required by *NFPA 72®*, *National Fire Alarm Code®*, as referenced in 8.5.4.7.1.

CHAPTER 23 • Existing

23.3.7.6 Openings in smoke barriers shall be protected in accordance with Section 8.5, unless otherwise permitted by the following:

- (1)* The total number of vision panels in any barrier shall not be restricted.

A.23.3.7.6(1) As an example, a smoke barrier is permitted to consist of fire-rated glazing panels mounted in a security grille arrangement.

- (2) Sliding doors in smoke barriers that are designed to normally be kept closed and are remotely operated from a continuously attended location shall not be required to be self-closing.

23.3.7.7 Not less than 0.55 net m² (6 net ft²) per occupant shall be provided on each side of the smoke barrier for the total number of occupants in adjoining compartments, and this space shall be readily available wherever occupants are moved across the smoke barrier in a fire emergency.

23.3.7.8 Doors shall provide resistance to the passage of smoke. Swinging doors shall be self-latching, or the opening resistance of the door shall be not less than 22 N (5 lbf). Such doors shall not be required to swing in the direction of egress travel.

23.3.7.9 Doors in smoke barriers shall conform with the requirements for doors in means of egress as specified in Section 23.2 and shall have locking and release arrangements according to the applicable use condition. The provisions of 23.2.11.7.2 shall not be used for smoke barrier doors serving a smoke compartment containing more than 20 persons.

23.3.7.10 Vision panels shall be provided in smoke barriers at points where the barrier crosses an exit access corridor.

23.3.7.11 Smoke dampers shall be provided in accordance with 8.5.4, unless otherwise permitted by 23.3.7.12.

23.3.7.12 Arrangements and positioning of smoke detectors required by 23.3.7.11 shall be permitted to prevent damage or tampering, or for other purposes, provided that the following criteria are met:

- (1) Such arrangements shall be capable of detecting any fire.
- (2) The placement of detectors shall be such that the speed of detection is equivalent to that provided by the spacing and arrangement required by *NFPA 72®*, *National Fire Alarm Code®*, as referenced in 8.5.4.7.1.

CHAPTER 22 • New

Smoke barriers and horizontal exits used to subdivide a building serve three purposes that are fundamental to the protection of occupants:

- (1) They limit the spread of fire and fire-produced contaminants.
- (2) They limit the number of occupants exposed to a single fire.
- (3) They provide for horizontal relocation of occupants by creating a safe area on the same floor.

The requirements of 22/23.3.7.1 and 22/23.3.7.3 for subdividing building spaces are illustrated in Exhibit 22/23.17. Exhibit 22/23.18 illustrates the requirements of 22/23.3.7.1(2). In Exhibit 22/23.18, the door from the resident housing building to the yard can be locked only to the degree that a smoke barrier door can be locked for the applicable use condition.

Although it does not specify a required fire resistance rating, 22/23.3.7.5 requires smoke barriers to have structural fire resistance. The intent is to eliminate the use of highly combustible or flimsy materials, such as plastic sheeting, that might possibly limit smoke movement but have little structural integrity.

CHAPTER 23 • Existing

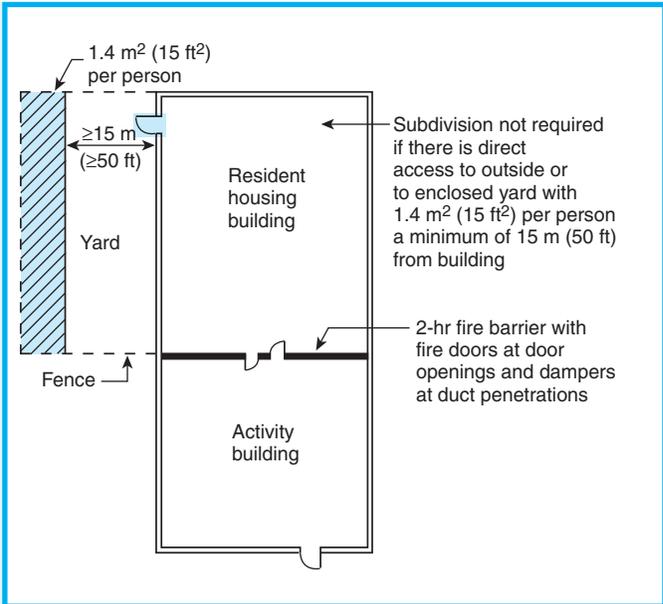

Exhibit 22/23.18 Alternatives to subdivision by smoke barriers.

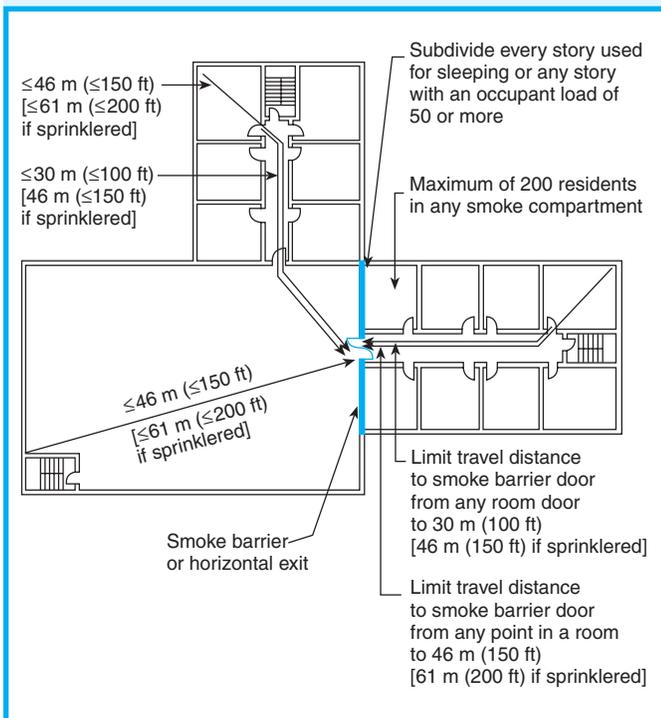

Exhibit 22/23.17 Subdivision of building spaces into smoke compartments using smoke barriers.

The doors in the required smoke barriers must resist the passage of smoke for the same reason that smoke barriers must resist the passage of smoke. The door constructed of materials that resist the passage of smoke will stop smoke from traveling across the door opening only if the door remains tightly closed. Therefore, 22/23.3.7.8 requires that the door, which 8.5.3.4 requires to be either self-closing or automatic closing, also must be self-latching or offer a 22-N (5-lbf) resistance to opening, as a minimum. This combination of requirements should help to ensure that the door will be closed under smoke conditions and remain closed, even under the pressures generated by a fire, to resist the passage of smoke.

The provisions of 22/23.2.11.7.2 allow up to 10 locks to require manual unlocking in a timely fashion and still be considered as providing the degree of remote unlocking necessary to satisfy the requirements of a Use Condition IV facility—as opposed to a Use Condition V facility. However, 22/23.3.7.9 does not allow locks on smoke barrier doors to be part of the maximum 10 manually unlocked locks where a smoke compartment houses more than 20 persons. This limitation emphasizes the importance of maintaining a means of egress system within a Use Condition IV facility (that is, where remote release is required), with more than 20 persons per smoke com-

partment, that allows resident movement to another smoke compartment without having to manually release the lock on the smoke barrier door. A manually released lock on the smoke barrier door would force

a reclassification of the facility to Use Condition V and compliance with the more stringent requirements applicable to that classification.

22.3.8* Special Protection Features—Subdivision of Resident Housing Spaces.

Subdivision of facility spaces shall comply with Table 22.3.8.

23.3.8* Special Protection Features—Subdivision of Resident Housing Spaces.

Subdivision of facility spaces shall comply with Table 23.3.8.

Table 22.3.8 Subdivision of Resident Housing Spaces

Feature	Use Condition			
	II	III	IV	V
Room to room separation	NR	NR	NR	SR
Room face to corridor separation	NR	NR	NR	SR
Room face to common space separation	NR	NR SR ≤15 m >15 m (≤50 ft)† (>50ft)†	NR SR ≤15 m >15 m (≤50 ft)† (>50 ft)†	SR
Common space to corridor separation	NR	NR	NR	SR
Total openings in solid room face where room face is required to be smoke resistant or fire rated‡	0.08 m ² (0.85 ft ²)	0.08 m ² (0.85 ft ²)	0.08 m ² (0.85 ft ²)	0.08 m ² (0.85 ft ²) where meeting one of the following: (1) kept in closed position except when in use by staff (2) closable from the inside (3) with smoke control

NR: No requirement.

SR: Smoke resistant.

Notes:

1. Doors in openings in partitions required to be smoke resistant (SR) in accordance with Table 22.3.8 shall be substantial doors of construction that resists the passage of smoke. Latches and door closers shall not be required on cell doors.

2. Under Use Condition II, Use Condition III, or Use Condition IV, a space subdivided by open construction (any combination of grating doors and grating walls or solid walls) shall be permitted to be considered one room if housing not more than 16 persons. The perimeter walls of such space shall be of smoke-resistant construction. Smoke detection shall be provided in such space. Under Use Condition IV, common walls between sleeping areas within the space shall be smoke resistant, and grating doors and fronts shall be permitted to be used. Under Use Condition II and Use Condition III, open dormitories shall be permitted to house more than 16 persons as permitted by other sections of this chapter.

3. Where barriers are required to be smoke resistant (SR), the provisions of Section 8.5 shall not apply.

†Travel distance through the common space to the exit access corridor.

‡“Total openings in solid room face” includes all openings (for example, undercuts, food passes, grilles), the total of which shall no exceed 0.08 m² (0.85 ft²). All openings shall be 915 mm (36 in.) or less above the floor.

Table 23.3.8 Subdivision of Resident Housing Spaces

Total openings in solid room face where room face is required to be smoke resistant or fire rated#	0.08 m ² (0.85 ft ²)		0.08 m ² (0.85 ft ²)				0.08 m ² (0.85 ft ²)		Where meeting one of the following: (1) kept in closed position except when in use by staff (2) closable from the inside (3) with smoke control		

NS: Not protected by automatic sprinklers.

AS: Protected by automatic sprinklers.

NR: No requirement.

SR: Smoke resistant.

FR: Fire rated—1 hour.

Notes:

1. Doors in openings in partitions required to be fire rated (FR) in accordance with Table 23.3.8 in other than required enclosures of exits or hazardous areas shall be substantial doors of construction that resists fire for not less than 20 minutes. Vision panels with wired glass or glass with not less than 45-minute fire-rated glazing shall be permitted. Latches and door closers shall not be required on cell doors.

2. Doors in openings in partitions required to be smoke resistant (SR) in accordance with Table 23.3.8 shall be substantial doors of construction that resists the passage of smoke. Latches and door closers shall not be required on cell doors.

3. Under Use Condition II, Use Condition III, or Use Condition IV, a space subdivided by open construction (any combination of grating doors and grating walls or solid walls) shall be permitted to be considered one room if housing not more than 16 persons. The perimeter walls of such space shall be of smoke-resistant construction. Smoke detection shall be provided in such space. Under Use Condition IV, common walls between sleeping areas within the space shall be smoke resistant, and grating doors and fronts shall be permitted to be used. Under Use Condition II and Use Condition III, open dormitories shall be permitted to house more than 16 persons as permitted by other sections of this chapter.

4. Where barriers are required to be smoke resistant (SR), the provisions of Section 8.5 shall not apply.

†Might be no requirement (NR) where one of the following is provided:

- (1) An approved automatic smoke detection system installed in all corridors and common spaces
- (2) Multitiered cell blocks meeting the requirements of 23.3.1.3

‡Might be no requirement (NR) in multitiered, open cell blocks meeting the requirements of 23.3.1.3.

§Travel distance through the common space to the exit access corridor.

#“Total openings in solid room face” includes all openings (for example, undercuts, food passes, grilles), the total of which shall not exceed 0.08 m² (0.85 ft²). All openings shall be 915 mm (36 in.) or less above the floor.

CHAPTER 22 • New

A.22.3.8 The requirements in Table 22.3.8 for smoke-resistant separations include taking the necessary precautions to restrict the spread of smoke through the air-handling system. However, the intent is not that smoke dampers are required to be provided for each opening. Smoke dampers would be one acceptable method; however, other techniques, such as allowing the fans to continue to run with 100 percent supply and 100 percent exhaust, would be acceptable.

Paragraph 22/23.3.8 provides for the separation of areas where residents are housed. This separation serves two basic needs: (1) It keeps a fire and its products confined to the area of origin, and (2) it protects those occupants located outside the area of origin. Table 22/23.3.8 establishes individual requirements based on the use condition involved. Where a common wall is used for different purposes, such as “room face to corridor” and “common space to

CHAPTER 23 • Existing

A.23.3.8 The requirements in Table 23.3.8 for smoke-resistant and fire-rated separations include taking the necessary precautions to restrict the spread of smoke through the air-handling system. However, the intent is not that smoke dampers are required to be provided for each opening. Smoke dampers would be one acceptable method; however, other techniques, such as allowing the fans to continue to run with 100 percent supply and 100 percent exhaust, would be acceptable.

corridor,” the most restrictive requirement needs to be applied to the entire wall. Table 22/23.3.8 and its notes specify a wide variety of options in addition to the locking options previously detailed in Chapters 22 and 23. Note 2 to Table 22.3.8 and Note 3 to Table 23.3.8 also allow a space that has been subdivided to be treated as a single room. In combination with the various locking options, this can facilitate day-to-day operations.

Section 22.4 Special Provisions

22.4.1 Limited Access Structures.

The provisions of Section 11.7 for limited access structures shall not apply.

Section 23.4 Special Provisions

23.4.1 Limited Access Structures.

23.4.1.1 Limited access structures used as detention and correctional occupancies shall comply with 23.4.1.2, unless otherwise permitted by the following:

- (1) The provisions of Section 11.7 for limited access less structures shall not apply.
- (2) The requirement of 23.4.1.1 shall not apply to buildings protected throughout by an approved automatic sprinkler system in accordance with 23.3.5.3.

23.4.1.2 Any one of the following means shall be provided to evacuate smoke from the smoke compartment of fire origin:

- (1) Operable windows on not less than two sides of the building, spaced not more than 9140 mm (360 in.) apart, that provide openings with dimensions of not less than 560 mm (22 in.) in width and 610 mm (24 in.) in height
- (2)* Manual or automatic smoke vents

A.23.4.1.2(2) The automatic smoke venting should be in accordance with NFPA 204, *Standard for Smoke and Heat Venting*, for light hazard occupancies.

- (3) Engineered smoke control system
- (4) Mechanical exhaust system providing not less than 6 air changes per hour

CHAPTER 22 • New

22.4.2 Underground Buildings.

See Section 11.7 for requirements for underground buildings.

22.4.3 High-Rise Buildings.

High-rise buildings shall comply with 11.8.2.

Paragraph 23.4.1.2 provides a variety of options for evacuating smoke from the smoke compartment of fire origin in limited access buildings.

Paragraph 23.4.3 retroactively requires existing, high-rise detention and correctional occupancy buildings to be protected throughout by approved, supervised automatic sprinkler systems. Addition-

22.4.4 Nonsprinklered Existing Building Renovations.

22.4.4.1 General. Modernizations or renovations of nonsprinklered existing buildings shall be permitted to meet the requirements of this chapter as modified by 22.4.4.2 through 22.4.4.13 in lieu of the sprinkler requirement of 22.3.5.2.

Chapter 22 requires that new detention and correctional occupancies be protected throughout by approved, supervised automatic sprinkler systems. However, in establishing the sprinkler requirement, the Technical Committee on Detention and Correctional Occupancies realized that rehabilitation, modernizations, and renovations might take place in nonsprinklered existing buildings. Thus, 22.4.4 provides additional criteria needed for the proper protection of nonsprinklered existing building renovations. For example, 22.4.4.5.2 establishes for nonsprinklered buildings a maximum travel distance of 46 m (150 ft) between any point in a room and an exit. Had the renovation in the nonsprinklered building been predicated on the provisions of 22.2.6.3, the travel distance limitation would have mistakenly been interpreted to be 61 m (200 ft) between any point in a room and an exit. The 61-m (200-ft) allowance is intended to apply only to sprinklered buildings.

CHAPTER 23 • Existing

(5) Other method acceptable to the authority having jurisdiction

23.4.2 Underground Buildings.

See Section 11.7 for requirements for underground buildings.

23.4.3 High-Rise Buildings.

Existing high-rise buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 23.3.5.3. A sprinkler control valve and a waterflow device shall be provided for each floor.

ally, a sprinkler control valve and waterflow device must be provided for each floor. Levels of a multilevel housing area complying with 23.3.1.2 and 23.3.1.3 do not constitute multiple floors and, thus, are not required to be provided with individual control valves and waterflow devices on each level.

Subsection 22.4.4 serves as a repository for provisions that were contained in Chapter 22 before sprinklers were mandated for new construction. Its provisions remind the user that the requirements interspersed throughout Chapter 22 are predicated on the presence of sprinkler protection. If sprinklers are not installed, additional requirements must be met in an attempt to achieve a level of life safety approaching that provided in a sprinklered building. However, even if all the former specifications for nonsprinklered buildings are met, the overall level of life safety will not necessarily be the same as that provided in a sprinklered facility. When the 1997 edition of the *Code* presented the first requirement for sprinklering of all new detention and correctional occupancies, the overall level of life safety was elevated from that provided by compliance with the nonsprinklered building option.

22.4.4.2 Minimum Construction Requirements (Non-sprinklered Buildings).

22.4.4.2.1 Detention and correctional occupancies in non-sprinklered buildings shall be limited to the types of building construction permitted by Table 22.4.4.2.1. (See 8.2.1.)

Table 22.4.4.2.1 Construction Type Limitations—Nonsprinklered Buildings

Type of Construction	1 Story with Basement	1 Story without Basement	2 Stories	3 Stories	>3 Stories and Not High-Rise	High-Rise
I(443)	X	X	X	X	X	NP
I(332)	X	X	X	X	X	NP
II(222)	X	X	X	X	X	NP
II(111)	X*	X	X*	NP	NP	NP
III(211)	X*	X*	X*	NP	NP	NP
IV(2HH)	X*	X*	X*	NP	NP	NP
V(111)	X*	X*	X*	NP	NP	NP
II(000)	NP	NP	NP	NP	NP	NP
III(200)	NP	NP	NP	NP	NP	NP
V(000)	NP	NP	NP	NP	NP	NP

X: Permitted types of construction.

NP: Not permitted.

*Permitted for other than Use Condition V.

22.4.4.2.2 A residential housing area complying with 22.4.4.6 shall be considered as a one-story building for purposes of applying Table 22.4.4.2.1.

22.4.4.3* Horizontal Exit Duct Penetrations (Nonsprinklered Buildings). Ducts shall be permitted to penetrate horizontal exits in accordance with 7.2.4.3.4(3) if protected by combination fire dampers/smoke leakage-rated dampers that meet the smoke damper actuation requirements of 8.5.4.

A.22.4.4.3 This provision is intended to promote the use of horizontal exits in detention and correctional occupancies. Horizontal exits provide an especially effective egress system for an occupancy in which the occupants, due to security concerns, are not commonly released to the outside. This provision offers a *Code*-specified equivalent alternative to the requirement of 7.2.4.3.4 that horizontal exits are not to be penetrated by ducts in nonsprinklered buildings. The intended continuity of the fire resistance-rated and smoke-resisting barrier is maintained by requiring that duct penetrations of horizontal exits be protected by combination fire damper/smoke leakage-rated dampers that will close upon activation of a smoke detector and a heat-actuated mechanism before the barrier's ability to resist the passage of smoke and fire is compromised.

22.4.4.4 Common Path of Travel (Nonsprinklered Buildings). A common path of travel shall not exceed 15 m (50 ft).

22.4.4.5 Travel Distance to Exits (Nonsprinklered Buildings).

22.4.4.5.1 The travel distance between any room door required as an exit access and an exit shall not exceed 30 m (100 ft).

22.4.4.5.2 The travel distance between any point in a room and an exit shall not exceed 46 m (150 ft).

22.4.4.6 Protection of Vertical Openings (Nonsprinklered Buildings).

22.4.4.6.1 Multilevel residential housing areas without enclosure protection between levels shall be permitted, provided that the conditions of 22.4.4.6.2 through 22.4.4.6.4 are met.

22.4.4.6.2* The entire normally occupied area, including all communicating floor levels, shall be sufficiently open and unobstructed so that a fire or other dangerous condition in any part is obvious to the occupants or supervisory personnel in the area.

A.22.4.4.6.2 It is not the intent of this requirement to restrict room face separations, which restrict visibility from the common space into individual sleeping rooms.

22.4.4.6.3 Egress capacity shall simultaneously accommodate all occupants of all communicating levels and areas, with all communicating levels in the same fire area considered as a single floor area for purposes of determining required egress capacity.

22.4.4.6.4* The height between the highest and lowest finished floor levels shall not exceed 3960 mm (156 in.). The number of levels shall not be restricted.

A.22.4.4.6.4 The vertical separation between the lowest floor level and the uppermost floor level is not to exceed 3960 mm (156 in.). Figure A.22.4.4.6.4 illustrates how the height is to be determined.

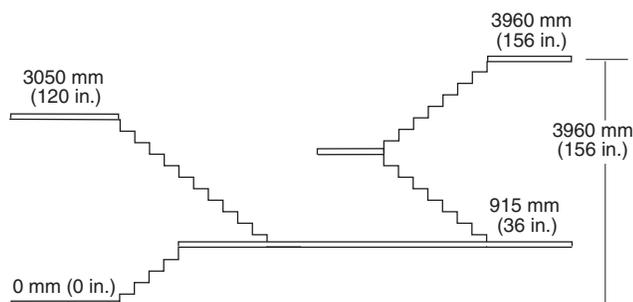

FIGURE A.22.4.4.6.4 Vertical Height Measurement.

22.4.4.7 Hazardous Areas (Nonsprinklered Buildings). Any hazardous area shall be protected in accordance with Section 8.7. The areas described in the Table 22.4.4.7 shall be protected as indicated.

**Table 22.4.4.7 Hazardous Area Protection—
Nonsprinklered Buildings**

Hazardous Area Description	Separation/Protection
Areas not incidental to residential housing	2 hours
Boiler and fuel-fired heater rooms	2 hours or 1 hour and sprinklers
Central or bulk laundries >9.3 m ² (>100 ft ²)	2 hours or 1 hour and sprinklers
Commercial cooking equipment	In accordance with 9.2.3
Commissaries	1 hour or sprinklers
Employee locker rooms	1 hour or sprinklers
Hobby/handicraft shops	1 hour or sprinklers
Maintenance shops	1 hour or sprinklers
Padded cells	2 hours or 1 hour and sprinklers
Soiled linen rooms	2 hours or 1 hour and sprinklers
Storage rooms >4.6 m ² (>50 ft ²) in area but ≤9.3 m ² (≤100 ft ²) in area storing combustible material	1 hour or sprinklers
Storage rooms >9.3 m ² (>100 ft ²) storing combustible materials	2 hours or 1 hour and sprinklers
Trash collection rooms	2 hours or 1 hour and sprinklers

22.4.4.8 Interior Finish (Nonsprinklered Buildings).

22.4.4.8.1 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A in corridors, in exits, and in any space not separated from corridors and exits by partitions capable of retarding the passage of smoke; and Class A, Class B, or Class C in all other areas.

22.4.4.8.2 Interior Floor Finish.

22.4.4.8.2.1 Interior floor finish shall comply with Section 10.2.

22.4.4.8.2.2 Interior floor finish in exit enclosures and exit access corridors shall be not less than Class I.

22.4.4.8.2.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

22.4.4.9 Detection, Alarm, and Communications Systems (Nonsprinklered Buildings).

22.4.4.9.1 Initiation. Initiation of the fire alarm system required by 22.3.4.1.1 shall be by manual means in accordance with 9.6.2 and by means of any required detection devices or detection systems, unless otherwise permitted by the following:

- (1) Manual fire alarm boxes shall be permitted to be locked, provided that staff is present within the area when it is occupied and staff has keys readily available to unlock the boxes.
- (2) Manual fire alarm boxes shall be permitted to be located in a staff location, provided that both of the following criteria are met:
 - (a) The staff location is attended when the building is occupied
 - (b) The staff attendant has direct supervision of the sleeping area.

22.4.4.9.2 Detection. An approved automatic smoke detection system shall be in accordance with Section 9.6, as modified by 22.4.4.9.2.1 and 22.4.4.9.2.2, throughout all resident sleeping areas and adjacent day rooms, activity rooms, or contiguous common spaces.

22.4.4.9.2.1 Smoke detectors shall not be required in sleeping rooms with four or fewer occupants in Use Condition II or Use Condition III.

22.4.4.9.2.2 Other arrangements and positioning of smoke detectors shall be permitted to prevent damage or tampering, or for other purposes. Such arrangements shall be capable of detecting any fire, and the placement of detectors shall be such that the speed of detection is equivalent to that provided by the spacing and arrangements required by the installation standards referenced in Section 9.6. Detectors shall be permitted to be located in exhaust ducts from cells, behind grilles, or in other locations. The equivalent performance of the design, however, shall be acceptable to the authority having jurisdiction in accordance with the equivalency concepts specified in Section 1.4.

22.4.4.10 Subdivision of Building Spaces (Nonsprinklered Buildings). Where smoke barriers are required by 22.3.7.1, they shall be provided as follows:

- (1) They shall limit the occupant load to not more than 200 residents in any smoke compartment.
- (2) They shall limit the travel distance to a door in a smoke barrier as follows:

- (a) The distance from any room door required as exit access shall not exceed 30 m (100 ft).
- (b) The distance from any point in a room shall not exceed 46 m (150 ft).

22.4.4.11* Subdivision of Resident Housing Spaces (Non-sprinklered Buildings). Subdivision of facility spaces shall comply with Table 22.4.4.11.

Table 22.4.4.11 Subdivision of Resident Housing Spaces—Nonsprinklered Buildings

Feature	Use Condition			
	II	III	IV	V
Room to room separation	NR	NR	SR	FR(½)
Room face to corridor separation	SR	SR	SR	FR
Room face to common space separation	NR	NR ≤15 m (≤50 ft)† SR >15 m (>50ft)†	SR	FR
Common space to corridor separation	FR	FR	FR	FR
Total openings in solid room face where room face is required to be smoke resistant or fire rated‡	0.08 m ² (0.85 ft ²) where meeting one of the following: (1) kept in closed position except when in use by staff (2) closable from the inside (3) with smoke control			

NR: No requirement.

SR: Smoke resistant.

FR(½): Fire rated—½ hour.

FR: Fire rated—1 hour.

Notes:

1. Doors in openings in partitions required to be fire rated (FR(½), FR) in accordance with Table 22.4.4.11 in other than required enclosures of exits or hazardous areas shall be substantial doors of construction that resists fire for not less than 20 minutes. Vision panels with wired glass or glass with not less than 45-minute fire-rated glazing shall be permitted. Latches and door closers shall not be required on cell doors.

2. Doors in openings in partitions required to be smoke resistant (SR) in accordance with Table 22.4.4.11 shall be substantial doors of construction that resists the passage of smoke. Latches and door closers shall not be required on cell doors.

3. Under Use Condition II, Use Condition III, or Use Condition IV, a space subdivided by open construction (any combination of grating doors and grating walls or solid walls) shall be permitted to be considered one room if housing not more than 16 persons. The perimeter walls of such space shall be of smoke-resistant construction. Smoke detection shall be provided in such space. Under Use Condition IV, common walls between sleeping areas within the space shall be smoke resistant, and grating doors and fronts shall be permitted to be used. In Use Condition II and Use Condition III, open dormitories shall be permitted to house more than 16 persons as permitted by other sections of this chapter.

4. Where barriers are required to be smoke resistant (SR), the provisions of Section 8.5 shall not apply.

†Travel distance through the common space to the exit access corridor.

‡“Total openings in solid room face” includes all openings (for example, undercuts, food passes, grilles), the total of which shall not exceed 0.08 m² (0.85 ft²). All openings shall be 915 mm (36 in.) or less above the floor.

A.22.4.4.11 The requirements in Table 22.4.4.11 for smoke-resistant and fire-rated separations include taking the necessary precautions to restrict the spread of smoke through the air-handling system. However, the intent is that smoke dampers are required to be provided for each opening. Smoke dampers would be one acceptable method; however, other techniques, such as allowing the fans to continue to run with 100 percent supply and 100 percent exhaust, would be acceptable.

22.4.4.12 Limited Access Structures (Nonsprinklered Buildings).

22.4.4.12.1 Limited access structures used as detention and correctional occupancies shall comply with 22.4.4.12.2. The provisions of Section 11.7 for limited access structures shall not apply.

22.4.4.12.2 Any one of the following means shall be provided to evacuate smoke from the smoke compartment of fire origin:

- (1) Operable windows on not less than two sides of the building, spaced not more than 9140 mm (360 in.) apart, that provide openings with dimensions of not less than 560 mm (22 in.) in width and 610 mm (24 in.) in height
- (2)* Manual or automatic smoke vents

A.22.4.4.12.2(2) The automatic smoke venting should be in accordance with NFPA 204, *Guide for Smoke and Heat Venting*, for light hazard occupancies.

- (3) Engineered smoke control system
- (4) Mechanical exhaust system providing not less than 6 air changes per hour
- (5) Other method acceptable to the authority having jurisdiction

22.4.4.13* Furnishings, Bedding, and Decorations (Nonsprinklered Buildings).

A.22.4.4.13 Personal property provides combustible contents for fire development. Therefore, adequate controls are needed to limit the quantity and combustibility of fuels available to burn to reduce the probability of room flashover. The provisions of 22.4.4.13 will not, by themselves, prevent room flashover if personal property controls are not provided.

22.4.4.13.1 Newly introduced upholstered furniture within detention and correctional occupancies shall be tested in accordance with the provisions of 10.3.2(2) and 10.3.3.

22.4.4.13.2* Newly introduced mattresses within detention and correctional occupancies shall be tested in accordance with the provisions of 10.3.2(3) and 10.3.4.

CHAPTER 22 • New

A.22.4.4.13.2 Mattresses used in detention and correctional facilities should be evaluated with regard to the fire hazards of the environment. The potential for vandalism and excessive wear and tear also should be taken into account when evaluating the fire performance of the mattress.

Section 22.5 Building Services

22.5.1 Utilities.

22.5.1.1 Utilities shall comply with the provisions of Section 9.1.

22.5.1.2 Alarms, emergency communication systems, and the illumination of generator set locations shall be provided with emergency power in accordance with NFPA 70, *National Electrical Code*.

22.5.2 Heating, Ventilating, and Air Conditioning.

22.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2 and shall be installed in accordance with the manufacturer's specifications, unless otherwise modified by 22.5.2.2.

22.5.2.2 Portable space-heating devices shall be prohibited, unless otherwise permitted by 22.5.2.4.

22.5.2.3 Any heating device other than a central heating plant shall be designed and installed so that combustible material cannot be ignited by the device or its appurtenances, and the following requirements also shall apply:

- (1) If fuel-fired, such heating devices shall comply with the following:
 - (a) They shall be chimney connected or vent connected.
 - (b) They shall take air for combustion directly from outside.
 - (c) They shall be designed and installed to provide for complete separation of the combustion system from the atmosphere of the occupied area.

CHAPTER 23 • Existing

Section 23.5 Building Services

23.5.1 Utilities.

23.5.1.1 Utilities shall comply with the provisions of Section 9.1.

23.5.1.2 Alarms, emergency communication systems, and the illumination of generator set installations shall be provided with emergency power in accordance with NFPA 70, *National Electrical Code*[®], unless otherwise permitted by 23.5.1.3.

23.5.1.3 Systems complying with earlier editions of NFPA 70, *National Electrical Code*[®], and not presenting a life safety hazard shall be permitted to continue to be used.

23.5.2 Heating, Ventilating, and Air Conditioning.

23.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2 and shall be installed in accordance with the manufacturer's specifications, unless otherwise permitted by the following:

- (1) The requirement of 23.5.2.1 shall not apply where otherwise modified by 23.5.2.2.
- (2) Systems complying with earlier editions of the applicable codes and not presenting a life safety hazard shall be permitted to continue to be used.

23.5.2.2 Portable space-heating devices shall be prohibited, unless otherwise permitted by 23.5.2.4.

23.5.2.3 Any heating device other than a central heating plant shall be designed and installed so that combustible material cannot be ignited by the device or its appurtenances, and the following requirements also shall apply:

- (1) If fuel-fired, such heating devices shall comply with the following:
 - (a) They shall be chimney connected or vent connected.
 - (b) They shall take air for combustion directly from outside.
 - (c) They shall be designed and installed to provide for complete separation of the combustion system from the atmosphere of the occupied area.

CHAPTER 22 • New

- (2) The heating system shall have safety devices to immediately stop the flow of fuel and shut down the equipment in case of either excessive temperatures or ignition failure.

22.5.2.4 Approved, suspended unit heaters shall be permitted in locations other than means of egress and sleeping areas, provided that both of the following criteria are met:

- (1) Such heaters are located high enough to be out of the reach of persons using the area.
- (2) Such heaters are vent connected and equipped with the safety devices required by 22.5.2.3.

22.5.2.5 Combustion and ventilation air for boiler, incinerator, or heater rooms shall be taken directly from and discharged directly to the outside.

22.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

22.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

22.5.4.1 Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

22.5.4.2 Rubbish chutes and linen chutes, including pneumatic rubbish and linen systems, shall be provided with automatic extinguishing protection in accordance with Section 9.7.

22.5.4.3 Trash chutes shall discharge into a trash collection room used for no other purpose and protected in accordance with Section 8.7.

22.5.4.4 Incinerators shall not be directly flue-fed, and floor chutes shall not directly connect with the combustion chamber.

Section 22.6 Reserved

Section 22.7 Operating Features

22.7.1 Attendants, Evacuation Plan, Fire Drills.

22.7.1.1 Detention and correctional facilities, or those portions of facilities having such occupancy, shall be provided

CHAPTER 23 • Existing

- (2) The heating system shall have safety devices to immediately stop the flow of fuel and shut down the equipment in case of either excessive temperatures or ignition failure.

23.5.2.4 Approved, suspended unit heaters shall be permitted in locations other than means of egress and sleeping areas, provided that both of the following criteria are met:

- (1) Such heaters are located high enough to be out of the reach of persons using the area.
- (2) Such heaters are vent connected and equipped with the safety devices required by 23.5.2.3.

23.5.2.5 Combustion and ventilation air for boiler, incinerator, or heater rooms shall be taken directly from and discharged directly to the outside.

23.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

23.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

23.5.4.1 Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

23.5.4.2 Rubbish chutes and linen chutes, including pneumatic rubbish and linen systems, shall be provided with automatic extinguishing protection in accordance with Section 9.7.

23.5.4.3 Trash chutes shall discharge into a trash collection room used for no other purpose and protected in accordance with Section 8.7.

23.5.4.4 Incinerators shall not be directly flue-fed, and floor chutes shall not directly connect with the combustion chamber.

Section 23.6 (Reserved)

Section 23.7 Operating Features

23.7.1 Attendants, Evacuation Plan, Fire Drills.

23.7.1.1 Detention and correctional facilities, or those portions of facilities having such occupancy, shall be provided

CHAPTER 22 • New

with 24-hour staffing, and the following requirements also shall apply:

- (1) Staff shall be within three floors or a 91-m (300-ft) horizontal distance of the access door of each resident housing area.
- (2) In addition, for Use Condition III, Use Condition IV, and Use Condition V, the arrangement shall be such that the staff involved starts the release of locks necessary for emergency evacuation or rescue and initiates other necessary emergency actions within 2 minutes of alarm.
- (3) The following shall apply to areas in which all locks are unlocked remotely in compliance with 22.2.11.7:
 - (a) Staff shall not be required to be within three floors or 91 m (300 ft) of the access door.
 - (b) The 10-lock, manual key exemption of 22.2.11.7.2 shall not be permitted to be used in conjunction with this alternative requirement.

22.7.1.2* Provisions shall be made so that residents in Use Condition III, Use Condition IV, and Use Condition V shall be able to notify staff of an emergency.

A.22.7.1.2 This requirement is permitted to be met by electronic or oral monitoring systems, visual monitoring, call signals, or other means.

22.7.1.3* The administration of every detention or correctional facility shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons in the event of fire, for their evacuation to areas of refuge, and for evacuation from the building when necessary.

A.22.7.1.3 Periodic, coordinated training should be conducted and should involve detention and correctional facility personnel and personnel of the fire department legally committed to serving the facility.

22.7.1.3.1 All employees shall be instructed and drilled with respect to their duties under the plan.

22.7.1.3.2 The plan shall be coordinated with and reviewed by the fire department legally committed to serve the facility.

22.7.1.4 Employees of detention and correctional occupancies shall be instructed in the proper use of portable fire extinguishers and other manual fire suppression equipment.

22.7.1.4.1 Such training shall be provided to new staff promptly upon commencement of duty.

22.7.1.4.2 Refresher training shall be provided to existing staff at not less than annual intervals.

CHAPTER 23 • Existing

with 24-hour staffing, and the following requirements also shall apply:

- (1) Staff shall be within three floors or a 91-m (300-ft) horizontal distance of the access door of each resident housing area.
- (2) In addition, for Use Condition III, Use Condition IV, and Use Condition V, the arrangement shall be such that the staff involved starts the release of locks necessary for emergency evacuation or rescue and initiates other necessary emergency actions within 2 minutes of alarm.
- (3) The following shall apply to areas in which all locks are unlocked remotely in compliance with 23.2.11.7:
 - (a) Staff shall not be required to be within three floors or 91 m (300 ft) of the access door.
 - (b) The 10-lock, manual key exemption of 23.2.11.7.2 shall not be permitted to be used in conjunction with this alternative requirement.

23.7.1.2* Provisions shall be made so that residents in Use Condition III, Use Condition IV, and Use Condition V shall be able to notify staff of an emergency.

A.23.7.1.2 This requirement is permitted to be met by electronic or oral monitoring systems, visual monitoring, call signals, or other means.

23.7.1.3* The administration of every detention or correctional facility shall have, in effect and available to all supervisory personnel, written copies of a plan for the protection of all persons in the event of fire, for their evacuation to areas of refuge, and for evacuation from the building when necessary.

A.23.7.1.3 Periodic, coordinated training should be conducted and should involve detention and correctional facility personnel and personnel of the fire department legally committed to serving the facility.

23.7.1.3.1 All employees shall be instructed and drilled with respect to their duties under the plan.

23.7.1.3.2 The plan shall be coordinated with and reviewed by the fire department legally committed to serve the facility.

23.7.1.4 Employees of detention and correctional occupancies shall be instructed in the proper use of portable fire extinguishers and other manual fire suppression equipment.

23.7.1.4.1 Such training shall be provided to new staff promptly upon commencement of duty.

23.7.1.4.2 Refresher training shall be provided to existing staff at not less than annual intervals.

CHAPTER 22 • New

22.7.2 Combustible Personal Property.

Books, clothing, and other combustible personal property allowed in sleeping rooms shall be stored in closable metal lockers or an approved fire-resistant container.

22.7.3 Heat-Producing Appliances.

The number of heat-producing appliances, such as toasters and hot plates, and the overall use of electrical power within a sleeping room shall be controlled by facility administration.

22.7.4* Furnishings, Bedding, and Decorations.

A.22.7.4 Personal property provides combustible contents for fire development. Therefore, adequate controls are needed to limit the quantity and combustibility of the fuels available to burn to reduce the probability of room flashover. The provisions of 22.7.4 will not, by themselves, prevent room flashover if personal property controls are not provided.

22.7.4.1 Draperies and curtains, including privacy curtains, in detention and correctional occupancies, shall be in accordance with the provisions of 10.3.1.

22.7.4.2 Reserved.

22.7.4.3 Reserved.

22.7.4.4 Combustible decorations shall be prohibited in any detention or correctional occupancy unless flame-retardant.

22.7.4.5 Wastebaskets and other waste containers shall be of noncombustible or other approved materials. Waste containers with a capacity exceeding 76 L (20 gal) shall be provided with a noncombustible lid or lid of other approved material.

22.7.5 Keys.

All keys necessary for unlocking doors installed in a means of egress shall be individually identified by both touch and sight.

CHAPTER 23 • Existing

23.7.2 Combustible Personal Property.

Books, clothing, and other combustible personal property allowed in sleeping rooms shall be stored in closable metal lockers or an approved fire-resistant container.

23.7.3 Heat-Producing Appliances.

The number of heat-producing appliances, such as toasters and hot plates, and the overall use of electrical power within a sleeping room shall be controlled by facility administration.

23.7.4* Furnishings, Bedding, and Decorations.

A.23.7.4 Personal property provides combustible contents for fire development. Therefore, adequate controls are needed to limit the quantity and combustibility of the fuels available to burn to reduce the probability of room flashover. The provisions of 23.7.4 will not, by themselves, prevent room flashover if personal property controls are not provided.

23.7.4.1 Draperies and curtains, including privacy curtains, in detention and correctional occupancies, shall be in accordance with the provisions of 10.3.1.

23.7.4.2 Newly introduced upholstered furniture within detention and correctional occupancies shall be tested in accordance with the provisions of 10.3.2(2) and 10.3.3.

23.7.4.3* Newly introduced mattresses within detention and correctional occupancies shall be tested in accordance with the provisions of 10.3.2(3) and 10.3.4.

A.23.7.4.3 Mattresses used in detention and correctional facilities should be evaluated with regard to the fire hazards of the environment. The potential for vandalism and excessive wear and tear also should be taken into account when evaluating the fire performance of the mattress.

23.7.4.4 Combustible decorations shall be prohibited in any detention or correctional occupancy unless flame-retardant.

23.7.4.5 Wastebaskets and other waste containers shall be of noncombustible or other approved materials. Waste containers with a capacity exceeding 76 L (20 gal) shall be provided with a noncombustible lid or lid of other approved material.

23.7.5 Keys.

All keys necessary for unlocking doors installed in a means of egress shall be individually identified by both touch and sight.

CHAPTER 22 • New

22.7.6 Portable Space-Heating Devices.

Portable space-heating devices shall be prohibited in all detention and correctional occupancies.

Paragraph 22/23.7.1.2 requires that residents in Use Condition III, Use Condition IV, and Use Condition V facilities be able to notify staff of an emergency. Use Condition IV and Use Condition V facilities rely on staff action to release locks to allow residents to leave their rooms; Use Condition III, Use Condition IV, and Use Condition V facilities rely on staff action to release locks to allow residents to move to an adjacent smoke compartment. The staff needs to be made aware of fire conditions early in a fire. Thus, in case residents discover a fire before automatic detection devices are initiated, they need a means of notifying staff.

A properly designed and well-tested fire emergency plan, as required by 22/23.7.1.3, is important in detention and correctional occupancies where residents depend heavily on staff performance for safety under fire conditions.

The provisions of 22/23.7.4 make use of the menu of provisions in Section 10.3 that apply to furnishings and contents, particularly those that address upholstered furniture and mattresses. Nevertheless, to prevent the occurrence of room flashover in the small room spaces characteristic of detention and correctional occupancies, the control of combustible personal property is also very important.

The provisions of 22/23.7.4.1 through 22/23.7.4.5—and the corresponding provisions applicable to health care occupancies—present the most vigorous regulations of contents and furnishings by this Code. It is appropriate that this be done for detention and correctional occupancies in consideration of the protect-in-place strategy required of this occupancy by the Code and the reluctance of staff to unlock doors to allow residents to move to the outside.

CHAPTER 23 • Existing

23.7.6 Portable Space-Heating Devices.

Portable space-heating devices shall be prohibited in all detention and correctional occupancies.

Draperies and curtains must be flame resistant. Paragraphs 23.7.4.2 and 23.7.4.3 require newly introduced upholstered furniture and mattresses to be resistant to cigarette ignition and have limited rates of heat release if the space is not sprinklered. Paragraphs 22.7.4.2 and 22.7.4.3 are shown as reserved because new detention and correctional occupancies are required to be sprinklered; in a sprinklered detention and correctional occupancy space, neither upholstered furniture nor mattresses are regulated on the assumption that the sprinklers will prevent room flashover.

CHAPTER 24

One- and Two-Family Dwellings

Although most people feel safest in their homes, fire deaths in the home account for some 65 percent of all fatalities attributable to fire in the United States. Chapter 24 highlights a number of factors that significantly mitigate the fire problem. A key and unique component that is addressed in this chapter, and that is selectively applied to the other residential chapters, is the means of escape (see Section 24.2). The concept of means of escape focuses on providing a second way out of an occupied room or space within a living unit, regardless of whether it is a single family home or a dwelling unit within an apartment building. Means of escape features do not need to meet the high standards and criteria that apply to the means of egress. In short, means of escape is an important yet broadly applied concept that is intended to reduce the chance of occupants becoming trapped in a room or space if the primary egress route is unavailable.

As in other occupancy chapters, the provisions of Chapter 24 achieve their intended level of safety by regulating the interior wall and ceiling finish and mandating the installation of smoke alarms. As is the case in other residential occupancies, a few carefully implemented features greatly improve the safety of occupants.

Section 24.1 General Requirements

24.1.1 Application.

24.1.1.1* The requirements of this chapter shall apply to one- and two-family dwellings, which shall include those buildings containing not more than two dwelling units in which each dwelling unit is occupied by members of a

single family with not more than three outsiders, if any, accommodated in rented rooms.

A.24.1.1.1 The *Code* specifies that wherever there are three or more living units in a building, the building is considered an apartment building and is required to comply with either Chapter 30 or Chapter 31, as appropriate. A townhouse unit is considered to be an apartment building if there are three or more units in the building. The type of wall required between units in order to consider them as separate buildings is normally established by the authority having jurisdiction. If the units are separated by a wall of sufficient fire resistance and structural integrity to be considered as separate buildings, then the provisions of Chapter 24 apply to each townhouse. Condominium is a form of ownership, not occupancy; for example, there are condominium warehouses, condominium apartments, and condominium offices.

The provisions of 24.1.1.1 state that, in one- and two-family dwellings, each dwelling unit can be “occupied by members of a single family with not more than three outsider.” The *Code* does not define the term *family*. The definition of *family* is subject to federal, state, and local regulations and might not be restricted to a person or a couple (two people) and their children. The following examples aid in differentiating between a single-family dwelling and a lodging or rooming house:

- (1) An individual or a couple (two people) who rent a house from a landlord and then sublease space for up to three individuals should be considered a family renting to a maximum of three outsiders, and the house should be regulated as a single-family dwelling in accordance with Chapter 24.
- (2) A house rented from a landlord by an individual or a couple (two people) in which space is subleased to four or more individuals, but not more than 16, should be

considered and regulated as a lodging or rooming house in accordance with Chapter 26.

- (3) A residential building that is occupied by four or more individuals, but not more than 16, each renting from a landlord, without separate cooking facilities, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.

Considerable debate has centered on the term *family*. It is not the intent of 24.1.1.1 to define the term; however, A.24.1.1.1 provides assistance in determining where the term is inappropriate and another chapter of the *Code* is to be used. If more than three outsiders are accommodated in a dwelling unit, the occupancy should be classified as a lodging or rooming house and should meet the requirements of Chapter 26. The reasoning behind this classification guideline is that outsiders do not tend to keep each other as informed about conditions within the building and more often keep their room doors closed when occupying their rooms than do family members. The lack of communication and reduced openness and awareness justify the additional alarm system, vertical opening, and corridor wall and door requirements that apply to lodging or rooming houses.

24.1.1.2 The requirements of this chapter shall apply to new buildings and to existing or modified buildings according to the provisions of 1.3.1 of this *Code*.

24.1.2 Multiple Occupancies.

24.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

24.1.2.2 No dwelling unit of a residential occupancy shall have its sole means of egress pass through any nonresidential occupancy in the same building.

24.1.2.3 Multiple dwelling units of a residential occupancy shall be permitted to be located above a nonresidential occupancy only where one of the following conditions exists:

- (1) Where the dwelling unit of the residential occupancy and exits therefrom are separated from the nonresidential occupancy by construction having a fire resistance rating of not less than 1 hour.
- (2) Where the nonresidential occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (3) Where the nonresidential occupancy is protected by an automatic fire detection system in accordance with Section 9.6.

One- and two-family dwellings are commonly found above stores, offices, and restaurants. Locating these occupancies in proximity to each other presents a life safety challenge for the occupants of the residential dwellings. The typical configuration of these buildings creates the potential for a significant time lapse before occupants of the residential dwellings become aware of an emergency in another part of the building and take the necessary action. The provisions of 24.1.2.2 and 24.1.2.3 are intended to provide added protection for the residential occupancy during that lapse. Therefore, these requirements are intended to apply wherever such a mixture of occupancies exists, whether in new construction or existing buildings.

24.1.3 Definitions.

Terms applicable to this chapter are defined in Chapter 3 of this *Code*; where necessary, other terms are defined in the text.

24.1.4 Classification of Occupancy.

See 24.1.1.1.

24.1.5 Classification of Hazard of Contents.

The contents of residential occupancies shall be classified as ordinary hazard in accordance with 6.2.2.

NFPA 13, *Standard for the Installation of Sprinkler Systems*¹, classifies the contents of a dwelling as “light” hazard for the purpose of designing automatic sprinkler systems. NFPA 13 classifies hazard on the basis of the challenge to the extinguishing capability of the automatic sprinkler system (light); hazard classification in this *Code* is based on the threat to life or life safety (ordinary).

24.1.6 Minimum Construction Requirements.

(No special requirements.)

24.1.7 Occupant Load.

(No requirements.)

Section 24.2* Means of Escape Requirements

A.24.2 The phrase “means of escape” indicates a way out of a residential unit that does not conform to the strict definition of means of egress but does meet the intent of

the definition by providing an alternative way out of a building. (See *means of escape* in 3.3.137.)

24.2.1 General.

The provisions of Chapter 7 shall not apply to means of escape unless specifically referenced in this chapter.

In 24.2.1, the term *means of escape* is used in contrast to the usual *means of egress*, because the escape paths required for a dwelling need not be the true exit access, exit, and exit discharge required for public buildings. The concept of means of escape is fully developed in Section 24.2. The intent is that at least one means of escape (primary) be of a high degree of quality that is similar to the means of egress components described in Chapter 7. Homes rarely have an exit arrangement complying with Chapter 7. The door through which occupants normally enter and leave the dwelling can typically serve as the primary means of escape. Another way out of the dwelling, such as through a large, operable window, is needed as the secondary means of escape. A secondary means of escape needs to be available for use if the route involving the primary means of escape becomes unusable during a fire or similar emergency.

Only the means of escape requirements of Chapter 24 are required to be met, unless Chapter 24 specifically references a means of egress provision of Chapter 7. For example, 24.2.5.1 mandatorily references the use of the provisions of 7.2.2 and 7.2.5 for stairs, ramps, and associated guards and handrails.

24.2.2 Number and Types of Means of Escape.

24.2.2.1 Number of Means of Escape.

24.2.2.1.1 In dwellings or dwelling units of two rooms or more, every sleeping room and every living area shall have not less than one primary means of escape and one secondary means of escape.

See the definition of *living area* in 3.3.16.5.

The benefit of providing two means of escape is based on the same concept as the requirements for two means of egress in other occupancies. Two separate means of escape reduce the probability of a person becoming trapped if one of the paths is obstructed by fire.

24.2.2.1.2 A secondary means of escape shall not be required where one of the following conditions are met:

- (1) The bedroom or living area has a door leading directly to the outside of the building at or to grade level.
- (2) The dwelling unit is protected throughout by an approved automatic sprinkler system in accordance with 24.3.5.

The sprinkler system referred to in 24.2.2.1.2(2) must be installed in accordance with one of the following:

- (1) NFPA 13, *Standard for the Installation of Sprinkler Systems*
- (2) NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*²
- (3) NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*³

The sprinkler provision in 24.2.2.1.2(2) is probably the most practical and common way to avoid providing secondary means of escape. The sprinkler provision might be used, for example, in an underground dwelling without windows or in a dwelling where the windows do not comply with 24.2.2.3(C).

24.2.2.2 Primary Means of Escape. The primary means of escape shall be a door, stairway, or ramp providing a means of unobstructed travel to the outside of the dwelling unit at street or ground level.

A door, stairway, or ramp providing a means of unobstructed travel to the outside is usually provided for the functional purposes of entering and leaving the dwelling. Therefore, the requirement for a primary means of escape is almost automatically met in a typical dwelling.

Where an attic bedroom is accessible only by means of a trap door or folding ladder, the room does not meet the *Code* requirements for primary means of escape. Such bedrooms must be provided with direct stair access. See 24.2.5.6.

The primary means of escape from a dwelling unit in an apartment building, or from a guest room in a hotel, is permitted to lead to a means of egress, such as a corridor leading to exit stairs, complying with Chapter 7.

24.2.2.3* Secondary Means of Escape. The secondary means of escape, other than existing approved means of escape, shall be one of the means specified in 24.2.2.3(A) through 24.2.2.3(C).

(A) It shall be a door, stairway, passage, or hall providing a way of unobstructed travel to the outside of the dwelling at street or ground level that is independent of and remote from the primary means of escape.

(B) It shall be a passage through an adjacent nonlockable space, independent of and remote from the primary means of escape, to any approved means of escape.

(C)* It shall be an outside window or door operable from the inside without the use of tools, keys, or special effort and shall provide a clear opening of not less than 0.53 m² (5.7 ft²). The width shall be not less than 510 mm (20 in.), and the height shall be not less than 610 mm (24 in.). The bottom of the opening shall be not more than 1120 mm (44 in.) above the floor. Such means of escape shall be acceptable where one of the following criteria are met:

- (1) The window shall be within 6100 mm (240 in.) of grade.
- (2) The window shall be directly accessible to fire department rescue apparatus as approved by the authority having jurisdiction.
- (3) The window or door shall open onto an exterior balcony.
- (4) Windows having a sill height below the adjacent ground level shall be provided with a window well meeting the following criteria:
 - (a) The window well shall have horizontal dimensions that allow the window to be fully opened.
 - (b) The window well shall have an accessible net clear opening of not less than 0.82 m² (9 ft²) with a length and width of not less than 915 mm (36 in.).
 - (c) A window well with a vertical depth of more than 1120 mm (44 in.) shall be equipped with an approved permanently affixed ladder or with steps meeting the following criteria:
 - i. The ladder or steps shall not encroach more than 150 mm (6 in.) into the required dimensions of the window well.
 - ii. The ladder or steps shall not be obstructed by the window.

A.24.2.2.3(C) A window with dimensions of 510 mm × 610 mm (20 in. × 24 in.) has an opening of 0.31 m² (3.3 ft²), which is less than the required 0.53 m² (5.7 ft²). Therefore, either the height or width needs to exceed the minimum requirement to provide the required clear area. [See Figure A.24.2.2.3(C).]

(D) Ladders or steps that comply with the requirements of 24.2.2.3(C)(4)(c) shall be exempt from the requirements of 7.2.2.

A.24.2.2.3 For use of emergency escape devices, refer to A.7.1.1.

The purpose of the secondary means of escape is to provide an occupant with an alternate escape route

when fire or smoke blocks the normal means of escape from the dwelling unit. The three types of secondary means of escape permitted by 24.2.2.3 follow:

(a) As stated in 24.2.2.3(A), the door, stairway, passage, or hall serving as the secondary means of escape must be independent of, and remote from, the primary means of escape required by 24.2.2.2. Exhibit 24.1 illustrates a dwelling unit where none of the windows complies with the requirements of 24.2.2.3(C) and a nonlockable door is located between bedrooms 2 and 3. As a result, both the primary and secondary means of escape from bedrooms 2 and 3 lead into the same hallway. A fire in or near this hallway would affect both means of escape for these rooms. Note that if the hallway within the dwelling unit is separated from all living spaces and leads to

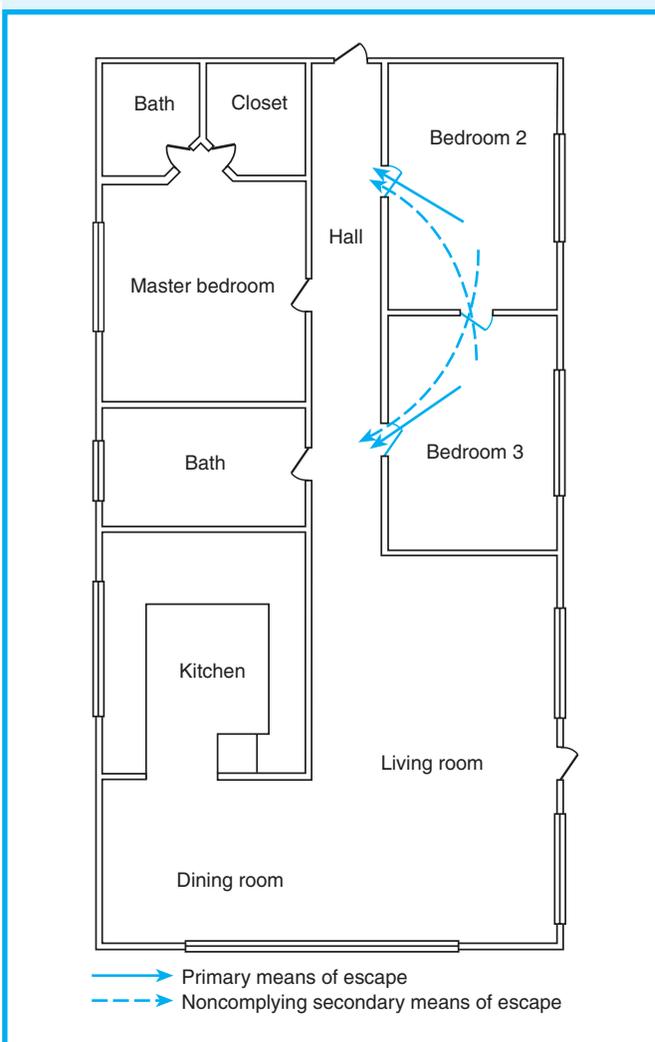

Exhibit 24.1 Noncomplying secondary means of escape arrangement.

two separate ways out of the dwelling unit, it might be judged that the hallway does, in fact, lead to two separate, independent, and remote means of escape.

Two doors leading out of a sleeping room might not be practical or effective in most single-family dwellings. In the apartment illustrated in Exhibit 24.2, bedrooms 1 and 2 each have a window (WNC) that does not comply as a secondary means of escape. In bedroom 1, a door that meets the criteria of being independent and remote from the main door provides the secondary means of escape. Bedrooms 2 and 3 are provided with compliant windows (W) as their secondary means of escape, and the living space has a compliant sliding glass door to the balcony.

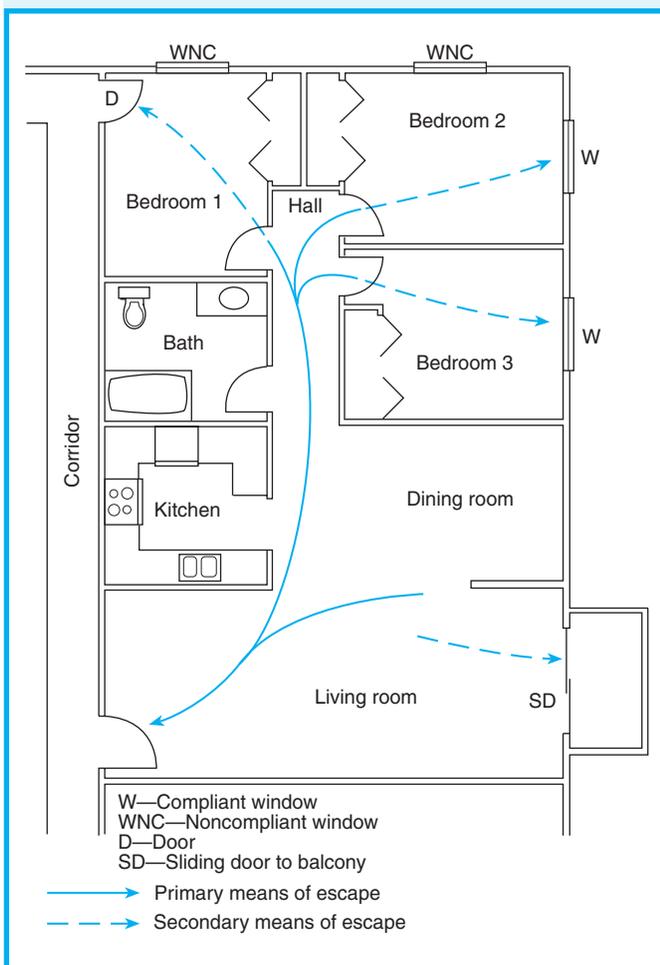

Exhibit 24.2 Secondary means of escape arrangement complying with 24.2.2.

(b) Passage through an adjacent nonlockable space, as addressed by 24.2.2.3(B), is illustrated in Exhibit 24.3. In this illustration, bedroom 3 has a win-

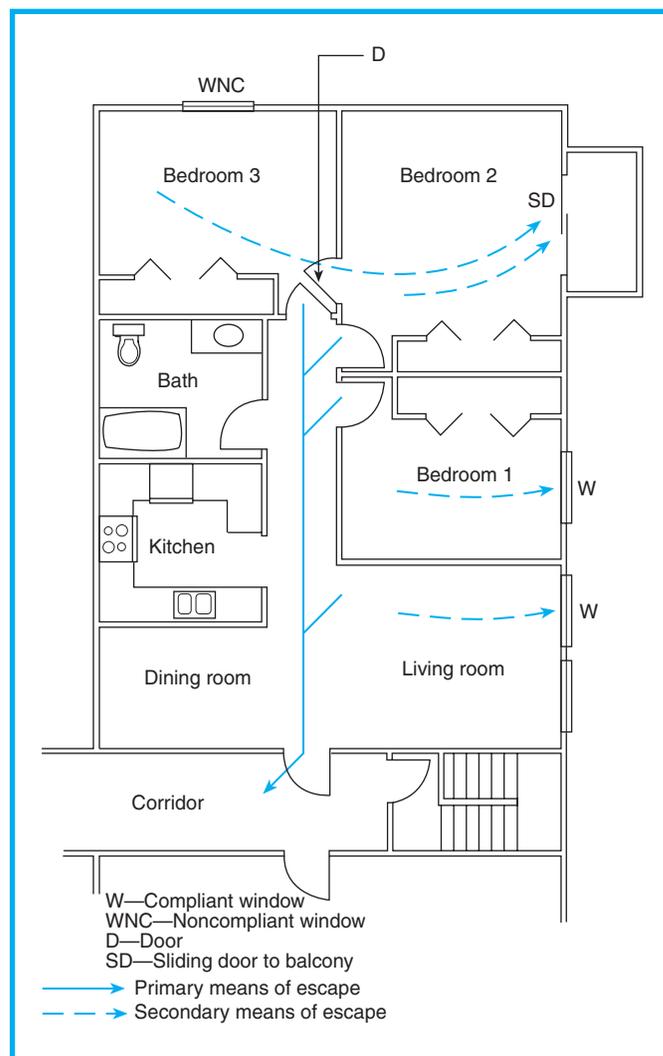

Exhibit 24.3 Alternative secondary means of escape arrangement complying with 24.2.2.

dow that does not comply with the provisions of 24.2.2.3(C); however, there is a compliant door between bedrooms 3 and 2 that provides a secondary means of escape using the compliant sliding door in bedroom 2 to the balcony.

(c) The use of an operable window providing an opening of the minimum dimensions specified in 24.2.2.3(C) is the secondary means of escape most often provided. Exhibit 24.4 illustrates the minimum dimensions required for escape windows. Note that a window providing only the minimum width and minimum height dimensions specified by 24.2.2.3(C) does not provide the required minimum area; if either the minimum width or minimum height dimension is used, the other dimension must be increased

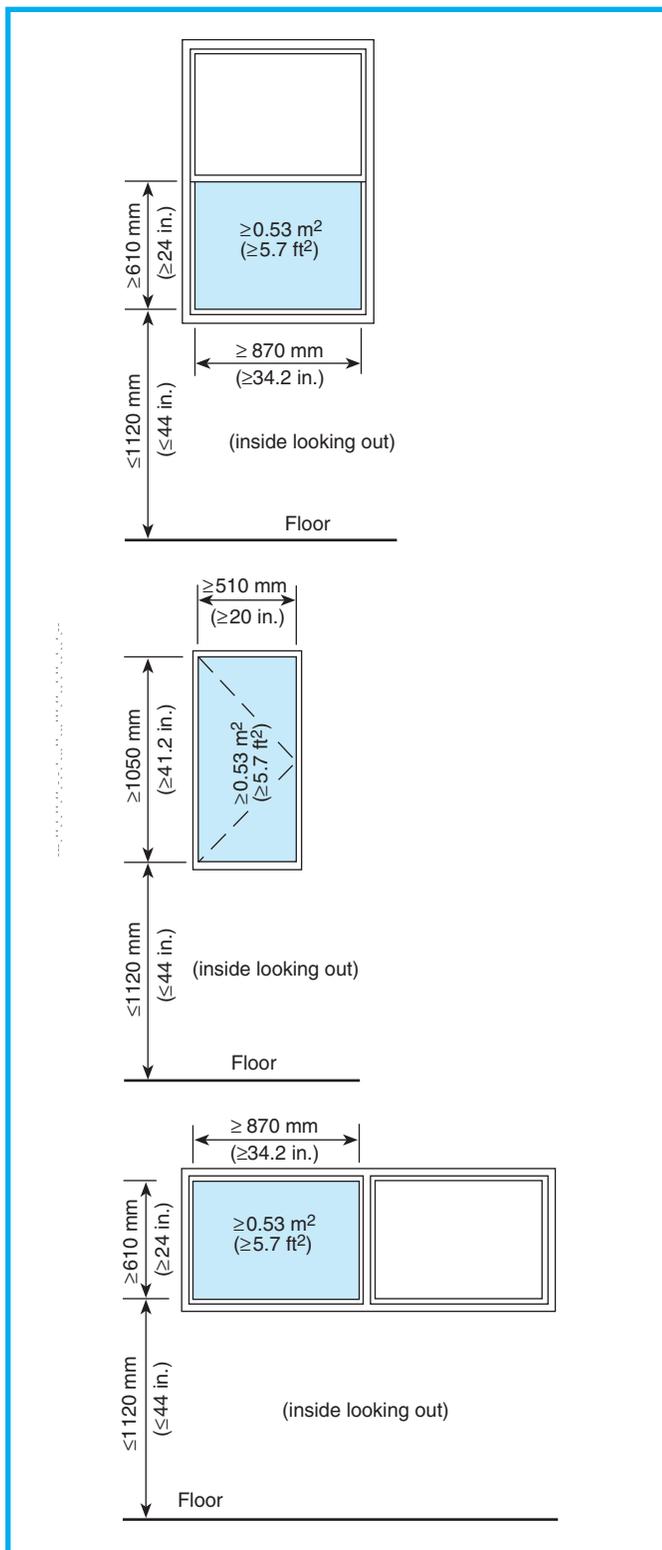

Exhibit 24.4 Escape window minimum opening dimensions.

to achieve the minimum area requirement. This, too, is illustrated in Exhibit 24.4.

The outside window addressed in 24.2.2.3(C) must comply with one of the following four accessibility arrangements.

- (1) The first arrangement makes it possible for an occupant to drop from the window because the window must be within 6100 mm (240 in.) of grade.
- (2) The second arrangement relies on the fire department to rescue an occupant from a window that is within reach of rescue apparatus. Such rescue can be achieved either by means of truck-mounted aerial ladders or ground ladders or by other means acceptable to the authority having jurisdiction.
- (3) The third arrangement allows an occupant to reach an exterior balcony to breathe fresh air while awaiting either rescue or fire extinguishment. This method could be used where the balcony is not within reach of rescue apparatus. See Exhibits 24.2 and 24.3 for examples of secondary means of escape utilizing balconies.
- (4) The fourth arrangement recognizes the increasing trend of developing or converting basements into living space such as home offices, playrooms, or sleeping areas. Fire in these areas or the areas above them could easily block the primary means of escape, which is usually a single stair to the upper level. This option provides requirements for the size of the window well, in addition to the window size, to provide sufficient space to operate the window and move up to grade level.

Existing secondary means of escape—approved by the authority having jurisdiction—are permitted by 24.2.2.3 to continue to be used. This provision limits the impact on existing buildings unless the means of escape is of extremely poor quality.

24.2.2.4 In buildings, other than existing buildings and other than those protected throughout by an approved, supervised automatic sprinkler system in accordance with 24.3.5, every story more than 185 m² (2000 ft²) in area within the dwelling unit shall be provided with two primary means of escape remotely located from each other.

24.2.3 Arrangement of Means of Escape.

Any required path of travel in a means of escape from any room to the outside shall not pass through another room or apartment not under the immediate control of the occupant

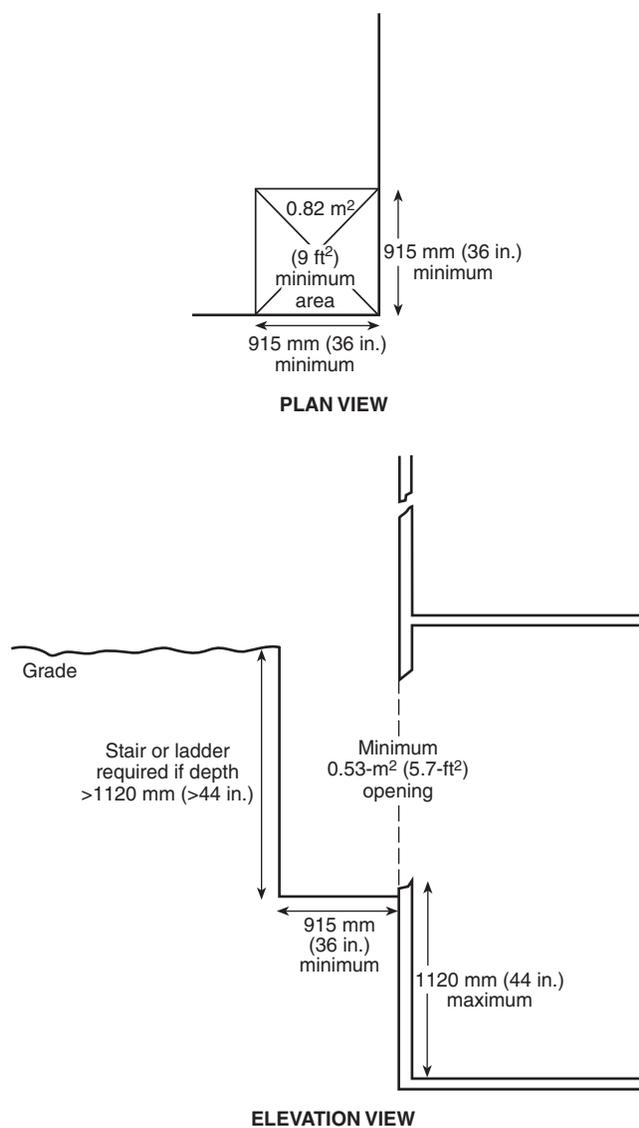

FIGURE A.24.2.2.3(C) Escape Window Utilizing a Window Well.

of the first room or through a bathroom or other space subject to locking.

A means of escape that relies on travel through an adjacent space might not be usable if the door separating the spaces is locked against escape. One- and two-family dwellings can have rooms occupied by up to three outsiders or could be arranged so that a second family must escape through the living space of the first family. This arrangement is often found in older homes that were not originally built as duplexes but that were later converted to this arrangement.

Any spaces through which escape will occur must be under the control of the person escaping.

24.2.4 Doors.

24.2.4.1 Doors in the path of travel of a means of escape, other than bathroom doors in accordance with 24.2.4.2, shall be not less than 710 mm (28 in.) wide.

24.2.4.2 Bathroom doors shall be not less than 610 mm (24 in.) wide.

Although Chapter 7 requires 810-mm (32-in.) clear width doors in new construction and 710-mm (28-in.) wide doors in existing buildings, 24.2.4.1 allows the use of 710-mm (28-in.) wide doors [610 mm (24 in.) for bathrooms] in both new and existing one- and two-family dwellings. This measurement, as illustrated in Exhibit 24.5, is a leaf width measurement of the door, not a clear width measurement of the door opening. In addition to one- and two-family dwellings, this requirement applies to doors within the guest rooms and guest suites of lodging or rooming houses, hotels and dormitories, and dwelling units of apartment buildings.

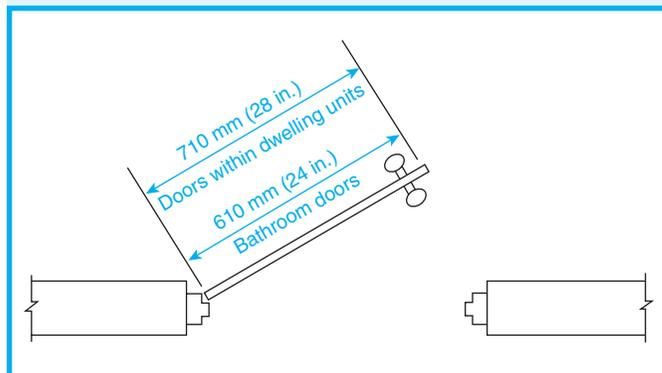

Exhibit 24.5 Minimum width of doors within a dwelling unit.

The 710-mm (28-in.) wide doors specified in 24.2.4.1 are used in some dwelling designs, but ease of access and the need to move furniture and appliances usually dictate a larger size.

24.2.4.3 Doors shall be not less than 1980 mm (78 in.) in nominal height.

24.2.4.4 Every closet door latch shall be such that children can open the door from inside the closet.

24.2.4.5 Every bathroom door shall be designed to allow opening from the outside during an emergency when locked.

During a fire, children will often seek refuge in bathrooms and closets. The provisions of 24.2.4.4 and 24.2.4.5 for releasing the latch from the inside and the lock from the outside of closet and bathroom doors allow for escape and facilitates rescue by parents or emergency response personnel.

24.2.4.6 Doors shall be swinging or sliding.

24.2.4.7* No door in any means of escape shall be locked against egress when the building is occupied. All locking devices that impede or prohibit egress or that cannot be easily disengaged shall be prohibited.

A.24.2.4.7 It is the intent of this requirement that security measures, where installed, do not prevent egress.

Dwelling units are prohibited from having any door locked against egress while the dwelling unit is occupied in accordance with 24.2.4.7. This requirement permits a door to have a locking device that allows the door to be opened from within the building for the purpose of escape but that does not allow the door to be opened from outside the building. Ordinary double-cylinder locks and key-operated chain locks do not meet this requirement. Several multiple-death fires have occurred when a door lock could not be released because the key could not be found.

The prohibition on locking applies only to doors or windows that are part of the required means of escape system. Often, the rear door of a dwelling is not part of the required escape system and, therefore, such a door is permitted to be equipped with a double-cylinder key-operated lock.

24.2.4.8 Floor levels at doors in the primary means of escape shall comply with 7.2.1.3, unless otherwise permitted by the following:

- (1) Where the door discharges to the outside or to an exterior balcony or exterior exit access, the floor level outside the door shall be permitted to be one step lower than the inside, but shall not be in excess of 180 mm (7 in.).
- (2) A door at the top of a stair shall be permitted to open directly at a stair, provided that the door does not swing over the stair and the door serves an area with an occupant load of fewer than 50 persons.

24.2.4.9 Forces to open doors shall comply with 7.2.1.4.5.

24.2.4.10 Latching devices for doors shall comply with 7.2.1.5.9.

24.2.5 Stairs, Ramps and Guards.

24.2.5.1 Stairs, ramps, guards, and handrails shall be in accordance with 7.2.2 for stairs, 7.2.2.4 for guards, and 7.2.5 for ramps, as modified by 24.2.5.1.1 through 24.2.5.1.3.

24.2.5.1.1 The provisions of 7.2.2.5, 7.2.5.5, and 7.7.3 shall not apply.

24.2.5.1.2 If serving as a secondary means of escape, stairs complying with the fire escape requirements of Table 7.2.8.4.1(a) or Table 7.2.8.4.1(b) shall be permitted.

24.2.5.1.3 If serving as a secondary means of escape, ramps complying with the existing ramp requirements of Table 7.2.5.2(b) shall be permitted.

Prior to this edition of the *Code*, stairs in dwelling units were permitted to have a modified geometry from that required in Chapter 7; new stairs were previously permitted to have maximum riser heights of 200 mm (7¾ in.) and minimum tread depths of 255 mm (10 in.) The provision to allow for modified tread and riser geometry for new stairs in dwelling units has been removed from the *Code* on the basis of data suggesting stairs not meeting the dimensional criteria in Chapter 7 are less safe to navigate than those that do, under both normal and emergency egress conditions. As such, all new stairs in dwelling units must meet the Chapter 7 dimensional criteria: maximum 180 mm (7 in.) risers and minimum 280 mm (11 in.) treads. Existing stairs are permitted to meet the criteria in Table 7.2.2.2.1(b).

It is important to keep in mind that carpeting might be installed on the stairs following construction of the stair itself, and after the home is occupied. Carpeting might have an adverse impact on the effective tread depth. Exhibit 24.6 illustrates the effect of carpeting on the stepping surface of the stair. Designing the stairs to the minimum geometry is insufficient; consideration must be given to floor coverings. If carpeting is to be installed on stairs, the determination of compliance with the dimensional requirements of the *Code* should be made after it is installed.

24.2.5.2 Interior stairways shall be provided with means capable of providing artificial light at the minimum level specified by 7.8.1.3 for exit stairs, measured at the center of treads and on landing surfaces within 610 mm (24 in.) of step nosings.

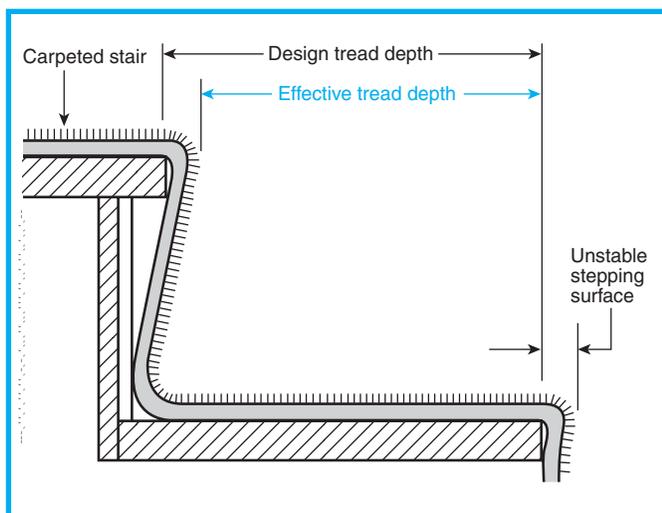

Exhibit 24.6 Effect of carpeting on tread depth.

24.2.5.3 For interior stairways, manual lighting controls shall be reachable and operable without traversing any step of the stair.

24.2.5.4 The clear width of stairs, landings, ramps, balconies, and porches shall be not less than 36 in. (910 mm), measured in accordance with 7.3.2.

24.2.5.5 Spiral stairs and winders in accordance with 7.2.2.2.3 and 7.2.2.2.4 shall be permitted within a single dwelling unit.

24.2.5.6 No sleeping rooms or living areas shall be accessible only by a ladder, a stair ladder, an alternating tread device, or folding stairs or through a trap door.

24.2.6 Hallways.

24.2.6.1 The width of hallways, other than existing approved hallways which shall be permitted to be continued to be used, shall be not less than 910 mm (36 in.).

24.2.6.2 The height of hallways, other than existing approved hallways which shall be permitted to be continued to be used, shall be not less than 2135 mm (84 in.) nominal, with clearance below projections from the ceiling of not less than 2030 mm (80 in.) nominal.

Within the dwelling unit, headroom clearance is regulated only in the hallways. Such regulation helps to ensure that the space above head height can accumulate smoke early in the fire to permit safe escape through the hallway, which will help to prevent the need for occupants to crawl near floor level to avoid the descending smoke layer.

24.2.7 Bulkheads.

24.2.7.1 Bulkhead Enclosures. Where provided, bulkhead enclosures shall provide direct access to the basement from the exterior.

24.2.7.2 Bulkhead Enclosure Stairways. Stairways serving bulkhead enclosures that are not part of the required primary means of escape and that provide access from the outside grade level to the basement shall be exempt from the provisions of 24.2.5.1 when the maximum height from the basement finished floor level to grade adjacent to the stairway does not exceed 2348 mm (96 in.), and the grade level opening to the stairway is covered by a bulkhead enclosure with hinged doors or other approved means.

Section 24.3 Protection

24.3.1 Protection of Vertical Openings.

(No requirements.)

24.3.2 Reserved.

24.3.3 Interior Finish.

24.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

24.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A, Class B, or Class C.

24.3.3.3 Interior Floor Finish. (No requirements.)

24.3.4 Detection, Alarm, and Communications Systems.

Smoke alarms or a smoke detection system shall be provided in accordance with either 24.3.4.1 or 24.3.4.2, as modified by 24.3.4.3.

24.3.4.1 Smoke alarms shall be installed in accordance with 9.6.2.10 in the following locations:

- (1) All sleeping rooms in other than existing one- and two-family dwellings
- (2) Outside of each separate sleeping area, in the immediate vicinity of the sleeping rooms
- (3) On each level of the dwelling unit, including basements

24.3.4.2 Dwelling units shall be protected by an approved smoke detection system in accordance with Section 9.6 and equipped with an approved means of occupant notification.

24.3.4.3 In existing one- and two-family dwellings, approved smoke alarms powered by batteries shall be permitted.

The reference to 9.6.2.10 in 24.3.4.1 requires smoke alarms to be hard-wired into the electrical system of the home or to be plug-in alarms. The provision of 24.3.4.3, which permits battery-powered smoke alarms in existing dwellings, gives dwelling occupants relief from retrofit requirements while providing needed protection. However, occupants of dwellings that use battery-operated smoke alarms must ensure that those alarms are tested and maintained properly. NFPA analysis has shown that 30 percent of smoke alarms were inoperative in homes that had smoke alarms and that had experienced fire. The primary reason for smoke alarm failure is that the battery was removed to avoid nuisance alarms. NFPA public education programs, such as the *Learn Not to Burn*[®] program, are effective tools for promoting proper smoke alarm maintenance.

Regardless of the power source, it is important that smoke alarms be properly located. Exhibits 24.7 and 24.8 illustrate the required locations of the smoke alarms per 24.3.4. Further information on the mounting, location, spacing, and performance of smoke alarms is found in Chapter 8 of *NFPA 72*[®], *National Fire Alarm Code*^{®4}.

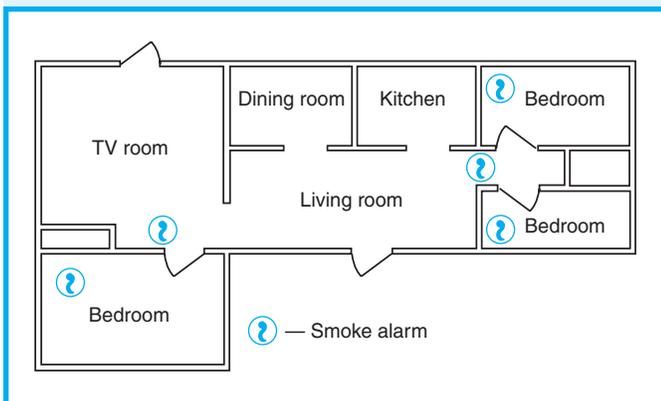

Exhibit 24.7 Required smoke alarm locations.

24.3.5* Extinguishment Requirements.

A.24.3.5 While automatic sprinklers are not required by this Code, they are recognized as an excellent addition to homes to enhance life safety and property protection. Automatic sprinklers can be part of a comprehensive package of fire protection and can assist in the overall master planning of a community. Where all of the buildings within an area are sprinklered, including the single-family dwellings, the response times and personnel of local fire departments can be established at different levels than if the buildings were not sprinklered, saving considerable amounts of tax dollars.

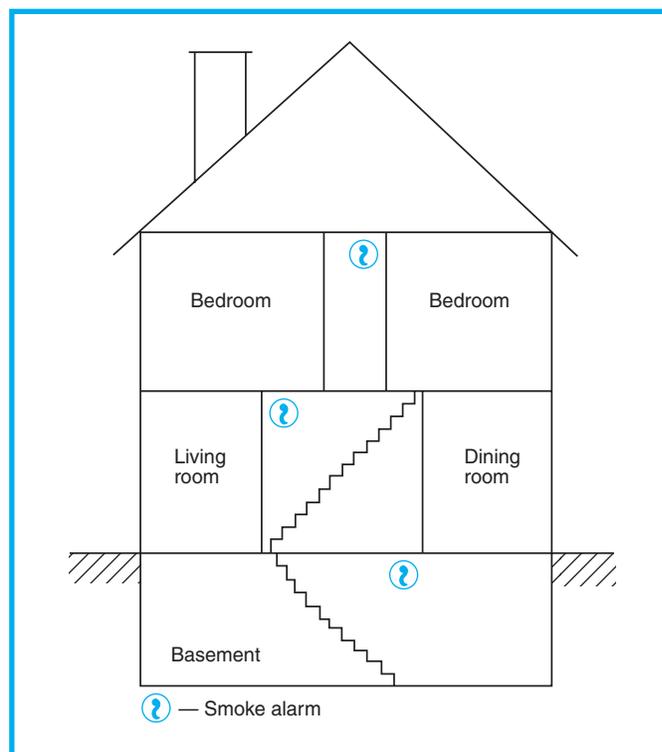

Exhibit 24.8 Required smoke alarm placement per level.

When whole developments are sprinklered, water mains, hydrant spacing, road widths, and building density can be altered to help alleviate the economic impact of the sprinklers.

24.3.5.1 Where an automatic sprinkler system is required or is used as an alternative method of protection, either for total or partial building coverage, the system shall be in accordance with Section 9.7.

24.3.5.2 In buildings up to and including four stories in height, systems in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, and with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, shall also be permitted.

NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, was developed after extensive research that included full-scale fire tests. It introduced the concept of a quick-response residential sprinkler. Unlike its industrial standard spray sprinkler counterpart, which is inherently slow to fuse its relatively

massive eutectic solder element, a quick-response, residential sprinkler operates very quickly once its rated temperature is sensed. Quick-response sprinklers begin to control a fire early in its growth. In addition to being quick to respond, residential sprinklers (as mandated by NFPA 13D) have a specifically designed spray pattern that delivers water to nearly the full height of the walls of small rooms that are typical of residential occupancies.

NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, was first published in 1989. It addresses residential sprinklers, which incorporate the quick-response sprinkler technology described in the preceding paragraph. NFPA 13R thus extends the technological and economic benefits of an NFPA 13D-type system to larger residential buildings, while requiring additional provisions that are commensurate with increased building size that will help to ensure improved protection against injury and life loss to building residents—including those occupying the room of fire origin. Note that where one- and two-family dwellings are protected with automatic sprinkler systems, they are permitted to meet the requirements of NFPA 13, NFPA 13D, or NFPA 13R.

Section 24.4 Reserved

Section 24.5 Building Services

24.5.1 Heating, Ventilating, and Air Conditioning.

24.5.1.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

24.5.1.2 Unvented fuel-fired heaters shall not be used unless they are listed and approved.

.....

CHAPTER 25

Reserved

Typically, the occupancy chapters are paired so that the even-numbered chapter in the pair addresses new facilities of the occupancy type and the odd-numbered chapter addresses existing facilities of the occupancy type. Chapter 24, which precedes this chapter, addresses both new and existing one- and two-family dwellings in a single chapter. Chapter 25 has been reserved to permit the chapter on lodging and rooming houses to be assigned an even number (that is, Chapter 26). The reserved chapter number might be used at a future date if the requirements for one- and two-family dwellings are split into a pair of chapters—one for new construction and one for existing buildings.

CHAPTER 26

Lodging or Rooming Houses

Chapter 26 addresses the requirements for both new and existing lodging or rooming houses. These facilities provide sleeping accommodations for 16 or fewer occupants on a transient basis. While some users of the *Code* might confuse lodging or rooming facilities with a hotel occupancy—or a board and care facility—the primary differences among the occupancies center on the total number of occupants served and the nature of any personal care that is provided. While some of these facilities might provide what appears to be longer-term, daily living accommodations, other facilities, such as a bed and breakfast facility, might serve on a short-term basis. If a bed-and-breakfast facility provides accommodations for more than 16 occupants, it would be appropriate to use Chapters 28 and 29 for hotels and dormitories to evaluate the requisite life safety features.

Commentary Table 26.1 is a guide to the appro-

priate occupancy chapter for multi-tenant residential occupancies.

Section 26.1 General Requirements

26.1.1 Application.

26.1.1.1* The requirements of this chapter shall apply to buildings that provide sleeping accommodations for 16 or fewer persons on either a transient or permanent basis, with or without meals, but without separate cooking facilities for individual occupants, except as provided in Chapter 24.

A.26.1.1.1 Bed and breakfast occupancies with more than 3, but fewer than 16, occupants are considered lodging and rooming houses.

Commentary Table 26.1 Comparative Factors for Classification of Residential Occupancies

Factor	Chapter 26 Lodging or Rooming Houses	Chapters 28 and 29 Hotels and Dormitories	Chapters 30 and 31 Apartment Buildings	Chapters 32 and 33 Residential Board and Care
Occupants of a transient nature?	Yes	Yes	No	No
Number of occupants in facility?	16 or fewer	More than 16	As few as 3. Application is based on presence of 3 or more independent living units	4 or more
Personal care services provided?	No	No	No	Yes

If sleeping accommodations for more than 16 people are provided, the occupancy should be classified as a hotel or dormitory. The reference to Chapter 24 concerns the provision that allows rooms to be occupied by a maximum of three outsiders in addition to family members in one- and two-family dwellings without changing the occupancy classification. Many of the facilities that house more than three outsiders but fewer than 16 people ordinarily would not be considered lodging or rooming houses but, nevertheless, do meet the definition—for example, a fire station that has a bunk room. A fire station with bunking facilities would normally be considered a mixed occupancy, depending on the arrangement of the facility. For example, the fire station in Exhibit 26.1 would be classified as a mixed occupancy because it contains assembly, business, lodging or rooming, industrial, and storage occupancies. By applying the most restrictive requirements, this building would require automatic sprinklers via the provisions of 26.3.5.1. If additional exits are added to provide separate means of egress for the bunk room, equipment shop, assembly hall, and apparatus bay and the various uses are separated in accordance with 6.1.14.4, as shown in Exhibit 26.2, the building is considered a multiple occupancy with separated uses, and the provisions for the occupancy within each space would be applied separately.

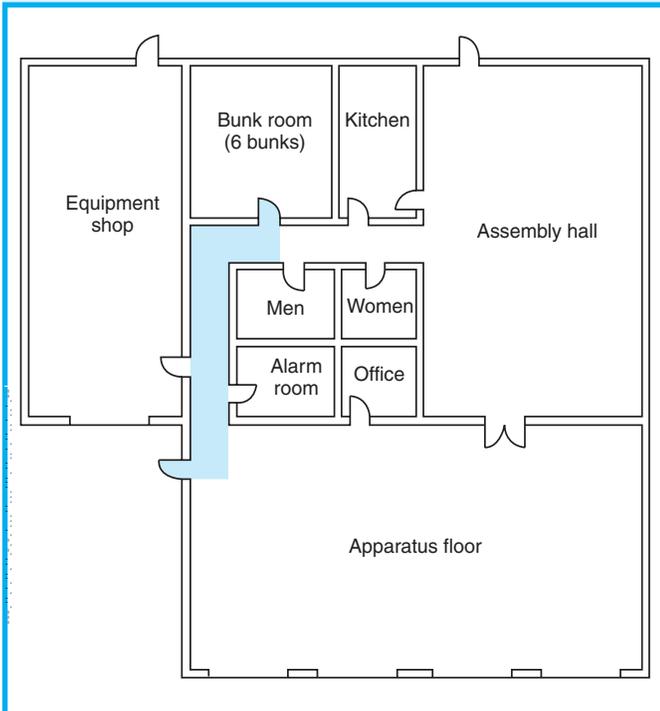

Exhibit 26.1 Fire station that is a mixed occupancy.

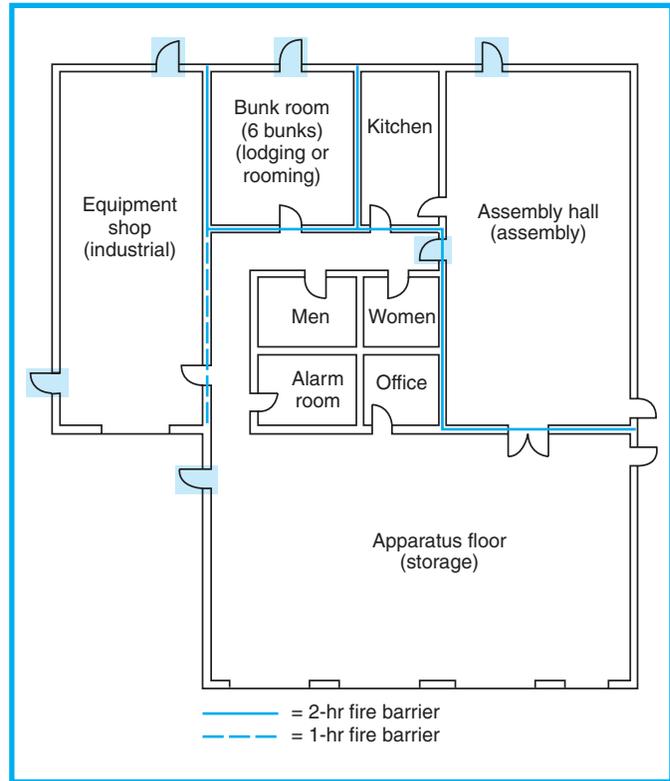

Exhibit 26.2 Fire station that is a multiple occupancy with separated uses.

26.1.1.2 The requirements of this chapter shall apply to new buildings and to existing or modified buildings according to the provisions of 1.3.1 of this Code.

26.1.2 Multiple Occupancies.

26.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

26.1.2.2 No lodging or rooming house shall have its sole means of egress pass through any nonresidential occupancy in the same building.

26.1.2.3 Lodging or rooming houses shall be permitted to be located above a nonresidential occupancy only where one of the following conditions exists:

- (1) Where the lodging or rooming house and exits therefrom are separated from the nonresidential occupancy by construction having a fire resistance rating of not less than 1 hour.
- (2) Where the nonresidential occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7.
- (3) Where the lodging or rooming house is located above a nonresidential occupancy, and the nonresidential occu-

pancy is protected by an automatic fire detection system in accordance with Section 9.6.

A nonresidential occupancy located below a lodging or rooming house presents a life safety challenge for the occupants of the residential space. The typical configuration of these buildings creates the potential for a significant time lapse before occupants of the residential occupancy become aware of an emergency in another part of the building and take the necessary action. The provisions of 26.1.2.2 and 26.1.2.3 are intended to provide added protection for the residential occupancy during that lapse. Therefore, these requirements are intended to apply wherever this mixture of occupancies exists, whether in new construction or in existing buildings.

26.1.3 Definitions.

Terms applicable to this chapter are defined in Chapter 3 of this *Code*; where necessary, other terms are defined in the text.

26.1.4 Classification of Occupancy.

See 26.1.1.1.

26.1.5 Classification of Hazard of Contents.

The contents of residential occupancies shall be classified as ordinary hazard in accordance with 6.2.2.

NFPA 13, *Standard for the Installation of Sprinkler Systems*¹, classifies the contents of a lodging or rooming house as light hazard for the purpose of designing automatic sprinkler systems. The difference in classification in the *Code* is based on the threat to life or life safety (ordinary), as opposed to the challenge to the extinguishing capability of the automatic sprinkler system (light).

26.1.6 Minimum Construction Requirements.

(No special requirements.)

26.1.7 Occupant Load.

See 26.1.1.1.

Section 26.2 Means of Escape Requirements

26.2.1 Number and Types of Means of Escape.

26.2.1.1 Primary Means of Escape.

26.2.1.1.1 Every sleeping room and living area shall have access to a primary means of escape complying with Chapter 24 and located to provide a safe path of travel to the outside.

26.2.1.1.2 Where the sleeping room is above or below the level of exit discharge, the primary means of escape shall be an interior stair in accordance with 26.2.2, an exterior stair, a horizontal exit in accordance with 7.2.4, or an existing fire escape stair in accordance with 7.2.8.

The concept of means of escape has been fully developed in Chapter 24. Provisions for means of escape—rather than means of egress—are used in 26.2.1.1.1 and 26.2.1.1.2 because the escape paths required for a lodging or rooming house are more similar to those provided for a dwelling than those for public buildings. The *Code* requires at least one means of escape from levels above or below the level of exit discharge to be an enclosed interior stair, an exterior stair, a horizontal exit, or an existing fire escape. The intent is that at least one means of escape (primary) be of a high degree of quality that is similar to the means of egress components described in Chapter 7. Most lodging or rooming houses are converted homes that rarely have an exit arrangement complying with Chapter 7. However, the *Code* recognizes the issue of public liability associated with lodging guests and includes requirements in Chapter 26 that provide a level of escape quality higher than that normally found in a single-family home.

The protection of the primary means of escape as required by 26.2.1.1—often accomplished by the protection of vertical openings in accordance with 26.2.2 and 26.3.1—is the major distinction between the requirements applicable to one- and two-family dwellings and those applicable to lodging or rooming houses. Another distinction is the requirement in 26.3.5.1 for the provision of automatic sprinklers in new lodging or rooming houses. By protecting the escape path from exposure to unprotected vertical openings—such as the unenclosed stairs normally found in single-family dwellings—the *Code* helps to ensure that the occupants of a lodging or rooming house can reach a point of safety. This protection is important, because the occupants of a lodging or rooming house characteristically occupy their rooms with the doors closed. Therefore, they lack the awareness of emergency conditions that is experienced by members of a family who live together within a dwelling where doors are usually open.

Exhibits 26.3 through 26.8 illustrate six possible methods of complying with the means of escape pro-

visions of 26.2.1.1, as affected by the provisions of 26.2.2 and 26.3.1.

26.2.1.2 Secondary Means of Escape. In addition to the primary route, each sleeping room and living area shall have a second means of escape in accordance with 24.2.2, unless the sleeping room or living area has a door leading directly outside the building with access to grade or to a stairway that meets the requirements for exterior stairs in 26.2.1.1.

The *Code* specifies that the secondary means of escape must comply with 24.2.2. Secondary means of escape is exempted by 24.2.2.1.2 if the building is sprinklered in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*; NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*²; or NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*³. Because most new lodging or rooming houses are required to be protected with sprinklers in accordance with 26.3.5.1, secondary means of escape will seldom be required. Where existing, nonsprinklered lodging or rooming houses are deficient with respect to secondary means of escape, protection of vertical openings, or required door closers on sleeping room doors, sprinklering provides a viable alternative to correcting such deficiencies individually.

26.2.1.3 Two Primary Means of Escape. In other than existing buildings and those protected throughout by an approved, supervised automatic sprinkler system in accordance with 26.3.5, every story more than 185 m² (2000 ft²) in area or with travel distance to the primary means of escape more than 23 m (75 ft) shall be provided with two primary means of escape remotely located from each other.

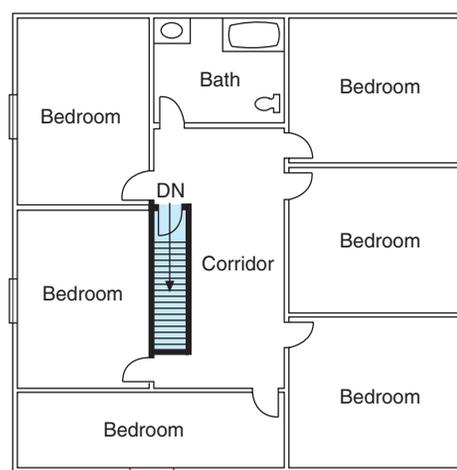

26.2.2 Stairways.

26.2.2.1 Interior stairways, other than those in accordance with 26.2.2.2 or 26.2.2.3, shall comply with 7.2.2.5.3 and shall be enclosed by ½-hour fire barriers with all openings protected with smoke-actuated automatic-closing or self-closing doors having a fire resistance comparable to that required for the enclosure.

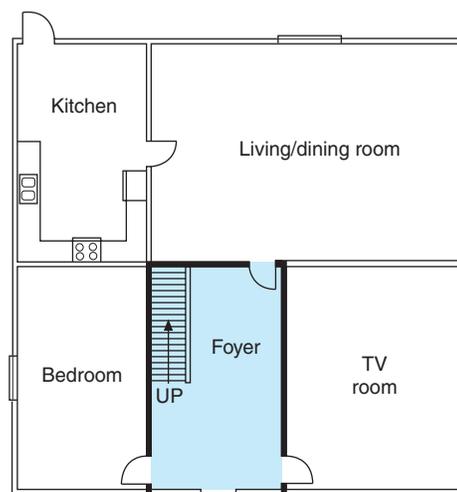

26.2.2.2 Where an interior stair connects the street floor with the story next above or below only, but not with both, the interior stair shall be required to be enclosed only on the street floor.

26.2.2.3 Stairways shall be permitted to be unenclosed in accordance with 26.3.1.1.2 and 26.3.1.1.3.

In Exhibit 26.3, an enclosed interior stair in accordance with 26.2.2.1 is shown on the first floor. The stair discharges directly to the outside and serves as the primary means of escape for this nonsprinklered rooming house. The entry foyer is separated from the rest of the first floor by walls with a ½-hour fire resistance rating, and the doors are self-closing with a 20-minute fire protection rating. The entry foyer cannot be used for any other purpose, such as a

Second Floor

First Floor

Exhibit 26.3 Means of escape—existing nonsprinklered lodging or rooming house.

lounge for the occupants. Walls with a ½-hour fire resistance rating and a self-closing door with a 20-minute fire protection rating also enclose the stairs on the second floor. The walls and door provide the necessary separation between the second floor corridor and the vertical opening. Compliant windows in all sleeping and living spaces provide the secondary means of escape. Note that if the stair illustrated in Exhibit 26.3 connects only the street floor and the floor above (or floor below), it is permitted to be open to other than the street floor, per 26.2.2.2.

Exhibit 26.4 illustrates the use of 26.2.2.2. To meet the criteria for this provision, stairs A and B connect only two floors and are separated from the rest of the first floor. Stair A cannot extend to the second floor, and stair B cannot extend to the basement. The arrangement of stair A protects the residents on the first and second floors from fire and smoke in the basement. The arrangement of stair B protects the residents on the second floor from fire and smoke on the street-level floor.

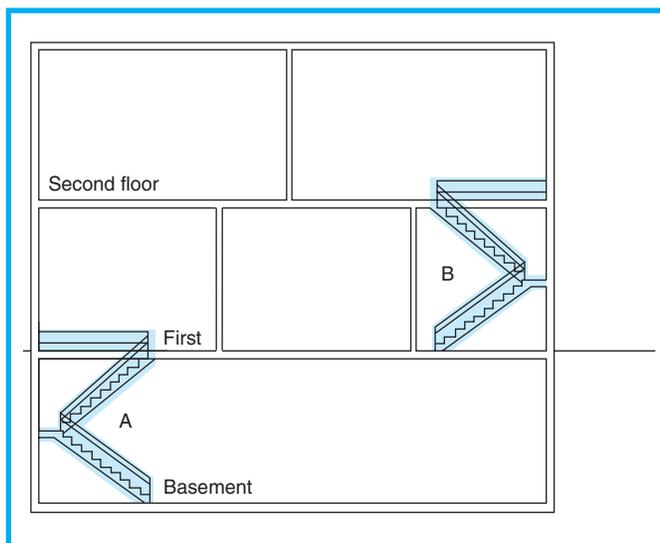

Exhibit 26.4 A two-story stairway.

26.2.2.4 Winders in accordance with 7.2.2.2.4 shall be permitted.

26.2.3 Doors.

26.2.3.1 Doors in a means of escape, other than bathroom doors in accordance with 26.2.3.2, and paths of travel in a means of escape shall be not less than 710 mm (28 in.) wide.

26.2.3.2 Bathroom doors shall be not less than 610 mm (24 in.) wide.

26.2.3.3 Every closet door latch shall be such that it can be readily opened from the inside in case of emergency.

26.2.3.4 Every bathroom door shall be designed to allow opening from the outside during an emergency when locked.

26.2.3.5 Door locking arrangements shall comply with either 26.2.3.5.1 or 26.2.3.5.2.

26.2.3.5.1* No door in any means of escape shall be locked against egress when the building is occupied.

A.26.2.3.5.1 It is the intent of this requirement that security measures, where installed, do not prevent egress.

26.2.3.5.2 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted, provided that not more than one such device is located in any one escape path.

A lodging or rooming house is prohibited by 26.2.3.5.1 from having any door locked against egress (escape) while the building is occupied. This requirement permits a door to have a locking device that allows the door to be opened from within the building for the purpose of escape but does not permit the door to be opened from outside the building. Ordinary double-cylinder locks and chain locks do not meet these provisions.

The language of 7.2.1.5.2 is clear: locks, if provided, are not to require the use of a key, a tool, or special knowledge or effort for operation from the egress side. This requirement prohibits double-cylinder locks and chain locks that require a key to operate the door from the inside. The use of a simple operation to open a door is required by 7.2.1.5.9; locks that require two-handed knobs and similar operations are prohibited.

Chapter 7 recognizes the need for security chains or rods on guest room doors and allows one releasing device in addition to the door knob or lever. The typical guest room door has three devices: a latch, a lock, and a security chain or rod. However, the *Code* allows only two releasing actions for new installations. This requirement is met by using a latch and lockset equipped with a lock bolt that automatically retracts when the latch handle is turned from the inside; therefore, only one releasing action is needed for the two devices. The second action is the release of the security chain or rod. However, neither device requires the use of a key, a tool, or special knowledge or effort. In existing installations, three releasing devices are permitted: the security device, the lock, and the latch.

The use of the delayed-egress lock detailed in 7.2.1.6.1 is recognized by 26.2.3.5.2, provided not more than once such device is encountered in any single escape path. Use of a delayed-egress lock requires that the building be protected throughout by either an automatic sprinkler system or a fire detection system. The 15-second or 30-second delay permitted by 7.2.1.6.1 does not affect the immediate release of the lock upon activation of the sprinklers or detectors, or upon loss of power to the lock. This device helps provide the security needed for doors that are used infrequently in lodging or rooming houses. At the same time, doors remain available for emergency use. Chains and padlocks do not provide this protection.

26.2.3.6 Doors serving a single dwelling unit shall be permitted to be provided with a lock in accordance with 7.2.1.5.6.

Section 26.3 Protection

26.3.1 Protection of Vertical Openings.

26.3.1.1 Vertical openings shall comply with 26.3.1.1.1, 26.3.1.1.2, or 26.3.1.1.3.

26.3.1.1.1 Vertical openings shall be protected so that no primary escape route is exposed to an unprotected vertical opening.

26.3.1.1.1.1 The vertical opening shall be considered protected if the opening is cut off and enclosed in a manner that provides a smoke- and fire-resisting capability of not less than ½ hour.

26.3.1.1.1.2 Any doors or openings shall have a smoke- and fire-resisting capability equivalent to that of the enclosure and shall be automatic-closing on detection of smoke or shall be self-closing.

26.3.1.1.2 In buildings three or fewer stories in height that are protected throughout by an approved automatic sprinkler system in accordance with 26.3.5, unprotected vertical openings shall be permitted, provided that a primary means of escape from each sleeping area is provided that does not pass through a portion of a lower floor unless such portion is separated from all spaces on that floor by construction having a ½-hour fire resistance rating.

26.3.1.1.3 Stair enclosures shall not be required in buildings two or fewer stories in height where both of the following conditions exist:

- (1) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 26.3.5.1.
- (2) The allowance of 24.2.2.1.2 to omit a secondary means of escape is not used.

An outside stair is used as the primary means of escape in Exhibit 26.5. Compliant windows in each of the bedrooms provide the secondary means of escape. The interior stair in this arrangement is just a convenience stair, independent of the required means of escape. If no sprinkler system is provided, the stairs must be enclosed in accordance with 26.3.1.1.1, as depicted in Exhibit 26.5. If a sprinkler system is provided, either 26.3.1.1.2 or 26.3.1.1.3 are permitted to be applied.

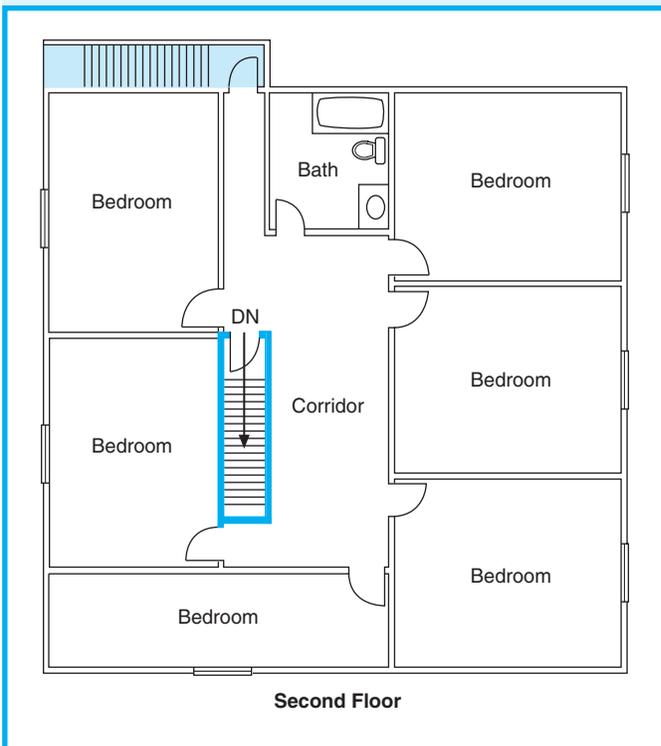

Exhibit 26.5 Means of escape—outside stair use.

A vertical opening of up to three stories is permitted by 26.3.1.1.2 to be unprotected in a fully sprinklered, maximum three-story, lodging or rooming house, provided that the primary means of escape is separated on the lower floor(s). Exhibit 26.6 illustrates a three-story, fully sprinklered lodging or rooming house. The stairs are open from the first to the third floor. However, ½-hour fire resistance-rated walls

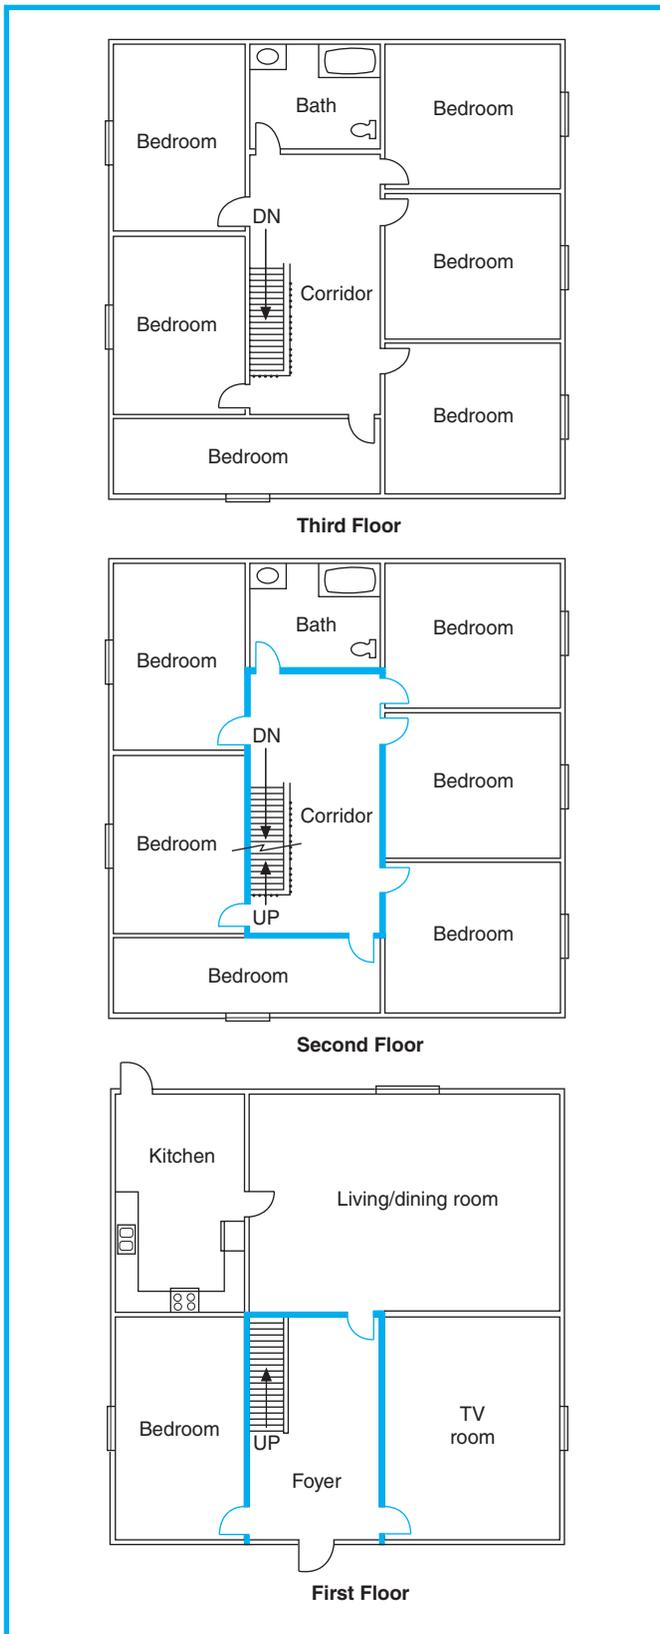

Exhibit 26.6 Means of escape—three-story sprinklered lodging or rooming house.

separate the living spaces from the stairs on floors one and two.

In bed-and-breakfast facilities, it is often important to retain the historical integrity or homelike ambience of the building. Separation or enclosure of a decorative main stair would effectively eliminate the characteristics that draw people to these facilities. On the other hand, it is necessary to provide appropriate protection to guests. Exhibit 26.7 illustrates a two-story bed-and-breakfast facility that is protected with automatic sprinklers. Once again, the stair serves as the primary means of escape. In this case, 26.3.1.1.3 is used to allow the stair to remain unenclosed on both levels. It is important to note that the use of this provision has an impact on the secondary means of escape. Even though 24.2.2.1.2 permits the elimination of the secondary means of escape in fully

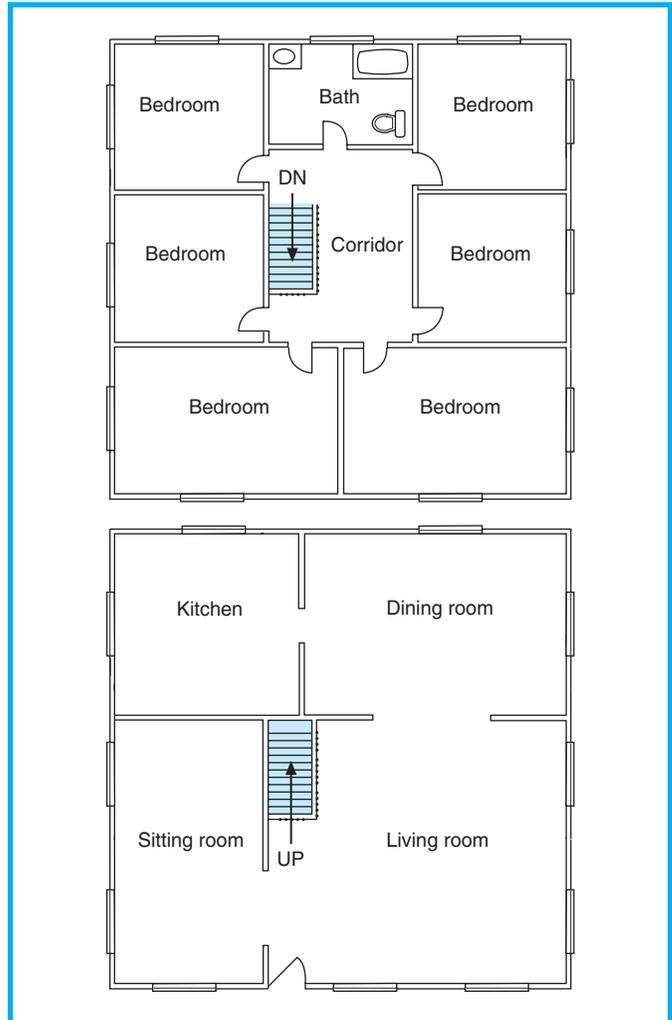

Exhibit 26.7 Means of escape—two-story, sprinklered bed-and-breakfast facility.

sprinklered buildings, 26.3.1.1.3(2) specifically prohibits the use of 24.2.2.1.2 if the automatic sprinklers are used for the purpose of protecting the vertical opening. The result is that all windows from the sleeping rooms or living areas must comply as a secondary means of escape if this arrangement is to be permitted.

26.3.1.2* Exterior stairs shall be protected against blockage caused by fire within the building.

A.26.3.1.2 Such protection can be accomplished by separation by physical distance, arrangement of the stairs, protection of the openings exposing the stairs, or a combination thereof.

26.3.2 Interior Finish.

26.3.2.1 General. Interior finish shall be in accordance with Section 10.2.

26.3.2.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A, Class B, or Class C.

26.3.2.3 Interior Floor Finish.

26.3.2.3.1 Newly installed interior floor finish shall comply with Section 10.2.

26.3.2.3.2 Newly installed interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

26.3.3 Detection, Alarm, and Communications Systems.

26.3.3.1 General.

26.3.3.1.1 Lodging and rooming houses, other than those meeting 26.3.3.1.2, shall be provided with a fire alarm system in accordance with Section 9.6.

26.3.3.1.2 A fire alarm system in accordance with Section 9.6 shall not be required in existing lodging and rooming houses that have an existing smoke detection system meeting or exceeding the requirements of 26.3.3.5.1 where that detection system includes not less than one manual fire alarm box per floor arranged to initiate the smoke detection alarm.

In existing lodging or rooming houses, existing multiple-station smoke detectors and a manual fire alarm box arranged as a system are permitted by 26.3.3.1.2 to substitute for a standard fire alarm system in accordance with *NFPA 72®*, *National Fire Alarm Code®*⁴.

26.3.3.2 Initiation. Initiation of the required fire alarm system shall be by manual means in accordance with 9.6.2, or by alarm initiation in accordance with 9.6.2.1(3) in buildings protected throughout by an approved automatic sprinkler system in accordance with 26.3.5.

26.3.3.3 Notification. Occupant notification shall be provided automatically in accordance with 9.6.3, as modified by 26.3.3.3.1 and 26.3.3.3.2.

26.3.3.3.1* Visible signals for the hearing impaired shall not be required where the proprietor resides in the building and there are five or fewer rooms for rent.

A.26.3.3.3.1 The proprietor is the owner or owner's agent with responsible charge.

26.3.3.3.2 Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.

26.3.3.4 Detection. (Reserved)

26.3.3.5 Smoke Alarms.

26.3.3.5.1 Approved single-station smoke alarms, other than existing smoke alarms meeting 26.3.3.5.3, shall be installed in accordance with 9.6.2.10 in every sleeping room.

26.3.3.5.2 The smoke alarms required by 26.3.3.5.1 shall not be required to be interconnected.

26.3.3.5.3 Existing battery-powered smoke alarms, rather than house electric-powered smoke alarms, shall be permitted where the facility has demonstrated to the authority having jurisdiction that the testing, maintenance, and battery replacement programs will ensure reliability of power to the smoke alarms.

The installation of a smoke alarm in each sleeping room is required by 26.3.3.5.1. This requirement applies retroactively to existing lodging or rooming houses, as well as to new construction.

While 26.3.3.5.3 allows existing battery-powered smoke alarms to remain in place if approved by the authority having jurisdiction, newly installed smoke alarms must be powered by the building electrical service. This requirement applies to both new and existing lodging or rooming houses in accordance with 9.6.2.10.

26.3.4 Separation of Sleeping Rooms.

26.3.4.1 All sleeping rooms shall be separated from escape route corridors by smoke partitions in accordance with Section 8.4.

26.3.4.2 There shall be no louvers or operable transoms in corridor walls.

26.3.4.3 Air passages shall not penetrate corridor walls unless they are properly installed heating and utility installations other than transfer grilles.

26.3.4.4 Transfer grilles shall be prohibited in corridor walls.

26.3.4.5 Doors shall be provided with latches or other mechanisms suitable for keeping the doors closed.

26.3.4.6 Doors shall not be arranged to prevent the occupant from closing the door.

26.3.4.7 In buildings other than those protected throughout by an approved, automatic sprinkler system in accordance with 26.3.5, doors shall be self-closing or automatic-closing upon detection of smoke.

The requirements of 26.3.4 are similar to those for corridor walls and doors in hotels and apartment buildings; however, no fire resistance rating is required. Unlike hotels and apartment buildings, door closers are exempted in sprinklered lodging or rooming houses. See Exhibit 26.8.

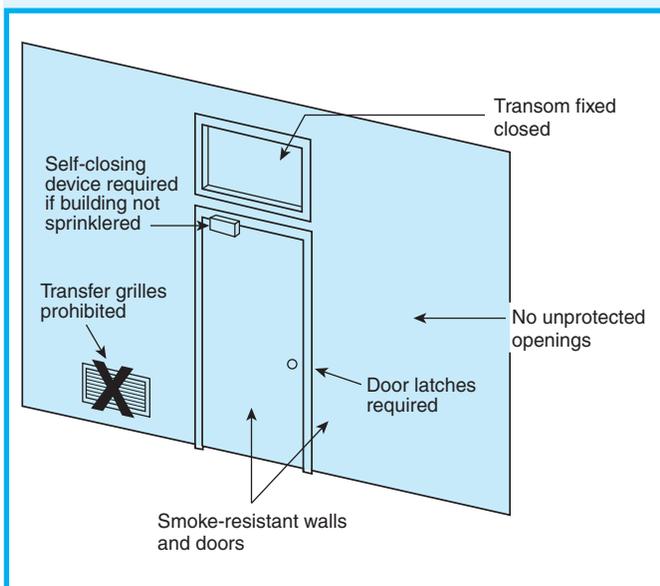

Exhibit 26.8 Sleeping room/escape route separation.

26.3.5 Extinguishment Requirements.

26.3.5.1 All new lodging or rooming houses, other than those meeting 26.3.5.2, shall be protected throughout by an approved automatic sprinkler system in accordance with 26.3.5.3.

26.3.5.2 An automatic sprinkler system shall not be required where every sleeping room has a door opening directly to the outside of the building at street or ground level, or has a door opening directly to the outside leading to an exterior stairway that meets the requirements of 26.2.1.1.

Exhibit 26.9 illustrates an arrangement where each room has a door leading directly to an exterior balcony and exterior stairs to grade. Per 26.2.1.2, this design eliminates the requirement for secondary means of escape. Therefore, no protection of the interior stairs is required. If no sleeping rooms are located on the first floor, or if the first floor sleeping rooms are arranged to discharge directly outside, an automatic sprinkler system is not required in this building.

With the exception of those lodging or rooming houses in which each sleeping room has a door providing direct access to the exterior at grade or to an exterior stairway, new lodging or rooming houses must be protected throughout with an approved automatic sprinkler system.

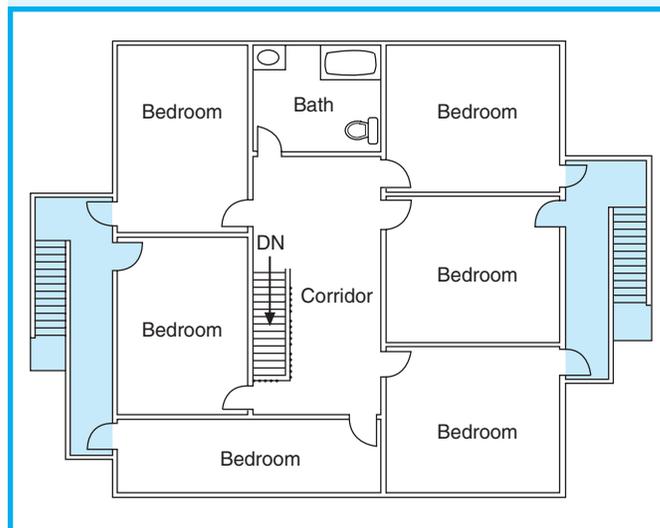

Exhibit 26.9 Means of escape—nonsprinklered lodging or rooming house.

If a new lodging or rooming house is part of a multiple occupancy and is treated as a mixed occupancy, the entire mixed occupancy is required to be sprinklered. To waive this requirement, the occupancies would have to be arranged so that the lodging or rooming house is treated as a separate occupancy in accordance with 6.1.14.4. This arrangement would require the egress systems for each occupancy to be separate. Doors that open directly to the outside from each of the occupancies usually achieve this separate egress.

26.3.5.3 Where an automatic sprinkler system is required or is used as an alternative method of protection, either for total or partial building coverage, the system shall be in accordance with Section 9.7 and 26.3.5.3.1 through 26.3.5.3.6.

26.3.5.3.1 Activation of the automatic sprinkler system shall actuate the fire alarm system in accordance with Section 9.6.

26.3.5.3.2 Systems in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted in buildings up to and including four stories in height.

26.3.5.3.3* Systems in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, shall be permitted where the following requirements are met:

- (1) The lodging or rooming house shall not be part of a mixed occupancy.
- (2) Entrance foyers shall be sprinklered.
- (3) Lodging or rooming houses with sleeping accommodations for more than eight occupants shall be treated as two-family dwellings with regard to the water supply.

A.26.3.5.3.3 The decision to permit the use of the criteria from NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, in these occupancies is based on the following:

- (1) The desire to obtain a level of fire suppression and control that is approximately equivalent to that delivered by residential facilities protected by such systems (*see the annex statement in NFPA 13D, Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*)
- (2) The fact that potential fire exposure and challenge to the suppression system in a small lodging and rooming occupancy is of the same nature and no more severe than that found in residences

Because there is such a wide variety of buildings that might fall into the classification of lodging or rooming houses, it is necessary to provide references to all three of the standards for the installation of automatic sprinkler systems.

The use of NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, is appropriate for many lodging or rooming houses.

In certain lodging or rooming house occupancies, the use of NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, is also appropriate. Some lodging or rooming houses might be similar in physical configuration to a one- or two-family dwelling, whereas others are not. For example, an NFPA 13D system would be appropriate for a single-family dwelling that is used as a bed-and-breakfast (lodging or rooming house classification for purposes of applying this Code) but not for a fire station with a bunk room. The following three provisions for the use of an NFPA 13D sprinkler system in lodging or rooming houses are contained in 26.3.5.3.3:

- (1) The lodging or rooming house must not be part of a mixed occupancy.
- (2) The entrance foyer must be sprinklered (not a requirement in NFPA 13D).
- (3) If the lodging or rooming house contains sleeping accommodations for more than eight occupants, the sprinkler system water supply must be designed in accordance with NFPA 13D criteria for two-family dwellings.

NFPA 13D requires the water supply for two-family dwellings with a common water main to be designed for a 30-minute duration rather than the 10-minute duration required for single-family dwellings.

26.3.5.3.4 In buildings sprinklered in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, closets less than 1.1 m² (12 ft²) in area in individual dwelling units shall not be required to be sprinklered.

26.3.5.3.5 In buildings sprinklered in accordance with NFPA 13, closets that contain equipment such as washers, dryers, furnaces, or water heaters shall be sprinklered regardless of size.

26.3.5.3.6 In existing lodging or rooming houses, sprinkler installations shall not be required in closets not exceeding 2.2 m² (24 ft²) and in bathrooms not exceeding 5.1 m² (55 ft²).

Section 26.4 Reserved

Section 26.5 Building Services

26.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

26.5.2 Heating, Ventilating, and Air Conditioning.

26.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

26.5.2.2 Unvented fuel-fired heaters other than gas space heaters in compliance with NFPA 54, *National Fuel Gas Code*, shall not be used.

26.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

CHAPTER 27

Reserved

Typically, the occupancy chapters are paired so that the even-numbered chapter in the pair addresses new facilities of the occupancy type and the odd-numbered chapter addresses existing facilities of the occupancy type. Chapter 26, which precedes this chapter, addresses both new and existing lodging or rooming houses in a single chapter. Chapter 27 has been reserved to permit the chapter on new hotels and dormitories to be assigned an even number (that is, Chapter 28). The reserved chapter number might be used at a future date if the requirements for lodging or rooming houses are split into a pair of chapters—one for new construction and one for existing buildings.

CHAPTERS 28 and 29

New and Existing Hotels and Dormitories

Chapters 28 and 29 address residential occupancies that are primarily transient in nature. Hotel and motel accommodations that are mainly used for stays of relatively short duration fit into this category. Dormitory occupancies, although typically used for up to nine months of near continuous occupancy in the case of a college dormitory, are also regulated by these chapters.

The hotel and dormitory classification is one of five residential occupancy types addressed by the *Life Safety Code*. Other residential occupancies include one- and two-family dwellings (Chapter 24), lodging or rooming houses (Chapter 26), apartment buildings (Chapters 30 and 31), and residential board and care facilities (Chapters 32 and 33).

The common principle of life safety that is applied to all residential occupancies addressed by Chapters 24 through 33 is highlighted by 6.1.8.1. It states that residential occupancies are those occupancies in which sleeping accommodations are provided for purposes other than health care or detention and correction. The presence of sleeping occupants is central to the provisions of Chapters 24 through 33, because occupants who are asleep will be unaware of a developing fire and, when awakened to be alerted to the emergency, might be somewhat confused. The definition of the term *residential occupancy* in 6.1.8.1 also differentiates between sleeping occupants in residential occupancies and those in health care or detention and correctional occupancies, which are also characterized by the occupants' incapability of self-preservation. The provisions of Chapters 24 through 33 are also based on the presence of hazards (such as cooking and heating equipment) in residential oc-

cupancies and the degree to which occupants are familiar with their living space. Occupants might have little or no familiarity, as in the case of the transient residents of hotels, or they might have the total familiarity that is common to residents of single-family dwellings.

Unfamiliar surroundings and the possibility of being asleep when a fire occurs are factors that jeopardize the safety of hotel guests in particular. Hotels pose an additional problem, because typical hotel building configurations often require escaping guests to traverse an interior corridor, which subsequently might expose them to the heat and smoke of corridor and room fires. In recognition of these potential hazards, the *Code* requires most new hotels and dormitories to be protected throughout by an approved, supervised automatic sprinkler system.

In recent years, hotels and motels have experienced a steady reduction in the number of fires, civilian casualties, and civilian injuries. Part of the explanation for these reductions is the increasing percentage of hotels that use smoke detection and automatic sprinkler systems. From 1994 to 1998, hotels and motels averaged 4900 structure fires per year as reported to fire departments across the United States. These fires resulted in a yearly average of 28 civilian deaths and 279 civilian injuries. These figures do not include lodging or rooming houses or residential board and care facilities, which are defined for fire reporting purposes as facilities that are limited to fewer than 16 occupants. During the same period, dormitories experienced an average of 2140 fires, 3 civilian deaths, and 102 civilian injuries per year.

CHAPTER 28 • New

Section 28.1 General Requirements**28.1.1 Application.**

28.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as hotel or dormitory occupancies (see 1.3.1)
- (2) Additions made to, or used as, a hotel or dormitory occupancy (see 4.6.7)
- (3) Alterations, modernizations, or renovations of existing hotel or dormitory occupancies (see 4.6.8)
- (4) Buildings or portions thereof upon change of occupancy to a hotel or dormitory occupancy (see 4.6.12)

28.1.1.2 Any dormitory divided into suites of rooms, with one or more bedrooms opening into a living room or study that has a door opening into a common corridor serving a number of suites, shall be classified as an apartment building.

28.1.1.3 The term *hotel*, wherever used in this *Code*, shall include a hotel, inn, club, motel, bed and breakfast, or any other structure meeting the definition of *hotel*.

Chapters 28 and 29 apply to various operations that do not specifically use the term *hotel* but are considered such by definition. The terms *dormitory* and *hotel* are defined in 3.3.48 and 3.3.113, respectively. In some cases, Chapters 28 and 29 apply even if the identification of the occupancy suggests the application of a different chapter. For example, a lodging or rooming house that accommodates more than 16 people is considered a hotel.

Conversely, some operations that one might expect to be covered by Chapters 28 and 29 are not. For example, 28/29.1.1.2 recognizes that the common dormitory design in which a group of bedrooms opens into a study or living room duplicates a typical apartment design in which several bedrooms open into a living room or kitchen. Because the design and the risk of fire are similar, the *Code* treats this

28.1.2 Multiple Occupancies.

28.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

28.1.2.2 No guest room or guest suite of a hotel or dormitory occupancy shall have its sole means of egress pass through any nonresidential occupancy in the same building.

CHAPTER 29 • Existing

Section 29.1 General Requirements**29.1.1 Application.**

29.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as hotel or dormitory occupancies, unless meeting 29.1.1.2. (*See also 28.1.1.*)

29.1.1.2 Any dormitory divided into suites of rooms, with one or more bedrooms opening into a living room or study that has a door opening into a common corridor serving a number of suites, shall be classified as an apartment building.

29.1.1.3 The term *hotel*, wherever used in this *Code*, shall include a hotel, inn, club, motel, bed and breakfast, or any other structure meeting the definition of *hotel*.

arrangement as that of an apartment building. Exhibit 28/29.1 illustrates the arrangement of a dormitory suite that would be treated as an apartment.

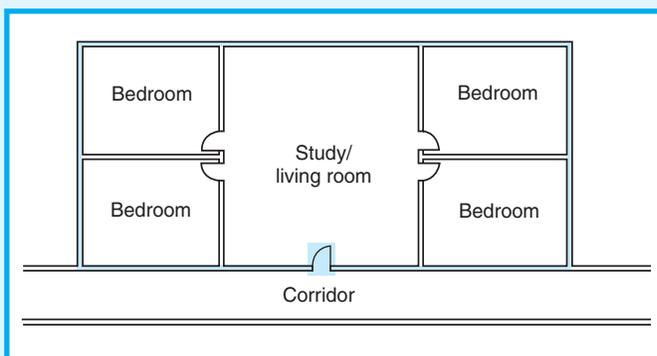

Exhibit 28/29.1 Dormitory suite apartment.

29.1.2 Multiple Occupancies.

29.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

29.1.2.2 No guest room or guest suite of a hotel or dormitory shall have its sole means of egress pass through any nonresidential occupancy in the same building.

CHAPTER 28 • New

Residential occupancies often exist in buildings that also house assembly, mercantile, or business occupancies. These nonresidential occupancies might pose an additional threat, because they are not typically occupied after regular business hours. An undetected fire in an unoccupied area has the potential to affect the tenability of the residential portion of the building before occupants can be awakened and

28.1.3 Definitions.

Terms applicable to this chapter are defined in Chapter 3 of this *Code* and include the terms in the list that follows:

- (1) **Dormitory.** See 3.3.48.
- (2) **Guest Room.** See 3.3.100.
- (3) **Guest Suite.** See 3.3.101.
- (4) **Hotel.** See 3.3.113.

In the definition of *dormitory* in 3.3.48, the wording “without individual cooking facilities” refers to the absence of cooking equipment, excluding small appliances such as coffee makers, microwave ovens, etc., in any room or unit of a dormitory. If such equipment is present throughout a facility, the occupancy should be classified as an apartment building. The wording “with or without meals” recognizes the presence of a central cafeteria used to serve meals for the occupants of a dormitory.

The requirements of Chapters 28 and 29 often are worded to apply specifically within a guest room or guest suite. The first sentence of A.3.3.48 clarifies that, where the chapters use the terms *guest room* and *guest suite*, the intent is that the requirement also be applied to dormitory rooms used for sleeping and living purposes.

A residential occupancy with sleeping accommo-

28.1.4 Classification of Occupancy.

See 28.1.3.

28.1.5 Classification of Hazard of Contents.

28.1.5.1 The contents of residential occupancies shall be classified as ordinary hazard in accordance with 6.2.2.

28.1.5.2 For the design of automatic sprinkler systems, the classification of contents in NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall apply.

CHAPTER 29 • Existing

take the appropriate actions for safe egress. Therefore, the requirements of 28/29.1.2 help to ensure that it is safe to have hotels or dormitories within such multiple occupancy buildings by providing the necessary protection where treated as mixed occupancies and separation where treated as separated occupancies.

29.1.3 Definitions.

Terms applicable to this chapter are defined in Chapter 3 of this *Code* and include the terms in the list that follows:

- (1) **Dormitory.** See 3.3.48.
- (2) **Guest Room.** See 3.3.100.
- (3) **Guest Suite.** See 3.3.101.
- (4) **Hotel.** See 3.3.113.

dations for more than 16 persons, even if referred to as a lodging or rooming house by its operators, is classified as a hotel and is regulated under the provisions of Chapter 28 or 29. In the A.3.3.113 annex verbiage on the definition of the term *hotel*, the reference to a 30-day time period helps to define *transient*. Where guest rooms or guest suites have individual cooking facilities the appropriate classification is “apartment building.” However, certain facilities (for example, extended-stay hotels) might contain the potential for hazards associated with both a hotel (unfamiliarity with surroundings) and an apartment building (higher fuel load, greater number of ignition sources, and travel through multiple rooms). In such cases, the authority having jurisdiction might permit the building to be classified as a mixed occupancy (hotel and apartment building) and apply the more restrictive requirements.

29.1.4 Classification of Occupancy.

See 29.1.3.

29.1.5 Classification of Hazard of Contents.

29.1.5.1 The contents of residential occupancies shall be classified as ordinary hazard in accordance with 6.2.2.

29.1.5.2 For the design of automatic sprinkler systems, the classification of contents in NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall apply.

CHAPTER 28 • New

NFPA 13, *Standard for the Installation of Sprinkler Systems*¹, classifies the contents of a hotel or dormitory occupancy building as light hazard for the purpose of designing automatic sprinkler systems. Classification

28.1.6 Minimum Construction Requirements.

(No special requirements.)

Although Chapters 28 and 29 do not establish minimum construction requirements, if the hotel contains an assembly occupancy, Chapters 12 and 13 do

28.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

Subsection 28/29.1.7 requires occupant load to be determined in accordance with the occupant load factors in Table 7.3.1.2. Note that the occupant load factors for residential use do not preclude the need for providing egress capacity from concentrated sleeping areas (for example, bunk rooms) based on the maximum probable population rather than on the calculated occupant load using floor area. If the actual population of a bunk room exceeds 1 person

Section 28.2 Means of Egress Requirements**28.2.1 General.**

28.2.1.1 Means of egress from guest rooms or guest suites to the outside of the building shall be in accordance with Chapter 7 and this chapter.

28.2.1.2 Means of escape within the guest room or guest suite shall comply with the provisions of Section 24.2 for one- and two-family dwellings.

28.2.1.3 For the purpose of application of the requirements of Chapter 24, the terms *guest room* and *guest suite* shall be synonymous with the terms *dwelling* or *living unit*.

CHAPTER 29 • Existing

in the *Code*, noted in 28/29.1.5.1, is based on the threat to life or life safety (ordinary) rather than the challenge to the extinguishing capability of the automatic sprinkler system (light).

29.1.6 Minimum Construction Requirements.

(No special requirements.)

establish minimum construction requirements based on the location of the assembly occupancy within the building.

29.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

per 18.6 m² (200 ft²), the egress capacity features (for example, door widths) must be designed based on the actual number of occupants. See Section 7.3 for further details on the use of occupant load for determining the capacity of the means of egress.

The occupant load calculations for areas of hotels used for nonresidential purposes should be based on the occupant load factors applicable to the use of the area.

Section 29.2 Means of Egress Requirements**29.2.1 General.**

29.2.1.1 Means of egress from guest rooms or guest suites to the outside of the building shall be in accordance with Chapter 7 and this chapter.

29.2.1.2 Means of escape within the guest room or guest suite shall comply with the provisions of Section 24.2 for one- and two-family dwellings.

29.2.1.3 For the purpose of application of the requirements of Chapter 24, the terms *guest room* and *guest suite* shall be synonymous with the terms *dwelling* or *living unit*.

CHAPTER 28 • New

Every guest room or guest suite must comply with Section 24.2, which addresses means of escape in one- and two-family dwellings, in accordance with 28/29.2.1. This mandatory reference to Section 24.2 is important for several reasons. First, it establishes a requirement for two means of escape from every sleeping room and living area of a guest suite having two rooms or more. Several acceptable types of secondary means of escape are established in 24.2.2, the most common of which is an operable window with specified minimum opening dimensions. No secondary means of escape is required if a guest suite is protected by an automatic sprinkler system. Note that 24.2.2 does not require that the entire building be sprinklered, only that the guest suite deficient with respect to the secondary means of escape be sprinklered. However, a mandate for complete building sprinkler protection might be specified elsewhere as in 28/29.3.5.1.

28.2.2 Means of Egress Components.

28.2.2.1 General.

28.2.2.1.1 Components of means of egress shall be limited to the types described in 28.2.2.2 through 28.2.2.12.

28.2.2.1.2 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5, exit enclosures shall have a fire resistance rating of not less than 1 hour, and the fire protection rating of doors shall be not less than 1 hour.

The general provisions for the means of egress components in hotels and dormitories modify the provisions of Chapter 7 in the following two areas:

- (1) Limits on the components of the means of egress
- (2) Protection of the means of egress

First, a general reference to the components of the means of egress in Chapter 7 is made in place of repeating its myriad provisions. Most of these components are permitted in both new and existing hotels and dormitories. Some of the components are permitted to be used in accordance with the provisions of Chapter 7 and the additional provisions of Chapters 28 and 29. For example, 28/29.2.2.2.2 permits the use of delayed-egress locks in accordance with 7.2.1.6.1

CHAPTER 29 • Existing

A second important provision of Section 24.2 is that the means of egress provisions of Chapter 7 do not apply within the guest room or guest suite unless they are specifically referenced. For example, the minimum width of means of escape doors within a guest room or guest suite is 710 mm (28 in.), rather than the 810-mm (32-in.) minimum width specified for means of egress by Chapter 7. The requirement of Chapter 7 applies to the door from the room or suite to the common corridor, because this door is the transition point at which means of escape ends and the standard means of egress begins. Chapter 24 also permits the use of winders and spiral stairs within a guest room or guest suite, and the provisions of Chapter 24 for headroom apply within the guest room or suite, superseding those of Chapter 7. See the commentary on Chapter 24 for additional information on means of escape from dwelling units.

29.2.2 Means of Egress Components.

29.2.2.1 General.

29.2.2.1.1 Components of means of egress shall be limited to the types described in 29.2.2.2 through 29.2.2.12.

29.2.2.1.2 In buildings protected throughout by an approved automatic sprinkler system in accordance with 29.3.5, exit enclosures shall have a fire resistance rating of not less than 1 hour, and the fire protection rating of doors shall be not less than 1 hour.

if not more than one such device is located in any single egress path.

If not permitted, no reference to an egress component is made in the specific occupancy chapter. For example, escalators and fire escape stairs are only permitted in existing hotels. Therefore, 29.2.2.8 and 29.2.2.9 contain specific references to such components, while 28.2.2.8 and 28.2.2.9 are reserved and contain no such reference. Neither chapter permits the use of slide escapes; consequently, no reference to slide escapes is made within the means of egress sections of either chapter.

Second, Chapter 28 recognizes the relatively low fuel loads of hotels and permits a fire resistance rating of 1 hour for exit enclosures and other vertical open-

CHAPTER 28 • New

ings (see 28.3.1.1.3) in buildings protected throughout by an approved, supervised automatic sprinkler system. See 29.3.1 for the unique vertical opening protection criteria for existing hotels and dormitories.

Because the *Code* currently requires that most new hotels and dormitories be protected throughout by an approved automatic sprinkler system, a 1-hour fire resistance-rated exit enclosure will typically be permitted in new construction. However, if 28.3.5.2—which exempts certain building arrangements from the sprinkler requirement—is utilized, the 1-hour rated enclosure option of 28.2.2.1.2 is not permitted. This situation dictates a default to the Chapter 7 exit enclosure requirements, which, because they are based on the number of stories connected by the exit enclosure, might require 2-hour fire resistance-rated enclosures. See 7.1.3.2 for requirements for exits.

The reduction to a 1-hour fire resistance-rated enclosure for exits is not permitted for assembly, mercantile, or business occupancies and, therefore, cannot be used where mixed hotel/assembly, hotel/mercantile, or hotel/business occupancies are involved. In facilities of four or more stories, where hotel occupancies and other occupancies are adequately separated in accordance with 6.1.14.4 and treated independently, a 1-hour exit enclosure in the

28.2.2.2 Doors.

28.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

28.2.2.2.2 Door locking arrangements shall comply with 28.2.2.2.2.1, 28.2.2.2.2.2, or 28.2.2.2.2.3.

28.2.2.2.2.1 No door in any means of egress shall be locked against egress when the building is occupied.

28.2.2.2.2.2 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted, provided that not more than one such device is located in any one egress path.

28.2.2.2.2.3 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

Hotels and dormitories are prohibited from having any door locked against egress while the building is occupied. This requirement permits a door to be equipped with a locking device that allows the door to be opened from within the building for the purpose

CHAPTER 29 • Existing

hotel portion and a 2-hour enclosure elsewhere might be permitted.

Exhibit 28/29.2 illustrates the modification to the requirements for protection of exit enclosures and other vertical openings in a fully sprinklered building. The provision for the 1-hour exit enclosure does not apply to other occupancies in a hotel complex or in mixed occupancies.

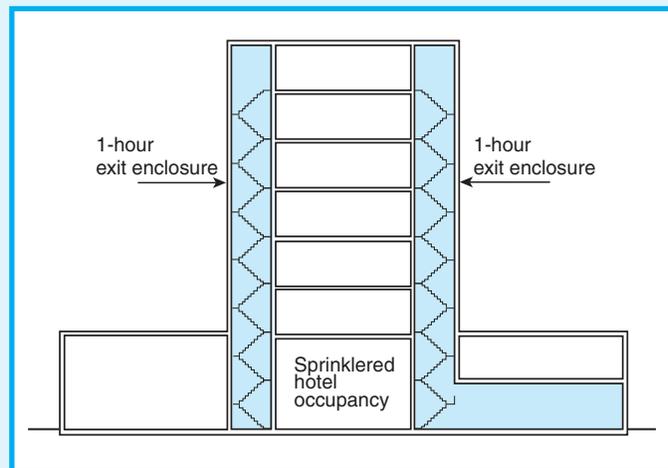

Exhibit 28/29.2 Exit enclosure separation—sprinklered building.

29.2.2.2 Doors.

29.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

29.2.2.2.2 Door locking arrangements shall comply with 29.2.2.2.2.1, 29.2.2.2.2.2, or 29.2.2.2.2.3.

29.2.2.2.2.1 No door in any means of egress shall be locked against egress when the building is occupied.

29.2.2.2.2.2 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted, provided that not more than one such device is located in any one egress path.

29.2.2.2.2.3 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

of egress but does not allow the door to be opened from outside the building.

The language of 7.2.1.5.2 is clear: Locks, if provided, are not to require the use of a key, a tool, or special knowledge or effort for operation from the

CHAPTER 28 • New

egress side of the building. This requirement prohibits double-cylinder locks and chain locks that require a key to operate the door from the inside. The use of a simple operation to open a door is required by 7.2.1.5.9; locks that require two-handed knobs and similar operations are prohibited.

Hotel room doors provide security for the occupants in the room. Recognizing this additional function, Chapter 7 permits the use of security chains or rods, as well as locks, on hotel room doors and also permits releasing devices in addition to the doorknob or lever. The permitted number of additional releasing actions differs for new and existing buildings. One additional releasing action is permitted for new construction and two additional actions are permitted in existing buildings. The typical hotel room door has three devices: a latch, a lock, and a security chain or rod. This arrangement is permitted in existing buildings, provided that only two additional releasing operations are needed for unlocking. This arrangement would also be permitted in new construction, provided that the latch and lock set are interconnected so that the lock bolt and the latch will retract simultaneously when the latch handle is turned from the inside; thus, only one releasing action is needed for the two devices. The second action is the release of the security chain or rod. The overriding requirement for

28.2.2.2.3 Revolving doors complying with 7.2.1.10 shall be permitted.

28.2.2.2.4 Horizontal sliding doors, as permitted by 7.2.1.14, shall not be used across corridors.

Note that the special form of horizontal sliding door detailed in 7.2.1.14 is prohibited for cross-corridor

28.2.2.3 Stairs. Stairs complying with 7.2.2 shall be permitted.

28.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

28.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

28.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

28.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

CHAPTER 29 • Existing

any of these devices is that they not require the use of a key, a tool, or special knowledge or effort to operate.

The use of the delayed-egress lock detailed in 7.2.1.6.1 is recognized in 28/29.2.2.2.2.2 if not more than one such lock is located in any single egress path. The use of a delayed-egress lock requires that the building be protected throughout by either an automatic sprinkler or automatic fire detection system. The 15-second or 30-second delay permitted by 7.2.1.6.1 does not affect the immediate release of the lock upon activation of sprinklers or detectors or upon loss of power to the lock. The delay device provides the security needed for doors that are used infrequently. At the same time, the door remains available for emergency use. Chains and padlocks do not provide these safety features.

Selected exit stair enclosure doors are permitted to be locked to prevent re-entry from the stairwell side by 7.2.1.5.7, while other stair enclosure doors must remain unlocked. If the selected re-entry provisions are not used, one of the other two options specified by 7.2.1.5.7 must be used for stair enclosures serving five or more stories. Doors are permitted to be locked to prevent re-entry from the stairwell if initiation of the building fire alarm system automatically unlocks the door; otherwise, all stair enclosure doors must remain unlocked at all times.

29.2.2.2.3 Revolving doors complying with 7.2.1.10 shall be permitted.

29.2.2.2.4 Horizontal sliding doors, as permitted by 7.2.1.14, shall not be used across corridors.

installations in both new and existing hotels and dormitories in accordance with 28/29.2.2.2.4.

29.2.2.3 Stairs. Stairs complying with 7.2.2 shall be permitted.

29.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

29.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

29.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

29.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

CHAPTER 28 • New

28.2.2.8 Reserved.**28.2.2.9 Reserved.**

28.2.2.10 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

28.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

28.2.2.12 Areas of Refuge.

28.2.2.12.1 Areas of refuge complying with 7.2.12 shall be permitted, as modified by 28.2.2.12.2.

28.2.2.12.2* In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5, the two accessible rooms or spaces separated from each other by smoke-resistive partitions in accordance with the definition of area of refuge in 3.3.17 shall not be required.

A.28.2.2.12.2 The provision of 28.2.2.12.2 permits the entire floor to serve as an area of refuge where it is protected in accordance with 28.3.5. The provision is acceptable because supervised automatic sprinkler systems have built-in signals for monitoring features of the system, such as the opening and closing of water control valves. Such systems also monitor pump power supplies, water tank levels, and conditions that will impair the satisfactory operation of the sprinkler system. Because of these monitoring features, supervised automatic sprinkler systems have a high level of satisfactory performance and response to fire conditions.

In new hotels and dormitories, areas accessible to persons with severe mobility impairment must be provided with accessible means of egress per 7.5.4.1. For stories above the level of exit discharge, where providing ramps is usually not feasible, areas of refuge (see 7.2.12) will typically be used to meet the requirements for accessible means of egress. A sprin-

CHAPTER 29 • Existing

29.2.2.8* Escalators. Escalators previously approved as a component in a means of egress shall be permitted to continue to be considered in compliance.

A.29.2.2.8 Due to the nature of escalators, they are no longer acceptable as a component in a means of egress. However, because many escalators have been used for exit access and exit discharge in the past, they are permitted to continue to be considered in compliance. Very few escalators have ever been installed in a manner to qualify as an exit. For information on escalator protection and requirements, see previous editions of the *Code*.

29.2.2.9 Fire Escape Stairs. Fire escape stairs complying with 7.2.8 shall be permitted.

29.2.2.10 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

29.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

29.2.2.12 Areas of Refuge.

29.2.2.12.1 Areas of refuge complying with 7.2.12 shall be permitted, as modified by 28.2.2.12.2.

29.2.2.12.2* In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 29.3.5, the two accessible rooms or spaces separated from each other by smoke-resistive partitions in accordance with the definition of area of refuge in 3.3.17 shall not be required.

A.29.2.2.12.2 The provision of 29.2.2.12.2 permits the entire floor to serve as an area of refuge where it is protected in accordance with 29.3.5. The provision is acceptable because supervised automatic sprinkler systems have built-in signals for monitoring features of the system, such as the opening and closing of water control valves. Such systems also monitor pump power supplies, water tank levels, and conditions that will impair the satisfactory operation of the sprinkler system. Because of these monitoring features, supervised automatic sprinkler systems have a high level of satisfactory performance and response to fire conditions.

klered story of a hotel or dormitory is permitted to be considered an area of refuge by 28.2.2.12.2, even if an occupant does not have access to any of the guest rooms and is confined to the exit access corridor. Due to the effectiveness of the sprinkler system, an occupant with mobility impairment should be able to remain on the floor without experiencing untenable

CHAPTER 28 • New

conditions. However, because locked guest room doors create inaccessibility to spaces other than the corridor, the corridor effectively serves as the area of refuge. The authority having jurisdiction might choose to require demonstrations of tenability, as required by 7.2.12.3.2, if the aggregate corridor area on the story is less than 93 m² (1000 ft²), regardless of the area of the entire floor.

Existing hotels and dormitories are exempt from

28.2.3 Capacity of Means of Egress.

28.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

28.2.3.2 Street floor exits shall be sufficient for the occupant load of the street floor plus the required capacity of stairs and ramps discharging onto the street floor.

When occupants from upper floors are discharged from exit stair enclosures onto the street floor (in accordance with 7.7.2) and mix with occupants of the street floor in attempting egress to the exterior, the result is an increased demand on street floor egress components, such as exit doors. Street floor exits must be sized to handle the combined capacity in accordance with 28/29.2.3.2.

Exhibit 28/29.3 illustrates the traditional, grand lobby design found in many hotels in which multiple exit stairs and street floor exits converge at one or two exterior door locations. The required aggregate capacity of doors A and B is based on the number of people expected to use them. Assuming that the street floor has an occupant load of 400 persons and each of the two enclosed exit stairs (that is, stair 1 and stair 2) discharging into the street floor has a required capacity of 200 persons (that is, a maximum of 50 percent of the 400-person occupant load of the second or third floor via stair 1 and a maximum of 50 percent of the 400-person occupant load of the basement via stair 2), the required egress capacity for the street floor would be 800 persons. The unobstructed door or level travel width required to accom-

28.2.3.3* Corridors, other than those within individual guest rooms or individual guest suites, shall be of sufficient width to accommodate the required occupant load, and shall be not less than 1120 mm (44 in.).

CHAPTER 29 • Existing

the provisions of 7.5.4.1; therefore, areas of refuge are not required but are permitted to serve within the means of egress. If an area of refuge is used within an existing hotel, 29.2.2.12.2 allows a sprinklered story of a hotel or dormitory to be considered an area of refuge, even if an occupant does not have access to any of the guest rooms and is confined to the exit access corridor.

29.2.3 Capacity of Means of Egress.

29.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

29.2.3.2 Street floor exits shall be sufficient for the occupant load of the street floor plus the required capacity of stairs and ramps discharging onto the street floor.

modate 800 persons is 4060 mm (160 in.). The opening provided by each pair of doors, A and B, needs to be 2030 mm (80 in.) in clear, unobstructed width.

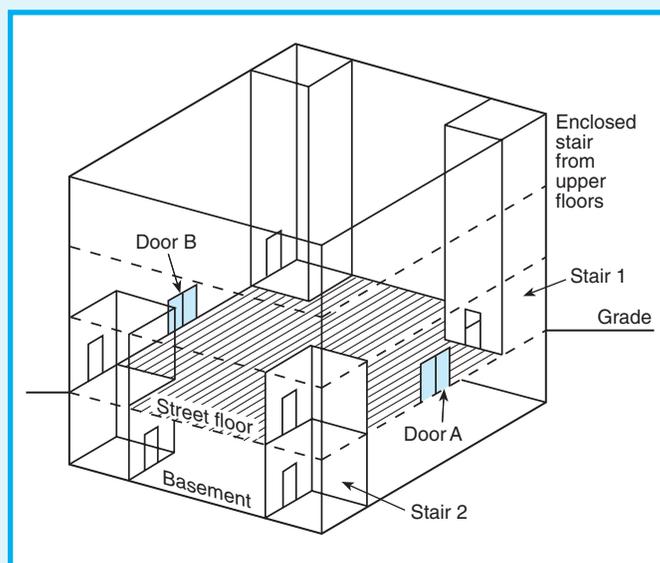

Exhibit 28/29.3 Egress capacity for street floor.

CHAPTER 28 • New

A.28.2.3.3 The exemption contained in 28.2.3.3 applies to corridors within an individual room or suite and does not apply where a suite can be subdivided and rented separately.

28.2.4 Number of Exits.

28.2.4.1 In buildings other than those complying with 28.2.4.2, not less than two separate exits shall be provided on each story. (See also Section 7.4.)

28.2.4.2 Buildings of four stories or less protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5, with not more than four guest rooms or guest suites per floor, shall be permitted to have a single exit under the following conditions:

- (1) The stairway is completely enclosed or separated by barriers having a fire resistance rating of not less than 1 hour, with self-closing 1-hour fire door assemblies protecting all openings between the stairway enclosure and the building.
- (2) The stairway does not serve more than one-half of a story below the level of exit discharge.
- (3) All corridors serving as access to exits have not less than a 1-hour fire resistance rating.
- (4) The travel distance from the entrance door of any guest room or guest suite to an exit does not exceed 10.7 m (35 ft).
- (5) Horizontal and vertical separation with a fire rating of not less than ½ hour is provided between guest rooms or guest suites.

Although 28.2.4 and 29.2.4 require a minimum of two separate exits from each floor, 7.4.1.2 requires a third exit when the occupant load of a floor exceeds 500 and a fourth exit when it exceeds 1000. The requirement of 7.4.1.2 will probably have little effect on modern hotel

28.2.5 Arrangement of Means of Egress.

28.2.5.1 Access to all required exits shall be in accordance with Section 7.5, as modified by 28.2.5.2.

28.2.5.2 The distance between exits addressed by 7.5.1.4 shall not apply to common nonlooped exit access corridors in buildings that have corridor doors from the guest room or guest suite that are arranged such that the exits are located in opposite directions from such doors.

28.2.5.3 In buildings not protected throughout by an approved, supervised automatic sprinkler system in accordance

CHAPTER 29 • Existing

29.2.4 Number of Exits.

29.2.4.1 In buildings other than those complying with 29.2.4.2, not less than two exits shall be accessible from every floor, including floors below the level of exit discharge and floors occupied for public purposes.

29.2.4.2 Buildings of four stories or less protected throughout by an approved, supervised automatic sprinkler system in accordance with 29.3.5, with not more than four guest rooms or guest suites per floor, shall be permitted to have a single exit under the following conditions:

- (1) The stairway is completely enclosed or separated by barriers having a fire resistance rating of not less than 1 hour, with self-closing 1-hour fire protection-rated doors protecting all openings between the stairway enclosure and the building.
- (2) The stairway does not serve more than one-half of a story below the level of exit discharge.
- (3) All corridors serving as access to exits have not less than a 1-hour fire resistance rating.
- (4) The travel distance from the entrance door of any guest room or guest suite to an exit does not exceed 10.7 m (35 ft).
- (5) Horizontal and vertical separation with a fire rating of not less than ½ hour is provided between guest rooms or guest suites.

design practices, because floors large enough to accommodate more than 500 persons would probably be provided with more than two exits based on travel distance limit considerations (see 28/29.2.6).

29.2.5 Arrangement of Means of Egress.

29.2.5.1 Access to all required exits shall be in accordance with Section 7.5.

29.2.5.2 Reserved.

29.2.5.3 In buildings not protected throughout by an approved, supervised automatic sprinkler system in accordance

CHAPTER 28 • New

with 28.3.5, common paths of travel shall not exceed 10.7 m (35 ft); travel within a guest room or guest suite shall not be included when calculating common path of travel.

28.2.5.4 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5, common path of travel shall not exceed 15 m (50 ft); travel within a guest room or guest suite shall not be included when determining common path of travel.

28.2.5.5 In buildings not protected throughout by an approved, automatic sprinkler system in accordance with 28.3.5, dead-end corridors shall not exceed 10.7 m (35 ft).

28.2.5.6 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5, dead-end corridors shall not exceed 15 m (50 ft).

28.2.5.7 Any guest room or any guest suite of rooms in excess of 185 m² (2000 ft²) shall be provided with not less than two exit access doors remotely located from each other.

The provisions for the arrangement of the means of egress for hotels differ significantly from the provisions in Chapter 7. The first difference appears in 28.2.5.2, which addresses the remoteness of exits. Applying the remoteness of exits provisions of 7.5.1.4 could result in a corridor that is longer than is necessary for the efficient use of the space. Some relief is offered by 28.2.5.2. Exhibit 28/29.4 helps to clarify the intent of 28.2.5.2. In illustration (a) of Exhibit 28/29.4, all four guest rooms/guest suites have access to two exits immediately upon leaving the guest room/guest suite and entering the exit access corridor. This arrangement meets the provisions of 28.2.5.2. Contrast this arrangement with that depicted in illustration (b) of Exhibit 28/29.4, where only guest rooms/guest suites A and B have access to two exits immediately upon leaving the guest room/guest suite and entering the exit access corridor. The other guest rooms/guest suites do not have immediate access to two exits. This arrangement does not meet the provisions of 28.2.5.2.

The concepts underlying the limitations imposed on common paths of travel and dead-end corridors are similar but not identical to those explained in the commentary on 7.5.1.5. Because of modifications made by Chapters 28 and 29 in defining where common path of travel begins, the difference between common paths of travel and dead-end corridors is less pronounced for hotels and dormitories. For most other occupancies, common path of travel is measured from the most remote point subject to occu-

CHAPTER 29 • Existing

with 29.3.5, common paths of travel shall not exceed 10.7 m (35 ft); travel within a guest room or guest suite shall not be included when calculating common path of travel.

29.2.5.4 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 29.3.5, common path of travel shall not exceed 15 m (50 ft); travel within a guest room or guest suite shall not be included when determining common path of travel.

29.2.5.5 Dead-end corridors shall not exceed 50 ft (15 m).

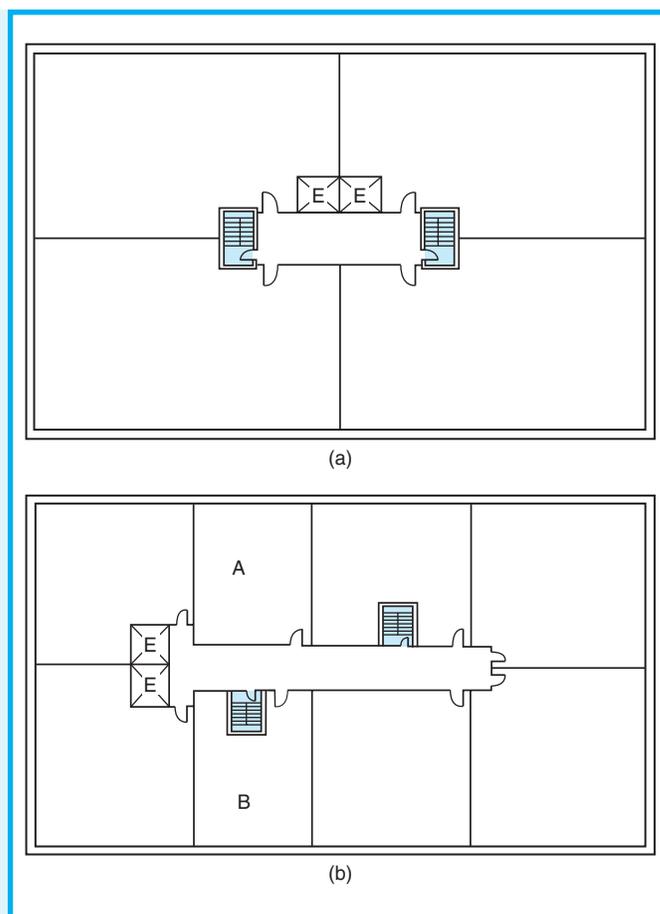

Exhibit 28/29.4 New hotels/dormitories—exit remoteness.

CHAPTER 28 • New

pancy to the point where occupants have a choice of traveling in independent directions (see 7.5.1.1.4 and the definition of *common path of travel* in 3.3.34). In hotels, the travel within the guest room, though regulated by 28/29.2.6.1 and 28/29.2.6.2 for distance, is not included as part of the common path of travel. Therefore, common path of travel, as illustrated by the solid arrows in Exhibit 28/29.5, is measured from the room door to the point where occupants have a choice of traveling in independent directions. This depiction can be thought of as a modified common path of travel, because measurement does not extend into the guest room or guest suite.

The distances permitted for common path of travel in new and existing hotels also differs. Because most new hotels are required to be sprinklered (see 28.3.5.1), the 10.7-m (35-ft) modified common path of travel and dead-end corridor limitations permitted by 28.2.5.3 and 28.2.5.5 will usually be supplanted by the 15-m (50-ft) limitation permitted by 28.2.5.4 and 28.2.5.6. However, if a building can comply with 28.3.5.2, which exempts sprinklers, the 10.7-m (35-ft) common path of travel and dead-end corridor limitations would apply.

In existing hotels, automatic sprinklers are not required. However, if the building is protected throughout by an approved, supervised automatic sprinkler system, the common path of travel is permitted to be 15 m (50 ft), which is the same distance

28.2.6 Travel Distance to Exits.

28.2.6.1 Travel distance within a guest room or guest suite to a corridor door shall not exceed 23 m (75 ft) in buildings not protected by an approved, supervised automatic sprinkler system in accordance with 28.3.5.

28.2.6.2 Travel distance within a guest room or guest suite to a corridor door shall not exceed 38 m (125 ft) in buildings protected by an approved, supervised automatic sprinkler system in accordance with 28.3.5.

28.2.6.3 Travel distance from the corridor door of any guest room or guest suite to the nearest exit shall comply with 28.2.6.3.1, 28.2.6.3.2, or 28.2.6.3.3.

28.2.6.3.1 Travel distance from the corridor door of any guest room or guest suite to the nearest exit, measured in accordance with Section 7.6, shall not exceed 30 m (100 ft).

28.2.6.3.2 Travel distance from the corridor door of any guest room or guest suite to the nearest exit, measured in

CHAPTER 29 • Existing

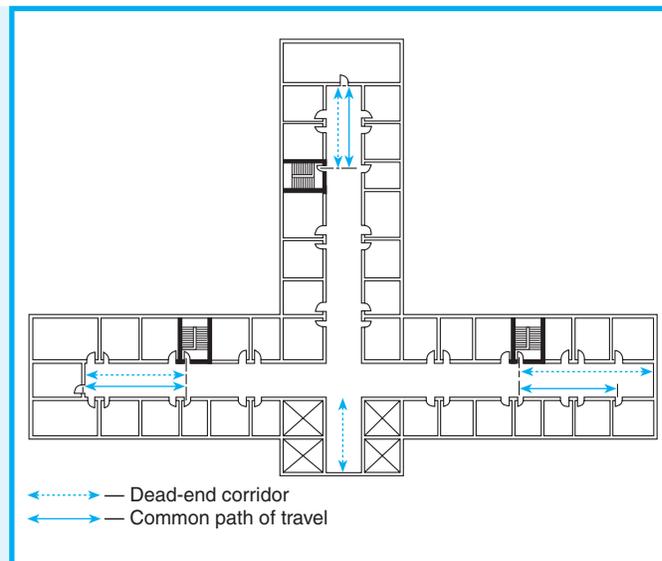

Exhibit 28/29.5 Modified common path of travel and dead-end corridors in a hotel.

permitted for the length of existing dead-end corridors, regardless of sprinkler system considerations.

While not considered part of the common path of travel, travel within a guest room or a guest suite in a new hotel is regulated by 28.2.5.7, which limits single exit access to rooms and suites not larger than 185 m² (2000 ft²).

29.2.6 Travel Distance to Exits.

29.2.6.1 Travel distance within a guest room or guest suite to a corridor door shall not exceed 23 m (75 ft) in buildings not protected by an approved, supervised automatic sprinkler system in accordance with 29.3.5.

29.2.6.2 Travel distance within a guest room or guest suite to a corridor door shall not exceed 38 m (125 ft) in buildings protected by an approved, supervised automatic sprinkler system in accordance with 29.3.5.

29.2.6.3 Travel distance from the corridor door of any guest room or guest suite to the nearest exit shall comply with 29.2.6.3.1, 29.2.6.3.2, or 29.2.6.3.3.

29.2.6.3.1 Travel distance from the corridor door of any guest room or guest suite to the nearest exit, measured in accordance with Section 7.6, shall not exceed 30 (100 ft).

29.2.6.3.2 Travel distance from the corridor door of any guest room or guest suite to the nearest exit, measured in

CHAPTER 28 • New

accordance with Section 7.6, shall not exceed 61 m (200 ft) for exterior ways of exit access arranged in accordance with 7.5.3.

28.2.6.3.3 Travel distance from the corridor door of any guest room or guest suite to the nearest exit shall comply with 28.2.6.3.3.1 and 28.2.6.3.3.2.

28.2.6.3.3.1 Travel distance from the corridor door of any guest room or guest suite to the nearest exit shall be measured in accordance with Section 7.6 and shall not exceed 61 m (200 ft) where the exit access and any portion of the building that is tributary to the exit access are protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5.

28.2.6.3.3.2 The portion of the building in which the 61-m (200-ft) travel distance is permitted shall be separated from the remainder of the building by construction having a fire resistance rating of not less than 1 hour for buildings not more than three stories in height, and 2 hours for buildings more than three stories in height.

Travel distance limitations are divided into the following two portions of the overall travel distance:

- (1) Travel within a room or suite of rooms to the room door
- (2) Travel from the corridor door to the nearest exit

This concept and the distance limitations specified in 28/29.2.6 are illustrated in Exhibit 28/29.6. If

28.2.7 Discharge from Exits.

28.2.7.1 Exit discharge shall comply with Section 7.7.

28.2.7.2* Any required exit stair that is located so that it is necessary to pass through the lobby or other open space to reach the outside of the building shall be continuously enclosed down to a level of exit discharge or to a mezzanine within a lobby at a level of exit discharge.

A.28.2.7.2 Where open stairways are permitted, they are considered as exit access to exits rather than as exits, and the requirements for travel distance to exits include the travel on such stairs. (*See 7.6.2.*)

28.2.7.3 The distance of travel from the termination of the exit enclosure to an exterior door leading to a public way shall not exceed 30 m (100 ft).

CHAPTER 29 • Existing

accordance with Section 7.6, shall not exceed 61 m (200 ft) for exterior ways of exit access arranged in accordance with 7.5.3.

29.2.6.3.3 Travel distance from the corridor door of any guest room or guest suite to the nearest exit, shall comply with 29.2.6.3.3.1 and 29.2.6.3.3.2.

29.2.6.3.3.1 Travel distance from the corridor door of any guest room or guest suite to the nearest exist shall be measured in accordance with Section 7.6, and shall not exceed 61 m (200 ft) where the exit access and any portion of the building that is tributary to the exit access are protected throughout by an approved, supervised automatic sprinkler system in accordance with 29.3.5.

29.2.6.3.3.2 The portion of the building in which the 61-m (200-ft) travel distance is permitted shall be separated from the remainder of the building by construction having a fire resistance rating of not less than 1 hour for buildings not more than three stories in height, and 2 hours for buildings more than three stories in height.

the travel distance within a room or suite or rooms is excessive, an additional remote door to the corridor can usually be added to correct the deficiency. Excessive travel distance within the corridor can usually be corrected by adding another exit.

29.2.7 Discharge from Exits.

29.2.7.1 Exit discharge shall comply with Section 7.7.

29.2.7.2* Any required exit stair that is located so that it is necessary to pass through the lobby or other open space to reach the outside of the building shall be continuously enclosed down to a level of exit discharge or to a mezzanine within a lobby at a level of exit discharge.

A.29.2.7.2 Where open stairways or escalators are permitted, they are considered as exit access to exits rather than as exits, and the requirements for travel distance to exits include the travel on such stairs and escalators. (*See 7.6.2.*)

29.2.7.3 The distance of travel from the termination of the exit enclosure to an exterior door leading to a public way shall not exceed 46 m (150 ft) in buildings protected throughout by an approved automatic sprinkler system in accordance with 29.3.5 and shall not exceed 30 m (100 ft) in all other buildings.

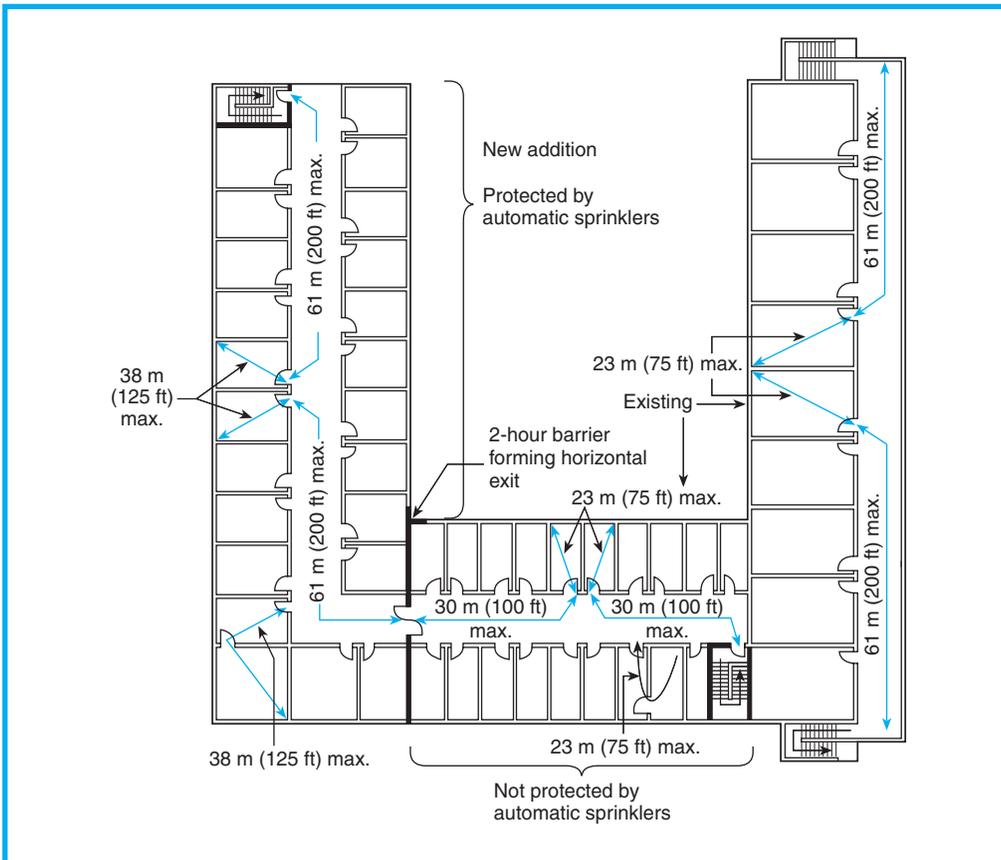

Exhibit 28/29.6 Travel distance measurement and limitations in hotels.

Section 7.7 allows a maximum of 50 percent of the number and capacity of exits to discharge through the street floor under limited conditions (see 7.7.2). Paragraph 28/29.2.7.2 modifies the restrictions of Section 7.7 by treating an exit that discharges onto a mezzanine within the lobby of a hotel (with subsequent open stair travel to the lobby floor on the level of exit discharge) as equivalent to an exit that discharges directly into the lobby at the level of exit discharge. Therefore, 50 percent of the exits can discharge onto a mezzanine; the other 50 percent must discharge directly outside. However, the distance from the termination of the exit enclosure to the exterior door is limited to a maximum of 30 m (100 ft) in new buildings. In existing buildings, the same 30-m (100-ft) limitation applies, unless the building is protected with automatic sprinklers, in which case the distance can be extended to 46 m (150 ft). The part of the exit discharge that occurs within the building

is depicted in Exhibit 28/29.7 by the arrow that connects the door at Stair 1 with the lobby door to the outside. See also the commentary on 7.7.2.

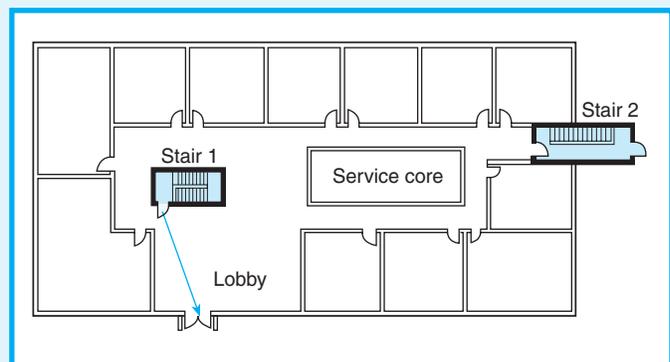

Exhibit 28/29.7 Exit discharge through street level.

CHAPTER 28 • New

28.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

28.2.9 Emergency Lighting.

28.2.9.1 Emergency lighting in accordance with Section 7.9 shall be provided.

28.2.9.2 The requirement of 28.2.9.1 shall not apply where each guest room or guest suite has an exit direct to the outside of the building at street or ground level.

28.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

28.2.11 Special Means of Egress Features.

(Reserved)

Section 28.3 Protection**28.3.1 Protection of Vertical Openings.**

28.3.1.1 Vertical openings shall comply with 28.3.1.1.1, 28.3.1.1.2, or 28.3.1.1.3.

28.3.1.1.1 Vertical openings shall be enclosed or protected in accordance with Section 8.6.

28.3.1.1.2 Vertical openings in accordance with 8.6.8.2 shall be permitted.

28.3.1.1.3 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5, the fire resistance of walls enclosing vertical openings shall be not less than 1 hour and the fire protection rating of doors shall be not less than 1 hour.

CHAPTER 29 • Existing

29.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

29.2.9 Emergency Lighting.

29.2.9.1 Emergency lighting in accordance with Section 7.9 shall be provided in all buildings with more than 25 rooms.

29.2.9.2 The requirement of 29.2.9.1 shall not apply where each guest room or guest suite has an exit direct to the outside of the building at street or ground level.

29.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

29.2.11 Special Means of Egress Features.

(Reserved)

Section 29.3 Protection**29.3.1 Vertical Openings.**

29.3.1.1 Vertical openings shall comply with 29.3.1.1.1, 29.3.1.1.2, 29.3.1.1.3, or 29.3.1.1.4.

29.3.1.1.1 Vertical openings shall be enclosed or protected in accordance with Section 8.6.

29.3.1.1.2 Vertical openings in accordance with 8.6.8.2 shall be permitted.

29.3.1.1.3 In buildings protected throughout by an approved automatic sprinkler system in accordance with 29.3.5, and in which exits and required ways of travel thereto are adequately safeguarded against fire and smoke within the building, or where every individual room has direct access to an exterior exit without passing through any public corridor, the protection of vertical openings that are not part of required exits shall not be required where approved by the authority having jurisdiction and where such openings do not endanger required means of egress.

29.3.1.1.4 In buildings not more than two stories in height, unprotected openings shall be permitted by the authority having jurisdiction to continue to be used where the building is protected throughout by an approved automatic sprinkler system in accordance with 29.3.5.

CHAPTER 28 • New

New hotels, except those in buildings not more than three stories in height where all guest sleeping rooms have a door to the exterior at grade or to an exterior exit access balcony, must be protected throughout by an approved, supervised automatic sprinkler system (see 28.3.5.1 and 28.3.5.2). Therefore, most new hotels, by virtue of their compliance with the sprinkler requirements of 28.3.5.1, are permitted to use the 1-hour vertical enclosure protection option in accordance with 28.3.1.1.3 regardless of the number of stories the vertical opening connects. See also the commentary following 28/29.2.2.1.2 for discussion on the requirements for exits.

The enclosure of vertical openings in existing hotels is provided by means of a performance approach. Openings must be either enclosed in accordance with Section 8.6, or they must satisfy the objectives of 4.5.5. Note, however, that no such performance approach is provided for new hotels.

The provisions of 28.3.1.1.2 and 29.3.1.1.2 are the same and permit an open stair connecting a maximum of two levels within a guest suite. This stair is permitted to serve as a means of escape (see 8.6.8.2 for the provisions for convenience openings).

28.3.1.2 No floor below the level of exit discharge used only for storage, heating equipment, or purposes other than residential occupancy shall have unprotected openings to floors used for residential purposes.

28.3.2 Protection from Hazards.

28.3.2.1 General. All rooms containing high-pressure boilers, refrigerating machinery, transformers, or other service equipment subject to possible explosion shall not be located directly under or directly adjacent to exits and shall be effectively cut off from other parts of the building as specified in Section 8.4.

28.3.2.2 Hazardous Areas.

28.3.2.2.1 Any hazardous area shall be protected in accordance with Section 8.4.

28.3.2.2.2 The areas described in Table 28.3.2.2.2 shall be protected as indicated.

28.3.2.2.3 Where sprinkler protection without fire-rated separation is used, areas shall be separated from other spaces by smoke partitions complying with Section 8.4.

CHAPTER 29 • Existing

Existing unprotected openings are permitted by 29.3.1.1.3 under the following conditions:

- (1) Openings are approved by the authority having jurisdiction.
- (2) The building is totally sprinklered.
- (3) Exits and exit accesses are adequately safeguarded against fire and smoke in the remainder of the building.
- (4) In lieu of condition (3), every room has direct access to an exterior exit that does not require travel through a public corridor.
- (5) Shafts that enclose required exit stairs are protected.

Existing unprotected vertical openings are permitted by 29.3.1.1.4 under the following conditions:

- (1) Openings are approved by the authority having jurisdiction.
- (2) The building is not more than two stories.
- (3) The building is totally sprinklered.

29.3.1.2 No floor below the level of exit discharge used only for storage, heating equipment, or purposes other than residential occupancy shall have unprotected openings to floors used for residential purposes.

29.3.2 Protection from Hazards.

29.3.2.1 General. All rooms containing high-pressure boilers, refrigerating machinery, transformers, or other service equipment subject to possible explosion shall not be located directly under or directly adjacent to exits and shall be effectively cut off from other parts of the building as specified in Section 8.4.

29.3.2.2 Hazardous Areas.

29.3.2.2.1 Any hazardous area shall be protected in accordance with Section 8.7.

29.3.2.2.2 The areas described in Table 29.3.2.2.2 shall be protected as indicated.

29.3.2.2.3 Where sprinkler protection without fire-rated separation is used, areas shall be separated from other spaces by smoke partitions complying with Section 8.4.

CHAPTER 28 • New

Table 28.3.2.2.2 Hazardous Area Protection

Hazardous Area Description	Separation/Protection
Boiler and fuel-fired heater rooms serving more than a single guest room or guest suite	1 hour and sprinklers
Employee locker rooms	1 hour or sprinklers
Gift or retail shops	1 hour or sprinklers
Bulk laundries	1 hour and sprinklers
Guest laundries $\leq 9.3 \text{ m}^2$ ($\leq 100 \text{ ft}^2$) outside of guest rooms or guest suites	1 hour or sprinklers†
Guest laundries $> 9.3 \text{ m}^2$ ($> 100 \text{ ft}^2$) outside of guest rooms or guest suites	1 hour and sprinklers
Maintenance shops	1 hour and sprinklers
Storage rooms‡	1 hour or sprinklers
Trash collection rooms	1 hour and sprinklers

†Where automatic sprinkler protection is provided, no enclosure shall be required.

‡Where storage areas not exceeding 2.2 m^2 (24 ft^2) are directly accessible from the guest room or guest suite, no separation or protection shall be required.

Note the differences in the hazardous area protection requirements for new and existing hotels. In new construction, many areas are required to be separated by construction with a 1-hour fire resistance rating and be protected by automatic sprinklers. In existing construction, automatic sprinklers are often used as an alternative to rated construction, with the exception of trash collection rooms and maintenance

28.3.3 Interior Finish.

28.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

28.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be permitted as follows:

- (1) Exit enclosures—Class A
- (2) Lobbies and corridors—Class A or Class B
- (3) Other spaces—Class A, Class B, or Class C

28.3.3.3 Interior Floor Finish.

28.3.3.3.1 Interior floor finish shall comply with Section 10.2.

CHAPTER 29 • Existing

Table 29.3.2.2.2 Hazardous Area Protection

Hazardous Area Description	Separation/Protection
Boiler and fuel-fired heater rooms serving more than a single guest room or guest suite	1 hour or sprinklers
Employee locker rooms	1 hour or sprinklers
Gift or retail shops $> 9.3 \text{ m}^2$ ($> 100 \text{ ft}^2$)	1 hour or sprinklers†
Bulk laundries	1 hour or sprinklers
Guest laundries $> 9.3 \text{ m}^2$ ($> 100 \text{ ft}^2$) outside of guest rooms or guest suites	1 hour or sprinklers†
Maintenance shops	1 hour and sprinklers
Rooms or spaces used for storage of combustibles and equipment in quantities deemed hazardous by the authority having jurisdiction‡	1 hour or sprinklers
Trash collection rooms	1 hour and sprinklers

†Where automatic sprinkler protection is provided, no enclosure shall be required.

‡Where storage areas not exceeding 2.2 m^2 (24 ft^2) are directly accessible from the guest room or guest suite, no separation or protection shall be required.

shops, where both protection methods would be required.

While the lists that appear in Tables 28.3.2.2.2 and 29.3.2.2.2 provide specific direction for certain hazardous contents areas, they are not all-inclusive. Other areas that are deemed hazardous need to be provided with the appropriate level of protection in accordance with Section 8.7.

29.3.3 Interior Finish.

29.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

29.3.3.2 Interior-Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be permitted as follows:

- (1) Exit enclosures—Class A or Class B
- (2) Lobbies and corridors—Class A or Class B
- (3) Other spaces—Class A, Class B, or Class C

29.3.3.3 Interior Floor Finish. In nonsprinklered buildings, newly installed interior floor finish in exits and exit access corridors shall be not less than Class II in accordance with 10.2.7.

CHAPTER 28 • New

28.3.3.3.2 Interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 28.3.6.1 shall be not less than Class II.

28.3.3.3.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

28.3.3.4* Furnishings and Decorations. New draperies, curtains, and other similar loosely hanging furnishings and decorations in hotels and dormitories shall be in accordance with the provisions of 10.3.1.

A.28.3.3.4 In nonsprinklered hotels, dormitories, or apartment buildings, new upholstered furniture located in corridors or areas not separated from corridors by corridor walls, as specified in the *Code*, should be tested in accordance with NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*. The char length is not to exceed 38 mm (1½ in.) and should be labeled to indicate such compliance.

Most new hotels and dormitories will be sprinklered in accordance with the requirements of Chapter 28. Although there are no mandatory references to the upholstered furniture and mattress provisions of 10.3.2 through 10.3.4, sprinklered building spaces are exempted from their provisions based on the assumption that the sprinklers will prevent room flash-

28.3.4 Detection, Alarm, and Communications Systems.

28.3.4.1 General. A fire alarm system in accordance with Section 9.6, except as modified by 28.3.4.2 through 28.3.4.5, shall be provided.

28.3.4.2 Initiation. The required fire alarm system shall be initiated by each of the following:

- (1) Manual means in accordance with 9.6.2
- (2) A manual fire alarm box located at the hotel desk or other convenient central control point under continuous supervision by responsible employees

CHAPTER 29 • Existing

29.3.3.4* Furnishings and Decorations. New draperies, curtains, and other similar loosely hanging furnishings and decorations in hotels and dormitories shall be in accordance with the provisions of 10.3.1.

A.29.3.3.4 In nonsprinklered hotels, dormitories, or apartment buildings, new upholstered furniture located in corridors or areas not separated from corridors by corridor walls, as specified in the *Code*, should be tested in accordance with NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*. The char length is not to exceed 38 mm (1½ in.), and should be labeled to indicate such compliance.

over. Existing hotels and dormitories are permitted to utilize sprinklers to take advantage of these provisions. For nonsprinklered hotels and dormitories, A.28/A.29.3.3.4 recommends that—as a minimum—the cigarette ignition resistance of new furniture be proven by testing.

29.3.4 Detection, Alarm, and Communications Systems.

29.3.4.1 General. A fire alarm system in accordance with Section 9.6, except as modified by 29.3.4.2 through 29.3.4.5.2, shall be provided in buildings other than those where each guest room has exterior exit access in accordance with 7.5.3, and the building does not exceed three stories in height.

29.3.4.2 Initiation. The required fire alarm system shall be initiated by each of the following:

- (1) Manual means in accordance with 9.6.2, unless there are other effective means to activate the fire alarm system, such as complete automatic sprinkler or automatic detection systems. The manual fire alarm box in accordance with 29.3.4.2(2) shall be required.
- (2) A manual fire alarm box located at the hotel desk or other convenient central control point under continuous supervision by responsible employees

CHAPTER 28 • New

- (3) Any automatic sprinkler system
- (4) Any required automatic detection system other than sleeping room smoke detectors

28.3.4.3 Notification.

28.3.4.3.1* Occupant notification shall be provided automatically in accordance with 9.6.3.

A.28.3.4.3.1 Visible signaling appliances might be governed by provisions of federal regulations in 28 CFR 36, Appendix A (Americans with Disabilities Act Accessibility Guidelines—ADAAG), Section 4.28, Alarms.

28.3.4.3.2 Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.

28.3.4.3.3* Guest rooms and guest suites specifically required and equipped to accommodate hearing impaired individuals shall be provided with a visible notification appliance.

A.28.3.4.3.3 A quantity of such rooms and suites might be required to be equipped to accommodate hearing impaired individuals based on the total number of rooms in a transient lodging facility. [See 28 CFR 36, Appendix A (Americans with Disabilities Act Accessibility Guidelines—ADAAG), Sections 9.1.3, 9.1.5, and 9.2.2(8).]

28.3.4.3.4 In occupiable areas, other than guest rooms and guest suites, visible notification appliances shall be provided.

28.3.4.3.5 Annunciation in accordance with 9.6.7 shall be provided in buildings exceeding two stories in height or having more than 50 guest rooms or guest suites.

28.3.4.3.6* Provisions shall be made for the immediate notification of the public fire department by telephone or other means in case of fire, and, where there is no public fire department, notification shall be made to the private fire brigade.

A.28.3.4.3.6 The provision for immediate notification of the public fire department is intended to include, but is not limited to, all of the arrangements in 9.6.4.2. Other arrangements that depend on a clerk or other member of the staff to notify the fire department might also be permitted. In such cases, however, it is essential that a trained staff member and an immediately available means of calling the fire department are continuously available. If a telephone is to be used, it should not be of any type or arrangement that requires a coin or the unlocking of a device to contact the fire department.

CHAPTER 29 • Existing

- (3) Any required automatic sprinkler system
- (4) Any required automatic detection system other than sleeping room smoke detectors.

29.3.4.3 Notification.

29.3.4.3.1 Occupant notification shall be provided automatically in accordance with 9.6.3.

29.3.4.3.2 Positive alarm sequence in accordance with 9.6.3.4, and a presignal system in accordance with 9.6.3.3, shall be permitted.

29.3.4.3.3 Reserved.

29.3.4.3.4 Reserved.

29.3.4.3.5 Reserved.

29.3.4.3.6* Provisions shall be made for the immediate notification of the public fire department by telephone or other means in case of fire, and, where there is no public fire department, notification shall be made to the private fire brigade.

A.29.3.4.3.6 The provision for immediate notification of the public fire department is intended to include, but is not limited to, all of the arrangements in 9.6.4.2. Other arrangements that depend on a clerk or other member of the staff to notify the fire department might also be permitted. In such cases, however, it is essential that a trained staff member and an immediately available means of calling the fire department are continuously available. If a telephone is to be used, it should not be of any type or arrangement that requires a coin or the unlocking of a device to contact the fire department.

CHAPTER 28 • New

The *Code* requires that, in addition to the normal distribution of manual fire alarm boxes (pull stations, see 9.6.2), the front desk, telephone operator's location, or similar location must also be equipped with one. The intent is that a manual fire alarm box is to be available at the location where staff would receive notification of an emergency phoned in by a guest.

The smoke alarms installed in sleeping rooms are usually single-station alarms that are provided for the sole purpose of notifying the occupants of a smoky condition within that room. Thus, the alarms are not a part of a required automatic detection system and are not required to initiate the building alarm system. The *Code*, in fact, prohibits room alarms from activating the system to prevent numerous activations that could pose a nuisance alarm problem in hotels (see 9.6.2.10.4). There are alarms available that annunciate at a central point, alert the occupants of the room, and notify management of a problem in that room without sounding an alarm throughout the facility.

The provision of 29.3.4.2(1) eliminates the requirements for manual fire alarm boxes to be located so that all portions of a building are within 60 m (200 ft) of a manual fire alarm box (see 9.6.2) in existing hotels where an automatic sprinkler system or an automatic fire detection system is provided throughout the building. The alarm system is still required; only the requirement for additional manual fire alarm boxes is eliminated.

The location of audible alarm devices in hotels affects their audibility. In most new construction, corridor walls are of such character (soundproof) that a sounding device would be needed in each guest room or guest suite to meet the performance criterion for audibility throughout the building. The use of sounding devices only in the corridor might necessitate their operation at dangerous sound levels to awaken guests in their rooms. See Supplement 2 of this handbook.

The permitted use of positive alarm sequence by 28/29.3.4.3.2 recognizes a technology similar to a presignal system but with additional fail-safe features. See the commentary on 9.6.3.4 for discussion on positive alarm sequence.

Presignal systems have repeatedly been involved in delaying alarms in multiple-death fires and are not permitted in new construction. However, the occurrence of nuisance alarms in hotels is real, and presignal systems continue to be permitted in existing buildings. Therefore, if the presignal is to be transmitted to a building staff location (for example,

CHAPTER 29 • Existing

front desk), 9.6.3.3 specifies that it must be received by trained staff. As a result, hotel employees assigned to signal-receiving locations must be well trained with respect to fire alarm signals and proper staff response to an alarm.

Neither 28.3.4.3.6 nor 29.3.4.3.6 requires a direct fire alarm connection to the fire department; however, direct connection is an excellent method of complying. The telephone addressed in A.28/A.29.3.4.3.6 needs to be equipped for direct outside dial without going through a switchboard and should not be a pay phone.

Single-station smoke alarms powered by the building's electrical system are required in each sleeping room and living area located in a guest room or guest suite. The intent is to alert the occupant of the room to the presence of a fire originating in that room or suite. Normally, the alarms are not tied into the building fire alarm [see 28/29.3.4.2(4)]. The expected course of action is as follows:

- (1) The smoke alarm alerts the occupant of the room; the occupant leaves the room.
- (2) The self-closing device on the corridor door returns the door to its closed and latched position.
- (3) The occupant pulls a manual fire alarm box, thereby initiating the building alarm system; the occupant proceeds to an exit and leaves building.
- (4) If the occupant fails to sound the alarm manually, compensation is provided in new construction by corridor smoke detectors or by automatic sprinklers (see 28.3.4.4 for corridor smoke detection requirements in new, nonsprinklered hotels and dormitories).

In addition to requiring a smoke alarm in each sleeping room, a smoke alarm is required in each living area within the guest room or guest suite. These alarms are required for the following two reasons:

- (1) The living area is often used for sleeping, even if such use was not the original intent.
- (2) Most sleeping rooms are arranged so that a fire in the living area will rapidly block escape from the sleeping area.

If a corridor smoke detection system is provided, it must be maintained, since the system is required for new construction, unless the building is sprinklered. Removal of the system would be considered a renovation, and renovations must comply with the requirements for new construction to the extent practical.

CHAPTER 28 • New

28.3.4.4 Detection. A corridor smoke detection system in accordance with Section 9.6 shall be provided in buildings other than those protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5.3.

28.3.4.5* Smoke Alarms. An approved single-station smoke alarm shall be installed in accordance with 9.6.2.10 in every guest room and every living area and sleeping room within a guest suite.

A.28.3.4.5 Caution needs to be exercised in locating smoke alarms with regard to their proximity to bathrooms, cooking facilities, and HVAC outlets in order to prevent nuisance alarms.

28.3.5 Extinguishment Requirements.

28.3.5.1 All buildings other than those complying with 28.3.5.2 shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5.3.

28.3.5.2 Automatic sprinkler protection shall not be required in buildings where all guest sleeping rooms or guest suites have a door opening directly to either of the following:

- (1) The outside at the street or grade level
- (2) Exterior exit access arranged in accordance with Section 7.5.3 in buildings up to and including three stories in height above grade.

28.3.5.3 Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be in accordance with Section 9.7, as modified by 28.3.5.4; in buildings up to and including four stories in height above grade, systems in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted.

CHAPTER 29 • Existing

29.3.4.4 Detection. (Reserved)

29.3.4.5* Smoke Alarms. An approved single-station smoke alarm shall be installed in accordance with 9.6.2.10 in every guest room and every living area and sleeping room within a guest suite.

A.29.3.4.5 Caution needs to be exercised in locating smoke alarms with regard to their proximity to bathrooms, cooking facilities, and HVAC outlets in order to prevent nuisance alarms.

29.3.4.5.1 These alarms shall not be required to be interconnected.

29.3.4.5.2 Single-station smoke alarms without a secondary (standby) power source shall be permitted.

29.3.5 Extinguishment Requirements.

29.3.5.1 All high-rise buildings, other than those where each guest room or guest suite has exterior exit access in accordance with 7.5.3, shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 29.3.5.3.

29.3.5.2 Reserved.

29.3.5.3* Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be in accordance with Section 9.7, as modified by 29.3.5.4, and 29.3.5.5; in buildings up to and including four stories in height above grade, systems in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted.

A.29.3.5.3 Although not required by the *Code*, the use of residential sprinklers or quick-response sprinklers is encouraged for new installations of sprinkler systems within dwelling units, apartments, and guest rooms. Caution should be exercised, as the system needs to be designed for the sprinkler being used.

CHAPTER 28 • New

28.3.5.4 The provisions for draft stops and closely spaced sprinklers in NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not be required for openings complying with 8.6.8.2 where the opening is within the guest room or guest suite.

28.3.5.5 Listed quick-response or listed residential sprinklers shall be used throughout guest rooms and guest room suites.

28.3.5.6 Open parking structures that comply with NFPA 88A, *Standard for Parking Structures*, and are contiguous with hotels or dormitories shall be exempt from the sprinkler requirements of 28.3.5.1.

28.3.5.7 In buildings other than those protected throughout with an approved, supervised automatic sprinkler system in accordance with 28.3.5.3, portable fire extinguishers shall be provided as specified in 9.7.4.1 in hazardous areas addressed by 28.3.2.2.

New hotel and dormitory buildings must be protected throughout by an approved, supervised automatic sprinkler system—unless the buildings are three or fewer stories in height and all guest rooms have doors to the exterior at grade or to exterior exit access balconies. The disproportionate percentage of deaths associated with residential occupancies and the conditions precipitating these fatalities in hotel settings (the need to wake sleeping occupants, and escape in unfamiliar surroundings) prompted the *Code* mandate that most new hotels have automatic sprinkler systems installed.

One objective of the *Code* is to protect occupants who are not intimate with the initial fire development from loss of life and improve the survivability of those who are intimate with the fire development, as stated in 4.1.1. Based on this objective, new hotels are required to use quick-response or residential sprinklers throughout guest rooms and guest suites, as per 28.3.5.5. The technology associated with quick-response and residential sprinklers helps to maintain tenability within the room of fire origin.

28.3.6 Corridors.

28.3.6.1 Walls. Exit access corridor walls shall comply with 28.3.6.1.1 or 28.3.6.1.2.

28.3.6.1.1 In buildings not complying with 28.3.6.1.2, exit access corridor walls shall consist of fire barriers in accor-

CHAPTER 29 • Existing

29.3.5.4 The provisions for draft stops and closely spaced sprinklers in NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not be required for openings complying with 8.6.8.2 where the opening is within the guest room or guest suite.

29.3.5.5 In guest rooms and in guest room suites, sprinkler installations shall not be required in closets not exceeding 2.2 m² (24 ft²) and in bathrooms not exceeding 5.1 m² (55 ft²).

29.3.5.6 Reserved.

29.3.5.7 In buildings other than those protected throughout with an approved, supervised automatic sprinkler system in accordance with 29.3.5.3, portable fire extinguishers shall be provided as specified in 9.7.4.1 in hazardous areas addressed by 29.3.2.2.

Automatic sprinklers are not required in all existing hotels and dormitories. Requirements for such systems, where they are installed, are specified by 29.3.5.3. Other portions of Chapter 29 offer significant incentives for installing sprinklers. Examples include a reduction in the fire resistance rating of exit enclosures (29.2.2.1.2) and an increase in common path of travel (29.2.5.4) and travel distance (29.2.6.2 and 29.2.6.3.3.1). In addition, the presence of sprinklers influences requirements addressing exit discharge (29.2.7), vertical openings (29.3.1), hazardous areas (29.3.2), interior finish (29.3.3), corridors (29.3.6), and smoke barriers (29.3.7).

Per 29.3.5.1, an automatic sprinkler system is required in existing high-rise hotels and dormitories, unless every guest room or guest suite has exterior exit access. The presence of exterior exit access eliminates the need to traverse a corridor where conditions might not remain tenable.

29.3.6 Corridors.

29.3.6.1 Walls. Exit access corridor walls shall comply with either 29.3.6.1.1 or 29.3.6.1.2.

29.3.6.1.1 In buildings not complying with 29.3.6.1.2, exit access corridor walls shall consist of fire barriers in accor-

CHAPTER 28 • New

dance with Section 8.3 that have not less than a 1-hour fire resistance rating.

28.3.6.1.2 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5, corridor walls shall have not less than a ½-hour fire resistance rating.

28.3.6.2 Doors. Doors that open onto exit access corridors shall have not less than a 20-minute fire protection rating in accordance with Section 8.3.

28.3.6.3 Reserved.

28.3.6.4 Doors that open onto exit access corridors shall be self-closing and self-latching.

28.3.6.5 Unprotected openings, other than those from spaces complying with 28.3.6.6, shall be prohibited in exit access corridor walls and doors.

28.3.6.6 Spaces shall be permitted to be unlimited in area and open to the corridor, provided that the following criteria are met:

- (1) The spaces are not used for guest rooms or guest suites or hazardous areas.
- (2) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 28.3.5.
- (3) The space does not obstruct access to required exits.

28.3.6.7 Transoms, louvers, or transfer grilles shall be prohibited in walls or doors of exit access corridors.

The provisions of 28/29.3.6 reflect concern for providing safety to persons occupying guest rooms during a fire. The minimum fire resistance rating (1 hour for new hotels and dormitories; ½ hour for existing ones) required for corridor wall construction is intended to prevent fire from moving from the corridor to a room or spreading from a room to the corridor.

Although the reduction to a ½-hour fire resistance rating—as allowed by 28.3.6.1.2—would result in little savings in new construction, it could be useful in rehabilitation, renovations, or conversions of ex-

CHAPTER 29 • Existing

dance with 8.2.3 that have not less than a ½-hour fire resistance rating.

29.3.6.1.2 In buildings protected throughout by an approved, automatic sprinkler system in accordance with 29.3.5, no fire resistance rating shall be required but the walls and all openings therein shall resist the passage of smoke.

29.3.6.2 Doors. Doors that open onto exit access corridors, other than those complying with 8.3.4 or in buildings meeting 29.3.6.3, shall have not less than a 20-minute fire protection rating in accordance with Section 8.3.

29.3.6.3 Where automatic sprinkler protection is provided in the corridor in accordance with 31.3.5.6 through 31.3.5.9, doors shall not be required to have a fire protection rating but shall resist the passage of smoke and be equipped with latches to keep doors tightly closed.

29.3.6.4 Doors that open onto exit access corridors shall be self-closing and self-latching.

29.3.6.5 Unprotected openings, other than those from spaces complying with 29.3.6.6, shall be prohibited in exit access corridor walls and doors.

29.3.6.6 Spaces shall be permitted to be unlimited in area and open to the corridor, provided that the following criteria are met:

- (1) The spaces are not used for guest rooms or guest suites or hazardous areas.
- (2) The space is protected throughout by an approved automatic sprinkler system in accordance with 29.3.5.
- (3) The space does not obstruct access to required exits.

29.3.6.7 Transoms, louvers, or transfer grilles shall be prohibited in walls or doors of exit access corridors, unless meeting 29.3.6.7.1, 29.3.6.7.2, or 29.3.6.7.3.

isting structures that are required to meet the provisions for new construction (see 4.6.8). Most existing lath and plaster walls provide 20-minute to 30-minute fire resistance ratings. If automatic sprinkler protection is provided throughout the building, the existing walls should not have to be replaced.

In existing buildings with automatic sprinklers, corridor walls are required only to resist the passage of smoke (see 29.3.6.1.2).

The fire-rated corridor door required by 28/29.3.6.2 provides a level of protection commensurate

CHAPTER 28 • New

with the expected fuel load in the room and the fire resistance of the corridor wall construction. The purpose is to box a fire out of a room or to box it within the room by means of corridor wall and door construction. Fuel load studies conducted by the former National Bureau of Standards (now the National Institute of Standards and Technology) demonstrated that residential occupancies typically have fuel loads capable of sustaining a fire for approximately 20 to 30 minutes.

Paragraph 29.3.6.3 permits a nonrated door that resists the passage of smoke in buildings that have corridor sprinkler protection installed in accordance with Option 3 for apartment buildings. See 31.3.5.6 and its commentary for information on apartment building Option 3 corridor sprinkler requirements. In Exhibits 28/29.8 and 28/29.9, the self-closing door is needed to complete the separation established by the fire resistance-rated corridor wall. No provisions permit omission of the self-closing device on the door. Although an existing wall is not required to be fire

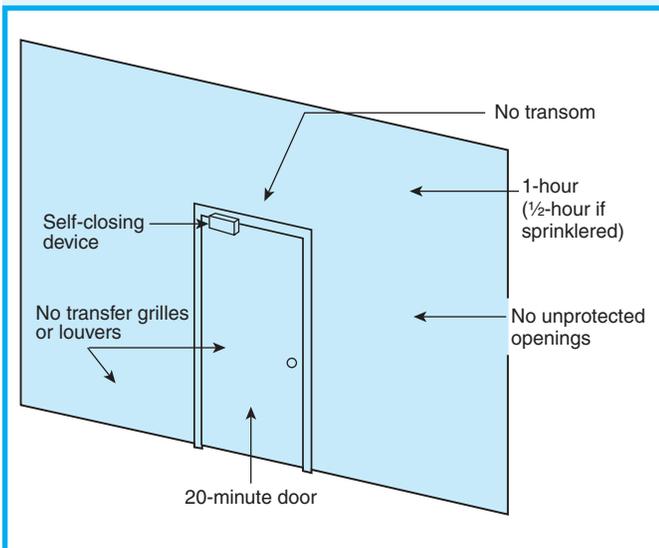

Exhibit 28/29.8 Protection of guest room corridors and openings in new hotels and dormitories.

CHAPTER 29 • Existing

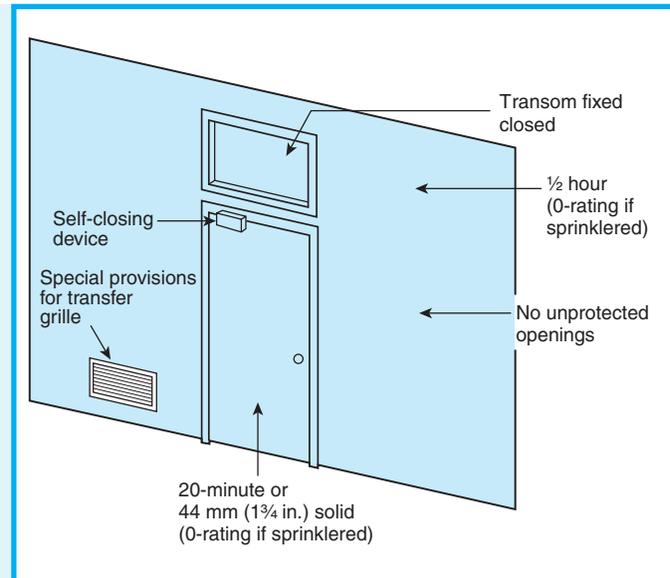

Exhibit 28/29.9 Protection of guest room corridors and openings in existing hotels and dormitories.

rated if sprinkler protection is provided, the wall needs to be solid and resist the passage of smoke.

A 20-minute fire protection rating is required for guest room corridor doors. NFPA 80, *Standard for Fire Doors and Fire Windows*², requires a fire-rated door to be self-closing; however, the requirement for self-closing doors is important enough to be repeated in 28/29.3.6.4, rather than relying only on the referenced document.

NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*³, prohibits corridors in hotels from being used as a portion of the system for supply, return, or exhaust air.

Operable transoms are prohibited in hotels based on multiple-death fires in which transoms allowed fire and smoke to move through corridors and into occupied rooms. However, existing hotels built prior to 1950 often use corridors for supply or return air. The *Code* continues to recognize this practice for existing hotels if the specific conditions of 29.3.6.7 are met.

29.3.6.7.1 Existing transoms shall be permitted but shall be fixed in the closed position and shall be covered or otherwise protected to provide a fire resistance rating not less than that of the wall in which they are installed.

CHAPTER 28 • New

28.3.7 Subdivision of Building Spaces.

Buildings shall be subdivided in accordance with 28.3.7.1 or 28.3.7.2.

28.3.7.1 In buildings not protected throughout by an approved, supervised automatic sprinkler system, each hotel guest room, including guest suites, and dormitory room shall be separated from other guest rooms or dormitory rooms by walls and floors constructed as fire barriers having fire resistance ratings of not less than one hour.

28.3.7.2 In buildings protected throughout by an approved, supervised automatic sprinkler system, each hotel guest room, including guest suites, and dormitory room shall be separated from other guest rooms or dormitory rooms by walls and floors constructed as fire barriers having fire resistance ratings of not less than ½ hour.

In new hotels and dormitories, a ½-hour fire resistance rated separation (1-hour if not sprinklered) between guest rooms, guest suites, and dormitory rooms is necessary to confine a fire to the room of fire origin. Hotel guest rooms are frequently provided with connecting doors to permit multiple rooms to be used by a single family or group and allow for access between the rooms. The requirement for a fire barrier separation between the rooms, therefore, necessitates the use of a fire protection rated door assembly for at least one of the doors in any guest room-to-guest room opening. The required fire pro-

CHAPTER 29 • Existing

29.3.6.7.2 The requirement of 29.3.6.7 shall not apply where a corridor smoke detection system is provided that, when sensing smoke, sounds the building alarm and shuts down return or exhaust fans that draw air into the corridor from the guest rooms. The transfer grille or louver shall be located in the lower one-third of the wall or door height.

29.3.6.7.3 The requirement of 29.3.6.7 shall not apply to buildings protected throughout by an approved automatic sprinkler system complying with 29.3.5 or buildings with corridor sprinkler protection in accordance with 31.3.5.6 through 31.3.5.9. The transfer grille or louver shall be located in the lower one-third of the wall or door height.

29.3.7 Subdivision of Building Spaces.

In buildings other than those meeting 29.3.7.1, 29.3.7.2, or 29.3.7.3, every guest room floor shall be divided into not less than two smoke compartments of approximately the same size by smoke barriers in accordance with Section 8.5.

29.3.7.1 Smoke barriers shall not be required in buildings protected throughout by an approved automatic sprinkler system in accordance with 29.3.5 or a corridor sprinkler system conforming to 31.3.5.6 through 31.3.5.9.

29.3.7.2 Smoke barriers shall not be required where each guest room is provided with exterior ways of exit access arranged in accordance with 7.5.3.

29.3.7.3 Smoke barriers shall not be required where the aggregate corridor length on each floor is not more than 46 m (150 ft).

29.3.7.4 Additional smoke barriers shall be provided so that the travel distance from a guest room corridor door to a smoke barrier shall not exceed 46 m (150 ft).

29.3.7.5 Smoke dampers shall not be required.

tection rating for such a door would be ¾ hour in a nonsprinklered building, and ½ hour in a sprinklered building, in accordance with Table 8.3.4.2.

All but relatively small floors of nonsprinklered existing buildings must be subdivided into two smoke compartments per 29.3.7. This requirement provides for horizontal movement of occupants, limits the number of rooms, and, therefore, limits the number of occupants exposed to a single fire that might render a corridor untenable. Because no fire-resistance rating is required for the barrier and smoke dampers are not required, the requirement is not

CHAPTER 28 • New

overly burdensome in typical hotel or dormitory construction. The exemption for automatic sprinklers reflects the excellent life-loss record of buildings equipped with sprinkler protection.

28.3.8 Special Protection Features.

(Reserved)

Section 28.4 Special Provisions**28.4.1 High-Rise Buildings.**

High-rise buildings shall comply with Section 11.8.

Section 28.5 Building Services**28.5.1 Utilities.**

Utilities shall comply with the provisions of Section 9.1.

28.5.2 Heating, Ventilating, and Air Conditioning.

28.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2, except as otherwise required in this chapter.

28.5.2.2 Unvented fuel-fired heaters, other than gas space heaters in compliance with NFPA 54, *National Fuel Gas Code*, shall not be used.

28.5.3 Elevators, Escalators, and Conveyors.

28.5.3.1 Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

28.5.3.2* In high-rise buildings, one elevator shall be provided with a protected power supply and shall be available for use by the fire department in case of emergency.

A.28.5.3.2 “Protected power supply” means a source of electrical energy of sufficient capacity to allow proper operation of the elevator and its associated control and communications systems. The power supply’s point of origin, system of distribution, type and size of overcurrent protection, degree of isolation from other portions of the building electrical system, and degree of mechanical protection should be such that it is unlikely that the supply would be disrupted at any

CHAPTER 29 • Existing

A horizontal exit is permitted to be used to comply with 29.3.7 and, thereby, to serve more than one function.

29.3.8 Special Protection Features.

(Reserved)

Section 29.4 Special Provisions**29.4.1 High-Rise Buildings.**

High-rise buildings shall comply with 29.3.5.1.

Section 29.5 Building Services**29.5.1 Utilities.**

Utilities shall comply with the provisions of Section 9.1.

29.5.2 Heating, Ventilating, and Air Conditioning.

29.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2, except as otherwise required in this chapter.

29.5.2.2 Unvented fuel-fired heaters, other than gas space heaters in compliance with NFPA 54, *National Fuel Gas Code*, shall not be used.

29.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

CHAPTER 28 • New

CHAPTER 29 • Existing

but the advanced stages of building fire involvement or by structural collapse.

A protected power supply might consist of, and should provide, not less than the level of reliability associated with an electrical distribution system with service equipment located and installed in accordance with 230.72(B) and 230.82(5) of NFPA 70, *National Electrical Code*[®]. The distribution system is not to have any other connection to the building electrical distribution system. A protected power supply is not required to incorporate two sources of energy or automatic transfer capability from a normal to an emergency source, for example, an alternate set of service conductors.

The number and type of elevators to be connected to a protected power supply should be limited, or the characteristics of the protected power supply should be selected to ensure conformance with 230.95 of NFPA 70, *National Electrical Code*[®], without the provision of ground fault protection for the supply.

An elevator installation supplied by a protected power supply should comply with Article 620 of NFPA 70, *National Electrical Code*[®], except that the energy absorption means required by 620.91 should always be connected on the load side of the disconnecting means. The energy absorption means should not consist of loads likely to become inoperative or disconnected under the conditions assumed to exist when the elevator is under the control of fire department personnel. Examples of such loads include light and power loads external to the elevator equipment room.

28.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 28.6 Reserved

Section 28.7 Operating Features

28.7.1 Hotel Emergency Organization.

28.7.1.1* Employees of hotels shall be instructed and drilled in the duties they are to perform in the event of fire, panic, or other emergency.

A.28.7.1.1 Employers are obligated to determine the degree to which employees are to participate in emergency activities. Regulations of the U.S. Department of Labor (OSHA) govern these activities and provide options for employers,

29.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 29.6 Reserved

Section 29.7 Operating Features

29.7.1 Hotel Emergency Organization.

29.7.1.1* Employees of hotels shall be instructed and drilled in the duties they are to perform in the event of fire, panic, or other emergency.

A.29.7.1.1 Employers are obligated to determine the degree to which employees are to participate in emergency activities. Regulations of the U.S. Department of Labor (OSHA) govern these activities and provide options for employers,

CHAPTERS 30 and 31

New and Existing Apartment Buildings

The apartment building classification is one of five residential occupancy types addressed by the *Life Safety Code*. Other residential occupancies include one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, and residential board and care facilities.

The common principle of life safety that is applied to all residential occupancies addressed by Chapters 24 through 33 is highlighted by 6.1.8.1, which states that residential occupancies are those occupancies in which sleeping accommodations are provided for purposes other than health care or detention and correction. The presence of sleeping occupants is central to the provisions of Chapters 24 through 33, because occupants who are asleep will be unaware of a developing fire and, when awakened to be alerted to the emergency, might be somewhat confused. The definition of the term *residential occupancy* in 6.1.8.1 also differentiates between sleeping occupants in residential occupancies and those in health care or detention and correctional occupancies, which are also characterized by the occupants' incapability of self-preservation. The provisions of Chapters 24 through 33 are also based on the presence of hazards (such as cooking and heating equipment) in residential occupancies and the degree to which occupants are familiar with their living space. Occupants might have little or no familiarity, as in the case of the transient residents of hotels, or they might have the total familiarity that is common to residents of single-family dwellings.

Apartment buildings pose an additional problem, because the typical building configuration often requires an escaping resident to traverse an interior

corridor, which subsequently might expose the resident to the heat and smoke of a corridor or dwelling unit fire. In recognition of these potential hazards, the *Code* requires most new apartment buildings to be protected throughout by an approved, supervised automatic sprinkler system.

From 1994 to 1998, apartments, townhouses, flats, and condominiums accounted for 96,200 structure fires per year, as reported to U.S. fire departments. Commentary Table 30/31.1 provides a breakdown of the contribution of apartment building fires to the overall home structure fire record during those years.

The causes of apartment building fires differ significantly from one- and two-family dwelling fires in building equipment areas. Heating and electrical equipment accounted for 28 percent of the fires in one- and two-family dwellings, while accounting for only 11 percent of the fires in apartment buildings. This difference is most likely due to the centralized arrangement of the heating and electrical systems typical of most apartment buildings. Equipment fires are usually the result of poor maintenance or human error. Heating and electrical systems tend to be more closely regulated, maintained, and supervised in apartment buildings, which results in a reduced chance of equipment malfunction.

The numbers of fires caused by occupants (for example, those due to cooking and smoking) is high in both categories of home structures.

These data demonstrate the importance of applying the *Code* to apartment buildings to help ensure fire safety, but they also demonstrate the continuing need for public education regarding the causes and prevention of home fires.

Commentary Table 30/31.1 Home Structure Fires, 1994-1998 Annual Averages

Occupancy	Fires	Civilian Deaths	Civilian Injuries
All home structures	406,400	3,498	18,092
Apartment, condominium, or tenement	96,200	632	5,848
1 or 2 living units with business	3,000	25	172
3 to 6 units	26,600	239	1,676
7 to 20 units	24,600	138	1,588
Over 20 units	31,900	170	1,923
Unclassified/unknown	10,200	60	488

Source: National estimates based on NFIRS and NFPA survey data.

Note: These are fires reported to U.S. municipal departments and so exclude fires reported only to federal or state agencies or industrial fire brigades. Fires are rounded to the nearest hundred, and deaths and injuries to the nearest one. Sums may not equal totals due to rounding.

Section 30.1 General Requirements

30.1.1 Application.

30.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as apartment occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, an apartment occupancy (*see 4.6.7*)
- (3) Alterations, modernizations, or renovations of existing apartment occupancies (*see 4.6.8*)
- (4) Buildings or portions thereof upon change of occupancy to an apartment occupancy (*see 4.6.12*)

Due to the disproportionate percentage of deaths associated with residential occupancies, the *Code*, with some exceptions, mandates sprinkler protection in new apartment buildings. For existing apartment buildings the *Code* provides four alternative protection packages referred to as *options*.

The options specify the varying degrees to which an apartment building is protected by fire detection or fire suppression systems as follows:

- (1) Option 1—no suppression or detection systems
- (2) Option 2—total automatic fire detection and notification (although 31.3.4.5.1 requires single-sta-

Section 31.1* General Requirements

A.31.1 See Table A.31.1.

31.1.1 Application.

31.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as apartment occupancies (*see also 30.1.1*). In addition, the building shall meet the requirements of one of the following options:

- (1) Option 1—Buildings without fire suppression or detection systems
- (2) Option 2—Buildings provided with a complete automatic fire detection and notification system
- (3) Option 3—Buildings provided with automatic sprinkler protection in selected areas
- (4) Option 4—Buildings protected throughout by an approved automatic sprinkler system

tion smoke alarms within each apartment unit, such detectors are not part of a system and are not located in all areas of the building; therefore, their presence does not signify an Option 2 apartment building)

- (3) Option 3—partial sprinkler protection (mainly corridor sprinklers—*see 31.3.5.6*)
- (4) Option 4—protection throughout by means of a supervised automatic sprinkler system

In recognition of the life safety benefits associated with a properly installed and maintained sprinkler system, an Option 4 apartment building is exempted

Table A.31.1 Alternate Requirements for Existing Apartment Buildings According to Protection Provided

R: Required (see Code for details and exemptions). NR: No requirements.

from the various Code provisions required of Option 1 through Option 3 apartment buildings. The benefits of such exemptions include the following:

- (1) Increased travel distance allowances
- (2) Reduction in required corridor fire resistance ratings

- (3) Decreased interior finish requirements
- (4) Exemption from the smoke barrier requirement

The protection requirements for new apartment buildings are equivalent to Option 4.

Table A.31.1 summarizes the different protection packages required, depending on whether an

CHAPTER 30 • New

existing apartment building follows Option 1, Option 2, Option 3, or Option 4.

This comprehensive approach provides an attempt at codifying system design. Although a total system would consist of many alternatives, the systems detailed in Options 1 through 4 are more limited, because only four options are available. How-

30.1.1.2 The term *apartment building*, wherever used in this Code, shall include an apartment house, tenement, garden apartment, or any other structure meeting the definition of *apartment building*.

30.1.2 Multiple Occupancies.

30.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

30.1.2.2 No dwelling unit of a residential occupancy shall have its sole means of egress pass through any nonresidential occupancy in the same building.

30.1.2.3 Multiple dwelling units shall be permitted to be located above a nonresidential occupancy only where one of the following conditions exists:

- (1) Where the dwelling units of the residential occupancy and exits therefrom are separated from the nonresidential occupancy by construction having a fire resistance rating of not less than 1 hour
- (2) Where the nonresidential occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7

Residential occupancies often exist in buildings that also house assembly, mercantile, or business occupancies. These nonresidential occupancies might pose an additional threat, because they are not typically occupied after regular business hours. An undetected fire in an unoccupied area has the potential to affect the tenability of the residential portion of

30.1.3 Definitions.

30.1.3.1 Terms applicable to this chapter are defined in Chapter 3 of this Code; where necessary, other terms are defined in the text.

CHAPTER 31 • Existing

ever, the user can identify the most appropriate option based on the existing building's size, height, and arrangement. The options provide an opportunity to coordinate the safety approach that best fits a building, rather than adapting a building to a single codified set of criteria.

31.1.1.2 The term *apartment building*, wherever used in this Code, shall include an apartment house, tenement, garden apartment, or any other structure meeting the definition of *apartment building*.

31.1.2 Multiple Occupancies.

31.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

31.1.2.2 No dwelling unit of a residential occupancy shall have its sole means of egress pass through any nonresidential occupancy in the same building.

31.1.2.3 Multiple dwelling units shall be permitted to be located above a nonresidential occupancy only where one of the following conditions exists:

- (1) Where the dwelling units of the residential occupancy and exits therefrom are separated from the nonresidential occupancy by construction having a fire resistance rating of not less than 1 hour
- (2) Where the nonresidential occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7
- (3) Where not more than two dwelling units are located above a nonresidential occupancy that is protected by an automatic fire detection system in accordance with Section 9.6

the building before occupants can be awakened and take the appropriate actions for safe egress. Therefore, the requirements of 30/31.1.2 help to ensure that it is safe to have apartments within these multiple occupancy buildings by providing the necessary protection and separation.

31.1.3 Definitions.

31.1.3.1 Terms applicable to this chapter are defined in Chapter 3 of this Code; where necessary, other terms are defined in the text.

CHAPTER 30 • New

30.1.3.2 Apartment Building. See 3.3.27.3.

The annex text associated with the definition of *apartment building* in 3.3.27.3 clarifies how town house–type apartments—particularly those under condominium ownership—should be classified for application of

30.1.4 Classification of Occupancy.

See 30.1.3.

30.1.5 Classification of Hazard of Contents.

The contents of residential occupancies shall be classified as ordinary hazard in accordance with 6.2.2.

NFPA 13, *Standard for the Installation of Sprinkler Systems*¹, classifies the contents of an apartment building as light hazard for the purpose of designing automatic sprinkler systems. The *Code* classifies the contents of

30.1.6 Minimum Construction Requirements.

(No special requirements.)

30.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

The amount of material presented in 30/31.1.7 was reduced for the 2000 edition of the *Code*, because all occupant load factors were moved to Table 7.3.1.2 where they are within the context of means of egress.

Section 30.2 Means of Egress Requirements

30.2.1 General.

30.2.1.1 Means of egress from dwelling units to the outside of the building shall be in accordance with Chapter 7 and this chapter.

CHAPTER 31 • Existing

31.1.3.2 Apartment Building. See 3.3.27.3.

the *Code*. It is often mistakenly believed that condominiums are a form of occupancy rather than a form of ownership.

31.1.4 Classification of Occupancy.

See 31.1.3.

31.1.5 Classification of Hazard of Contents.

The contents of residential occupancies shall be classified as ordinary hazard in accordance with 6.2.2.

an apartment building as ordinary hazard (see 30/31.1.5) on the basis of the threat to life or life safety, rather than the challenge to the extinguishing capability of the automatic sprinkler system.

31.1.6 Minimum Construction Requirements.

(No special requirements.)

31.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

The occupant load calculations for areas of apartment buildings used for nonresidential purposes should be based on the occupant load factors applicable to the use of the area.

Section 31.2 Means of Egress Requirements

31.2.1 General.

31.2.1.1 Means of egress from dwelling units to the outside of the building shall be in accordance with Chapter 7 and this chapter.

CHAPTER 30 • New

30.2.1.2 Means of escape within the dwelling unit shall comply with the provisions of Section 24.2 for one- and two-family dwellings.

Per 30/31.2.1.2, every dwelling unit is required to comply with Section 24.2, which addresses means of escape in one- and two-family dwellings. This mandatory reference to Section 24.2 is important for several reasons. First, it establishes a requirement for two means of escape from every sleeping room and living area of a dwelling unit having two rooms or more. Several acceptable types of secondary means of escape are established in 24.2.2.3, the most common of which is an operable window with specified minimum opening dimensions. No secondary means of escape is required if a dwelling unit is protected by an automatic sprinkler system. Note that 24.2.2.1.2 does not require the entire building to be sprinklered, only the dwelling unit that is deficient with respect to the secondary means of escape. However, a mandate for complete building sprinkler protection, such as that in 30.3.5.1, might be specified elsewhere.

A second important provision of Section 24.2 is that the means of egress provisions of Chapter 7 do not apply within the dwelling units unless they are specifically referenced. For example, the minimum width of means of escape doors within a dwelling unit is 710 mm (28 in.), rather than the 810-mm (32-in.) minimum width specified for means of egress by Chapter 7. The requirement of Chapter 7 applies to the door from the dwelling unit to the common corri-

30.2.2 Means of Egress Components.

30.2.2.1 General.

30.2.2.1.1 Components of means of egress shall be limited to the types described in 30.2.2.2 through 30.2.2.12.

30.2.2.1.2 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 30.3.5, exit enclosures shall have a fire resistance rating of not less than 1 hour, and doors shall have a fire protection rating of not less than 1 hour.

CHAPTER 31 • Existing

31.2.1.2 Means of escape within the dwelling unit shall comply with the provisions of Section 24.2 for one- and two-family dwellings.

dor, because this door is the transition point at which means of escape ends and the standard means of egress begins. Chapter 24 also permits the use of winders and spiral stairs within a dwelling unit, and the provisions of Chapter 24 for headroom apply within the dwelling unit, superseding those of Chapter 7. See the commentary on Chapter 24 for additional information on means of escape from living units.

The means of egress provisions of Chapter 7 are applied from the dwelling unit to the outside of the building. Many of the items contained in Section 30/31.2 are provisions that Chapter 7 provides as options that might be specifically recognized by an occupancy chapter; for example, 30/31.2.2.2.2 allows the use of delayed-egress locks in accordance with 7.2.1.6.1, with the additional proviso that not more than one such device is encountered in any single egress path. In other cases, a feature addressed by Chapter 7 is not permitted to be used in the means of egress of apartment buildings, because it is not specifically permitted by Section 30/31.2. The absence of slide escapes in the list of acceptable means of egress components in 30/31.2.2 is an example of a component that is not permitted. Also, Section 30/31.2 limits the degree to which Chapter 7 features can be used, such as the provision of maximum lengths for dead-end corridors and common paths of travel addressed in 30/31.2.5.

31.2.2 Means of Egress Components.

31.2.2.1 General.

31.2.2.1.1 Components of means of egress shall be limited to the types described in 31.2.2.2 through 31.2.2.12.

31.2.2.1.2 In buildings using Option 4, exit enclosures shall have a fire resistance rating of not less than 1 hour, and doors shall have a fire protection rating of not less than 1 hour.

31.2.2.1.3 In non-high-rise buildings using Option 2, Option 3, or Option 4, exit stair doors shall be permitted to be 44-mm (1³/₄-in.) thick, solid-bonded wood core doors, self-closing and self-latching, and in wood frames not less than 19 mm (3/4 in.) thick.

CHAPTER 30 • New

CHAPTER 31 • Existing

The general provisions for the means of egress components in apartment buildings modify the provisions of Chapter 7 in the following two areas:

- (1) Limits on the components of the means of egress
- (2) Protection of the means of egress

First, a general reference to the components of the means of egress in Chapter 7 is made in place of repeating its myriad provisions. Most of these components are permitted in both new and existing apartment buildings. Some of the components are permitted to be used in accordance with the provisions of Chapter 7 and the additional provisions of Chapters 30 and 31. For example, delayed-egress locks are permitted by 30/31.2.2.2.2, which allows their use in accordance with 7.2.1.6.1 if not more than one device is located in any single egress path.

If not permitted, no reference to an egress component is made in the specific occupancy chapter. For example, escalators and fire escape stairs are only permitted as means of egress components in existing apartment buildings. Therefore, 31.2.2.8 and 31.2.2.9 contain specific references to them, while 30.2.2.8 and 30.2.2.9 are reserved and contain no such reference. Neither chapter permits the use of slide escapes; consequently, no reference to slide escapes is made within the means of egress sections of either chapter.

Second, Chapters 30 and 31 recognize the relatively low fuel loads of apartment buildings and permit a fire resistance rating of 1 hour for exit enclosures and other vertical openings (see 30/31.3.1.1.4) in buildings protected throughout by an approved, supervised automatic sprinkler system.

Because the *Code* requires that most new apartment buildings be protected throughout by an approved automatic sprinkler system, a 1-hour fire resistance-rated exit enclosure will typically be permitted in new construction. However, if the provision of 30.3.5.2—which exempts certain building arrangements from the sprinkler requirement—is exercised, the 1-hour rated enclosure option of 30.2.2.1.2 is not

31.2.2.1.4 In buildings using Option 3, sprinklers shall also be provided within the exit enclosure in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

permitted. This situation dictates a default to the Chapter 7 exit enclosure requirements, which, because they are based on the number of stories connected by the exit enclosure, might require 2-hour fire resistance-rated enclosures. See 7.1.3.2 for details on exit enclosure requirements.

The reduction to a 1-hour fire resistance-rated enclosure for exits is not permitted for assembly, mercantile, or business occupancies and, therefore, cannot be used where mixed apartment/assembly, apartment/mercantile, or apartment/business occupancies are involved. In facilities of four or more stories, where apartment occupancies and other occupancies are adequately separated and treated independently in accordance with 6.1.14.4, 1-hour exit enclosures in the apartment portion and 2-hour enclosures elsewhere might be permitted.

Exhibit 30/31.1 illustrates the modification to the requirements for protection of exit enclosures and other vertical openings in a fully sprinklered apartment building.

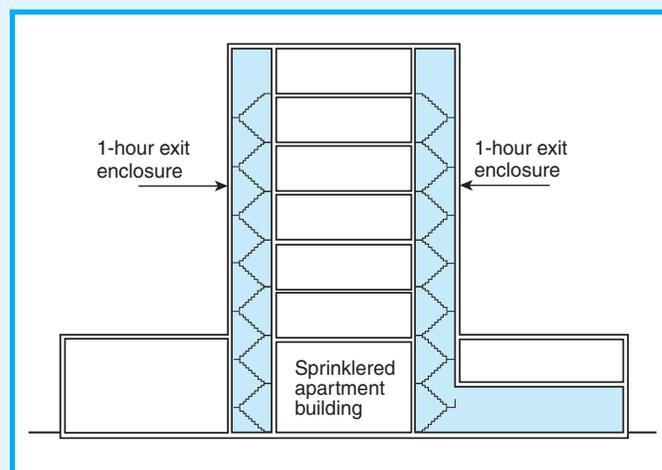

Exhibit 30/31.1 Exit enclosure separation—sprinklered apartment building.

30.2.2.2 Doors.

30.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

31.2.2.2 Doors.

31.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

CHAPTER 30 • New

30.2.2.2.2 Door locking arrangements shall comply with 30.2.2.2.2.1, 30.2.2.2.2.2, or 30.2.2.2.2.3.

30.2.2.2.2.1* No door in any means of egress shall be locked against egress when the building is occupied.

A.30.2.2.2.2.1 It is the intent of this requirement that security measures, where installed, should not prevent egress.

30.2.2.2.2.2 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted, provided that not more than one such device is located in any one egress path.

30.2.2.2.2.3 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

30.2.2.2.3 Revolving doors complying with 7.2.1.10 shall be permitted.

30.2.2.2.4 Horizontal sliding doors, as permitted by 7.2.1.14, shall not be used across corridors.

30.2.2.2.5 Apartment occupancies shall be exempt from the re-entry provisions of 7.2.1.5.7 when the exit enclosure serves directly only one dwelling unit per floor and such exit is a smokeproof enclosure in accordance with 7.2.3.

Apartment buildings are prohibited from having any door locked against egress while the building is occupied. This requirement permits a door to be equipped with a locking device that allows the door to be opened from within the building for the purpose of egress but does not allow the door to be opened from outside the building.

The language of 7.2.1.5.2 is clear: Locks, if provided, are not to require the use of a key, a tool, or special knowledge or effort for operation from the egress side of the building. This requirement prohibits double-cylinder locks and chain locks that require a key to operate the door from the inside. Paragraph 7.2.1.5.9.2 requires the use of a simple operation to open a door; locks that require two-handed knobs and similar operations are prohibited.

Apartment doors provide security for the occupants in the unit. Recognizing this additional function, Chapter 7 permits the use of security chains or rods, as well as locks, on apartment doors and also permits releasing devices in addition to the doorknob or lever. The permitted number of additional releasing actions differs for new and existing buildings.

CHAPTER 31 • Existing

31.2.2.2.2 Door locking arrangements shall comply with 30.2.2.2.2.1, 30.2.2.2.2.2, or 30.2.2.2.2.3.

31.2.2.2.2.1 No door in any means of egress shall be locked against egress when the building is occupied.

31.2.2.2.2.2 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted, provided that not more than one such device is located in any one egress path.

31.2.2.2.2.3 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

31.2.2.2.3 Revolving doors complying with 7.2.1.10 shall be permitted.

31.2.2.2.4 Horizontal sliding doors, as permitted by 7.2.1.14, shall not be used across corridors.

31.2.2.2.5 Apartment occupancies protected throughout by an approved, supervised automatic sprinkler system shall be exempt from the re-entry provisions of 7.2.1.5.7 where the exit enclosure serves directly only one dwelling unit per floor and such exit is a smokeproof enclosure in accordance with 7.2.3.

One additional releasing action is permitted for new apartment buildings, and two additional actions are permitted in existing apartment buildings. The typical apartment door has three devices: a latch, a lock, and a security chain or rod. This arrangement is permitted in existing buildings, provided that only two additional releasing operations are necessary. This arrangement would also be permitted in new construction, provided that the latch and lock set are interconnected so that the lock bolt and the latch will retract simultaneously when the latch handle is turned from the inside; thus, only one releasing action is needed for the two devices. The second action is the release of the security chain or rod. The overriding requirement for any of these devices is that they not require the use of a key, a tool, or special knowledge or effort to operate.

The use of the delayed-egress lock detailed in 7.2.1.6.1 is recognized in 30/31.2.2.2.2 if not more than one such lock is located in any single egress path. The use of a delayed-egress lock requires that the building be protected throughout by either an automatic sprinkler or automatic fire detection sys-

CHAPTER 30 • New

tem. The 15-second or 30-second delay permitted by 7.2.1.6.1 does not affect the immediate release of the lock upon activation of sprinklers or detectors or upon loss of power to the lock. The delay device provides the security needed for doors that are used infrequently. At the same time, the door remains available for emergency use. Chains and padlocks do not provide these safety features.

Selected exit stair enclosure doors are permitted to be locked against re-entry by 7.2.1.5.7, while other stair enclosure doors must remain unlocked. If the selected re-entry provisions are not used, one of the other two options specified by 7.2.1.5.7 must be used for stair enclosures serving five or more stories. Doors

30.2.2.3 Stairs.

30.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

30.2.2.3.2 Within any individual dwelling unit, unless protected by an approved automatic sprinkler system in accordance with 30.3.5, stairs more than one story above or below the entrance floor level of the dwelling unit shall not be permitted.

30.2.2.3.3 Spiral stairs complying with 7.2.2.2.3 shall be permitted within a single dwelling unit.

30.2.2.3.4 Winders complying with 7.2.2.2.4 shall be permitted within a single dwelling unit.

No level of an apartment unit in a nonsprinklered building is permitted to be located more than one story away from a dwelling unit entrance per 30/31.2.2.3.2. This requirement would usually prohibit an apartment unit from encompassing more than three stories: main, upper, and lower. However, if an apart-

30.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

30.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

30.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

30.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

CHAPTER 31 • Existing

are permitted to be locked against re-entry if initiation of the building fire alarm system automatically unlocks the door; otherwise, all doors must remain unlocked at all times.

A provision new to the 2003 edition of the *Code* permits the locking of stairway doors against re-entry in apartment buildings if the stair serves only one dwelling unit per floor and the stair enclosure is constructed as a smokeproof enclosure in accordance with 7.2.3.

Note that 30/31.2.2.4 restricts the use of the special form of horizontal sliding door to a greater extent than 7.2.1.14 by prohibiting cross-corridor installations.

31.2.2.3 Stairs.

31.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

31.2.2.3.2 Within any individual dwelling unit, unless protected by an approved automatic sprinkler system in accordance with 31.3.5, stairs more than one story above or below the entrance floor level of the dwelling unit shall not be permitted.

31.2.2.3.3 Spiral stairs complying with 7.2.2.2.3 shall be permitted within a single dwelling unit.

31.2.2.3.4 Winders complying with 7.2.2.2.4 shall be permitted.

ment has entrances at more than one level or if the building is sprinklered, more than three stories are permitted. Because 30/31.3.1.1.3 allows only two levels within an apartment unit to be open to each other in accordance with 8.6.8.2, the third level must be separated in accordance with Section 8.6.

31.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted. (*See also 31.2.11.*)

31.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

31.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

31.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

CHAPTER 30 • New

30.2.2.8 Reserved.

30.2.2.9 Reserved.

30.2.2.10 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

30.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

30.2.2.12 Areas of Refuge.

30.2.2.12.1 Areas of refuge complying with 7.2.12 shall be permitted, as modified by 30.2.2.12.2.

30.2.2.12.2* In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 30.3.5, the two accessible rooms or spaces separated from each other by smoke-resistive partitions in accordance with the definition of area of refuge in 3.3.17 shall not be required.

A.30.2.2.12.2 The provision of 30.2.2.12.2 permits the entire floor to serve as an area of refuge where it is protected in accordance with 31.3.5. The provision is acceptable because supervised automatic sprinkler systems have built-in signals for monitoring features of the system, such as the opening and closing of water control valves. Such systems also monitor pump power supplies, water tank levels, and conditions that will impair the satisfactory operation of the sprinkler system. Because of these monitoring features, supervised automatic sprinkler systems have a high level of satisfactory performance and response to fire conditions.

Areas accessible to persons with severe mobility impairment must be provided with accessible means of egress as per 7.5.4.1. Existing apartment buildings are exempt from the provisions of 7.5.4.1. Therefore, areas of refuge are not required in existing apartment buildings but are permitted to serve within the means of egress.

CHAPTER 31 • Existing

31.2.2.8* Escalators. Escalators previously approved as a component in the means of egress shall be permitted to continue to be considered as in compliance.

A.31.2.2.8 Due to the nature of escalators, they are no longer acceptable as a component in a means of egress. However, because many escalators have been used for exit access and exit discharge in the past, they are permitted to continue to be considered in compliance. Very few escalators have ever been installed in a manner to qualify as an exit. For information on escalator protection and requirements, see previous editions of the *Code*.

31.2.2.9 Fire Escape Stairs. Fire escape stairs complying with 7.2.8 shall be permitted.

31.2.2.10 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

31.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

31.2.2.12 Areas of Refuge.

31.2.2.12.1 Areas of refuge complying with 7.2.12 shall be permitted, as modified by 31.2.2.12.2.

31.2.2.12.2* In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 31.3.5, the two accessible rooms or spaces separated from each other by smoke-resistive partitions in accordance with the definition of area of refuge in 3.3.17 shall not be required.

A.31.2.2.12.2 The provision of 31.2.2.12.2 permits the entire floor to serve as an area of refuge where it is protected in accordance with 31.3.5. The provision is acceptable because supervised automatic sprinkler systems have built-in signals for monitoring features of the system, such as the opening and closing of water control valves. Such systems also monitor pump power supplies, water tank levels, and conditions that will impair the satisfactory operation of the sprinkler system. Because of these monitoring features, supervised automatic sprinkler systems have a high level of satisfactory performance and response to fire conditions.

For stories above the level of exit discharge, where providing ramps is usually not feasible, areas of refuge (see 7.2.12) will typically be used to meet the requirements for accessible means of egress in new apartment buildings. A sprinklered story of an apartment building is permitted to be considered an area of refuge by 30/31.2.2.12.2, even if an occupant does

CHAPTER 30 • New

not have access to any of the apartment units. Due to the effectiveness of the sprinkler system, an occupant with mobility impairment should be able to remain on the floor without experiencing untenable conditions. However, because locked apartment unit doors create inaccessibility to spaces other than the corri-

30.2.3 Capacity of Means of Egress.

30.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

30.2.3.2 Street floor exits shall be sufficient for the occupant load of the street floor plus the required capacity of stairs and ramps discharging onto the street floor.

30.2.3.3 Corridors with a required capacity of more than 50 persons as defined in Section 7.3 shall be of sufficient width to accommodate the required occupant load but have a width of not less than 1120 mm (44 in.).

30.2.3.4 Corridors with a required capacity of not more than 50 persons as defined in Section 7.3 shall be not less than 910 mm (36 in.) in width.

When occupants from upper floors are discharged from exit stair enclosures onto the street floor (in accordance with 7.7.2) and mix with occupants of the street floor in attempting egress to the exterior, the result is an increased demand on street floor egress components, such as exit doors. Therefore, street floor exits must be sized to handle the combined capacity in accordance with 30/31.2.3.2.

Exhibit 30/31.2 illustrates a lobby design that might be found in apartment buildings in which multiple exit stairs and street floor exits converge at one or two exterior door locations. The required aggregate capacity of doors A and B is based on the number of people expected to use them. Assuming that the street floor has an occupant load of 400 persons and each of the two enclosed exit stairs (that is, stair 1 and stair 2) discharging into the street floor has a required capacity of 200 persons (that is, a maximum of 50 percent of the 400-person occupant load of the second or third floor via stair 1 and a maximum of 50 percent of the 400-person occupant load of the basement via stair 2), the required egress capacity for the street floor would be 800 persons. The unobstructed door or level travel width required to accom-

CHAPTER 31 • Existing

modate 800 persons is 4060 mm (160 in.). The opening provided by each pair of doors, A and B, needs to be 2030 mm (80 in.) in clear, unobstructed width.

31.2.3 Capacity of Means of Egress.

31.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

31.2.3.2 Street floor exits shall be sufficient for the occupant load of the street floor plus the required capacity of stairs and ramps discharging onto the street floor.

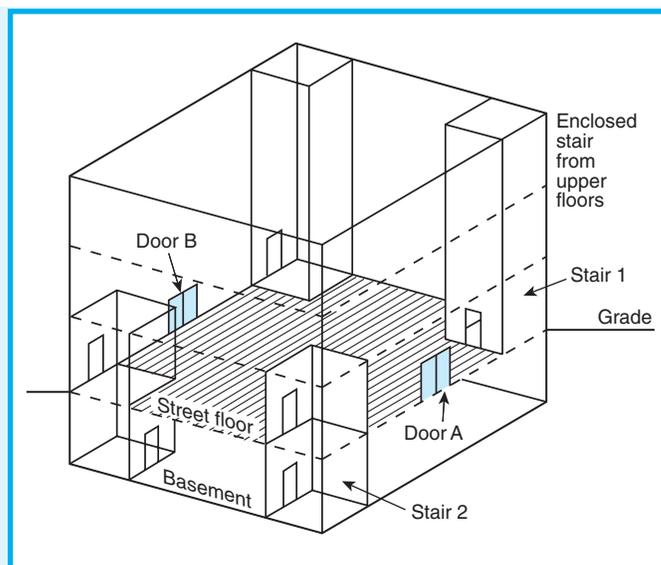

Exhibit 30/31.2 Egress capacity for street level.

modate 800 persons is 4060 mm (160 in.). The opening provided by each pair of doors, A and B, needs to be 2030 mm (80 in.) in clear, unobstructed width.

CHAPTER 30 • New

30.2.4 Number of Exits.

The minimum number of exits shall comply with 30.2.4.1, 30.2.4.2, or 30.2.4.3. (See also Section 7.4.)

30.2.4.1 Every dwelling unit shall have access to at least two separate exits remotely located from each other as required by 7.5.1.

30.2.4.2 Any dwelling unit shall be permitted to have a single exit provided that one of the following criteria is met:

- (1) The dwelling unit has an exit door opening directly to the street or yard at ground level.
- (2) The dwelling unit has direct access to an outside stair that complies with 7.2.2 and serves a maximum of two units, both of which are located on the same floor.
- (3) The dwelling unit has direct access to an interior stair that serves only that unit and is separated from all other portions of the building by fire barriers having a minimum 1-hour fire resistance rating with no opening therein.

30.2.4.3 Any building that is protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5, has four or fewer stories, and has not more than four dwelling units per story shall be permitted to have a single exit, provided that all of the following conditions apply:

- (1) The stairway is separated from the rest of the building by barriers having not less than a 1-hour fire resistance rating, with self-closing 1-hour fire door assemblies protecting all openings between the stairway enclosure and the building.
- (2) The stairway does not serve more than one-half story below the level of exit discharge.
- (3) All corridors serving as access to exits have a minimum 1-hr fire resistance rating.
- (4) There is not more than 10.7 m (35 ft) of travel distance from the entrance door of any dwelling unit to an exit.
- (5) One-half-hour fire-rated horizontal and vertical separation between dwelling units is provided.

CHAPTER 31 • Existing

31.2.4 Number of Exits.

The minimum number of exits shall comply with 31.2.4.1, 31.2.4.2, 31.2.4.3, 31.2.4.4, or 31.2.4.5.

31.2.4.1 Every dwelling unit shall have access to not less than two separate exits remotely located from each other as required by 7.5.1. (See also Section 7.4)

31.2.4.2 Any dwelling unit shall be permitted to have a single exit, provided that one of the following criteria is met:

- (1) The dwelling unit has an exit door opening directly to the street or yard at ground level.
- (2) The dwelling unit has direct access to an outside stair that complies with 7.2.2 and serves not more than two units, both located on the same floor.
- (3) The dwelling unit has direct access to an interior stair that serves only that unit and is separated from all other portions of the building by fire barriers having not less than a 1-hour fire resistance rating with no opening therein.

31.2.4.3 Buildings of four stories or less protected throughout by an approved, supervised automatic sprinkler system in accordance with 31.3.5.3 shall be permitted to have a single exit, provided the following conditions are met:

- (1) The stairway is separated from the rest of the building by barriers having not less than a 1-hour fire resistance rating, with self-closing doors having not less than a 1-hour fire protection rating protecting all openings between the stairway enclosure and the building.
- (2) The stairway does not serve more than one-half of a story below the level of exit discharge.
- (3) All corridors serving as access to exits have not less than a ½-hour fire resistance rating.
- (4) There is not more than 10.7 m (35 ft) of travel distance from the entrance door of any dwelling unit to an exit.
- (5) One-half hour fire-rated horizontal and vertical separation between dwelling units is provided.

31.2.4.4 Any building of three stories or less in its entirety shall be permitted to have a single exit, provided the following conditions are met:

- (1) The stairway is separated from the rest of the building by barriers having not less than a 1-hour fire resistance rating, with self-closing doors having not less than a 1-hour fire protection rating protecting all openings between the stairway enclosure and the building.

CHAPTER 30 • New

CHAPTER 31 • Existing

A single means of egress is permitted by 30/31.2.4.2 under the following conditions:

(a) The living unit has an exit leading directly to the street or yard at ground level. This arrangement is common in the case of town houses or row houses. Under this arrangement, the front door is the only required exit, so no provisions for a rear door are required. If a rear door is provided, it does not have to meet the locking or other requirements of the *Code*.

(b) The apartment has direct access to an outside stair serving a maximum of two apartments, both of which are on the same floor. The outside stair must be separated from the interior of the building as detailed in 7.2.2.6.3. This arrangement is detailed in Exhibit 30/31.3.

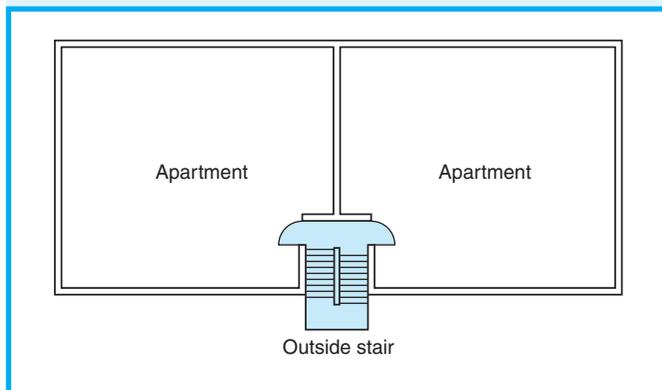

Exhibit 30/31.3 Outside stair serving two apartment units.

- (2) The stairway does not serve more than one-half of a story below the level of exit discharge.
- (3) All corridors serving as access to exits have not less than a 20-minute fire resistance rating.
- (4) The travel distance from the entrance door of any dwelling unit to an exit does not exceed 10.7 m (35 ft).
- (5) Horizontal and vertical separation with a fire rating of not less than ½ hour is provided between dwelling units.

31.2.4.5 A building of any height, with not more than four dwelling units per floor, with a smokeproof enclosure or outside stair in accordance with the requirements of 7.2.3 as the exit, where such exit is immediately accessible to all dwelling units served thereby, shall be permitted to have a single exit. “Immediately accessible” means that the travel distance from the entrance door of any dwelling unit to an exit shall not exceed 6100 mm (240 in.).

(c) The single exit is a private stairway serving one apartment only and is separated from all abutting apartment units, including those on lower floors, by 1-hour rated construction. Note that this stairway is required to be separated only from other spaces by the required 1-hour construction; it is not required to be separated from the apartment unit that it serves. This arrangement is detailed in Exhibit 30/31.4.

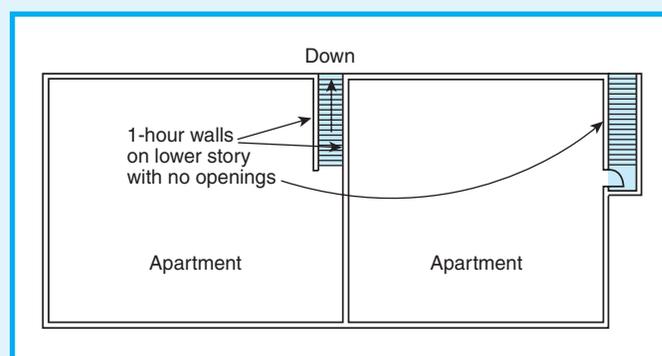

Exhibit 30/31.4 Stair serving one apartment unit.

Garden-type apartment buildings, where the apartment unit entrance doors open either directly into a single-exit stair enclosure or into a vestibule or short corridor leading to a single, enclosed exit stair, are addressed by 30.2.4.3. In other situations, the stair is open to the exterior or is enclosed by glass at the front of the building. A single exit under this

CHAPTER 30 • New

arrangement is permitted if additional conditions can be met.

Exhibit 30/31.5 illustrates the provisions of 30.2.4.3 where the following requirements are met:

- (1) The building must be sprinklered in accordance with 30.3.5.
- (2) The building must be not more than four stories high.
- (3) The building must have not more than four apartment units per floor.
- (4) The single exit stair must be separated from the building by construction with a minimum 1-hour fire resistance rating.
- (5) The exit enclosure doors (E) must be 1-hour fire protection-rated and self-closing, as do apartment unit doors (A) if they open directly into the exit enclosure.
- (6) If the apartment unit doors (A) open into a corridor, they must be 20-minute fire protection-rated.

A frequent violation of this provision is the use of a nonrated door and the lack of a door closer. The travel distance from the apartment unit door to the exit enclosure door (A–E) is not permitted to exceed 10.7 m (35 ft). Both horizontal and vertical 30-minute fire resistance-rated separation are required between apartment units.

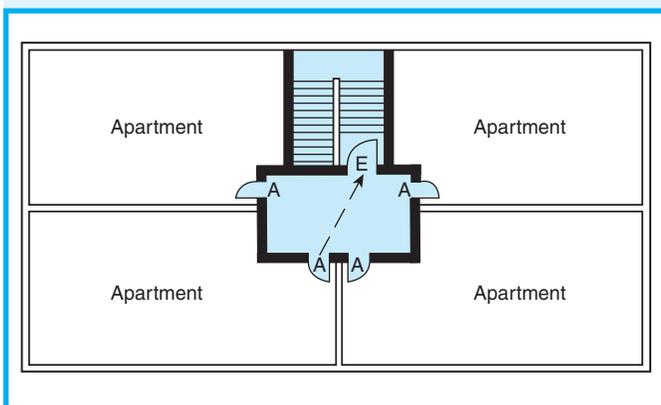

Exhibit 30/31.5 New apartment building—single-exit arrangement.

30.2.5 Arrangement of Means of Egress.

30.2.5.1 Access to all required exits shall be in accordance with Section 7.5, as modified by 30.2.5.3.

CHAPTER 31 • Existing

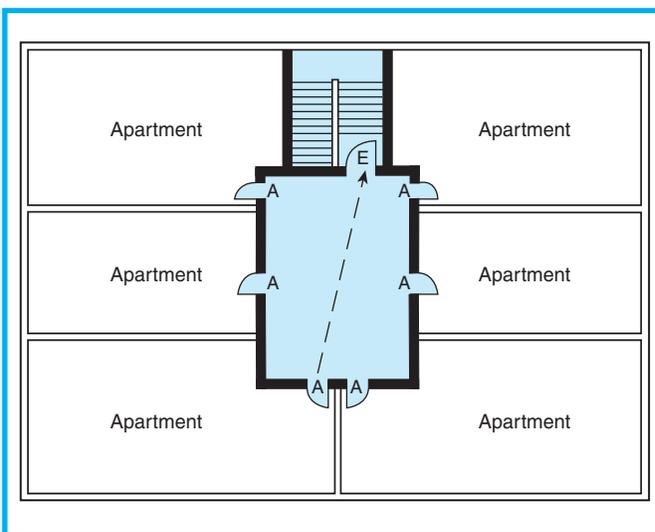

Exhibit 30/31.6 Existing apartment building—single-exit arrangement.

For existing apartment buildings, 31.2.4.3 differs by not limiting the number of apartment units per floor, as depicted in Exhibit 30/31.6, and permitting the corridor fire resistance rating to be $\frac{1}{2}$ hour instead of 1 hour.

The provision of 31.2.4.4 is similar to 31.2.4.3 in that it permits a single exit from a typical garden-type apartment building. However, the apartment building is not required to be sprinklered and is limited to being not more than three stories high.

The provision of 31.2.4.5 for existing apartment buildings describes an uncommon arrangement. Note that there are no height limitations, but only four apartment units per floor are permitted. Furthermore, apartments must have immediate access to a smokeproof enclosure or to an outside stair that meets the requirements of a smokeproof enclosure. The exemptions to the requirements for outside stairs in Chapter 7 for unprotected openings that expose a stair would not apply in this case, because the Code specifically references 7.2.3 on smokeproof enclosures. Unprotected openings that expose the stair are prohibited by 7.2.3.

31.2.5 Arrangement of Means of Egress.

31.2.5.1 Access to all required exits shall be in accordance with Section 7.5.

CHAPTER 30 • New

30.2.5.2 The distance between exits addressed by 7.5.1.3 shall not apply to nonlooped exit access corridors in buildings that have corridor doors from the dwelling units that are arranged such that the exits are located in opposite directions from such doors.

30.2.5.3 Common path of travel shall comply with 30.2.5.3.1 or 30.2.5.3.2.

30.2.5.3.1 No common path of travel shall exceed 10.7 m (35 ft) in buildings not protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5. Travel within a dwelling unit shall not be included when calculating common path of travel.

30.2.5.3.2 No common path of travel shall exceed 15 m (50 ft) in buildings protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5. Travel within a dwelling unit shall not be included when determining common path of travel.

30.2.5.4 Dead-end corridors shall be limited in accordance with either 30.2.5.4.1 or 30.2.5.4.2.

30.2.5.4.1 Dead-end corridors shall not exceed 10.7 m (35 ft) in buildings not protected throughout by an approved, automatic sprinkler system in accordance with 30.3.5.

30.2.5.4.2 Dead-end corridors shall not exceed 15 m (50 ft) in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 30.3.5.

The provisions for the arrangement of the means of egress in apartment buildings differ significantly from the provisions in Chapter 7. The first difference appears in 30.2.5.2, which addresses the remoteness of exits. Applying the exit remoteness provisions of 7.5.1.3 could result in a corridor that is longer than is necessary for the efficient use of the space. Some relief is offered by 30.2.5.2. Exhibit 30/31.7 helps to clarify the intent of 30.2.5.2. In illustration (a) of Exhibit 30/31.7, all four dwelling units have access to two exits immediately upon leaving the dwelling unit and entering the exit access corridor. This arrangement meets the provisions of 30.2.5.2. Contrast this arrangement with that depicted in illustration (b) of Exhibit 30/31.7, where only dwelling units A and B have access to two exits immediately upon leaving the dwelling unit and entering the exit access corridor. This arrangement does not meet the provisions of 30.2.5.2.

CHAPTER 31 • Existing

31.2.5.2 Reserved.

31.2.5.3 Common path of travel shall comply with 31.2.5.3.1 or 31.2.5.3.2.

31.2.5.3.1 No common path of travel shall exceed 10.7 m (35 ft) in buildings not protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 31.3.5. Travel within a dwelling unit shall not be included when calculating common path of travel.

31.2.5.3.2 No common path of travel shall exceed 15 m (50 ft) in buildings protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 31.3.5. Travel within a dwelling unit shall not be included when calculating common path of travel.

31.2.5.4 Dead-end corridors shall not exceed 15 m (50 ft).

The concepts underlying the limitations imposed on common paths of travel and dead-end corridors are similar but not identical to those explained in the commentary on 7.5.1.5. Because of modifications made by Chapters 30 and 31 in defining where common path of travel begins, the difference between common paths of travel and dead-end corridors is less pronounced for apartment buildings. For most other occupancies, common path of travel is measured from the most remote point subject to occupancy to the point where occupants have a choice of traveling in independent directions (see 7.5.1.1.4 and the definition of *common path of travel* in 3.3.34). For apartment buildings, the travel distance within the dwelling unit, though regulated by 30/31.2.6.1, is not included as part of the common path of travel. Therefore, common path of travel, as illustrated by the solid arrows in Exhibit 30/31.8, is measured from the room door to the point where occupants have a choice of

CHAPTER 30 • New

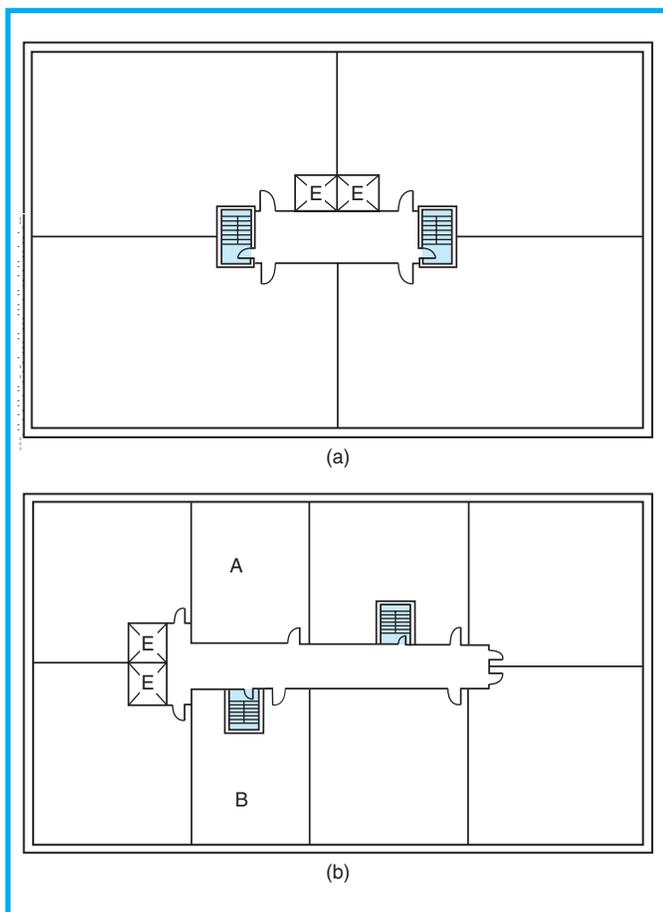

Exhibit 30/31.7 New apartment buildings—exit remoteness.

traveling in independent directions. This depiction can be thought of as a modified common path of travel, because measurement does not extend into the dwelling unit.

The distances permitted for common path of travel in new and existing apartment buildings also differ. Because most new apartment buildings are

30.2.6 Travel Distance to Exits.

30.2.6.1 Travel distance within a dwelling unit (apartment) to a corridor door shall not exceed 23 m (75 ft) in buildings not protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5.

30.2.6.2 Travel distance within a dwelling unit (apartment) to a corridor door shall not exceed 38 m (125 ft) in buildings protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5.

CHAPTER 31 • Existing

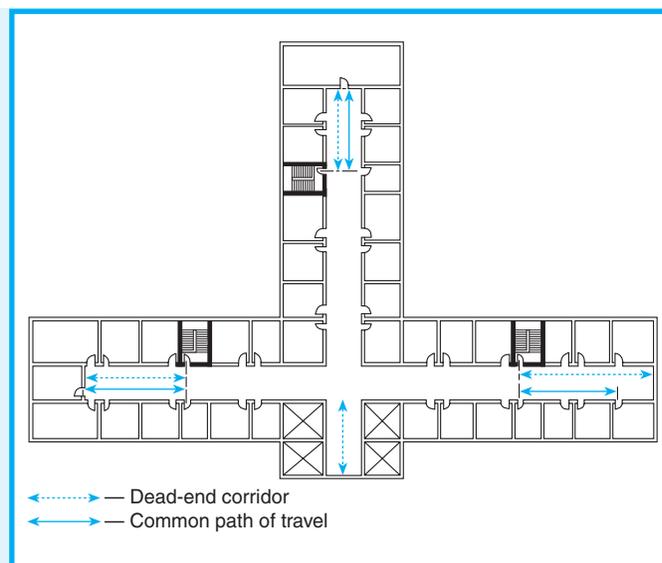

Exhibit 30/31.8 Modified common path of travel and dead-end corridors in an apartment building.

required to be sprinklered (see 30.3.5.1), the 10.7-m (35-ft) modified common path of travel and dead-end corridor limitations permitted by 30.2.5.3.1 and 30.2.5.4.1 will usually be supplanted by the 15-m (50-ft) limitation permitted by 30.2.5.3.2 and 30.2.5.4.2. However, if a building can comply with 30.3.5.2, which exempts sprinklers, the 10.7-m (35-ft) common path of travel and dead-end corridor limitations would apply.

In most existing apartment buildings, automatic sprinklers are not required. However, if the building is protected throughout by an approved, supervised automatic sprinkler system, the common path of travel is permitted to be 15 m (50 ft), which is the same distance permitted for the length of existing dead-end corridors, regardless of sprinkler system considerations.

31.2.6 Travel Distance to Exits.

31.2.6.1 Travel distance within a dwelling unit (apartment) to a corridor door shall not exceed the following limits:

- (1) For buildings using Option 1 or Option 3—23 m (75 ft)
- (2) For buildings using Option 2 or Option 4—38 m (125 ft)

31.2.6.2 The travel distance from a dwelling unit (apartment) entrance door to the nearest exit shall not exceed the following limits, as modified by 31.2.6.3:

CHAPTER 30 • New

30.2.6.3 The travel distance from a dwelling unit (apartment) entrance door to the nearest exit shall be limited in accordance with 30.2.6.3.1, 30.2.6.3.2, or 30.2.6.3.3.

30.2.6.3.1 The travel distance from a dwelling unit (apartment) entrance door to the nearest exit shall not exceed 30 m (100 ft).

30.2.6.3.2 In buildings protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5, the travel distance from a dwelling unit (apartment) entrance door to the nearest exit shall not exceed 61 m (200 ft).

30.2.6.3.3 The travel distance from a dwelling unit (apartment) entrance door to the nearest exit shall not exceed 61 m (200 ft) for exterior ways of exit access arranged in accordance with 7.5.3.

30.2.6.4 The travel distance from areas other than those within living units to the exit measured in accordance with Section 7.6 shall not exceed 61 m (200 ft), or 83 m (250 ft) in buildings protected throughout by an approved, supervised, automatic sprinkler system installed in accordance with 30.3.5.6.

The travel distance limitations specified in 30/31.2.6 divide the measurement into the following two portions of the overall travel distance:

- (1) Travel within an apartment unit to the door to the common space of the building
- (2) Travel from the corridor door to the nearest exit

If the travel distance within an apartment unit is excessive, an additional remote door to the corridor can usually be added to correct the deficiency. The presence of automatic sprinklers or the use of exterior ways of exit access modifies travel distance requirements. In existing buildings, the presence of a fire detection and notification system or a partial sprinkler system (Option 2 or Option 3) also modifies travel

30.2.7 Discharge from Exits.

Exit discharge shall comply with Section 7.7.

CHAPTER 31 • Existing

- (1) For buildings using Option 1—30 m (100 ft)
- (2) For buildings using Option 2 or Option 3—46 m (150 ft)
- (3) For buildings using Option 4—61 m (200 ft)

31.2.6.3 Travel distance to exits shall not exceed 60 m (200 ft) for exterior ways of exit access arranged in accordance with 7.5.3.

distance requirements, though not to the extent of a complete automatic sprinkler system (Option 4).

Many apartment buildings have common activity rooms, lounges, lobbies, and similar spaces that are neither living units, as addressed by 30.2.6.1 and 30.2.6.2, nor exit access corridor-like spaces, as addressed by 30.2.6.3. Travel distance limitations from areas other than those within living units of new apartment buildings are established by 30.2.6.4. The maximum 61-m (200-ft) travel distance allowance, which can be increased to 83 m (250 ft) in sprinklered buildings, treats the travel distance in one continuous measurement. For example, the travel distance limitation would apply to the full distance of travel through an activity room and the associated exit access corridors to the exit.

31.2.7 Discharge from Exits.

31.2.7.1 Exit discharge shall comply with Section 7.7.

31.2.7.2 Any required exit stairway that is located so that it is necessary to pass through the lobby or other open space to reach the outside of the building shall be continuously enclosed to a level of exit discharge or to a mezzanine within a lobby at a level of exit discharge.

CHAPTER 30 • New

Section 7.7 allows a maximum of 50 percent of both the number and capacity of exits to discharge through the street level under limited conditions (see 7.7.2).

The restrictions of Section 7.7 are further modified by 31.2.7.2 and 31.2.7.3 for existing apartment buildings. In this arrangement, an exit that discharges onto a mezzanine within the lobby of an apartment building (with subsequent open stair travel to the lobby floor on the level of exit discharge) is considered equivalent to an exit that discharges directly into the lobby at the level of exit discharge. Therefore, 50 percent of the exits can discharge onto a mezzanine; the other 50 percent must discharge directly outside. However, the distance from the termination of the exit enclosure to the exterior door is limited to a maximum of 30 m (100 ft) unless the building is protected with automatic sprinklers, in which case the distance can be extended to 46 m (150 ft). The part of the exit discharge that occurs within the building is depicted

30.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

30.2.9 Emergency Lighting.

Emergency lighting in accordance with Section 7.9 shall be provided in all buildings with more than 12 dwelling units or more than three stories in height, unless every dwelling unit has a direct exit to the outside of the building at grade level.

30.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10 in all buildings requiring more than one exit.

30.2.11 Special Means of Egress Features.

(Reserved)

CHAPTER 31 • Existing

31.2.7.3 The distance of travel from the termination of the exit enclosure to an exterior door leading to a public way shall not exceed 46 m (150 ft) in buildings protected throughout by an approved automatic sprinkler system and shall not exceed 30 m (100 ft) in all other buildings.

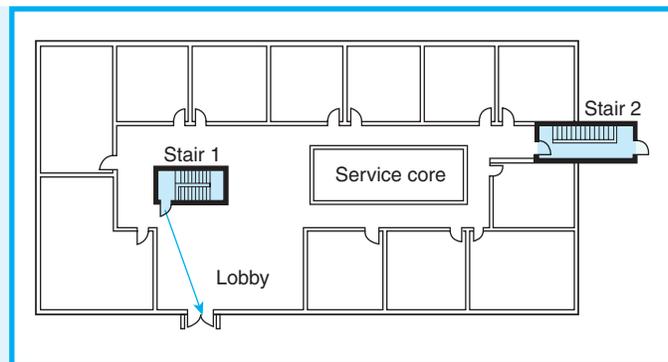

Exhibit 30/31.9 Exit discharge through street level.

in Exhibit 30/31.9 by the arrow that connects the door at stair 1 with the lobby door to the outside. See also the commentary following 7.7.2.7.

31.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

31.2.9 Emergency Lighting.

Emergency lighting in accordance with Section 7.9 shall be provided in all buildings with more than 12 dwelling units or more than three stories in height, unless every dwelling unit has a direct exit to the outside of the building at grade level.

31.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10 in all buildings requiring more than one exit.

31.2.11* Special Means of Egress Features.

In high-rise buildings using Option 1, Option 2, or Option 3, smokeproof enclosures shall be provided in accordance with 7.2.3.

The provision of 30/31.2.9 exempting emergency lighting does not apply to all apartment buildings with exterior exit access but only to those where each apartment unit has direct exit at grade (no vertical travel).

Existing, nonsprinklered high-rise apartment

Section 30.3 Protection

30.3.1 Protection of Vertical Openings.

30.3.1.1 Vertical openings shall comply with 30.3.1.1.1, 30.3.1.1.2, or 30.3.1.1.3.

30.3.1.1.1 Vertical openings shall be enclosed or protected in accordance with Section 8.6.

30.3.1.1.2 Where the provisions of 8.6.6 are used, the requirements of 30.3.5.8 shall be met.

30.3.1.1.3 Vertical openings in accordance with 8.6.8.2 shall be permitted.

30.3.1.1.4 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 30.3.5, the fire resistance of walls enclosing vertical openings shall be not less than 1 hour, and the fire protection rating of doors shall be not less than 1 hour.

30.3.1.2 No floor below the level of exit discharge used only for storage, heating equipment, or purposes other than residential occupancy open to the public shall have unprotected openings to floors used for residential purposes.

30.3.1.3 No unenclosed vertical opening shall be permitted in any building or fire section with only one exit.

The protection of vertical openings is provided by a reference to Section 8.6 for both new and existing apartment buildings. However, automatic sprinkler protection is required throughout new apartment

A.31.2.11 The provision of 31.2.11 recognizes the need to provide smoke control in existing buildings. Smokeproof enclosures can be accomplished without the use of a vestibule in accordance with 7.2.3.

buildings are affected by 31.2.11. If smokeproof enclosures meeting 7.2.3 are not already provided, it might be more practical to add sprinkler protection than to modify stairs to meet the requirements for smokeproof enclosures.

Section 31.3 Protection

31.3.1 Protection of Vertical Openings.

31.3.1.1 Vertical openings shall comply with 31.3.1.1.1, 31.3.1.1.2, or 31.3.1.1.3.

31.3.1.1.1 Vertical openings shall be enclosed or protected in accordance with Section 8.6.

31.3.1.1.2 Reserved.

31.3.1.1.3 Vertical openings in accordance with 8.6.8.2 shall be permitted.

31.3.1.1.4 In buildings protected throughout by an approved, automatic sprinkler system in accordance with 31.3.5, and in which exits and required ways of travel thereto are adequately safeguarded against fire and smoke within the building, or where every individual room has direct access to an exterior exit without passing through any public corridor, the protection of vertical openings that are not part of required exits shall not be required.

31.3.1.2 No floor below the level of exit discharge used only for storage, heating equipment, or purposes other than residential occupancy open to the public shall have unprotected openings to floors used for residential purposes.

buildings where the building has a communicating space in accordance with 8.6.6.

The provision of 30/31.3.1.1.3 has traditionally permitted an unenclosed stair to be located within

CHAPTER 30 • New

an apartment unit (living unit) for the purpose of connecting two adjacent stories. The open stair typically serves as means of escape for occupants of a living unit. The provisions of 8.6.8.2 do not permit the opening to serve as required means of egress. It is not the *Code's* intent to prohibit an open stair from serving as means of escape for occupants of a dwelling unit.

In the case of a three-story apartment unit, only two of the three stories can be connected by an open stair. The stair connecting the third level must be enclosed in accordance with Section 8.6.

Atria are permitted in both new and existing apartment buildings (see 8.6.7). However, 8.6.7 requires total automatic sprinkler protection in build-

30.3.2 Protection from Hazards.

30.3.2.1 Hazardous Areas. Any hazardous area shall be protected in accordance with Section 8.7.

30.3.2.1.1 The areas described in Table 30.3.2.1.1 shall be protected as indicated.

Table 30.3.2.1.1 Hazardous Area Protection

Hazardous Area Description	Separation/Protection
Boiler and fuel-fired heater rooms serving more than a single dwelling unit	1 hour and sprinklers
Employee locker rooms	1 hour or sprinklers
Gift or retail shops	1 hour or sprinklers
Bulk laundries	1 hour and sprinklers
Laundries $\leq 9.3 \text{ m}^2$ ($\leq 100 \text{ ft}^2$) outside of dwelling units	1 hour or sprinklers†
Laundries $> 9.3 \text{ m}^2$ ($> 100 \text{ ft}^2$) outside of dwelling units	1 hour and sprinklers
Maintenance shops	1 hour and sprinklers
Storage rooms outside of dwelling units	1 hour or sprinklers
Trash collection rooms	1 hour and sprinklers

†Where sprinklers are provided, separation shall not be required.

30.3.2.1.2 Where sprinkler protection without fire-rated separation is used, areas shall be separated from other spaces by smoke partitions complying with Section 8.4.

CHAPTER 31 • Existing

ings with atria. Therefore, an existing apartment building would be permitted to have an atrium only where Option 4 (complete sprinkler protection) is used.

New apartment buildings, other than those meeting 30.3.5.2, must be protected throughout by an approved, supervised automatic sprinkler system. Therefore, most new apartment buildings, by virtue of their compliance with the sprinkler requirements of 30.3.5.1, are permitted to use the 1-hour vertical enclosure protection option in accordance with 30.3.1.1.4, regardless of the number of stories connected by the vertical opening. See also 30.2.2.1.2 and its associated commentary.

31.3.2 Protection from Hazards.

31.3.2.1 Hazardous Areas. Any hazardous area shall be protected in accordance with Section 8.7.

31.3.2.1.1 The areas described in Table 31.3.2.1.1 shall be protected as indicated.

Table 31.3.2.1.1 Hazardous Area Protection

Hazardous Area Description	Separation/Protection
Boiler and fuel-fired heater rooms serving more than a single dwelling unit	1 hour or sprinklers
Employee locker rooms	1 hour or sprinklers
Gift or retail shops $> 9.3 \text{ m}^2$ ($> 100 \text{ ft}^2$)	1 hour or sprinklers†
Bulk laundries	1 hour or sprinklers
Laundries $> 9.3 \text{ m}^2$ ($> 100 \text{ ft}^2$) outside of dwelling units	1 hour or sprinklers†
Maintenance shops	1 hour or sprinklers
Rooms or spaces used for storage of combustible supplies and equipment in quantities deemed hazardous by the authority having jurisdiction	1 hour or sprinklers
Trash collection rooms	1 hour or sprinklers

†Where sprinklers are provided, separation shall not be required.

31.3.2.1.2 Where sprinkler protection without fire-rated separation is used, areas shall be separated from other spaces by smoke partitions complying with Section 8.4.

CHAPTER 30 • New

CHAPTER 31 • Existing

Note the differences in the hazardous area protection requirements for new and existing apartment buildings as specified in Tables 30.3.2.1.1 and 31.3.2.1.1. In new apartment buildings, many of the areas are required to be separated by construction with a 1-hour fire resistance rating and protected by automatic sprinklers. In existing apartment buildings, automatic sprinklers are sometimes used as an alternative to the separation requirement.

While the lists that appear in Tables 30.3.2.1.1 and 31.3.2.1.1 provide specific direction for certain hazardous contents areas, they are not all-inclusive. Other areas that are deemed hazardous need to be provided with the appropriate level of protection in accordance with Section 8.7.

30.3.3 Interior Finish.

30.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

30.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be permitted as follows:

- (1) Exit enclosures—Class A
- (2) Lobbies and corridors—Class A or Class B
- (3) Other spaces—Class A, Class B, or Class C

30.3.3.3 Interior Floor Finish.

30.3.3.3.1 Interior floor finish shall comply with Section 10.2.

30.3.3.3.2 Interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 30.3.6 shall be not less than Class II.

30.3.3.3.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

30.3.4 Detection, Alarm, and Communications Systems.

30.3.4.1 General.

30.3.4.1.1 Apartment buildings with more than three stories or with more than 11 dwelling units, other than those meeting 30.3.4.1.2 or 30.3.4.1.3, shall be provided with a fire alarm system in accordance with Section 9.6, except as modified by 30.3.4.2 through 30.3.4.5.2.

30.3.4.1.2 A fire alarm system shall not be required in buildings where each dwelling unit is separated from other contiguous dwelling units by fire barriers (*see Section 8.3*) having a fire resistance rating of not less than 1 hour, and where each dwelling unit has either its own independent exit or its own independent stairway or ramp discharging at grade.

31.3.3 Interior Finish.

31.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

31.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with 10.2 shall be permitted as follows:

- (1) Exit enclosures—Class A or Class B
- (2) Lobbies and corridors—Class A or Class B
- (3) Other spaces—Class A, Class B, or Class C

31.3.3.3 Interior Floor Finish. In buildings utilizing Option 1 or Option 2, newly installed interior floor finish in exits and exit access corridors shall be not less than Class II in accordance with 10.2.7.

31.3.4 Detection, Alarm, and Communications Systems.

31.3.4.1 General.

31.3.4.1.1 Apartment buildings with more than three stories or with more than 11 dwelling units, other than those meeting 31.3.4.1.2, shall be provided with a fire alarm system in accordance with Section 9.6, except as modified by 31.3.4.2 through 31.3.4.5.2.

31.3.4.1.2 A fire alarm system shall not be required where each dwelling unit is separated from other contiguous dwelling units by fire barriers (*see Section 8.3*) having a fire resistance rating of not less than ½ hour, and where each dwelling unit has either its own independent exit or its own independent stairway or ramp discharging at grade.

CHAPTER 30 • New

30.3.4.1.3 A fire alarm system shall not be required in buildings that are protected throughout by an approved, automatic sprinkler system in accordance with 30.3.5.1, that do not exceed four stories in height, and that contain not more than 16 dwelling units.

The intent of 30/31.3.4.1.2 is to exempt town house-type apartment buildings from the requirement for a fire alarm system because, during a fire, each apartment unit retains safe egress routes for longer than is typical of standard apartment buildings

30.3.4.2 Initiation.

30.3.4.2.1 Initiation of the required fire alarm system shall be by manual means in accordance with 9.6.2, unless the building complies with 30.3.4.2.2.

30.3.4.2.2 Initiation of the required fire alarm system by manual means shall not be required in buildings not exceeding four stories in height, containing not more than 16 dwelling units, and protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5.1.

30.3.4.2.3 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 30.3.5, required fire alarm systems shall be initiated upon operation of the automatic sprinkler system.

30.3.4.3 Notification.

30.3.4.3.1 Occupant notification shall be provided automatically in accordance with Section 9.6, and the following shall also apply:

- (1) Visible signals shall be installed in units designed for the hearing impaired.
- (2) Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.

CHAPTER 31 • Existing

with interior exit access corridors. The safe egress route helps to ensure that any delay in occupant notification resulting from the absence of an alarm system can be tolerated without undue risk.

31.3.4.2 Initiation.

31.3.4.2.1 Initiation of the required fire alarm system shall be by manual means in accordance with 9.6.2 unless the building complies with 31.3.4.2.2.

31.3.4.2.2 Initiation of the required fire alarm system by manual means shall not be required in buildings not exceeding four stories in height, containing not more than 16 dwelling units, and protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 31.3.5.3.

31.3.4.2.3 In buildings using Option 2, the required fire alarm system shall be initiated by the automatic fire detection system in addition to the manual initiation means of 31.3.4.2.1.

31.3.4.2.4 In buildings using Option 3, the required fire alarm system shall be initiated upon operation of the automatic sprinkler system in addition to the manual initiation means of 31.3.4.2.1.

31.3.4.2.5 In buildings using Option 4, the required fire alarm system shall be initiated upon operation of the automatic sprinkler system in addition to the manual initiation means of 31.3.4.2.1.

31.3.4.3 Notification.

31.3.4.3.1 Occupant notification shall be provided automatically in accordance with Section 9.6, and the following shall also apply:

- (1) Visible signals shall be installed in units designed for the hearing impaired.
- (2) Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.
- (3) Existing approved presignal systems shall be permitted in accordance with 9.6.3.3.

CHAPTER 30 • New

30.3.4.3.2 Annunciation in accordance with 9.6.7 shall be provided unless the building complies with either 30.3.4.3.3 or 30.3.4.3.4.

30.3.4.3.3 Annunciation shall not be required in buildings not exceeding two stories in height and having not more than 50 rooms.

30.3.4.3.4 Annunciation shall not be required in buildings that are protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5.1, that do not exceed four stories in height, and that contain not more than 16 dwelling units.

30.3.4.3.5 Fire department notification shall be accomplished in accordance with 9.6.4.

30.3.4.4 Detection. (Reserved)

30.3.4.5 Smoke Alarms.

30.3.4.5.1* Approved single-station smoke alarms shall be installed in accordance with 9.6.2.10 outside every sleeping area in the immediate vicinity of the bedrooms and on all levels of the dwelling unit, including basements.

A.30.3.4.5.1 Previous editions of the *Code* permitted the single-station smoke alarm required by 30.3.4.5.1 to be omitted from each apartment where a complete automatic smoke detection system was installed throughout the building. With such a system, when one detector is activated, an alarm is sounded throughout the building. Experience with complete smoke detection systems in apartment buildings has shown that numerous nuisance alarms are likely to occur. Where there is a problem with frequent nuisance alarms, occupants ignore the alarm, or the system is either disconnected or otherwise rendered inoperative.

30.3.4.5.2 In buildings other than those protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5, approved single-station smoke alarms shall be installed in every sleeping room in accordance with 9.6.2.10.

Existing apartment buildings using Option 2 are protected throughout by a fire detection system (see 31.3.4.4). The increased travel distance permitted in an Option 2 apartment building (see 31.2.6.1 and 31.2.6.2) is based on early occupant notification of

CHAPTER 31 • Existing

31.3.4.3.2 An annunciator panel, whose location shall be approved by the authority having jurisdiction, connected with the required fire alarm system shall be provided, unless the building meets 31.3.4.3.3 or 31.3.4.3.4.

31.3.4.3.3 Annunciation shall not be required in buildings not exceeding two stories in height and having not more than 50 rooms.

31.3.4.3.4 Annunciation shall not be required in buildings that are protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 31.3.5.3, that do not exceed four stories in height, and that contain not more than 16 dwelling units.

31.3.4.3.5 Fire department notification shall be accomplished in accordance with 9.6.4.

31.3.4.4 Detection. In buildings using Option 2, a complete automatic fire detection system in accordance with 9.6.1.3 shall be required.

31.3.4.5 Smoke Alarms.

31.3.4.5.1 In buildings other than those equipped throughout with an existing, complete automatic detection system, approved single-station smoke alarms shall be installed in accordance with 9.6.2.10, as modified by 31.3.4.5.2, outside every sleeping area in the immediate vicinity of the bedrooms and on all levels of the dwelling unit, including basements.

31.3.4.5.2 Single-station smoke alarms without a secondary (standby) power source shall be permitted.

fire. Therefore, the detectors must initiate the alarm system in addition to the initiation provided by manual fire alarm boxes.

The corridors of existing apartment buildings using Option 3 are protected by sprinklers (see

CHAPTER 30 • New

31.3.5.6). The activation of the sprinkler system must initiate the alarm system in addition to the initiation provided by manual fire alarm boxes.

Existing apartment buildings using Option 4 are protected throughout by automatic sprinkler systems (see 31.3.5.9). The activation of the sprinkler system must initiate the alarm system in addition to the initiation provided by manual fire alarm boxes.

Automatic fire alarm annunciation is exempted by 30/31.3.4.3.4 based on the presence of automatic sprinklers and small building size. Given the additional limitation on building height and number of units, it is believed that fire in a fully sprinklered building can be controlled to a level that permits a delay by responding emergency forces in locating a fire.

In existing apartment buildings using Option 2, a total automatic fire detection system is required and must be interconnected with the building fire alarm system in accordance with 31.3.4.2.3. This system is required in addition to the single-station smoke alarms required by 31.3.4.5. Note that 31.3.4.4 does not require the fire detection system to be comprised solely of smoke detectors but, instead, allows the use of either heat or smoke detectors, or combinations of the two. Heat detectors are allowed by 31.3.4.4 because they are used as part of a system that is separate from the single-station smoke alarms addressed in 31.3.4.5. The single-station smoke alarms will alert occupants within an apartment of a fire originating within that unit. When an occupant leaves the apartment, the door closes and latches behind the occupant (see 31.3.6.4), and the occupant pulls a manual fire alarm box. If the occupant fails to sound the alarm manually and the fire continues to develop in the apartment, the heat detectors will initiate the building fire alarm system prior to the fire becoming a threat to other apartment units. Fire detection systems have proved very effective where used. In addition, because the system is required to be tied into the building fire alarm system, the use of heat detectors instead of system smoke detectors would eliminate many nuisance alarms that might occur because of cooking or smoking.

30.3.5 Extinguishment Requirements.

30.3.5.1 All buildings, other than those complying with 30.3.5.2, shall be protected throughout by an approved, supervised automatic sprinkler system installed in accordance with 30.3.5.3.

CHAPTER 31 • Existing

The smoke alarm(s) required by 30/31.3.4.5.1 should be located in the hall area(s) that provides access to rooms used for sleeping. In multilevel living units, the smoke alarm covering the upper level should normally be located at the top of the stairs. The smoke alarm(s) should be mounted on the ceiling or on the wall; those mounted on the wall should be within 300 mm (12 in.) of, but no closer than 100 mm (4 in.) to, the ceiling. The smoke alarm should be remotely located from the cooking area. Where unusual factors such as room configuration, air movement, or stagnant air pockets must be considered, the authority having jurisdiction and the designer should determine the placement of the smoke alarms. See *NFPA 72®*, *National Fire Alarm Code®*², for additional details.

Note that 9.6.2.10 requires smoke alarms to be powered by house current, which should be achieved by using directly wired or plug-in type smoke detectors. Battery-powered units do not meet the requirements of 9.6.2.10.

It is not the *Code's* intent to prohibit interconnecting smoke alarms within a single apartment. If an apartment unit needs more than one smoke alarm, interconnection will probably be required to meet the performance criterion for audibility detailed in 9.6.2.10.3.

In new apartment buildings, 30.3.4.5.2 supplements the smoke alarms required by 30.3.4.5.1 within individual apartment units by requiring the installation of smoke alarms within every sleeping room of each unit. Such installation provides rapid notification to those occupants intimate with a fire originating within a sleeping room. Smoke alarms are required in the bedrooms of nonsprinklered apartment units, regardless of direct egress arrangements. In sprinklered buildings, sleeping room smoke alarms are exempted by 30.3.4.5.2. This provision does not equate sprinklers with smoke alarms; instead, it emphasizes that smoke alarms are needed as well as exits direct to grade level.

31.3.5 Extinguishment Requirements.

31.3.5.1 Reserved.

CHAPTER 30 • New

30.3.5.2 Sprinkler systems shall not be required in buildings where every dwelling unit complies with one of the following:

- (1) An exit door opening directly to the street or yard at ground level
- (2) Direct access to an outside stair that complies with 7.2.2 and serves a maximum of two units, both located on the same floor
- (3) Direct access to an interior stair serving only that unit and separated from all other portions of the building by fire barriers having a 1-hour fire resistance rating with no openings therein

30.3.5.3 Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be installed in accordance with Section 9.7, as modified by 30.3.5.4 and 30.3.5.5. In buildings up to and including four stories in height above grade, systems in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted.

30.3.5.4 In buildings sprinklered in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, closets less than 1.1 m² (12 ft²) in area in individual dwelling units shall not be required to be sprinklered. Closets that contain equipment such as washers, dryers, furnaces, or water heaters shall be sprinklered regardless of size.

30.3.5.5 The draft stop and closely spaced sprinkler requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not be required for convenience openings complying with 8.6.8.2 where the convenience opening is within the dwelling unit.

30.3.5.6 Listed quick-response or listed residential sprinklers shall be used throughout all dwelling units.

CHAPTER 31 • Existing

31.3.5.2 Reserved.

31.3.5.3* Where an automatic sprinkler system is installed, either for total or partial building coverage, the system shall be installed in accordance with Section 9.7, as modified by 31.3.5.4 and 31.3.5.5. In buildings up to and including four stories in height above grade, systems in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted.

A.31.3.5.3 Although not required by the *Code*, the use of residential sprinklers or quick-response sprinklers is encouraged for new installations of sprinkler systems within dwelling units, apartments, and guest rooms. Caution should be exercised, because the system needs to be designed for the sprinkler being used.

31.3.5.4 In individual dwelling units, sprinkler installation shall not be required in closets not exceeding 2.2 m² (24 ft²) and in bathrooms not exceeding 5.1 m² (55 ft²). Closets that contain equipment such as washers, dryers, furnaces, or water heaters shall be sprinklered regardless of size.

31.3.5.5 The draft stop and closely spaced sprinkler requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not be required for convenience openings complying with 8.6.8.2 where the convenience opening is within the dwelling unit.

31.3.5.6 Buildings using Option 3 shall be provided with the following:

- (1) Automatic sprinklers in the corridor along the corridor ceiling
- (2) An automatic sprinkler within any dwelling unit that has a door opening to the corridor, with such sprinkler positioned over the center of the door, unless the door to the dwelling unit has not less than a 20-minute fire protection rating and is self-closing

CHAPTER 30 • New

30.3.5.7 Open parking structures complying with NFPA 88A, *Standard for Parking Structures*, that are contiguous with apartment buildings shall be exempt from the sprinkler requirements of 30.3.5.1.

30.3.5.8 Buildings with unprotected openings in accordance with 8.6.6 shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 30.3.5.

30.3.5.9 Reserved.

30.3.5.10 Reserved.

30.3.5.11 Portable fire extinguishers in accordance with 9.7.4.1 shall be provided in hazardous areas addressed by 30.3.2.1, unless the building is protected throughout with an approved, supervised automatic sprinkler system in accordance with 30.3.5.3.

CHAPTER 31 • Existing

31.3.5.7 The sprinkler installation required in 31.3.5.6 shall meet the requirements of Section 9.7 in terms of workmanship and materials.

31.3.5.8 The installation of the corridor sprinklers required in 31.3.5.6 shall not exceed the maximum spacing and protection area requirements of the installation standards referenced in 31.3.5.3.

31.3.5.9 Buildings using Option 4 shall be protected throughout by an approved automatic sprinkler system in accordance with 31.3.5.3 and meeting the requirements of Section 9.7 for supervision for buildings more than six stories in height.

31.3.5.10 All high-rise buildings, other than those meeting 31.3.5.10.1 or 31.3.5.10.2, shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 31.3.5.3.

31.3.5.10.1 An automatic sprinkler system shall not be required where every dwelling unit has exterior exit access in accordance with 7.5.3.

31.3.5.10.2* An automatic sprinkler system shall not be required in buildings having an approved, engineered life safety system in accordance with 31.3.5.10.3.

A.31.3.5.10.2 This system might consist of a combination of any or all of the following systems:

- (1) Partial automatic sprinkler protection
- (2) Smoke detection alarms
- (3) Smoke control
- (4) Compartmentation or other approved systems, or both

31.3.5.10.3 Where required by 31.3.5.10.2, an engineered life safety system shall be developed by a registered professional engineer experienced in fire and life safety system design, approved by the authority having jurisdiction, and include any or all of the following:

- (1) Partial automatic sprinkler protection
- (2) Smoke detection systems
- (3) Smoke control systems
- (4) Compartmentation
- (5) Other approved systems

31.3.5.11 Portable fire extinguishers in accordance with 9.7.4.1 shall be provided in hazardous areas addressed by 31.3.2.1, unless the building is protected throughout with an approved, supervised automatic sprinkler system in accordance with 31.3.5.3.

The Code permits NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*³, to be used, within its scope, in place of NFPA 13, *Standard for the Installation of Sprinkler Systems*. However, the provision of 30.3.5.6, which requires the use of listed quick-response sprinklers or listed residential sprinklers within dwelling units, supersedes any sprinkler options permitted by NFPA 13R or NFPA 13.

Small closets are exempted from being sprinklered by 30.3.5.4 because of the limited fuel load characteristic of apartment unit closets. The closets exempted are limited to those within a living unit; closets in common building areas are not exempted.

In the 1997 edition of the Code, it was the intent that 30.3.5.4 override the requirements in both NFPA 13 and NFPA 13R. As a result of subsequent changes to NFPA 13R, the provision now applies only where the sprinkler system is designed in accordance with NFPA 13. The last sentence of 30.3.5.4 clarifies that the nonsprinklered closet cannot contain mechanical equipment and its associated ignition sources and potential for fire spread.

Those features that define residential occupancies also contribute to their associated poor life loss statistics. Approximately 82 percent of all fire deaths that occurred in the United States from 1995 through 1999 occurred in residential settings. More specifically, 13 percent of all deaths took place in apartment building fires. In recognition of the fire problem in residential occupancies and the proven life safety benefit of properly installed and maintained sprinkler systems, the Code requires sprinklers in new apartment buildings, unless the provisions of 30.3.5.2 are met.

The sprinkler exemption can be applied only where each living unit within a building is provided with one of the following:

- (1) A door opening to the outside at grade level
- (2) Direct access to an outside stair that serves no more than two units, both of which access the stair on the same story
- (3) Direct access to an interior stair that serves only the unit itself and that is properly separated from the remainder of the building

The direct access required from each living unit to the outside, in combination with the early warning provided by the sleeping room smoke alarms required by 30.3.4.5.2, provides an acceptable alterna-

tive to sprinklers. The conditions under which this exemption is permitted are equivalent to those that allow a single exit in accordance with 30.2.4.2.

Exhibit 30/31.10 depicts egress arrangements for two-story nonsprinklered apartment buildings with outside stairs. Illustration (a) depicts two units on the second floor that have direct access to the outside stair. Illustration (b) depicts an apartment building with four units on the second floor. In this case, the stairs are separated by a barrier so that each serves only two dwelling units.

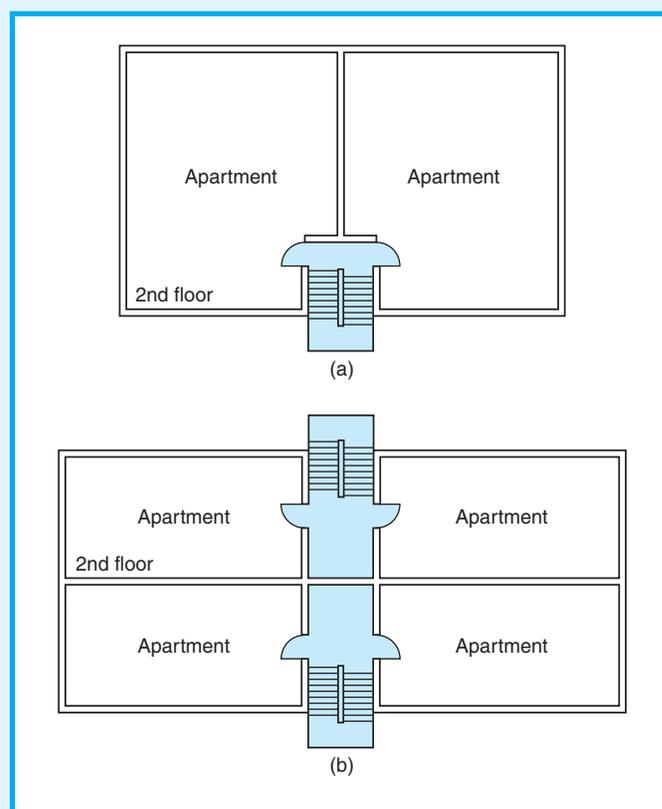

Exhibit 30/31.10 Two-story apartment buildings—exempt from sprinkler system requirement.

Exhibit 30/31.11 depicts an egress arrangement for a three-story, nonsprinklered apartment building meeting the provisions of 30.3.5.2. Each apartment has its own egress system direct to ground.

For existing apartment buildings, Option 3 and Option 4 require automatic sprinkler installation. Exhibit 30/31.12 illustrates the sprinkler location requirements for an Option 3 existing apartment

CHAPTER 30 • New

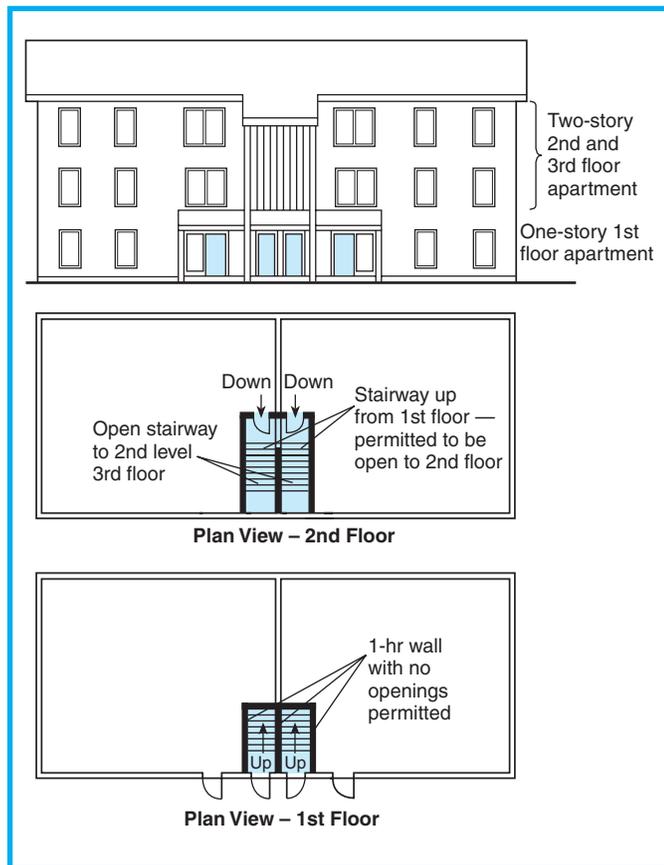

Exhibit 30/31.11 Three-story apartment buildings—exempt from sprinkler system requirement.

building. A 20-minute fire protection-rated, self-closing corridor door is permitted by 31.3.5.6(2) to serve in lieu of the sprinklers positioned inside each apartment unit in the vicinity of the corridor door; however, the corridor sprinklers must still be provided.

The *Code* provides numerous incentives for existing apartment buildings to use Option 4 (complete sprinkler protection), as detailed in 31.3.5.9. Some of the more significant incentives that apply to existing apartment buildings are provided in 31.2.4.3, 31.2.6, 31.2.11, 31.3.6.3, and 31.3.7.1.

One of the objectives of the *Code* is to provide a structure that will protect occupants who are not intimate with the initial fire development for the time needed to evacuate (see 4.1.1). Given that objective, new apartment buildings are required to use quick-response or residential sprinklers throughout apartment units. The use of approved residential or quick-response sprinklers within dwelling units of

CHAPTER 31 • Existing

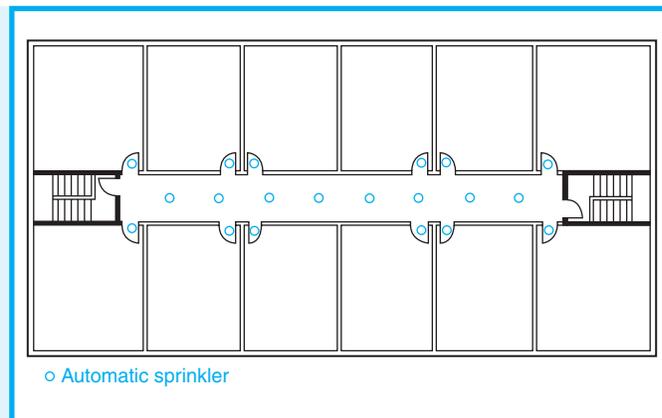

Exhibit 30/31.12 Option 3 sprinkler protection for existing apartment buildings.

existing apartment buildings is encouraged by A.31.3.5.3. The *Code's* intent is to obtain the quick response provided by these sprinklers as well as the high-spray pattern provided by residential sprinklers. The technology associated with quick-response and residential sprinklers helps to maintain tenability within the room of fire origin.

Designers of sprinkler systems must use caution, as residential and quick-response sprinklers cannot always be installed in a system that was originally designed for standard sprinklers. Situations also exist where residential or quick-response sprinklers might not be listed for use, such as an area with vaulted ceilings. In such cases, the designer could provide the best alternative sprinkler.

Approved supervised sprinkler systems are required throughout existing high-rise apartment buildings per 31.3.5.10. (See the definition of *high-rise building* in 3.3.27.7.) However, the *Code* does provide two alternatives. The first exempts sprinklers throughout if each living unit has direct exterior exit access. The *Code* also permits the application of an approved, engineered life safety system in lieu of installing sprinklers throughout. Although not required, the annex note suggests that this engineered life safety system should include some combination of automatic sprinkler protection, detection, smoke control, and compartmentation. The *Code* further requires that this alternative approach be approved by the authority having jurisdiction. During the planning phase, the designer should meet with the authority having jurisdiction to determine whether a system is acceptable.

CHAPTER 30 • New

30.3.6 Corridors.

30.3.6.1 Walls. Exit access corridor walls shall comply with 30.3.6.1.1 or 30.3.6.1.2.

30.3.6.1.1 In buildings not complying with 30.3.6.1.1, exit access corridor walls shall consist of fire barriers in accordance with Section 8.3 that have not less than a 1-hour fire resistance rating.

30.3.6.1.2 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 30.3.5.3, corridor walls shall have not less than a ½-hour fire resistance rating.

30.3.6.2 Doors Doors that open onto exit access corridors shall have not less than a 20-minute fire protection rating in accordance with Section 8.3.

30.3.6.3 Reserved.

30.3.6.4 Doors that open onto exit access corridors shall be self-closing and self-latching.

30.3.6.5 Unprotected openings, other than those from spaces complying with 30.3.6.5, shall be prohibited in exit access corridor walls and doors.

30.3.6.6 Spaces shall be permitted to be unlimited in area and open to the corridor, provided that the following criteria are met:

- (1) The spaces are not used for guest rooms or guest suites or hazardous areas.
- (2) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 30.3.5.
- (3) The space does not obstruct access to required exits.

30.3.6.7 Transoms, louvers, or transfer grilles shall be prohibited in walls or doors of exit access corridors.

The provisions of 30/31.3.6 reflect concern for providing safety for occupants in their apartments during a fire. The minimum 1-hour fire resistance rating required for corridor wall construction in new, non-sprinklered apartment buildings is intended to prevent fire from moving from the corridor to an apartment or from an apartment to the corridor.

The minimum ½-hour fire resistance rating required for corridor wall construction in existing

CHAPTER 31 • Existing

31.3.6 Corridors.

31.3.6.1* Walls. Exit access corridor walls shall consist of fire barriers in accordance with Section 8.3 that have not less than a ½-hour fire resistance rating.

A.31.3.6.1 The intent is to recognize that existing partitions of sound wood lath and plaster, wire lath and plaster, or gypsum lath and plaster construction have demonstrated the ability to contain most room fires. Recent data on archaic construction methods have established the fire resistance rating of such construction at about 20 minutes. Such construction meets the intent of 31.3.6.1.

31.3.6.2 Doors. Doors that open onto exit access corridors, other than those complying with 8.3.4 and in buildings meeting 31.3.6.3, shall have not less than a 20-minute fire protection rating in accordance with Section 8.3.

31.3.6.3 In buildings using Option 3 or Option 4, doors shall be constructed to resist the passage of smoke.

31.3.6.4 Doors that open onto exit access corridors shall be self-closing and self-latching.

31.3.6.5 Unprotected openings, other than those from spaces complying with 31.3.6.6, shall be prohibited in exit access corridor walls and doors.

31.3.6.6 Spaces shall be permitted to be unlimited in area and open to the corridor, provided that the following criteria are met:

- (1) The spaces are not used for guest rooms or guest suites or hazardous areas.
- (2) The building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 31.3.5.3.
- (3) The space does not obstruct access to required exits.

31.3.6.7 Transoms, louvers, or transfer grilles shall be prohibited in walls or doors of exit access corridors.

apartment buildings recognizes that most existing lath and plaster walls provide a 30-minute fire resistance rating.

The provision of 30.3.6.1.2 also permits a reduction to a ½-hour fire resistance rating in new sprinklered apartment buildings. Although this reduction would result in little savings in new construction, it could be useful in rehabilitation, renovations, or conversions of existing structures that are required to

CHAPTER 30 • New

meet the provisions for new construction (see 4.6.8). If automatic sprinkler protection is provided throughout the building, the existing corridor walls should not have to be replaced.

The installation and proper maintenance of the required self-closing device on the door between an apartment and the common corridor could lead to a significant reduction in fatalities caused by fire in apartment buildings. Studies of typical apartment fires indicate that fire spreads beyond the apartment of origin because doors are left open as occupants escape.

In other cases, fatalities occur when occupants who suspect a fire open the door to a room fully involved with fire or cause full fire involvement of the room by introducing oxygen through the open door. Spring-loaded hinges or closers will cause these doors to close and latch, preventing smoke or fire from spreading down the corridor and exposing other occupants.

The door required by 30/31.3.6.2 provides a level of protection commensurate with the expected fuel load in the apartment unit and the fire resistance of the corridor wall construction. The purpose is to box a fire out of or within an apartment unit by means of corridor wall and door construction. Fuel load studies conducted by the former National Bureau of Standards (now the National Institute of Standards and Technology) demonstrated that residential occupancies typically have fuel loads capable of sustaining a fire for approximately 20 to 30 minutes.

Exhibits 30/31.13 and 30/31.14 detail the wall construction and opening protection requirements of 30.3.6 and 31.3.6, respectively.

30.3.7 Subdivisions of Building Spaces.

Buildings shall be subdivided in accordance with 30.3.7.1 or 30.3.7.2.

30.3.7.1 In buildings not meeting 30.3.7.2, dwelling units shall be separated from each other by walls and floors constructed as fire barriers having fire resistance ratings of not less than 1 hour.

CHAPTER 31 • Existing

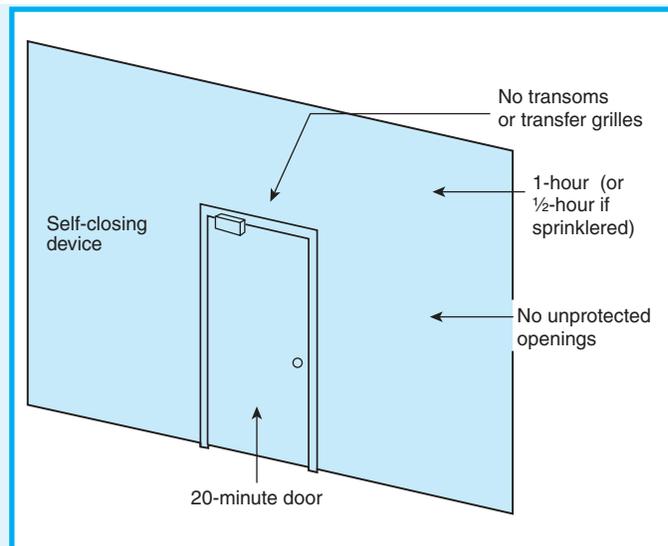

Exhibit 30/31.13 Corridor wall construction in new apartment building.

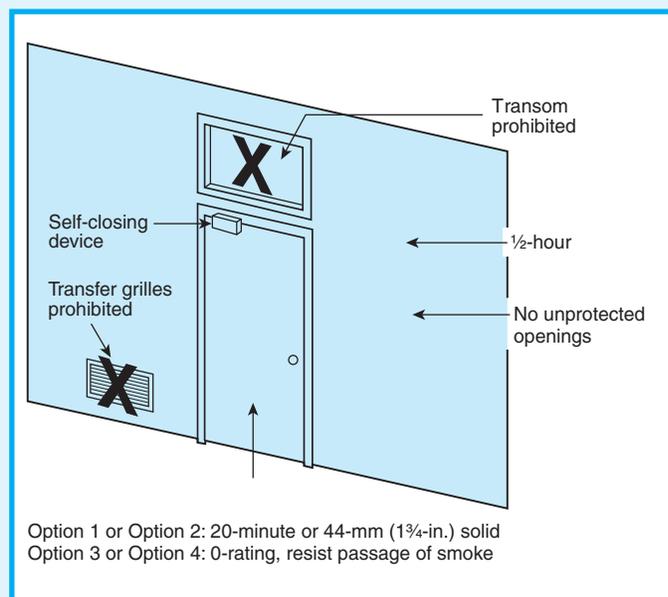

Exhibit 30/31.14 Corridor wall construction in existing apartment building.

31.3.7 Subdivision of Building Spaces—Smoke Barriers.

In buildings other than those meeting 31.3.7.1, 31.3.7.2, 31.3.7.3, 31.3.7.4, or 31.3.7.5, the following shall be met:

- (1) Smoke barriers in accordance with Section 8.5 shall be provided in exit access corridors to establish not less than two compartments approximately equal in size.

CHAPTER 30 • New

30.3.7.2 In buildings protected throughout by an approved, supervised, automatic sprinkler system, dwelling units shall be separated from each other by walls and floors constructed as fire barriers having fire resistance ratings of not less than ½ hour.

The smoke barriers required by 31.3.7 for existing apartment buildings are relatively easy to provide, because no fire resistance rating is required and smoke dampers are exempted where ducts penetrate such barriers. In most cases, installing a set of cross-corridor doors with smoke-actuated automatic closers will meet the requirement. Exemptions to the smoke barrier requirement are provided for sprin-

30.3.8 Special Protection Features.

(Reserved)

Section 30.4 Special Provisions

30.4.1 High-Rise Buildings.

High-rise buildings shall comply with Section 11.8. Subsections 30.3.5.4 and 30.3.5.5 shall be permitted.

Section 30.5 Building Services

30.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

30.5.2 Heating, Ventilating, and Air Conditioning.

30.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

CHAPTER 31 • Existing

- (2) The length of each smoke compartment, measured along the corridor, shall not exceed 61 m (200 ft).
- (3) Smoke dampers shall not be required.

31.3.7.1 Smoke barriers shall not be required in buildings using Option 4.

31.3.7.2 Smoke barriers shall not be required in buildings having exterior exit access in accordance with 7.5.3 that provides access to two exits.

31.3.7.3 Smoke barriers shall not be required in buildings complying with 31.2.4.2, 31.2.4.3, 31.2.4.4, or 31.2.4.5.

31.3.7.4 Smoke barriers shall not be required in buildings with exits not more than 15 m (50 ft) apart.

31.3.7.5 Smoke barriers shall not be required where each dwelling unit has direct access to the exterior at grade.

klered buildings (31.3.7.1), buildings with a single exit (31.3.7.3), and buildings that do not use corridors as required exit access (31.3.7.2 and 31.3.7.5).

The provision of 31.3.7.4 does not require smoke barriers every 15 m (50 ft) but exempts a smoke barrier located on a floor where the exit stairs are spaced no farther than 15 m (50 ft) apart, measured along the corridor.

31.3.8 Special Protection Features.

(Reserved)

Section 31.4 Special Provisions

31.4.1 High-Rise Buildings.

High-rise buildings shall comply with 31.2.11 and 31.3.5.10.

Section 31.5 Building Services

31.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

31.5.2 Heating, Ventilating, and Air Conditioning.

31.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

CHAPTERS 32 and 33

New and Existing Residential Board and Care Occupancies

The primary characteristics that differentiate residential board and care occupancies from other residential occupancies is the assumed ability (or lack thereof) of occupants to evacuate themselves in the event of a fire or similar emergency and the availability or level of personal care services. *Personal care*, as defined in 3.3.163, includes assistance with many of the activities of daily living. Personal care services might include assisting residents with bathing and dressing and helping residents with bill payment and similar household maintenance-related tasks. Personal care does not include nursing home-type care, nor does it include medical care.

Prior to the 2003 edition of the *Code*, application of the requirements for both new and existing residential board and care facilities required the determination of the occupants' evacuation capability — that is, the occupants' ability to move, as a group, to a point of safety in the event of a fire. Evacuation capability was broken down into three subclasses—“prompt,” “slow,” and “impractical.” Ongoing evaluation by the authority having jurisdiction was required to ensure the facility was not being used outside the limitations of its design (for example, a facility designed and constructed using the provisions for slow evacuation capability actually having an evacuation capability that is impractical). When tasked with the development of provisions for residential board and care facilities to be included in the new *NFPA 5000™*, *Building Construction and Safety Code™*¹, the NFPA Technical Committee on Board and Care Facilities recognized that because a facility's population is expected to change over time, its evacuation capability will likely change over time as well. It was not, then, practical to simply insert the require-

ments from this *Code* into *NFPA 5000*. As such, the committee modified the requirements for new board and care facilities so as to not depend on the facility's occupants' evacuation capability.

For consistency with *NFPA 5000*, the committee also revised the provisions of Chapter 32 of this *Code*, which addresses new facilities, so they no longer depend on the determination of evacuation capability. Chapter 33, which addresses existing facilities, retains the evacuation capability provisions so as to not place existing facilities out of compliance. Since new board and care facilities might contain occupants who do not have the ability to evacuate by themselves, they must be designed and constructed to facilitate the “defend in place” occupant protection strategy, much like health care occupancies. To utilize the defend in place strategy, the building must be able to withstand the effects of fire for the time necessary to either evacuate the occupants or relocate them to a safe location within the building.

Chapters 32 and 33 classify residential board and care occupancies based on the number of residents. For this purpose, the chapters are further subdivided to address requirements for small (16 or fewer residents) and large (more than 16 residents) facilities. As the number of residents put at risk by fire increases, the requirements naturally become stricter.

Of the determinations that must be made to classify a residential board and care occupancy (that is, availability of personal care, number of residents, and, in the case of existing facilities, evacuation capability), the most difficult is evacuation capability. Evacuation capability is to be established on the basis of the occupants' (that is, residents and staff, working together) ability to move to a safe location, such as an

CHAPTER 32 • New

enclosed exit stair or a point outside of the structure. Paragraph 3.3.57 provides a definition of *evacuation capability*; A.3.3.57 provides guidance on classifying evacuation capability.

Where an existing facility does not comply with the requirements for new facilities in Chapter 32, Chapter 33 requires facility management to furnish the authority having jurisdiction with an evacuation capability determination conducted using a procedure acceptable to the AHJ. If such documentation is not furnished, the evacuation capability is set, by default, as impractical.

Protection features for residential board and care occupancies range from regulating the allowable types of construction to mandating alarm and detection systems, to mandating automatic sprinkler protection for all new facilities.

Another unique portion of Chapters 32 and 33

CHAPTER 33 • Existing

is Section 32/33.4, which addresses the location of a residential board and care occupancy within an apartment building. The apartment building itself is evaluated on its suitability to house the residential board and care occupancy. The apartment units used as a residential board and care occupancy are judged individually based on the requirements of Section 32/33.2, which applies to small residential board and care occupancies.

As in the case of other occupancy chapters that address occupants with limited self-preservation capability, Chapters 32 and 33 rely on staff intervention and staff support to assist the residents during fire and similar emergencies. It is the responsibility of the staff to understand and implement the emergency plan for the facility. The plan must include a method for familiarizing residents with the procedures to be followed during a fire.

Section 32.1 General Requirements

32.1.1* Application.

A.32.1.1 The requirements of Chapter 32 are designed to accommodate typical changes in the capabilities of the resident, such as those due to accidents, temporary illness, cyclical variations in capabilities, and gradual aging. This approach is based on the assumption that the capabilities of the resident will be evaluated not less than annually, and for residents with geriatric problems or degenerative diseases, not less than every 6 months. Also, residents should be re-evaluated after each accident or illness that requires hospitalization.

The requirements of Chapter 32 were developed on the assumption that the occupants will normally evacuate the building in fire emergencies. During fire exit drills, all occupants should evacuate the building with staff assistance as needed. Exceptions can be made in facilities where the residents cannot be evacuated practically. Managers of board and care homes with nursing home backgrounds sometimes are not aware of the differences between the requirements of 18.7.1 and 32.7.3.

32.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as residential board and care occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, residential board and care occupancies (*see 4.6.7*)

Section 33.1 General Requirements

33.1.1* Application.

A.33.1.1 The requirements of Chapter 33 are designed to accommodate typical changes in the capabilities of the resident, such as those due to accidents, temporary illness, cyclical variations in capabilities, and gradual aging. This approach is based on the assumption that the capabilities of the resident will be evaluated not less than annually, and for residents with geriatric problems or degenerative diseases, not less than every 6 months. Also, residents should be re-evaluated after each accident or illness that requires hospitalization.

The requirements of Chapter 33 were developed on the assumption that the occupants will normally evacuate the building in fire emergencies. During fire exit drills, all occupants should evacuate the building with staff assistance as needed. Exceptions can be made in facilities with an evacuation capability rating of impractical. Managers of board and care homes with nursing home backgrounds sometimes are not aware of the differences between the requirements of 19.7.1 and 33.7.3.

33.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as residential board and care occupancies (*see also 32.1.1*).

CHAPTER 32 • New

- (3) Alterations, modernizations, or renovations of residential board and care occupancies (*see 4.6.8*)
- (4) Buildings or portions thereof upon change of occupancy to a residential board and care occupancy (*see 4.6.12*)

32.1.1.2 Reserved.

32.1.1.3 This chapter is divided into five sections as follows:

- (1) Section 32.1—General Requirements
- (2) Section 32.2—Small Facilities (that is, sleeping accommodations for not more than 16 residents)
- (3) Section 32.3—Large Facilities (that is, sleeping accommodations for more than 16 residents)
- (4) Section 32.4—Suitability of an Apartment Building to House a Board and Care Occupancy
- (5) Section 32.7—Operating Features (*Sections 32.5 and 32.6 are reserved.*)

32.1.1.4 Conversion. For the purposes of this chapter, exceptions for conversions shall apply only for a change of occupancy from an existing residential or health care occupancy to a residential board and care occupancy.

Residential board and care occupancies take many forms: assisted living facilities, halfway houses, retirement homes, rooming houses, and community living centers, among others. Regardless of the label, the level of care that is provided is the key to identifying a residential board and care facility.

In recent years, the number of retirement community facilities has grown. These facilities might provide different living arrangements for the elderly within the same building or a group of buildings. They also might offer any combination of independent living facilities (apartments), board and care facilities, and full nursing facilities. It is important that the occupancy classification for each building or area be properly identified and that proper separation between the occupancies be provided as necessary. See 32/33.1.2 for details on multiple occupancies involving board and care facilities.

From 1990 to 2000, NFPA documented multiple-death fires in 19 board and care occupancies resulting in 103 deaths. Commentary Table 32/33.1 provides a partial list of those fires.

CHAPTER 33 • Existing

33.1.1.2* Any facility meeting the requirements of Chapter 32 shall not be required to meet those of Chapter 33.

A.33.1.1.2 The provision of 33.1.1.2 was added after Chapter 32 was revised in its entirety to avoid potential conflicts between the two chapters. Occupancies meeting Chapter 32 are deemed to comply with Chapter 33.

33.1.1.3 This chapter is divided into five sections as follows:

- (1) Section 33.1—General Requirements
- (2) Section 33.2—Small Facilities (that is, sleeping accommodations for not more than 16 residents)
- (3) Section 33.3—Large Facilities (that is, sleeping accommodations for more than 16 residents)
- (4) Section 33.4—Suitability of an Apartment Building to House a Board and Care Occupancy
- (5) Section 33.7—Operating Features (*Sections 33.5 and 33.6 are reserved.*)

33.1.1.4 Conversion. For the purposes of this chapter, exceptions for conversions shall apply only for a change of occupancy from an existing residential or health care occupancy to a residential board and care occupancy.

Commentary Table 32/33.1 Residential Board and Care Multiple-Death Fires

Year	Location	Fatalities
1990	Bessemer, AL	4
1991	Colorado Springs, CO	9
1992	Detroit, MI	10
1994	Broward County, FL	5
1995	Mississauga, Ontario	8
1996	Laurinberg, NC	8
1996	Shelby County, TN	4
1996	Ste. Genevieve, Quebec	7
1997	Harveys Lake, PA	10
1998	Arlington, WA	8
2000	Philadelphia, PA	3

Source: National estimates based on NFIRS and NFPA survey data.

The following were major contributing factors in these fires:

- (1) Lack of automatic sprinklers
- (2) Doors open to the room of fire origin

CHAPTER 32 • New

- (3) Doors open to stairs or unprotected vertical openings
- (4) Ineffective staff or resident training or response

Chapters 32 and 33 address basic fire protection features for board and care facilities while maintaining the ability to operate such a facility in a noninstitutional environment. The requirements for small board and care facilities are similar to the provisions for one- and two-family dwellings and lodging or rooming houses. The requirements for existing large facilities, other than those in which residents are classified as impractical to evacuate, are similar to the requirements for new hotels; the requirements for new large facilities are similar to those for health care facilities because of the potential for occupants who are unable to evacuate themselves in the event of a fire. Existing large facilities in which residents are classified as impractical to evacuate must comply with the requirements of Chapter 19 or Chapter 32 (see 33.1.1.2 and 33.3.1.2.2). While the provisions of Chapters 32 and 33 might be similar to those of other residential occupancies, certain requirements differ due to the unique characteristics of board and care facilities—such as the varying degrees to which occupants are able to respond to a fire emergency.

The requirements of Chapters 32 and 33 are based on two main concepts, as follows:

- (1) Larger buildings are more difficult to evacuate than smaller buildings and require more built-in fire protection.
- (2) Occupants who are more difficult to evacuate require more built-in fire protection than occupants who are easier to evacuate. (Chapter 32 essentially assumes impractical evacuation capability, while Chapter 33 requires ongoing evaluation to determine evacuation capability.)

It is also anticipated that a small facility typically will be located in a structure that has the appearance of, and that operates in a manner similar to, a dwell-

CHAPTER 33 • Existing

ing. The operation and size of a small facility also demands unique consideration with respect to the fire protection features provided. Certain fire protection features that are appropriate for large facilities, such as smoke barriers, might not be appropriate and might not provide adequate protection in small facilities. For this reason, 33.2.1.2.1.2, which permits small facilities to comply with the requirements for large facilities, applies only to those facilities that have previously met the criteria for the exemption. The 1985 edition of the *Code* permitted small facilities to comply with the requirements for large facilities in lieu of the provisions for small facilities. As stated in 33.2.1.2.1.2, a small facility that has previously been approved, based on the requirements for a large facility, is permitted to continue to be evaluated as a large facility. However, any other small facility must meet the provisions for a small facility and is not permitted to meet the provisions for a large facility as an alternative.

Several requirements in Chapter 32 are exempted for conversions. Where a building previously occupied as another type of residential occupancy or a health care occupancy is converted to a board and care facility, such change of use must comply with the requirements for new construction in accordance with 4.6.12. This requirement would apply where a hotel, apartment building, lodging or rooming house, dwelling, hospital, nursing home, or limited care facility is converted to a residential board and care facility. However, certain provisions of Chapter 32 are intended to eliminate undue hardship while maintaining a reasonable degree of life safety. In such cases, the specific wording of Chapter 32 exempts the existing building from meeting a requirement that would otherwise apply to a new board and care facility. For example, 32.2.2.5.1.2 permits existing 710-mm-(28-in.-) wide doors in converted facilities to remain in use rather than being replaced with the 810-mm-(32-in.-) wide doors normally required in new board and care facilities.

32.1.2 Multiple Occupancies.

32.1.2.1 Multiple occupancies shall be in accordance with 6.1.14.

32.1.2.2 Reserved.

33.1.2 Multiple Occupancies.

33.1.2.1 Multiple occupancies shall comply with 6.1.14 in buildings other than those meeting 33.1.2.2.

33.1.2.2 The requirement of 33.1.2.1 shall not apply to apartment buildings housing residential board and care occu-

CHAPTER 32 • New

32.1.2.3 No board and care occupancy shall have its sole means of egress or means of escape pass through any nonresidential or non-health care occupancy in the same building.

32.1.2.4 No board and care occupancy shall be located above a nonresidential or non-health care occupancy unless the board and care occupancy and exits therefrom are separated from the nonresidential or non-health care occupancy by construction having a fire resistance rating of not less than 2 hours.

The location of a board and care occupancy in a multiple-occupancy building presents a life safety challenge for the occupants of the board and care occupancy. The typical configuration of such buildings creates the potential for significant time to elapse before occupants of the board and care occupancy become aware of an emergency in another part of the building and take the necessary action. The requirements of 32/33.1.2 help to ensure that it is safe to locate board and care occupancies within these multiple-occupancy buildings by providing the necessary protection and separation. (See 6.1.14 for details on multiple occupancies.)

The requirements in 32/33.1.2.4 mandate that where a residential board and care facility is located above another type of occupancy, that board and care facility and its exit system must be separated from the other occupancy. Therefore, if a new residential board and care occupancy is located on the second floor, the exit stair must have a 2-hour fire-rated enclosure, even though 7.1.3.2 permits a 1-hour fire-rated enclosure. Where the separation requirements in Chapters 32 and 33 differ from those in Table 6.1.14.4.1, the more restrictive requirements apply —

32.1.3 Definitions.

A list of terms used in this chapter follows:

CHAPTER 33 • Existing

pancies in conformance with Section 33.4. In such facilities, any safeguards required by Section 33.4 that are more restrictive than those for other housed occupancies shall apply only to the extent prescribed by Section 33.4.

33.1.2.3 No board and care occupancy shall have its sole means of egress or means of escape pass through any nonresidential or non-health care occupancy in the same building.

33.1.2.4 No board and care occupancy shall be located above a nonresidential or non-health care occupancy unless one of the following conditions is met:

- (1) The board and care occupancy and exits therefrom are separated from the nonresidential or non-health care occupancy by construction having a fire resistance rating of not less than 2 hours.
- (2) The nonresidential or non-health care occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7 and is separated therefrom by construction with a fire-resistance rating of 1 hour.

that is, those with the higher fire resistance rating. Note that the requirements of 32/33.1.2.4 requiring rated separations supersede the option provided by Chapter 6 for unseparated, mixed occupancies.

The provision of 33.1.2.2 clarifies that existing board and care facilities located within an apartment building need not comply with the requirements for mixed apartment/board and care occupancy. The provisions of Section 33.4 apply to the entire building and supplement the provisions of Chapter 31 for apartment buildings. In addition, the apartment unit housing a board and care facility must comply with the provisions of Section 33.2 (see 33.4.1.2). Where a new board and care facility is constructed as part of a new apartment building or opens in an existing apartment building, it must comply with the requirements of Chapter 6 for multiple occupancies, as well as those of Section 32.4.

The provisions of 32/33.1.2.3 and 32/33.1.2.4 are intended to provide added protection for the board and care occupancy during evacuation. They apply wherever a mixture of board and care and nonresidential or non-health care occupancies exists, whether in a new or existing building.

33.1.3 Definitions.

A list of terms used in this chapter follows:

CHAPTER 32 • New

- (1) **Personal Care.** See 3.3.163.
- (2) **Point of Safety.** See 3.3.168.
- (3) **Residential Board and Care Occupancy.** See 3.3.152.13.
- (4) **Residential Board and Care Resident.** See 3.3.182.
- (5) **Staff (Residential Board and Care).** See 3.3.209.
- (6) **Thermal Barrier.** See 3.3.23.3.

A number of key terms, such as *evacuation capability*, *personal care*, and *point of safety*, are referenced in 32/33.1.3. The user needs to understand these terms to make effective use of the requirements for board and care facilities.

Evacuation capability (see definition in 3.3.57) is an underlying factor for the Chapter 33 provisions for existing facilities. However, in most occupancy chapters, the *Code* assumes that the building occupants have an evacuation capability similar to that of others within that occupancy, and the requirements are based on the ability of occupants to reach safety by means of exits. In Chapter 32 and the institutional occupancy chapters (health care and detention and correctional), the *Code* assumes that many of the building occupants will be incapable of evacuating the building, and the protection of life from fire is achieved by the defend-in-place method. In large residential buildings (hotels and apartment buildings), where evacuation capability might be affected due to the large size of the building, substantial, built-in fire protection is required.

In Chapter 33, evacuation capability must be determined before proceeding to identify applicable requirements. The numerous and diverse types of facilities that are included in residential board and care facilities preclude all occupants from having the same evacuation capability. For example, the occupants in an orphanage, a shelter for battered spouses, a group home for highly functioning mentally handicapped persons, or a halfway house for prison parolees might have normal evacuation capability. In facilities housing elderly, physically impaired persons, occupants might be slow moving or might need assistance in recognizing the need for evacuation. In some facilities, evacuation of the building might not be practical at all.

Evacuation capability for an entire facility is not

CHAPTER 33 • Existing

- (1) **Evacuation Capability.** See 3.3.57.
- (2) **Impractical Evacuation Capability.** See 3.3.57.1.
- (3) **Personal Care.** See 3.3.163.
- (4) **Point of Safety.** See 3.3.168.
- (5) **Prompt Evacuation Capability.** See 3.3.57.2.
- (6) **Residential Board and Care Occupancy.** See 3.3.152.13.
- (7) **Residential Board and Care Resident.** See 3.3.182.
- (8) **Slow Evacuation Capability.** See 3.3.57.3.
- (9) **Staff (Residential Board and Care).** See 3.3.209.
- (10) **Thermal Barrier.** See 3.3.23.3.

determined based on the resident who is least capable. A facility that houses one impaired resident might have excellent evacuation capability if the staff or an assigned resident “buddy” is able to provide the assistance needed to effect a prompt evacuation of the entire group. Evacuation capability is based on the ability to relocate to a point of safety that is not necessarily a public way (see the definition of *point of safety* in 3.3.168). The protection features required by Chapter 33 are intended to coordinate with the evacuation capability of the occupants. As such, the fire endurance of the structure, the interior finish materials, and the types and arrangement of means of escape and exits, as well as the corridor enclosure provisions, vary depending on whether a facility houses occupants who are prompt, slow, or impractical to evacuate. Facilities that are impractical to evacuate use the defend-in-place concept. In small facilities, this concept is achieved by improving the protection of vertical openings. In large facilities, the concept is achieved by mandating the use of the health care provisions of Chapters 18 and 19. In all cases, an existing facility is permitted to meet the requirements for new facilities in Chapter 32 in lieu of Chapter 33 (see 33.1.1.2).

Personal care (see definition in 3.3.163) has significance, because the occupants of a board and care facility require care. Personal care is not medical care, as might be provided in a hospital or nursing home, but, rather, a form of assistance in meeting the demands of daily living. The term *transient medical care*, as used in A.3.3.163, refers to the kind of medical care that is normally provided in the home by one family member for another. Transient medical care does not refer to skilled nursing or acute medical care.

Point of safety (see definition in 3.3.168) is another term that is specifically used in Chapters 32 and 33. It is well recognized that there are many buildings

CHAPTER 32 • New

from which evacuation of all occupants to the outside cannot be achieved within a reasonable amount of time. Chapters 32 and 33 establish the criteria for a point of safety within the building. Essentially, a point of safety is an area where residents can remain in safety until the fire is extinguished or until outside assistance can arrive to complete evacuation to the exterior.

Several sections of editions of the *Code* published in the 1980s referred to a finish rating of 15 or 20

32.1.4 Acceptability of Means of Egress or Escape.

No means of escape or means of egress shall be considered as complying with the minimum criteria for acceptance unless emergency evacuation drills are regularly conducted using that route in accordance with the requirements of 32.7.3.

32.1.5* Fire resistance-rated assemblies shall comply with Section 8.3.

A.32.1.5 The provisions of 8.3.1(3) address a ½-hour fire resistance rating. The information in A.8.3.1(3) addresses common materials used in ½-hour fire resistance-rated barriers.

32.1.6 Reserved.

32.1.7 Reserved.

CHAPTER 33 • Existing

minutes. The term *finish rating* is similar to, but not as widely used as, the term *thermal barrier* (see definition in 3.3.23.3). For this reason, Chapters 32 and 33 use the term *thermal barrier* in lieu of *finish rating* in specifying the protection of structural elements and the separation of areas where automatic sprinkler protection is omitted. As noted in A.3.3.23.3, finish ratings might be used to determine a material's acceptability as a thermal barrier.

33.1.4 Acceptability of Means of Egress or Escape.

No means of escape or means of egress shall be considered as complying with the minimum criteria for acceptance unless emergency evacuation drills are regularly conducted using that route in accordance with the requirements of 33.7.3.

33.1.5* Fire resistance-rated assemblies shall comply with Section 8.3.

A.33.1.5 The provisions of 8.3.1(3) address a ½-hour fire resistance rating. The information in A.8.3.1(3) addresses common materials used in ½-hour fire resistance-rated barriers.

33.1.6 Changes in Facility Size.

A change in facility size from small to large shall be considered a change in occupancy subclassification and shall require compliance with the provisions applicable to new construction.

33.1.7* Changes in Group Evacuation Capability.

A change in evacuation capability to a slower level shall be permitted where the facility conforms to the requirements applicable to new construction, conversions, and the new evacuation capability.

A.33.1.7 When the group evacuation capability changes to a level of greater risk, the owner/operator of the facility needs to take such action as is necessary, within a reasonable time frame, to restore the evacuation capability of the facility to that for which it was approved. If subsequent evaluations indicate that the original evacuation capability of the facility cannot or is not being maintained at the original level of risk, the facility would be considered as having changed the occupancy subclassification to one of greater risk, and the safeguards required for the level of greater risk would apply. If a facility improves its original evacuation capability to one of less risk, a re-evaluation and upgrading to the requirements for new construction is not needed.

CHAPTER 32 • New

The acceptability of the means of egress or escape is addressed by 32/33.1.4. Exits and means of escape are worthless unless residents are familiar with them and are comfortable using them. An exit or means of escape that is never used in drills will probably not be used during an emergency evacuation. This does not mean that, if windows serve as secondary means of escape, a resident must practice escaping via the window during a drill. However, during drills it would be important to identify the appropriate windows

Section 32.2 Small Facilities

32.2.1 General.

32.2.1.1 Scope.

32.2.1.1.1 Section 32.2 shall apply to residential board and care occupancies providing sleeping accommodations for not more than 16 residents.

32.2.1.1.2 Where there are sleeping accommodations for more than 16 residents, the occupancy shall be classified as a large facility in accordance with Section 8.3.

32.2.1.2 Reserved.

CHAPTER 33 • Existing

and ensure that residents are familiar with the operation of the windows and their proper use during escape.

Changes that might occur during the life of an existing board and care occupancy are addressed by 33.1.6 and 33.1.7. Physical/structural growth will be easily identified, since permits would normally be required for such changes. Changes in evacuation capability might be subtler and will require a close review of the facility's fire drill records.

Section 33.2 Small Facilities

33.2.1 General.

33.2.1.1 Scope.

33.2.1.1.1 Section 32.2 shall apply to residential board and care occupancies providing sleeping accommodations for not more than 16 residents.

33.2.1.1.2 Where there are sleeping accommodations for more than 16 residents, the occupancy shall be classified as a large facility in accordance with Section 33.3.

33.2.1.2 Requirements Based on Evacuation Capability.

33.2.1.2.1 Small facilities, other than those meeting 33.2.1.2.1.1 or 33.2.1.2.1.2, shall comply with the requirements of Section 33.2 as indicated for the appropriate evacuation capability; the ability of all occupants, residents, staff, and family members shall be considered in determining evacuation capability.

33.2.1.2.1.1* Facilities where the authority having jurisdiction has determined equivalent safety is provided in accordance with Section 1.4 shall not be required to comply with Section 33.2.

A.33.2.1.2.1.1 In determining equivalency for existing buildings, conversions, modernizations, renovations, or unusual design concepts, the authority having jurisdiction might permit evaluations based on residential board and care occupancies fire safety evaluation system (FSES) in NFPA 101A, *Guide on Alternative Approaches to Life Safety*.

33.2.1.2.1.2 Facilities that were previously approved as complying with the requirements for a large facility having the same evacuation capability shall not be required to comply with Section 33.2.

The importance of an accurate evaluation of evacuation capabilities in existing facilities cannot be overstated. Ineffective resident or staff response was a contributing factor in the majority of the multiple-death fires listed in Commentary Table 32/33.1.

Determining a facility's evacuation capability is not simply a matter of timing a fire drill in the middle of the day. Many variables affect a resident's capability to evacuate, and these variables must be carefully considered and factored into the documentation presented to the authority having jurisdiction for approval. Some variables that should be considered follow.

(a) *Time of Day.* An occupant's ability to evacuate might be slowed dramatically when the person must be awakened. In such a situation, the occupant must process the information that evacuation is necessary and then begin evacuating.

(b) *Medication.* Many individuals in board and care occupancies take various medications for behavior control or as sleeping aids. If an individual is medicated, he or she might need additional assistance in responding and evacuating.

(c) *Mobility and Location of Occupants.* Once individuals become aware of an emergency and take action, their ability to move through the building must be considered. Individuals using wheelchairs, walkers, or canes are further slowed when using stairs or ramps or when opening doors.

(d) *Staff Assistance.* Though the *Code* does not specify minimum staffing levels, staffing levels

33.2.1.2.2 Facility management shall furnish to the authority having jurisdiction, upon request, an evacuation capability determination using a procedure acceptable to the authority having jurisdiction; where such documentation is not furnished, the evacuation capability shall be classified as impractical.

should be considered, especially where high resident-to-staff ratios exist. Given the additional needs mentioned in (a) through (c), the staff will be limited in their ability to affect evacuation time where multiple residents need assistance.

The evacuation capability of the population of a board and care occupancy might vary over time. The required documentation should be reviewed regularly to ensure that it accurately represents the current evacuation capability of the residents and staff.

When determining equivalency in accordance with 33.2.1.2.1.1, it is important to note that the equivalency measurement systems of the 2001 edition of NFPA 101A, *Guide on Alternative Approaches to Life Safety*², were calibrated against the requirements of the 2000 edition of NFPA 101 and might not accurately evaluate equivalency with the requirements of the 2003 edition of the *Life Safety Code*. At the time this handbook went to press, the 2004 edition of NFPA 101A was being prepared. Once issued, the 2004 edition of NFPA 101A can be used to measure equivalency against the requirements of the 2003 edition of the *Code*.

The provision of 33.2.1.2.1.2 continues to recognize an existing situation that resulted from compliance with a provision of the 1985 edition of the *Code* that permitted small board and care facilities to comply with the requirements for large facilities. The protection features applicable to large facilities might not necessarily provide adequate protection for small facilities. See the commentary on 33.1.1.4.

32.2.1.3 Minimum Construction Requirements. (No requirements.)

33.2.1.3 Minimum Construction Requirements.

33.2.1.3.1 Prompt Evacuation Capability. (No special requirements.)

33.2.1.3.2 Slow Evacuation Capability.

33.2.1.3.2.1 The facility shall be housed in a building where the interior is fully sheathed with lath and plaster or other material providing a 15-minute thermal barrier, as modified

CHAPTER 32 • New

CHAPTER 33 • Existing

by 33.2.1.3.2.3 through 33.2.1.3.2.7, including all portions of bearing walls, bearing partitions, floor construction, and roofs.

33.2.1.3.2.2 All columns, beams, girders, and trusses shall be similarly encased or otherwise shall provide not less than a ½-hour fire resistance rating.

33.2.1.3.2.3 Exposed steel or wood columns, girders, and beams (but not joists) located in the basement shall be permitted.

33.2.1.3.2.4 Buildings of Type I, Type II(222), Type II(111), Type III(211), Type IV, or Type V(111) construction shall not be required to meet 33.2.1.3.2. (*See 8.2.1.*)

33.2.1.3.2.5 Areas protected by approved automatic sprinkler systems in accordance with 33.2.3.5 shall not be required to meet 33.2.1.3.2.

33.2.1.3.2.6 Unfinished, unused, and essentially inaccessible loft, attic, or crawl spaces shall not be required to meet 33.2.1.3.2.

33.2.1.3.2.7 Where the facility can demonstrate to the authority having jurisdiction that the group is capable of evacuating the building in 8 minutes or less or achieves an E-score of three or less using the board and care occupancies evacuation capability determination methodology of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, the requirements of 33.2.1.3.2 shall not apply.

33.2.1.3.3 Impractical Evacuation Capability. Nonsprinklered buildings shall be of any construction type in accordance with 8.2.1 other than Type II(000), Type III(200), or Type V(000) construction. Buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 33.2.3.5 shall be permitted to be of any type of construction.

Because 32.2.3.5.1 requires new small board and care facilities to be sprinklered, no additional requirements with respect to minimum building construction types apply for new construction. However, no sprinkler mandate is specified for existing board and care occupancies. Therefore, 33.2.1.3.2 and 33.2.1.3.3 establish minimum construction requirements to provide an adequate level of safety for existing small facilities with slow or impractical evacuation capability.

Exhibit 32/33.1 illustrates the concept of sheathing the interior of a small board and care facility building with a slow evacuation capability to achieve

the 15-minute thermal barrier that is required by 33.2.1.3.2. The nonsprinklered areas (A, C, and D) are required to have sheathing to protect bearing walls, floor construction, and roofs. The heavy timber columns and girders in area A do not require sheathing but must provide a minimum fire resistance rating of 30 minutes. As permitted by 33.2.1.3.2.5, the sprinklered areas of the building are exempt from the sheathing requirement.

The provision of 33.2.1.3.2.7 is intended to allow unsheathed, unsprinklered wood frame construction in facilities that house groups capable of evacuation

CHAPTER 32 • New

to a point of safety within 8 minutes. For such groups, the additional evacuation time provided by fire-resistant sheathing is not necessary.

All existing small facilities with impractical evacuation capability must be protected with a supervised automatic sprinkler system per 33.2.3.5.3. The provision of 33.2.1.3.3 allowing any construction type is permitted if the entire building, not only the residential board and care facility, is protected with a supervised automatic sprinkler system.

CHAPTER 33 • Existing

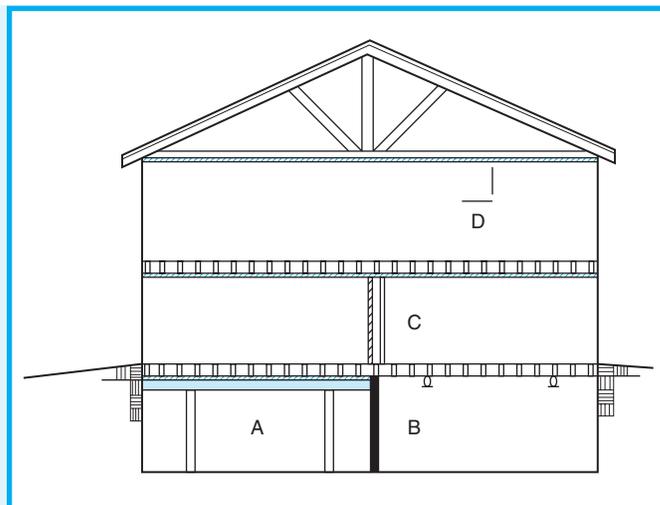

Exhibit 32/33.1 Sheathing requirements in a small facility with slow evacuation capability.

32.2.2 Means of Escape.

32.2.2.1 Reserved.

32.2.2.2 Primary Means of Escape.

32.2.2.2.1 Every sleeping room and living area shall have access to a primary means of escape located to provide a safe path of travel to the outside.

33.2.2 Means of Escape.

33.2.2.1 Number of Means of Escape.

33.2.2.1.1 Each normally occupied story of the facility shall have not less than two remotely located means of escape that do not involve using windows, unless the facility meets 33.2.2.1.4 or 33.2.2.1.5.

33.2.2.1.2 Not less than one of these means of escape shall be in accordance with 33.2.2.2.

33.2.2.1.3 The provisions of Chapter 7 shall not apply to means of escape unless specifically referenced in this chapter.

33.2.2.1.4 In prompt evacuation capability facilities, one means of escape shall be permitted to involve windows complying with 33.2.2.3(3).

33.2.2.1.5 A second means of escape from each story shall not be required where the entire building is protected throughout by an approved automatic sprinkler system complying with 33.2.3.5 and the facility has two means of escape; this provision shall not be permitted to be used in conjunction with 33.2.2.3.2.

33.2.2.2 Primary Means of Escape.

33.2.2.2.1 Every sleeping room and living area shall have access to a primary means of escape located to provide a safe path of travel to the outside.

CHAPTER 32 • New

32.2.2.2.2 Where sleeping rooms or living areas are above or below the level of exit discharge, the primary means of escape shall be an interior stair in accordance with 32.2.2.4, an exterior stair, a horizontal exit, or a fire escape stair.

32.2.2.3 Secondary Means of Escape.

32.2.2.3.1 Sleeping rooms, other than those complying with 32.2.2.3.2, and living areas in facilities without a sprinkler system installed in accordance with 32.2.3.5 shall have a second means of escape consisting of one of the following:

- (1) A door, stairway, passage, or hall providing a way of unobstructed travel to the outside of the dwelling at street or ground level that is independent of, and remotely located from, the primary means of escape
- (2) A passage through an adjacent nonlockable space, independent of, and remotely located from, the primary means of escape to any approved means of escape
- (3)* An outside window or door operable from the inside without the use of tools, keys, or special effort, and providing a clear opening of not less than 0.53 m² (5.7 ft²) with the width not less than 510 mm (20 in.) and the height not less than 610 mm (24 in.). The bottom of the opening shall be not more than 1120 mm (44 in.) above the floor. Such means of escape shall be acceptable if one of the following is met:
 - (a) The window is within 6100 mm (240 in.) of grade.
 - (b) The window is directly accessible to fire department rescue apparatus as approved by the authority having jurisdiction.
 - (c) The window or door opens onto an exterior balcony.

A.32.2.2.3.1(3) A window with dimensions of 510 mm × 610 mm (20 in. × 24 in.) has an opening of 0.31 m² (3.3 ft²), which is less than the required 0.53 m² (5.7 ft²). Therefore, either the height or width needs to exceed the minimum requirement to provide the required clear area.

32.2.2.3.2 Sleeping rooms that have a door leading directly to the outside of the building with access to grade or to an exterior stairway meeting the requirements of 32.2.2.6.3 shall be considered as meeting all the requirements for a second means of escape.

CHAPTER 33 • Existing

33.2.2.2.2 Where sleeping rooms or living areas are above or below the level of exit discharge, the primary means of escape shall be an interior stair in accordance with 33.2.2.4, an exterior stair, a horizontal exit, or a fire escape stair.

33.2.2.2.3 In slow and impractical evacuation capability facilities, the primary means of escape for each sleeping room shall not be exposed to living areas and kitchens unless the building is protected by an approved automatic sprinkler system in accordance with 33.2.3.5 utilizing quick-response or residential sprinklers throughout.

33.2.2.2.4 Standard response sprinklers shall be permitted for use in hazardous areas in accordance with 33.2.3.2.

33.2.2.3 Secondary Means of Escape. In addition to the primary route, each sleeping room shall have a second means of escape that consists of one of the following, unless the provisions of 33.2.2.3.1, 33.2.2.3.2, or 33.2.2.3.3 are met.

- (1) A door, stairway, passage, or hall providing a way of unobstructed travel to the outside of the dwelling at street or ground level that is independent of, and remotely located from, the primary means of escape
- (2) A passage through an adjacent nonlockable space, independent of and remotely located from, the primary means of escape to any approved means of escape
- (3)* An outside window or door operable from the inside without the use of tools, keys, or special effort that provides a clear opening of not less than 0.53 m² (5.7 ft²). The width shall be not less than 510 mm (20 in.), and the height shall be not less than 610 mm (24 in.). The bottom of the opening shall be not more than 1120 mm (44 in.) above the floor. Such means of escape shall be acceptable where one of the following is met:
 - (a) The window shall be within 6100 mm (240 in.) of grade.
 - (b) The window shall be directly accessible to fire department rescue apparatus as approved by the authority having jurisdiction.
 - (c) The window or door shall open onto an exterior balcony.

A.33.2.2.3(3) A window with dimensions of 510 mm × 610 mm (20 in. × 24 in.) has an opening of 0.31 m² (3.3 ft²), which is less than the required 0.53 m² (5.7 ft²). Therefore, either the height or width needs to exceed the minimum requirement to provide the required clear area.

33.2.2.3.1 Sleeping rooms that have a door leading directly to the outside of the building with access to grade or to a stairway that meets the requirements of exterior stairs in 33.2.2.2.2 shall be considered as meeting all the requirements for a second means of escape.

33.2.2.3.2 A second means of escape from each sleeping room shall not be required where the facility is protected throughout by an approved automatic sprinkler system in accordance with 33.2.3.5.

33.2.2.3.3 Existing approved means of escape shall be permitted to continue to be used.

The provisions of 32/33.2.2.1, 32/33.2.2.2, and 32/33.2.2.3 establish the criteria for acceptable means of escape in small board and care facilities. In new facilities, every sleeping room and living area must be provided with access to a primary and secondary means of escape per 32.2.2.2 and 32.2.2.3, much like the other residential occupancies. Note, however, that the requirement for secondary means of escape is exempted when the building is sprinklered per 32.2.2.3.1. In existing facilities, 33.2.2.1 requires each story of the facility to be provided with at least two means of escape. Only one of the means of escape must meet the provisions for a primary means of escape. The second means of escape is permitted to be a window, provided that the window complies with 33.2.2.3(3) and the facility evacuation capability is prompt.

In existing facilities, the second means of escape from each floor is not required if the entire building housing the residential board and care facility is protected throughout by an automatic sprinkler system in accordance with 33.2.3.5. In this instance, the single means of escape must meet the criteria for a primary means of escape specified in 33.2.2.2. However, the facility itself must have at least two means of escape.

Where a window is considered as a secondary means of escape within a sleeping room, the window must meet the criteria detailed in 33.2.2.3(3), but use of the window is not limited to any specific evacuation capability. Windows are not permitted to serve as a primary means of escape.

The provisions of 32/33.2.2.2 specify a primary means of escape that is arranged so that an occupant can travel safely to the outside at grade level. The intent of the requirement is to ensure that use of the primary means of escape will not be lost due to fire from another floor. Exhibit 32/33.2 depicts an exterior stair (A) that serves as the primary means of escape for the second floor. Occupants of the second floor can travel safely to the outside at grade, because the

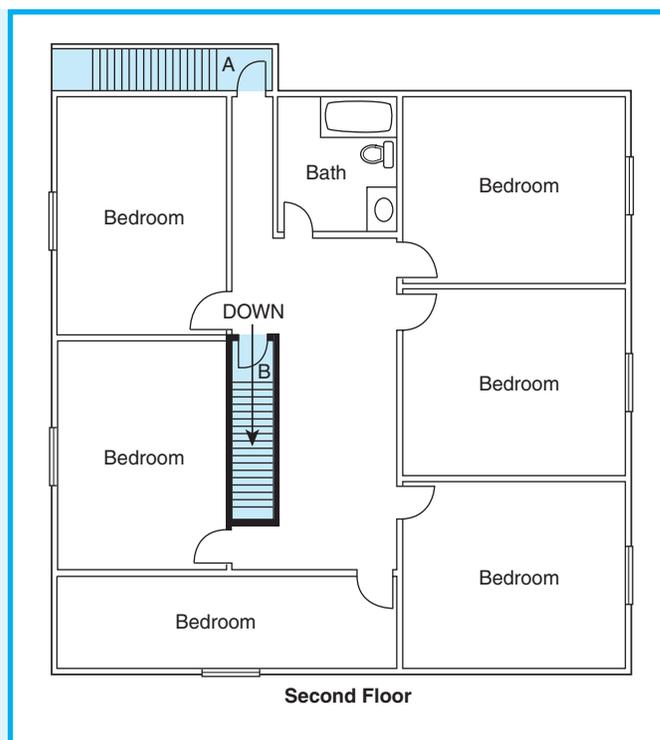

Exhibit 32/33.2 Exterior stair used as primary means of escape.

interior stair (B) is separated from the second floor by enclosing construction on the second floor.

The primary means of escape from rooms above or below grade level will involve vertical travel, such as stairs. For this reason, the *Code* establishes a higher level of reliability by requiring the primary means of escape to be an enclosed interior stair, an exterior stair, a horizontal exit, or an existing fire escape stair. In Exhibit 32/33.2, this requirement is met by using the exterior stair as the primary means of escape from the second floor, even if the partially enclosed (top only) interior stair is used for day-to-day travel between floors.

In existing board and care occupancies with slow

CHAPTER 32 • New

and impractical evacuation capability, and without quick-response or residential sprinklers throughout, 33.2.2.2.3 prohibits the primary means of escape from being exposed to common living spaces and kitchens. Therefore, the primary means of escape from a sleeping room is not permitted to include travel through a day room, a common use space, or a space that is open to a common living space. Exhibit 32/33.3 depicts an example meeting this requirement. By using the outside balconies and exterior stairs as the primary means of escape, the means of escape can be used by occupants of the second floor without exposing them to a fire involving the contents of a common living area.

The objective of 33.2.2.2.3 is to reduce the probability that smoke and heat from a fire involving the contents of a common living area will adversely affect the use of the primary means of escape. The requirement is based, in part, on historical fire experience, which indicates that fires in residential board and care facilities frequently originate in the furniture and contents of common living spaces.

In recognition of the fact that an automatic sprinkler system using quick-response or residential sprinklers provides a high level of protection, 33.2.2.2.3 permits the primary means of escape to be exposed to common living areas where such sprinkler protection is provided. Furthermore, 33.2.2.2.4 permits standard response sprinklers to be used, in lieu of quick-response or residential sprinklers, in hazardous areas that are required to be separated from other parts of the building by the requirements of 33.2.3.2. The provision for standard response sprinklers is allowed because sleeping residents do not occupy hazardous areas.

A secondary means of escape from each sleeping and living area is required for existing small board and care facilities and new nonsprinklered small board and care facilities (as permitted for conversions by 32.2.3.5.2). The main purpose for the secondary means of escape is to provide the occupants with a reasonable escape alternative when fire or smoke blocks the primary means of escape. Three acceptable methods for providing a secondary means of escape are outlined by 32.2.2.3.1(1) through (3) for new facilities and 33.2.2.3(1) through (3) for existing facilities. Exhibit 32/33.4 illustrates these three methods.

The doors marked A in Exhibit 32/33.4 meet the intent of 32.2.2.3.1(1) and 33.2.2.3(1), because they are independent of and remotely located from the pri-

CHAPTER 33 • Existing

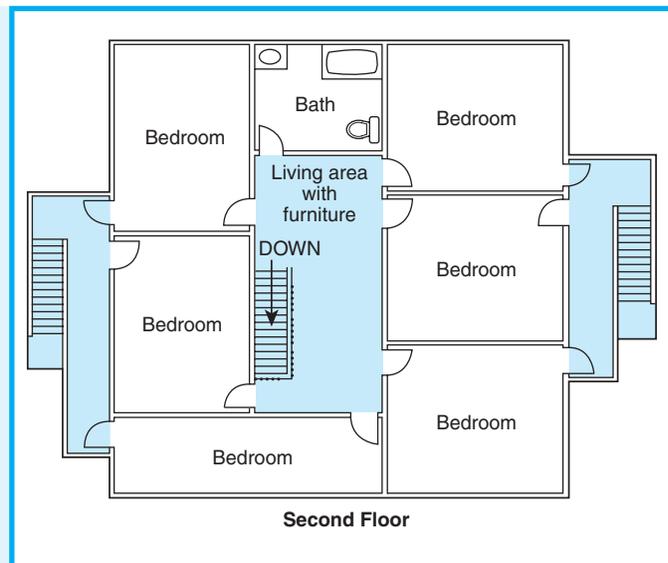

Exhibit 32/33.3 Alternate arrangement for exterior stairs used as primary means of escape in existing facilities.

mary means of escape required by 32/33.2.2.2. If the sleeping room has a second door that leads to the same hallway as the door serving as a primary means of escape, little additional protection is provided, because fire or smoke could affect use of both doors at approximately the same time. If the corridor within the facility into which a sleeping room door opens is separated from all common living spaces, it might be determined that the arrangement is acceptable, provided that the corridor does actually lead to two separate, independent, and remote means of escape. This arrangement is similar to that permitted in other occupancies in which protected corridors are provided. In this case, requiring two doors from the sleeping room to the corridor would provide little additional safety.

The doors marked B in Exhibit 32/33.4 provide a secondary means of escape that passes through an adjacent space, such as another sleeping room. The unlocked doors that lead from bedroom 2 into bedroom 4, and from bedroom 3 into bedroom 5 provide free and unobstructed access in accordance with 32.2.2.3.1(2) and 33.2.2.3(2). Once a resident reaches bedroom 4 or bedroom 5, the secondary means of escape is window C in accordance with 32.2.2.3.1(3) and 33.2.2.3(3).

The windows that are marked C in Exhibit 32/33.4 comply with the minimum dimensions specified

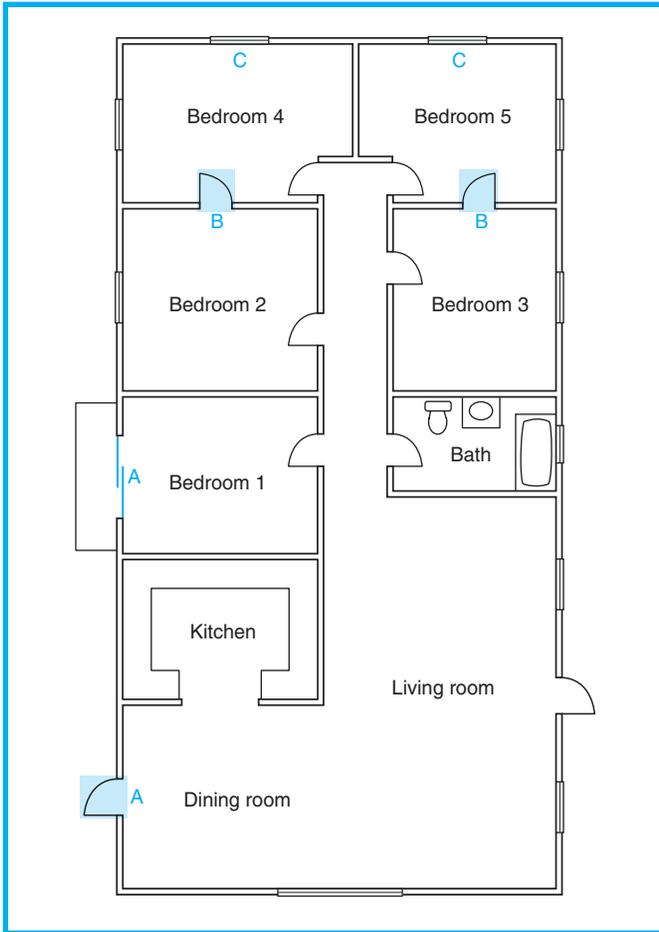

Exhibit 32/33.4 Secondary means of escape options.

in 32.2.2.3.1(3) and 33.2.2.3(3) and are permitted as a second means of escape from a story of an existing small facility only if the evacuation capability is prompt (see 33.2.2.1.4). However, the use of an operable window of the minimum dimensions specified in 32.2.2.3.1(3) and 33.2.2.3(3) is permitted as a secondary means of escape from sleeping rooms and living areas, regardless of the residents' evacuation capability.

Exhibit 32/33.5 illustrates the minimum dimensions required for secondary means of escape windows. Note that the minimum width dimension cannot be simultaneously used with the minimum height dimension, because the minimum area requirement will not be satisfied. If either the minimum height or minimum width dimension is used, the other dimension must be increased to yield the required opening area.

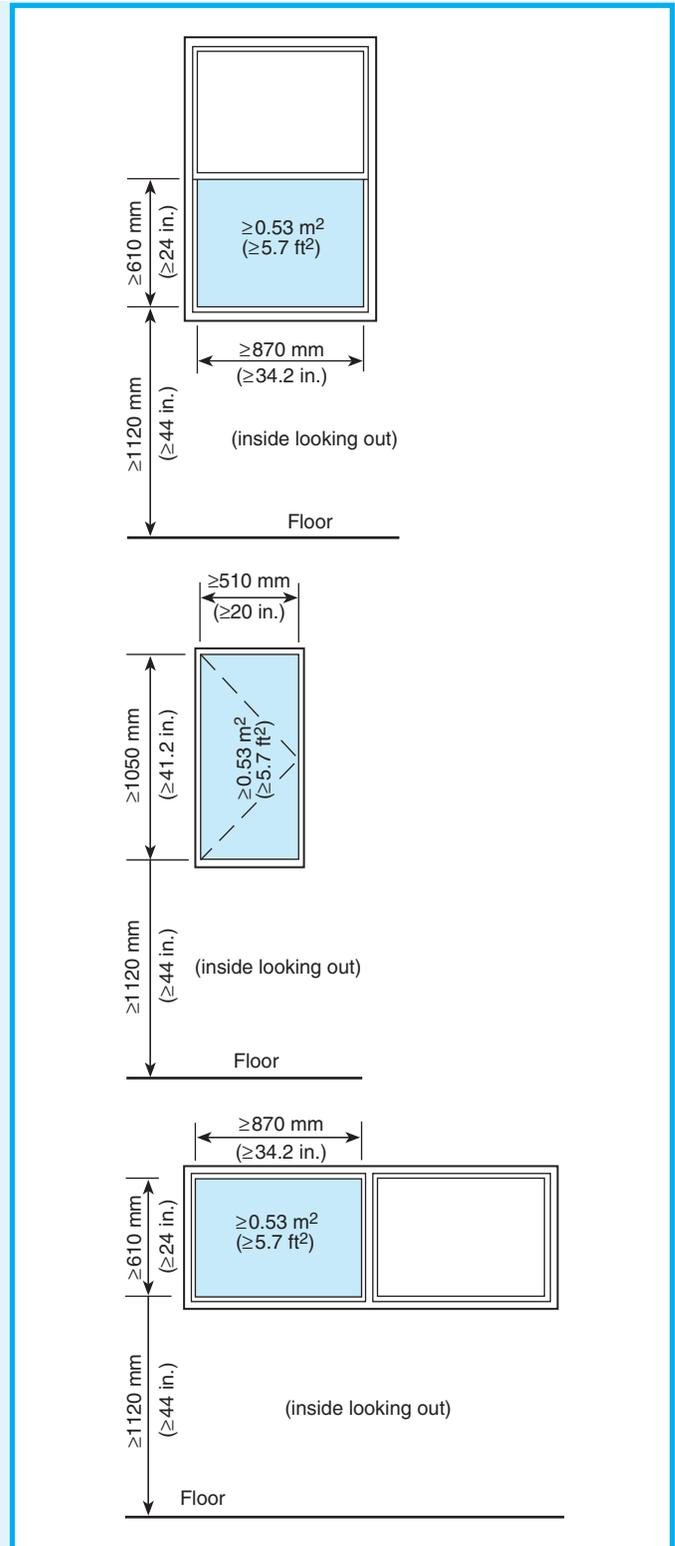

Exhibit 32/33.5 Minimum dimensions for escape windows.

CHAPTER 32 • New

In addition to the minimum size of the window, the utility of the window must be ensured by one of the following three alternatives:

- (1) The window must be within 6100 mm (240 in.) of grade so that dropping from the open window is possible.
- (2) The fire department must be capable of rescuing the occupant from the window. (The authority having jurisdiction must determine acceptable means of fire department rescue, such as by means of aerial ladder apparatus or ground ladders, and additional criteria necessary for approval, such as fire department vehicle accessibility.)
- (3) The occupant must be capable of reaching an exterior balcony to breath fresh air while awaiting either rescue or fire extinguishment.

A facility is exempted from providing secondary means of escape from sleeping rooms by meeting one of three conditions. First, 32.2.2.3.2 and 33.2.2.3.1 allow such an exemption if the sleeping room has a door leading directly to the outside of the building with

32.2.2.4 Interior Stairs Used for Primary Means of Escape. Interior stairs shall be protected in accordance with 32.2.2.4.1 through 32.2.2.4.4, unless they meet 32.2.2.4.5, 32.2.2.4.6, or 32.2.2.4.7.

32.2.2.4.1 Interior stairs shall be enclosed with ½-hour fire barriers in accordance with Section 8.3.

32.2.2.4.2 Stairs shall comply with 7.2.2.5.3.

32.2.2.4.3 The entire primary means of escape shall be arranged so that occupants are not required to pass through a portion of a lower story unless that route is separated from all spaces on that story by construction having a minimum ½-hour fire resistance rating.

32.2.2.4.4 In buildings of construction other than Type II(000), Type III(200), or Type V(000), the supporting construction shall be protected to afford the required fire resistance rating of the supported wall.

CHAPTER 33 • Existing

access to grade. In this case, the door to the outside serves as the equivalent of both the primary and secondary means of escape. Exhibit 32/33.3 illustrates such an arrangement.

Second, the secondary means of escape is exempted where a residential board and care facility is protected throughout with an automatic sprinkler system in accordance with 32/33.2.3.5. However, 33.2.2.3.2 is not permitted to be used in conjunction with 33.2.2.1.5, because the result would be a single means of escape from each room and each floor. Therefore, in existing facilities, the secondary means of escape from sleeping rooms are exempted only if a second means of escape is provided from each floor and the facility is protected by an automatic sprinkler system.

Third, the secondary means of escape are exempted where an existing board and care facility is provided with a means of escape arrangement that has been approved by the authority having jurisdiction per 33.2.2.3.3.

33.2.2.4 Interior Stairs Used for Primary Means of Escape. Interior stairs used for primary means of escape shall comply with 33.2.2.4.1 through 33.2.2.4.6.

33.2.2.4.1 Interior stairs shall be enclosed with ½-hour fire barriers, in accordance with Section 8.3, and shall comply with 7.2.2.5.3.

33.2.2.4.2 The entire primary means of escape shall be arranged so that it is not necessary for occupants to pass through a portion of a lower story unless that route is separated from all spaces on that story by construction having not less than a ½-hour fire resistance rating.

33.2.2.4.3 In buildings of construction other than Type II(000), Type III(200), or Type V(000), the supporting construction shall be protected to afford the required fire resistance rating of the supported wall.

33.2.2.4.4 Stairs that connect a story at street level to only one other story shall be permitted to be open to the story that is not at street level.

CHAPTER 32 • New

32.2.2.4.5 Stairs that connect a story at street level to only one other story shall be permitted to be open to the story that is not the street level.

32.2.2.4.6 In buildings not exceeding three stories in height and protected by an approved, automatic sprinkler system in accordance with 32.2.3.5, stair enclosures shall not be required, provided there still remains a primary means of escape from each sleeping area that does not require occupants to pass through a portion of a lower floor, unless that route is separated from all spaces on that floor by construction having a ½-hour fire resistance rating.

32.2.2.4.7 Stairs serving a maximum of two stories in buildings protected with an approved automatic sprinkler system in accordance with 32.2.3.5 shall be permitted to be unenclosed.

The intent of 32/33.2.2.4 is to require that an interior stair serving as a primary means of escape be enclosed. It does not mandate that an interior stair used for day-to-day use, but not considered a primary means of escape, be enclosed. However, the stair might require separation from the floor to prevent exposure of occupants to unsafe conditions while they travel through the primary means of escape (see 32/33.2.2.2, 32/33.2.3.1, and Exhibit 32/33.2 and its associated commentary).

If the interior stair serves as primary means of escape, it must be arranged so that occupants are not required to pass through occupied or furnished portions of lower floors. Passage through unfurnished vestibule-like areas on lower floors is permitted if such vestibules are separated from occupied

CHAPTER 33 • Existing

33.2.2.4.5 Stair enclosures shall not be required in buildings, that are comprised of three or fewer stories, and that house prompt or slow evacuation capability facilities protected throughout by an approved automatic sprinkler system in accordance with 33.2.3.5 that uses quick-response or residential sprinklers, provided that a primary means of escape from each sleeping area still exists that does not pass through a portion of a lower floor, unless that route is separated from all spaces on that floor by construction having a ½-hour fire resistance rating.

33.2.2.4.6 Stair enclosures shall not be required in buildings that are comprised of two or fewer stories, that house prompt evacuation capability facilities with not more than eight residents, and are protected by an approved automatic sprinkler system in accordance with 33.2.3.5 that uses quick-response or residential sprinklers.

33.2.2.4.7 The provisions of 33.2.2.3.2, 33.2.3.4.3.5, or 33.2.3.4.3.6 shall not be used in conjunction with 33.2.2.4.6.

33.2.2.4.8 Stairs shall be permitted to be open at the topmost story only where all of the following are met:

- (1) The building shall have three or fewer stories.
- (2) The building shall house prompt or slow evacuation capability facilities.
- (3) The building shall be protected by an approved automatic sprinkler system in accordance with 33.2.3.5.
- (4) The entire primary means of escape of which the stairs are a part shall be separated from all portions of lower stories.

and furnished areas by walls and doors. These vestibules provide safety equivalent to that provided by a stair enclosure.

It is the intent of the *Code* that interior stairs in accordance with 32/33.2.2.4, and all its associated exemptions (32.2.2.4.5 through 32.2.2.4.7 and 33.2.2.4.4 through 33.2.2.4.6), qualify as enclosed interior stairs permitted by 32/33.2.2.2 to serve as the primary means of escape.

The intent of 32.2.2.4.5 and 33.2.2.4.4 is to permit a stair that connects the first floor to the second floor to be open to the second floor but separated from the effects of fire on the first floor. This provision also permits a stair that connects the basement level to the first floor to be open to the basement level but separated from the effects of fire on the first floor.

CHAPTER 32 • New

CHAPTER 33 • Existing

This partially enclosed interior stair can serve as a primary means of escape in accordance with 32/33.2.2.2.

Exhibit 32/33.6 illustrates a partially enclosed (separated from ground floor) interior stair in accordance with 32.2.2.4.5 and 33.2.2.4.4 that serves as the primary means of escape for the second floor. This partially enclosed interior stair is considered to be the equivalent of an enclosed interior stair. The separating walls and doors on the first floor serve the

dual purposes of enclosing the stair on that floor and providing a route that does not expose occupants to occupied or furnished areas of the first floor. Thus, the first floor stair “lobby” cannot be used as a lounge and cannot contain furniture and furnishings.

The intent of 32.2.2.4.6 and 33.2.2.4.5 is to permit an unenclosed interior stair to serve as the equivalent of an enclosed interior stair in new small facilities and existing small facilities with prompt or slow evacuation capability. However, the buildings must be of three or fewer stories and must be protected throughout with an automatic sprinkler system using quick-response or residential sprinklers. Exhibit 32/33.6 can also be used to illustrate the provisions of 32.2.2.4.6 and 33.2.2.4.5. Although the enclosing walls around the vestibule on the first floor serve as the stair enclosure on that floor in accordance with 32.2.2.4.5 and 33.2.2.4.4, the same enclosing walls serve to protect the escape path from the areas that are occupied or furnished on the first floor in accordance with 32.2.2.4.6 and 33.2.2.4.5. Additionally, given the presence of sprinklers and other criteria of 32.2.2.4.6 and 33.2.2.4.5, the open stair can extend to a third level.

The provisions of 32.2.2.4.7 and 33.2.2.4.6 permit a two-story open stair (and its associated exposure to the areas that are occupied or furnished, or both, on the ground floor) to serve as primary means of escape for new small facilities and existing small facilities (not more than eight residents) with prompt evacuation capability, if the facility is sprinklered using quick-response or residential sprinklers. This provision, in effect, equates such a board and care facility with a one- or two-family dwelling. An unenclosed interior stair meeting the criteria of this provision is considered the equivalent of an enclosed interior stair.

For existing facilities, the *Code* prohibits the use of the following provisions, in conjunction with 33.2.2.4.6:

- (1) Paragraph 33.2.2.3.2, which exempts bedrooms from a required secondary means of escape if the building is sprinklered
- (2) Paragraphs 33.2.3.4.3.5 and 33.2.3.4.3.6, which exempt common space smoke detectors where the building is sprinklered and the bedrooms are provided with smoke alarms

Multiple use of these provisions that are intended for application to sprinklered buildings could result

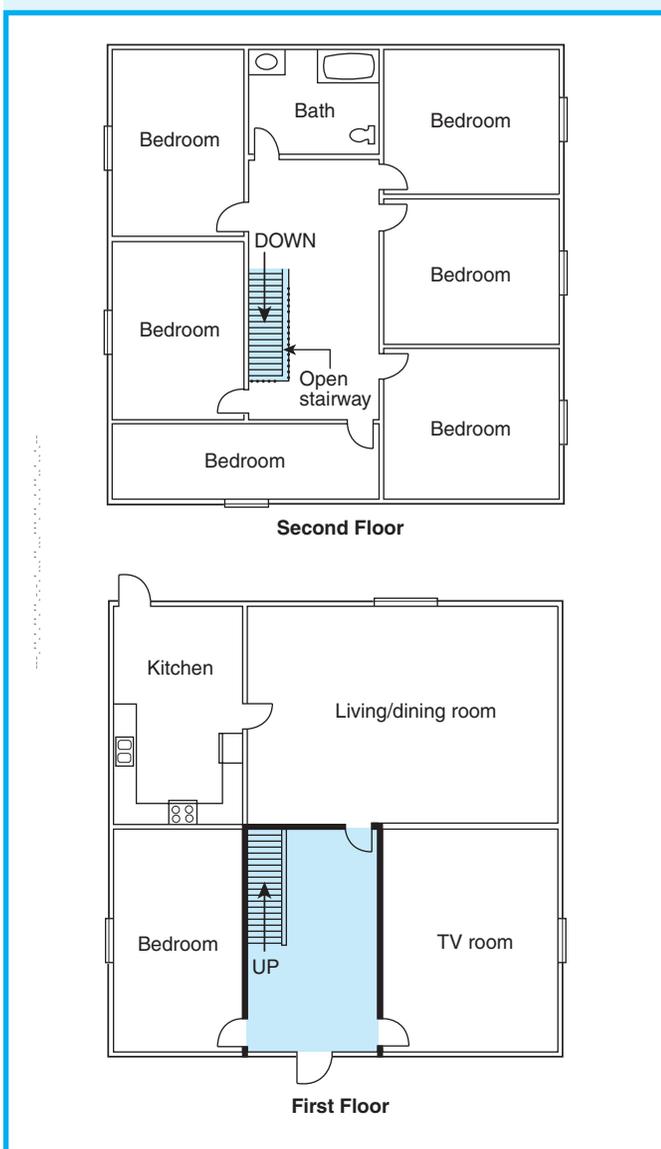

Exhibit 32/33.6 Partially enclosed interior stair.

CHAPTER 32 • New

in a level of life safety less than that required by Chapters 32 and 33.

In existing buildings, 33.2.2.4.8 permits stairs to be open at the topmost story only where the entire primary means of escape associated with the stairs is separated from all portions of lower stories. In addition, this provision requires the following:

32.2.2.5 Doors.

32.2.2.5.1 Doors, other than those meeting 32.2.2.5.1.1 and 32.2.2.5.1.2, and paths of travel to a means of escape shall be at least 810 mm (32 in.) wide.

32.2.2.5.1.1 Bathroom doors shall be at least 610 mm (24 in.) wide.

32.2.2.5.1.2 In conversions (*see* 32.1.1.3), 710-mm (28-in.) doors shall be permitted.

32.2.2.5.2 Reserved.

32.2.2.5.3 Doors shall be swinging or sliding.

32.2.2.5.4 Every closet door latch shall be readily opened from the inside.

32.2.2.5.5 Every bathroom door shall be designed to allow opening from the outside during an emergency when locked.

32.2.2.5.6 No door in any means of escape, other than those meeting 32.2.2.5.6.1 or 32.2.2.5.6.2, shall be locked against egress when the building is occupied.

32.2.2.5.6.1 Delayed egress locks complying with 7.2.1.6.1 shall be permitted on exterior doors only.

32.2.2.5.6.2 Access-controlled egress locks complying with 7.2.1.6.2 shall be permitted.

32.2.2.5.7 Forces to open doors shall comply with 7.2.1.4.5.

32.2.2.5.8 Door latching devices shall comply with 7.2.1.5.9.

32.2.2.5.9 Floor levels at doors shall comply with 7.2.1.3.

If an existing dwelling were converted to a small board and care facility, the provisions of 4.6.12 would require that such a change of occupancy meet the requirements of Chapter 32 for new board and care facilities. The provision of 32.2.2.5.1.2 recognizes the hardship and minor improvement that would be real-

CHAPTER 33 • Existing

- (1) Buildings are to be of three or fewer stories.
- (2) Buildings are to house facilities with prompt or slow evacuation capability.
- (3) Buildings are to be protected by an approved automatic sprinkler system in accordance with 33.2.3.5.

33.2.2.5 Doors.

33.2.2.5.1 Doors, other than bathroom doors addressed in 33.2.2.5.2, and paths of travel to a means of escape shall be not less than 710 mm (28 in.) wide.

33.2.2.5.2 Bathroom doors shall be not less than 610 mm (24 in.) wide.

33.2.2.5.3 Doors shall be swinging or sliding.

33.2.2.5.4 Every closet door latch shall be readily opened from the inside.

33.2.2.5.5 Every bathroom door shall be designed to allow opening from the outside during an emergency when locked.

33.2.2.5.6 No door in any means of escape, other than those meeting 33.2.2.5.6.1 or 33.2.2.5.6.2, shall be locked against egress when the building is occupied.

33.2.2.5.6.1 Delayed egress locks complying with 7.2.1.6.1 shall be permitted on exterior doors only.

33.2.2.5.6.2 Access-controlled egress locks complying with 7.2.1.6.2 shall be permitted.

33.2.2.5.7 Forces to open doors shall comply with 7.2.1.4.5.

33.2.2.5.8 Door latching devices shall comply with 7.2.1.5.4.

ized if existing 710-mm (28-in.) wide doors were required to be replaced by 810-mm (32-in.) wide doors.

Residential board and care facilities are prohibited from having any door in the means of escape locked against egress while the building is occupied

CHAPTER 32 • New

in accordance with 32/33.2.2.5.6. This prohibition is consistent with a fundamental means of egress provision of Chapter 7. Chapter 7 permits a door to have a locking device that allows the door to be easily opened from within the facility for the purpose of egress but does not allow the door to be opened from

32.2.2.6 Stairs.

32.2.2.6.1 Stairs shall comply with 7.2.2 unless otherwise specified in this chapter.

32.2.2.6.2 Winders complying with 7.2.2.2.4 shall be permitted only in conversions.

32.2.2.6.3* Exterior stairs shall be protected against blockage caused by fire within the building.

A.32.2.2.6.3 Exterior stair protection can be accomplished through separation by physical distance, arrangement of the stairs, protection of the openings exposing the stairs, or other means acceptable to the authority having jurisdiction.

32.2.3 Protection.**32.2.3.1 Protection of Vertical Openings.**

32.2.3.1.1 Vertical openings, other than those meeting 32.2.3.1.3, shall be separated by smoke partitions in accordance with Section 8.4 that prevent the passage of smoke from one story to another story.

32.2.3.1.2 Smoke partitions described in 32.2.3.1.1 shall have a fire resistance rating of not less than ½ hour in accordance with Section 8.3.

32.2.3.1.3 Stairs shall be permitted to be open where complying with 32.2.2.4.6 or 32.2.2.4.7.

Exterior stairs do not have to meet the Chapter 7 requirements for outside stairs per 32/33.2.2.6.3. However, if the exterior stair is to be used as a primary means of escape, protection should be provided to

CHAPTER 33 • Existing

outside the facility. Ordinary double-cylinder locks and chain locks do not meet these provisions.

Although resident sleeping room doors are located in the means of escape, it is the intent of 32/33.2.2.5.8 that the multiple latching/locking devices addressed by 7.2.1.5.9.2 and 7.2.1.5.9.3 be permitted.

33.2.2.6 Stairs.

33.2.2.6.1 Stairs shall comply with 7.2.2, unless otherwise specified in this chapter.

33.2.2.6.2 Winders complying with 7.2.2.2.4 shall be permitted.

33.2.2.6.3* Exterior stairs shall be protected against blockage caused by fire within the building.

A.33.2.2.6.3 Exterior stair protection can be accomplished through separation by physical distance, arrangement of the stairs, protection of the openings exposing the stairs, or other means acceptable to the authority having jurisdiction.

33.2.3 Protection.**33.2.3.1 Protection of Vertical Openings.**

33.2.3.1.1 Vertical openings, other than stairs complying with 33.2.2.4.4, 33.2.2.4.5, or 33.2.2.4.6, shall be protected so as not to expose a primary means of escape.

33.2.3.1.2 Vertical openings required to be protected by 33.2.3.1.1 shall be considered protected if separated by smoke partitions in accordance with Section 8.4 that prevent the passage of smoke from one story to any primary means of escape on another story.

33.2.3.1.3 Smoke partitions used to protect vertical openings shall have a fire resistance rating of not less than ½ hour.

33.2.3.1.4 Any doors or openings to the protected vertical opening shall be capable of resisting fire for not less than 20 minutes.

reduce the likelihood that a fire within the facility will render the stair useless. Although this provision applies to small board and care facilities, note that 7.2.2.6.3.1(2) exempts outside stairs that serve a two-

story building from the protection requirements of 7.2.2.6.3 if a remotely located second exit is provided. In such a case, the presence of an additional remote means of escape might be judged as adequate to eliminate the need to protect the exterior stair from a fire within the building. A.32/A.33.2.2.6.3 provide additional guidance on protecting exterior stairs in small board and care facilities.

For new, small board and care facilities, 32.2.3.1 mandates the enclosure of vertical openings with smoke partitions in accordance with Section 8.4 having a minimum ½ hour fire resistance rating. See the definition of *smoke partition* in 3.3.202.

A smoke partition that limits the transfer of smoke is different from a smoke barrier that restricts smoke movement from one side of a barrier to the other. A smoke partition should be thought of as a barrier that reasonably limits, but doesn't prevent, smoke transfer. As such, suspended ceiling systems and monolithic surfaced ceilings are available that provide resistance to smoke transfer that is approximately equal to the traditional nonrated corridor wall or partition. See Section 8.4 and its commentary for more on smoke partitions.

Per 32.2.3.1.3, stairs are permitted to be open if they meet one of the options provided by 32.2.2.4.6 or 32.2.2.4.7. The two open-stair options for new facilities are summarized as follows:

- (1) Paragraph 32.2.2.4.6 permits open stairs in sprinklered buildings not exceeding three stories in height, as long as each story is provided with a primary means of escape that is arranged so that occupants are not required to pass through a lower floor unless that path is separated from all spaces on the lower floors by ½-hour rated fire barriers.
- (2) Paragraph 32.2.2.4.7 permits completely open stairs in sprinklered buildings provided the stair serves (connects) not more than two stories.

In existing, small board and care facilities, vertical openings are permitted to be unenclosed, except in cases where, by leaving the vertical opening unen-

32.2.3.2 Hazardous Areas.

32.2.3.2.1* Any space where there is storage or activity having fuel conditions exceeding those of a one- or two-family dwelling and that possesses the potential for a fully

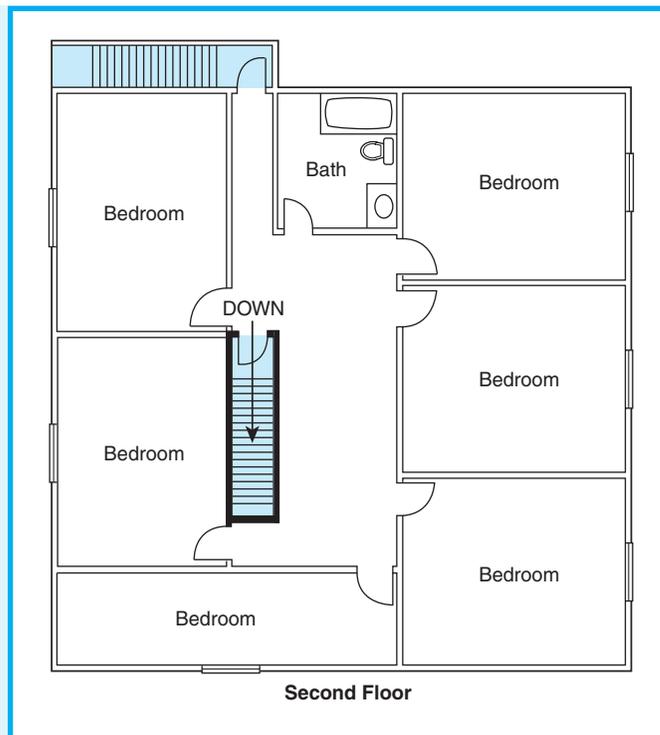

Exhibit 32/33.7 Vertical opening protected so as not to expose the primary means of escape.

closed, the primary means of escape route is exposed to the unprotected vertical opening. Exhibit 32/33.7 illustrates an interior stair that, if it were not enclosed, would create an unprotected vertical opening. The interior stair is not part of the primary means of escape, but the vertical opening it creates must be enclosed, so that the route to the exterior stair (which serves as the primary means of escape for the second floor) is not exposed to an unprotected vertical opening. The enclosure around the vertical opening must be, at a minimum, a smoke partition.

In Exhibit 32/33.8, the vertical opening created by the interior stair does not expose the primary means of escape, which is the direct route from each bedroom to the exterior balconies and stairs.

33.2.3.2 Hazardous Areas.

33.2.3.2.1 Any space where there is storage or activity having fuel conditions exceeding those of a one- or two-family dwelling and that possesses the potential for a fully involved

CHAPTER 32 • New

CHAPTER 33 • Existing

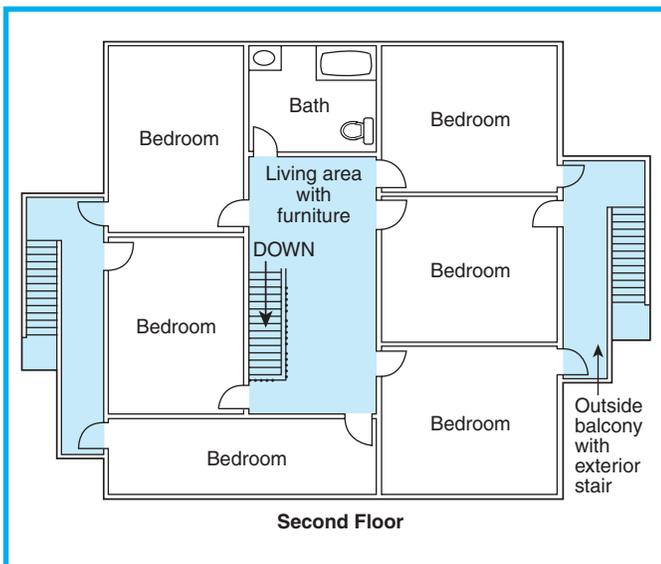

Exhibit 32/33.8 Vertical opening not exposing the primary means of escape.

involved fire shall be protected in accordance with 32.2.3.2.4 and 32.2.3.2.5.

A.32.2.3.2.1 Spaces containing approved, properly installed and maintained furnaces and heating equipment, furnace rooms, and cooking and laundry facilities should not be classified as hazardous areas solely on the basis of such equipment.

32.2.3.2.2 Spaces requiring protection by 32.2.3.2.1 shall include, but shall not be limited to, areas for cartoned storage, food, or household maintenance items in wholesale or institutional-type quantities and concentrations, or mass storage of residents' belongings.

32.2.3.2.3 Reserved.

32.2.3.2.4 When the space is on the same floor as, and is in or abuts, a primary means of escape or a sleeping room, it shall be protected by one of the following means:

- (1) An enclosure with a fire resistance rating of at least 1 hour in accordance with 8.2.3, and protected by an automatic fire detection system connected to the fire alarm system provided in 32.2.3.4.1
- (2) An automatic sprinkler system in accordance with

fire shall be protected in accordance with 33.2.3.2.4 and 33.2.3.2.5.

33.2.3.2.2 Spaces requiring protection by 33.2.3.2.1 shall include, but shall not be limited to, areas for cartoned storage, food or household maintenance items in wholesale or institutional-type quantities and concentrations, or mass storage of residents' belongings.

33.2.3.2.3 Areas containing approved, properly installed and maintained furnaces and heating equipment, furnace rooms, and cooking and laundry facilities shall not be classified as hazardous areas solely on the basis of such equipment.

33.2.3.2.4 Any hazardous area that is on the same floor as, and is in or abuts, a primary means of escape or a sleeping room shall be protected by one of the following means:

- (1) Protection shall be an enclosure with a fire resistance rating of not less than 1 hour, with a self-closing or automatic-closing fire door in accordance with 7.2.1.8 that has a fire protection rating of not less than $\frac{3}{4}$ hour.
- (2) Protection shall be automatic sprinkler protection, in

CHAPTER 32 • New

32.2.3.5, and a smoke partition in accordance with Section 8.4, located between the space and the sleeping area or primary escape route. Any doors in such separation shall be self-closing or automatic-closing in accordance with 7.2.1.8.

32.2.3.2.5 Other spaces shall be protected by one of the following:

- (1) An enclosure having a fire resistance rating of at least $\frac{1}{2}$ hour, with a self-closing or automatic-closing door in accordance with 7.2.1.8, equivalent to at least a 44-mm ($1\frac{3}{4}$ -in.) thick, solid bonded wood core construction and protected by an automatic fire detection system connected to the fire alarm system provided in 32.2.3.4.1
- (2) Automatic sprinkler protection in accordance with 32.2.3.5, regardless of enclosure

It is recognized that small board and care facilities closely resemble one- and two-family dwellings. However, one of the most notable differences between the two is the type of hazards that might be present. In a small board and care facility, greater quantities of household maintenance and cleaning products, cartoned food, and mass storage of residents' belongings result in areas where a fire could quickly grow to full room involvement. These are the areas that 32/33.2.3.2.1 and 32/33.2.3.2.2 intend to be separated in accordance with 32/33.2.3.2.4 and 32/33.2.3.2.5.

The protection of hazardous contents areas is based on the potential impact that a fire in the hazardous contents would have on a primary means of escape or on sleeping rooms. If the hazardous area is located on the same floor as sleeping rooms or a primary means of escape, and if a sleeping room or means of escape is exposed to the hazardous area, one of the following two protection options is permitted:

- (1) The hazardous contents room must be separated from the remainder of the floor by construction with at least a 1-hour fire rating, and automatic fire detection connected to the alarm system must be provided.
- (2) Automatic sprinkler protection must be provided within the hazardous contents room, and the separating construction must meet the requirements for smoke partitions in Section 8.4, but is not required to be fire-rated.

CHAPTER 33 • Existing

accordance with 33.2.3.5, and a smoke partition, in accordance with Section 8.4, located between the hazardous area and the sleeping area or primary escape route. Any doors in such separation shall be self-closing or automatic-closing in accordance with 7.2.1.8.

33.2.3.2.5 Other hazardous areas shall be protected by one of the following:

- (1) An enclosure having a fire resistance rating of not less than $\frac{1}{2}$ hour, with a self-closing or automatic-closing door in accordance with 7.2.1.8 that is equivalent to not less than a 440-mm ($1\frac{3}{4}$ -in.) thick, solid-bonded wood core construction
- (2) Automatic sprinkler protection in accordance with 33.2.3.5, regardless of enclosure

If the hazardous area is located on a different floor or does not abut a primary means of escape or sleeping rooms, it is considered less endangering and can be protected using one of the following two methods:

- (1) The hazardous contents room must be separated from the remainder of the floor by construction with at least a $\frac{1}{2}$ -hour fire rating, and automatic fire detection connected to the alarm system must be provided.
- (2) Automatic sprinkler protection must be provided within the hazardous contents room, and no smoke-resisting separating construction is required.

For example, consider a basement in a wood frame building housing a small board and care facility. The basement, which is used only for the storage of combustible materials, is not a required means of escape. If the basement storage area does not abut a sleeping area on the same floor and is sprinklered, sheathing the ceiling to provide fire resistance separation is not required. In applying the provisions of 32.2.3.2, note that the sprinkler protection required in nearly all new small board and care facilities by 32.2.3.5.1 should make the protection of hazardous contents areas relatively easy.

CHAPTER 32 • New

32.2.3.3 Interior Finish.

32.2.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

32.2.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A, Class B, or Class C.

32.2.3.3.3 Interior Floor Finish.

32.2.3.3.3.1 Interior floor finish shall comply with Section 10.2.

32.2.3.3.3.2 Reserved.

32.2.3.3.3.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2 as applicable.

32.2.3.4 Detection, Alarm, and Communication Systems.

32.2.3.4.1 Fire Alarm Systems. A manual fire alarm system shall be provided in accordance with Section 9.6.

32.2.3.4.2 Occupant Notification. Occupant notification shall be provided automatically, without delay, in accordance with 9.6.3.

32.2.3.4.3 Smoke Alarms.

32.2.3.4.3.1 Approved smoke alarms shall be provided in accordance with 9.6.2.10 on all levels, including basements, but excluding crawl spaces and unfinished attics.

CHAPTER 33 • Existing

33.2.3.3 Interior Finish.

33.2.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

33.2.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be as follows:

- (1) Class A or Class B in facilities other than those having prompt evacuation capability
- (2) Class A, Class B, or Class C in facilities having prompt evacuation capability

33.2.3.3.3 Interior Floor Finish. No requirements.

33.2.3.4 Detection, Alarm, and Communications Systems.

33.2.3.4.1 Fire Alarm Systems. A manual fire alarm system shall be provided in accordance with Section 9.6, unless the provisions of 33.2.3.4.1.1 or 33.2.3.4.1.2 are met.

33.2.3.4.1.1 A fire alarm system shall not be required where there are interconnected smoke detectors meeting the requirements of 33.2.3.4.3 and there is not less than one manual fire alarm box per floor arranged to continuously sound the smoke detector alarms.

33.2.3.4.1.2 Other manually activated continuously sounding alarms acceptable to the authority having jurisdiction shall be permitted in lieu of a fire alarm system.

33.2.3.4.2 Occupant Notification. Occupant notification shall be in accordance with 9.6.3.

33.2.3.4.3* Smoke Alarms.

A.33.2.3.4.3 Most often smoke alarms sounding an alarm at 85 dBA or greater, installed outside the bedroom area, will meet the intent of this requirement. Smoke alarms remotely located from the bedroom might not be loud enough to awaken the average person. In such cases, it is recommended that smoke alarms be interconnected so that the activation of any smoke alarm will cause all smoke alarms to activate.

33.2.3.4.3.1 Approved smoke alarms shall be provided in accordance with 9.6.2.10, unless otherwise indicated in 33.2.3.4.3.5 and 33.2.3.4.3.6.

CHAPTER 32 • New

32.2.3.4.3.2 Additional smoke alarms shall be installed in all living areas as defined in 3.3.16.5.

32.2.3.4.3.3 Each sleeping room shall be provided with an approved smoke alarm in accordance with 9.6.2.10.

In both new and existing board and care facilities, a means of manually initiating the fire alarm system is required. However, 33.2.3.4.1 contains two provisions for existing facilities. The use of a “system” of interconnected, multiple-station smoke alarms is permitted by 33.2.3.4.1.1 to meet the manual fire alarm box requirement by providing one manual fire alarm box that is integrated with the smoke alarms on each floor. In addition, 33.2.3.4.1.2 recognizes that, in a small existing building, a sophisticated fire alarm system that employs components listed for use in fire alarm systems might not be necessary. The requirements can be satisfied by the installation of electric bells activated by a clearly identified switch on each floor where approved by the authority having jurisdiction.

The requirement of 32.2.3.4.3.1 does not mandate a system of smoke detectors in a small facility. If the building is small enough, single-station smoke alarms might meet the criterion of audibility in all sleeping areas. However, if the building is of significant size or consists of multiple levels, interconnected multiple-station smoke alarms will probably be

CHAPTER 33 • Existing

33.2.3.4.3.2 Smoke alarms shall be powered from the building electrical system and, when activated, shall initiate an alarm that is audible in all sleeping areas.

33.2.3.4.3.3 Smoke alarms shall be installed on all levels, including basements but excluding crawl spaces and unfinished attics.

33.2.3.4.3.4 Additional smoke alarms shall be installed for living rooms, dens, day rooms, and similar spaces.

33.2.3.4.3.5 Smoke alarms in accordance with 33.2.3.4.3.1 shall not be required where buildings are protected throughout by an approved automatic sprinkler system, in accordance with 33.2.3.5, that uses quick-response or residential sprinklers, and are protected with approved smoke alarms installed in each sleeping room, in accordance with 9.6.2.10, that are powered by the building electrical system.

33.2.3.4.3.6 Smoke alarms in accordance with 33.2.3.4.3.1 shall not be required where buildings are protected throughout by an approved automatic sprinkler system, in accordance with 33.2.3.5, that uses quick-response or residential sprinklers, with existing battery-powered smoke alarms in each sleeping room, and where, in the opinion of the authority having jurisdiction, the facility has demonstrated that testing, maintenance, and a battery replacement program ensure the reliability of power to the smoke alarms.

needed. Additional smoke alarms are required in living rooms and day rooms.

Prior to the 2003 edition of the *Code*, several provisions allowed for the omission of smoke alarms from small board and care facilities. However, given the wider acceptance of unprotected vertical openings permitted by 32.2.3.1, the smoke alarm exceptions are no longer permitted for new facilities.

Several conditions for exempting smoke alarms from existing small board and care facilities, however, are provided. To waive the requirement for common space smoke alarms as permitted by 33.2.3.4.3.5 and 33.2.3.4.3.6, the entire building must be protected with an automatic sprinkler system using quick-response or residential sprinklers in accordance with 33.2.3.5, and the bedrooms must be provided with smoke alarms. If the existing smoke alarms in the bedrooms are battery powered, they do not need to be replaced with house-powered smoke alarms if the authority having jurisdiction judges that the facility has an adequate testing, maintenance, and battery replacement program.

CHAPTER 32 • New

32.2.3.5 Extinguishment Requirements.

32.2.3.5.1* All facilities, other than those meeting 32.2.3.5.2, shall be protected throughout by an approved, automatic sprinkler system installed in accordance with 32.2.3.5.3 using quick response or residential sprinklers.

A.32.2.3.5.1 Where any provision requires the use of an automatic sprinkler system in accordance with 32.2.3.5, the provision of 32.2.3.5.2 is not permitted to be used.

32.2.3.5.2* In conversions, sprinklers shall not be required in small board and care homes, serving eight or fewer residents, when all occupants have the ability as a group to move reliably to a point of safety within 3 minutes.

A.32.2.3.5.2 Where a facility utilizing 32.2.3.5.2 contains residents who can no longer comply with the 3-minute evacuation response, 33.1.7 requires the facility to comply with the requirements for new construction, including automatic sprinkler protection. See also A.33.1.7.

32.2.3.5.3 Where an automatic sprinkler system is installed, for either total or partial building coverage, the following requirements shall be met:

- (1) The system shall be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, and shall initiate the fire alarm system in accordance with 32.2.3.4.1.
- (2) The adequacy of the water supply shall be documented to the authority having jurisdiction.

32.2.3.5.3.1 An automatic sprinkler system in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted in facilities up to and including four stories in height. All habitable areas and closets shall be sprinklered.

32.2.3.5.3.2* An automatic sprinkler system with a 30-minute water supply, and complying with the following requirements and with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, shall be permitted.

- (1) All habitable areas and closets shall be sprinklered.
- (2) Facilities with more than eight residents shall be treated as two-family dwellings with regard to water supply.

A.32.2.3.5.3.2 The decision to permit the use of the criteria from NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, in these occupancies is based on the following:

CHAPTER 33 • Existing

33.2.3.5 Automatic Extinguishing Systems.

33.2.3.5.1 Reserved.

33.2.3.5.2 Where an automatic sprinkler system is installed, for either total or partial building coverage, the following requirements shall be met:

- (1) The system shall be in accordance with Section 9.7 and shall activate the fire alarm system in accordance with 33.2.3.4.1, modified by 33.2.3.5.2.1 through 33.2.3.5.2.6.
- (2) The adequacy of the water supply shall be documented to the authority having jurisdiction.

33.2.3.5.2.1* In prompt evacuation capability facilities, the following requirements shall be met:

- (1) An automatic sprinkler system in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, shall be permitted.
- (2) Automatic sprinklers shall not be required in closets not exceeding 2.2 m² (24 ft²) and in bathrooms not exceeding 5.1 m² (55 ft²), provided that such spaces are finished with lath and plaster or materials providing a 15-minute thermal barrier.

A.33.2.3.5.2.1 The decision to permit the use of the criteria from NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes* in these occupancies is based on the following:

- (1) The desire to obtain a level of fire suppression and control approximately equivalent to that delivered by residential facilities protected by such systems NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*
- (2) The fact that potential fire exposure and challenge to the suppression system in a small board and care facility are of the same nature and are no more severe than those found in residences

Chapter 33 permits the use of NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. In

CHAPTER 32 • New

- (1) The desire to obtain a level of fire suppression and control approximately equivalent to that delivered by residential facilities protected by such systems (see the appendix statement in NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*)
- (2) The fact that potential fire exposure and challenge to the suppression system in a small board and care facility are of the same nature and are no more severe than those found in residences

Chapter 32 permits the use of NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. The requirements of NFPA 13D and NFPA 13R have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy.

NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, contains additional requirements for a piping system serving both sprinkler and domestic needs.

32.2.3.5.4 Automatic sprinkler systems installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be provided with electrical supervision in accordance with 9.7.2.

32.2.3.5.5 Automatic sprinkler systems installed in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, shall be provided with valve supervision by one of the following methods:

- (1) A single listed control valve that shuts off both domestic and sprinkler systems and a separate shutoff for the domestic system only
- (2) Electrical supervision in accordance with 9.7.2
- (3) Valve closure that causes the sounding of an audible signal in the facility

CHAPTER 33 • Existing

some circumstances, such as those for impractical evacuation capabilities, the requirements of NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy.

33.2.3.5.2.2 In slow and impractical evacuation capability facilities, the following requirements shall be met:

- (1) An automatic sprinkler system in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, with a 30-minute water supply, shall be permitted.
- (2) All habitable areas and closets shall be sprinklered.
- (3) Automatic sprinklers shall not be required in bathrooms not exceeding 5.1 m² (55 ft²), provided that such spaces are finished with lath and plaster or materials providing a 15-minute thermal barrier.

33.2.3.5.2.3 In prompt and slow evacuation facilities, where an automatic sprinkler system is in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, sprinklers shall not be required in closets not exceeding 2.2 m² (24 ft²) and in bathrooms not exceeding 5.1 m² (55 ft²), provided that such spaces are finished with lath and plaster or materials providing a 15-minute thermal barrier.

33.2.3.5.2.4 In prompt and slow evacuation capability facilities up to and including four stories in height, systems installed in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted.

33.2.3.5.2.5 In impractical evacuation capability facilities up to and including four stories in height, the following requirements shall be met:

- (1) Systems installed in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted.
- (2) All habitable areas and closets shall be sprinklered.
- (3) Automatic sprinklers shall not be required in bathrooms not exceeding 5.1 m² (55 ft²), provided that such spaces are finished with lath and plaster or materials providing a 15-minute thermal barrier.

CHAPTER 32 • New

32.2.3.5.6 Sprinkler piping serving not more than six sprinklers for any isolated hazardous area shall be permitted to be installed in accordance with 9.7.1.2 and shall meet the following requirements:

- (1) In new installations, where more than two sprinklers are installed in a single area, water flow detection shall be provided to initiate the fire alarm system required by 32.2.3.4.1.
- (2) Duration of water supplies shall be as required by 32.2.3.5.3.2.

New small board and care facilities must be protected by an automatic sprinkler system using quick-response or residential sprinklers in accordance with 32.2.3.5.1. This requirement recognizes the ability of quick-response and residential sprinklers to maintain tenability in the room of origin during most fire scenarios.

The provision of 32.2.3.5.2 recognizes the difficulties in retrofitting buildings that are converted to small board and care facilities and provides some relief in these situations.

The provision of 33.2.3.5.2 does not require the installation of automatic sprinkler systems in existing small board and care facilities. Rather, it establishes the criteria for installing automatic sprinkler systems that are provided voluntarily for the purpose of applying one of the sprinkler modifications to another *Code* requirement.

Although a small board and care facility is of a different occupancy classification than a dwelling or mobile home, 32.2.3.5.3.2 and 33.2.3.5.2 permit the use of residential sprinkler systems installed in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*³, for the reasons explained in A.32.2.3.5.3.2 and A.33.2.3.5.2.1. In new facilities

CHAPTER 33 • Existing

33.2.3.5.2.6 Initiation of the fire alarm system shall not be required for existing installations in accordance with 33.2.3.5.6.

33.2.3.5.3 Impractical Evacuation Capability. All impractical evacuation capability facilities shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 33.2.3.5.2.

33.2.3.5.4 Reserved.

33.2.3.5.5 Reserved.

33.2.3.5.6 Sprinkler piping serving not more than six sprinklers for any isolated hazardous area shall be permitted to be installed in accordance with 9.7.1.2 and shall meet the following requirements:

- (1) In new installations, where more than two sprinklers are installed in a single area, waterflow detection shall be provided to initiate the fire alarm system required by 33.2.3.4.1.
- (2) Duration of water supplies shall be as required for the sprinkler systems addressed in 33.2.3.5.2.

and existing facilities with impractical evacuation capability, occupants might not be immediately evacuated; therefore, the normal 10-minute water supply duration specified in NFPA 13D is required to be increased to 30 minutes. Also, in new facilities and existing facilities with impractical evacuation capability, sprinklers are required in closets and all habitable areas.

The exemption for sprinklers in the bathrooms and closets of existing facilities as permitted by 33.2.3.5.2.3 supplements the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*⁴. In addition to meeting the size limitation requirements, the walls and ceilings of bathroom and closet spaces must have a 15-minute thermal barrier rating to qualify for the sprinkler exemption. The 15-minute thermal barrier rating includes walls and ceilings behind fixtures such as prefabricated tub and shower enclosures.

The use of sprinkler systems installed in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*⁵, is recognized by 32.2.3.5.3.1, 33.2.3.5.2.4, and 33.2.3.5.2.5. In all new facilities and existing facilities with impractical evacuation capability, closets and habitable areas (other than existing small bathrooms) must be sprinklered.

CHAPTER 32 • New

In existing facilities with prompt and slow evacuation capability, the sprinkler systems might need to be supervised, depending on the requirements of the installation standard used. For new small board and care facilities, 32.2.3.5.4 requires electrical supervision of automatic sprinkler systems installed in accordance with NFPA 13 and NFPA 13R. Paragraph 32.2.3.5.5 requires supervision of NFPA 13D systems by one of three methods: a single valve controlling both the domestic and sprinkler water supply, electrical supervision in accordance with 9.7.2, or an audible alarm device that sounds when the sprinkler water supply valve is closed.

All existing small facilities with impractical evacuation capability must be sprinklered per 33.2.3.5.3. In a mixed occupancy, if sprinkler protection is provided only in the board and care facility, and not throughout the building, any modifications to requirements predicated on complete building sprinkler coverage are not permitted to be used.

The importance of the role of the sprinkler system in protecting occupants who cannot readily evacuate the building (defend-in-place strategy) requires that

CHAPTER 33 • Existing

sprinkler systems in all new facilities and existing facilities with impractical evacuation capability be supervised in accordance with 9.7.2, or as specified in 32.2.3.5.5 for new, small facilities with NFPA 13D systems. Note that 9.7.2 requires electrical supervision of control valves and the transmission of waterflow alarms to a monitoring station. NFPA 13D and NFPA 13R permit the sprinkler systems to be installed with the domestic water supply valve as the only means to shut off the sprinklers; no valves control only the sprinkler system.

The provisions of 32/33.2.3.5.6 that require water supply duration to be in accordance with 32.2.3.5.3.2 and 33.2.3.5.2 affect facilities where unlimited public water is not available and captive sources such as tanks are used. Either a 10-minute or 30-minute water supply duration is needed, depending on whether the facility is new or existing, and, if existing, whether it is of prompt, slow, or impractical evacuation capability. Because 9.7.1.2 requires 6.1 mm/min (0.15 gpm/ft²) for up to six sprinklers protecting an isolated hazardous area, a significant water reserve might be necessary.

32.2.3.6 Construction of Corridor Walls.

32.2.3.6.1 Corridor walls, other than those meeting 32.2.3.6.2, shall meet the following requirements:

- (1) The separation walls of sleeping rooms shall be capable of resisting fire for at least ½ hour, which shall be considered to be achieved if the partitioning is finished on both sides with lath and plaster or material providing a 15-minute thermal barrier.
- (2) Sleeping room doors shall be substantial doors, such as those of 44-mm (1¾-in.) thick, solid bonded wood core construction or of other construction of equal or greater stability and fire integrity.
- (3) Any vision panels shall be fixed fire window assemblies in accordance with 8.3.4 or shall be wired glass not exceeding 0.84 m² (1296 in.²) each in area and installed in approved frames.

32.2.3.6.2 The requirements of 32.2.3.6.1 shall not apply to corridor walls that are smoke partitions in accordance

33.2.3.6 Construction of Corridor Walls.

33.2.3.6.1 Unless otherwise indicated in 33.2.3.6.1.1 through 33.2.3.6.1.4, corridor walls shall meet the following requirements:

- (1) The separation walls of sleeping rooms shall be capable of resisting fire for not less than ½ hour, which shall be considered to be achieved if the partitioning is finished on both sides with lath and plaster or materials providing a 15-minute thermal barrier.
- (2) Sleeping room doors shall be substantial doors, such as those of 440 mm (1¾-in.) thick, solid-bonded wood core construction or other construction of equal or greater stability and fire integrity.
- (3) Any vision panels shall be fixed fire window assemblies in accordance with 8.3.4 or shall be wired glass not exceeding 0.84 m² (1296 in.²) each in area and installed in approved frames.

33.2.3.6.1.1 In prompt evacuation capability facilities, all sleeping rooms shall be separated from the escape route by smoke partitions in accordance with Section 8.4, and door closing shall be regulated by 33.2.3.6.4.

33.2.3.6.1.2 The requirement of 33.2.3.6.1 shall not apply to corridor walls that are smoke partitions in accordance with

CHAPTER 32 • New

with Section 8.4 where the facility is protected in accordance with 32.2.3.5, and the following shall also apply:

- (1) In such instances, there shall be no limitation on the type or size of glass panels.
- (2) Door closing shall comply with 32.2.3.6.4.

32.2.3.6.3 There shall be no louvers, operable transoms, or other air passages penetrating the wall other than properly installed heating and utility installations other than transfer grilles, which shall be prohibited.

32.2.3.6.4 Doors shall meet the following requirements:

- (1) Doors shall be provided with latches or other mechanisms suitable for keeping the doors closed.
- (2) No doors shall be arranged to prevent the occupant from closing the door.
- (3) Doors shall be self-closing or automatic-closing in accordance with 7.2.1.8 in buildings other than those protected throughout by an approved, automatic sprinkler system in accordance with 32.2.3.5.

The intent of 32/33.2.3.6.1 in requiring corridor walls to have a ½-hour fire resistance rating is to require a nominal resistance to burn-through, particularly where the fire rating of existing partitions cannot be documented. Examples of acceptable partition assemblies include, but are not limited to, 13-mm- (0.5-in.-) thick gypsum board, wood lath and plaster, or metal lath and plaster.

Per 32.2.3.6.2 and 33.2.3.6.1.2, fire resistance-rated materials are not required where sprinkler protection

CHAPTER 33 • Existing

Section 8.4 and that are protected by automatic sprinklers in accordance with 33.2.3.5 on both sides of the wall and door, and the following shall also apply:

- (1) In such instances, there shall be no limitation on the type or size of glass panels.
- (2) Door closing shall be regulated by 33.2.3.6.4.

33.2.3.6.1.3 Sleeping arrangements that are not located in sleeping rooms shall be permitted for nonresident staff members, provided that the audibility of the alarm in the sleeping area is sufficient to awaken staff who might be sleeping.

33.2.3.6.1.4 In previously approved facilities, where the facility has demonstrated to the authority having jurisdiction that the group is capable of evacuating the building in 8 minutes or less, or where the group achieves an E-score of three or less using the board and care occupancies evacuation capability determination methodology of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, sleeping rooms shall be separated from escape routes by walls and doors that are smoke resistant.

33.2.3.6.2 Reserved.

33.2.3.6.3 No louvers or operable transoms or other air passages shall penetrate the wall, except properly installed heating and utility installations other than transfer grilles, which shall be prohibited.

33.2.3.6.4 Doors shall meet the following requirements:

- (1) Doors shall be provided with latches or other mechanisms suitable for keeping the doors closed.
- (2) No doors shall be arranged to prevent the occupant from closing the door.
- (3) Doors shall be self-closing or automatic-closing in accordance with 7.2.1.8 in buildings other than those protected throughout by an approved automatic sprinkler system in accordance with 33.2.3.5.2.

is provided on both sides of the corridor wall and door. Complete sprinkler protection, as required for new construction by 32.2.3.5.1 and permitted for existing facilities by 33.2.3.5, would clearly meet this criterion. Therefore, this provision represents the most typical case where corridor walls and doors are required only to meet the requirements for smoke partitions (see Section 8.4).

There are many existing board and care facilities that employ sleep-in staff. Placing a staff cot in the

CHAPTER 32 • New

supervisor's station, living room, or other room does not reclassify that room as a sleeping room. The provision in 32.2.3.6.1.3 is intended to permit staff members to sleep in locations that are not separated from the corridors.

Paragraph 32.2.3.6.1.4 permits a previously approved situation to continue to be recognized in existing small facilities with residents who perform in

32.2.4 Reserved.

32.2.5 Building Services.

32.2.5.1 Utilities. Utilities shall comply with Section 9.1.

32.2.5.2 Heating, Ventilating, and Air Conditioning.

32.2.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with 9.2.1 and 9.2.2, unless otherwise required in this chapter.

32.2.5.2.2 No stove or combustion heater shall be located to block escape in case of fire caused by the malfunction of the stove or heater.

32.2.5.2.3 Unvented fuel-fired heaters shall not be used in any residential board and care facility.

32.2.5.3 Elevators, Escalators, and Conveyors. Elevators, escalators, and conveyors shall comply with Section 9.4.

The provision of 32/33.2.5.2.2 does not require a kitchen containing a stove to be completely separated by smoke partitions, only that the stove be located so that a malfunction does not result in a blockage of the means of escape. If, in the opinion of the authority having jurisdiction, the location of the stove would

CHAPTER 33 • Existing

the faster half of the overall slow evacuation capability category. This provision cannot be used for a first-time evaluation of the adequacy of smoke-resisting corridor walls.

Doors in corridor walls are required by 32/33.2.3.6.4(3) to be self-closing or automatic closing, unless the entire building is protected throughout by an approved automatic sprinkler system.

33.2.4 Reserved.

33.2.5 Building Services.

33.2.5.1 Utilities. Utilities shall comply with Section 9.1.

33.2.5.2 Heating, Ventilating, and Air Conditioning.

33.2.5.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of 9.2.1 and 9.2.2, except as otherwise required in this chapter.

33.2.5.2.2 No stove or combustion heater shall be located to block escape in case of fire caused by the malfunction of the stove or heater.

33.2.5.2.3 Unvented fuel-fired heaters shall not be used in any residential board and care facility.

cause the means of escape to be blocked in the event of a malfunction, the application of 32/33.2.3.2 might be appropriate for mitigating the hazard.

The use of a typical kerosene portable heater, as well as other fuel-fired, nonvented heaters, is prohibited by 32/33.2.5.2.3.

Section 32.3 Large Facilities

32.3.1 General.

32.3.1.1 Scope.

32.3.1.1.1 Section 32.3 shall apply to residential board and care occupancies providing sleeping accommodations for more than 16 residents.

Section 33.3 Large Facilities

33.3.1 General.

33.3.1.1 Scope.

33.3.1.1.1 Section 33.3 shall apply to residential board and care occupancies providing sleeping accommodations for more than 16 residents.

CHAPTER 32 • New

32.3.1.1.2 Facilities having sleeping accommodations for not more than 16 residents shall comply with Section 32.2.

32.3.1.2 Reserved.

CHAPTER 33 • Existing

33.3.1.1.2 Facilities having sleeping accommodations for not more than 16 residents shall be evaluated in accordance with Section 33.2.

33.3.1.1.3 Facilities meeting the requirements of Section 33.3 shall be considered to have met the requirements of Section 33.2 for prompt evacuation capability or slow evacuation capability.

33.3.1.2 Requirements Based on Evacuation Capability.

33.3.1.2.1 Prompt and Slow. Large facilities classified as prompt or slow evacuation capability, other than those meeting 33.3.1.2.1.1 or 33.3.1.2.1.2, shall comply with the requirements of Section 33.3 as indicated for the appropriate evacuation capability.

33.3.1.2.1.1* Facilities where the authority having jurisdiction has determined equivalent safety is provided in accordance with Section 1.4 shall not be required to comply with the requirements of Section 33.3, as indicated for the appropriate evacuation capability.

A.33.3.1.2.1.1 In determining equivalency for existing buildings, conversions, modernizations, renovations, or unusual design concepts, the authority having jurisdiction might permit evaluations based on the residential board and care occupancies fire safety evaluation system (FSES) in NFPA 101A, *Guide on Alternative Approaches to Life Safety*.

33.3.1.2.1.2 Facilities that were previously approved as complying with 33.3.1.2.2 shall not be required to comply with the requirements of Section 33.3, as indicated for the appropriate evacuation capability.

33.3.1.2.2* Impractical. Large facilities classified as impractical evacuation capability shall meet the requirements for limited care facilities in Chapter 19, unless the authority having jurisdiction has determined equivalent safety is provided in accordance with Section 1.4.

A.33.3.1.2.2 In determining equivalency for existing buildings, the authority having jurisdiction might permit evaluations based on the health care occupancies fire safety evaluation system (FSES) in NFPA 101A, *Guide on Alternative Approaches to Life Safety*, substituting Table A.33.3.1.2.2 mandatory safety requirements values for those contained in NFPA 101A, *Guide on Alternative Approaches to Life Safety*.

33.3.1.2.3 Evacuation Capability Determination.

33.3.1.2.3.1 Facility management shall furnish to the authority having jurisdiction, upon request, an evacuation capa-

Table A.33.3.1.2.2 Substitute Mandatory Safety Requirements Values

Zone Location	Containment S _a	Extinguishment S _b	People Movement S _c
First floor	5	6	3
Above or below first floor	9	8	5
Over 75 ft (23 m) in height	9	8	5

bility determination using a procedure acceptable to the authority having jurisdiction.

33.3.1.2.3.2 Where the documentation required by 33.3.1.2.3.1 is not furnished, the evacuation capability shall be classified as impractical.

The importance of an accurate evaluation of evacuation capabilities in existing facilities cannot be overstated. Ineffective resident or staff response was a contributing factor in the majority of the multiple-death fires listed in Commentary Table 32/33.1.

Determining a facility's evacuation capability is not simply a matter of timing a fire drill in the middle of the day. Many variables affect a resident's capability to evacuate, and these variables must be carefully considered and factored into the documentation presented to the authority having jurisdiction for approval. Some variables that should be considered follow.

(a) *Time of Day.* An occupant's ability to evacuate might be slowed dramatically when the person must be awakened. In such a situation, the occupant must process the information that evacuation is necessary and then begin evacuating.

(b) *Medication.* Many individuals in board and care occupancies take various medications for behavior control or as sleeping aids. If an individual is medicated, he or she might need additional assistance in responding and evacuating.

(c) *Mobility and Location of Occupants.* Once individuals become aware of an emergency and take action, their ability to move through the building must be considered. Individuals using wheelchairs, walkers, or canes are further slowed when using stairs or ramps or when opening doors.

(d) *Staff Assistance.* Though the *Code* does not specify minimum staffing levels, staffing levels

should be considered, especially where high resident-to-staff ratios exist. Given the additional needs mentioned in (a) through (c), the staff will be limited in their ability to affect evacuation time where multiple residents need assistance.

The evacuation capability of the population of a board and care occupancy might vary over time. The required documentation should be reviewed regularly to ensure that it accurately represents the current evacuation capability of the residents and staff.

When determining equivalency in accordance with 33.3.1.2.1.1 or 33.3.1.2.2, it is important to note that the equivalency measurement systems of the 2001 edition of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, were calibrated against the requirements of the 2000 edition of NFPA 101 and might not accurately evaluate equivalency with the requirements of the 2003 edition of the *Life Safety Code*. At the time this handbook went to press, the 2004 edition of NFPA 101A was being prepared. Once issued, the 2004 edition of NFPA 101A can be used to measure equivalency against the requirements of the 2003 edition of the *Code*.

The difficulty in moving occupants to the outside of a facility with an impractical evacuation capability is comparable to that of doing so in a health care facility. Therefore, 33.3.1.2.2 mandates that existing large board and care facilities with impractical evacuation capability are subject to the requirements of Chapter 19, rather than those of Chapter 33. Chapter 19 employs a detailed defend-in-place strategy. If the equivalency methodologies of NFPA 101A, *Guide on*

CHAPTER 32 • New

Alternative Approaches to Life Safety, are to be applied to a large board and care facility with impractical evacuation capability, the health care fire safety evaluation system (FSES) must be used instead of the board and care FSES.

Note that the requirements in Section 32.3 for new, large board and care facilities, which are new

32.3.1.3 Minimum Construction Requirements. Building construction shall be in accordance with Chapter 7 of *NFPA 5000™, Building Construction and Safety Code™*.

CHAPTER 33 • Existing

to the 2003 edition of the *Code*, are predicated on the assumption the facility might be occupied by residents classified as impractical with regard to evacuation capability. As such, no evaluation of evacuation capability is required in facilities meeting the requirements of Chapter 32.

33.3.1.3 Minimum Construction Requirements.

33.3.1.3.1 Construction requirements for large facilities shall be as required by 33.3.1.3.

33.3.1.3.2 Where noted as “fully sheathed,” the interior shall be covered with lath and plaster or materials providing a 15-minute thermal barrier.

33.3.1.3.3 For the purpose of construction requirements, stories shall be counted as follows:

- (1) Stories shall be counted starting with the primary level of exit discharge and ending with the highest occupied level.
- (2) Where the primary level of exit discharge is not readily apparent, the primary level of exit discharge of a building shall be that story that is level with or above finished grade of the exterior wall line for 50 percent or more of its perimeter.
- (3) Building levels below the primary level shall not be counted as a story in determining the height of the building.

33.3.1.3.4 The minimum construction requirements (*see* 8.2.1), based on the highest story normally used by board and care residents, shall be as follows.

- (1) Unless meeting the requirement of (2), one- or two-story facilities shall be any construction type that meets the requirements for 1-hour or greater fire resistance rating, that is Type IV(2HH), that is fully sheathed, or that is protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5.
- (2) One-story prompt evacuation capability facilities having 30 or fewer residents shall be permitted to be of any type construction.
- (3) Unless meeting the requirements of (3), three- to six-story facilities shall be Type I, Type II, or Type III construction that meets the requirements for 1-hour or greater fire resistance rating; Type IV construction that is protected throughout by an approved automatic sprinkler

system in accordance with 33.3.3.5; or any other type of construction that is both sheathed and protected throughout by an approved automatic sprinkler system installed in accordance with 33.3.3.5, other than Type V(000).

- (4) Three- to four-story facilities of Type V(000) construction that are both fully sheathed and protected throughout by an approved, supervised automatic sprinkler system in accordance with 33.3.3.5 shall be considered to have met the requirements of 33.3.1.3.4(3).
- (5) Unless meeting the requirements of (6), facilities more than six stories high shall be any Type I or Type II(222) construction, and any Type II(111), Type III(211), or Type IV(2HH) construction that is protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5.
- (6) Any building of Type I, Type II(222), or Type II(111) construction shall be permitted to include roofing systems involving combustible supports, decking, or roofing, provided that the following criteria are met:
 - (a) The roof covering meets Class A requirements in accordance with NFPA 256, *Standard Methods of Fire Tests of Roof Coverings*.
 - (b) The roof is separated from all occupied portions of the building by a noncombustible floor assembly having not less than a 2-hour fire resistance rating that includes not less than 64 mm (2½ in.) of concrete or gypsum fill, and the attic or other space so developed shall be either unused or protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5.1.

Because evacuation strategies might be limited to moving residents to a point of safety, the *Code* regulates construction type to ensure building stability if the residents are to remain inside. The stability of the building is maintained either by the use of an automatic sprinkler system (as required for new con-

struction by 32.3.3.5.1) or by the use of fire-resistant construction. Although 33.3.1.3 specifically prescribes the permitted construction types for existing large board and care facilities, 32.3.1.3 references *NFPA 5000, Building Construction and Safety Code*. Commentary Table 32/33.2 summarizes the building construc-

Type V(000)†	AS‡	AS‡	AS§	AS§	NP	NP	NP

X = Permitted.
 AS = Permitted if sprinklered as required by 33.3.3.5.
 NP = Not permitted.
 † = Permitted up to one story, unsheathed and unsprinklered if housing 30 or fewer residents with prompt evacuation capability.
 ‡ = Permitted if sheathed or sprinklered (sprinklers as required by 33.3.3.5).
 § = Permitted if sheathed and sprinklered (sprinklers as required by 33.3.3.5).

tion requirements for new, large board and care facilities from *NFPA 5000*; Commentary Table 32/33.3 summarizes the permissible types of construction for existing large board and care facilities from 33.3.1.3.

Note that in 33.3.1.3.4(2), existing buildings from which there is a reasonable expectation of prompt evacuation to the exterior are exempted from the minimum construction requirements.

32.3.1.4 Occupant Load. The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space, or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

33.3.1.4 Occupant Load. The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

The determination of actual occupant load should be based on the total number of residents, staff, and visitors. If the actual occupant load of the facility exceeds the occupant load calculated on the basis of one person per 18.6 m² (200 ft²), as stipulated in Table 7.3.1.2, the egress capacity must be designed to meet

the actual (larger) occupant load. However, if the actual occupant load is smaller than the calculated occupant load, the minimum egress capacity must not be less than that required for the calculated (larger) occupant load.

32.3.2 Means of Egress.

32.3.2.1 General. Means of egress shall be in accordance with Chapter 7.

33.3.2 Means of Egress.

33.3.2.1 General. Means of egress shall be in accordance with Chapter 7.

CHAPTER 32 • New

32.3.2.2 Means of Egress Components.

32.3.2.2.1 General. Components of means of egress shall be limited to the types described in 32.3.2.2.2 through 32.3.2.2.10.

32.3.2.2.2 Doors. Doors in means of egress shall be as follows:

- (1) Doors complying with 7.2.1 shall be permitted.
- (2) Doors within individual rooms and suites of rooms shall be permitted to be swinging or sliding.
- (3) No door, other than those meeting (4) or (5), shall be equipped with a lock or latch that requires the use of a tool or key from the egress side.
- (4) Delayed egress locks in accordance with 7.2.1.6.1 shall be permitted, provided not more than one device is located in any egress path.
- (5) Access-controlled egress doors in accordance with 7.2.1.6.2 shall be permitted.
- (6) Doors located in the means of egress that are permitted to be locked under other provisions of Chapter 32, other than those meeting (4) or (5), shall have adequate provisions made for the rapid removal of occupants by means such as remote control of locks, keying of all locks to keys carried by staff at all times, or other such reliable means available to staff at all times.
- (7) Only one such locking device as described in (6) shall be permitted on each door.

32.3.2.2.3 Stairs. Stairs complying with 7.2.2 shall be permitted.

32.3.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

32.3.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

32.3.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

32.3.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

32.3.2.2.8 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

32.3.2.2.9 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

32.3.2.2.10 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

A general reference to Chapter 7 is made in 32/33.3.2.1 rather than repeating specific provisions. Many of

CHAPTER 33 • Existing

33.3.2.2 Means of Egress Components.

33.3.2.2.1 General. Components of means of egress shall be limited to the types described in 33.3.2.2.2 through 33.3.2.2.10.

33.3.2.2.2 Doors. Doors in means of egress shall be as follows:

- (1) Doors complying with 7.2.1 shall be permitted.
- (2) Doors within individual rooms and suites of rooms shall be permitted to be swinging or sliding.
- (3) No door in any means of egress, other than those meeting (4) or (5), shall be locked against egress when the building is occupied.
- (4) Delayed-egress locks in accordance with 7.2.1.6.1 shall be permitted, provided that not more than one device exists in a means of egress.
- (5) Access-controlled egress doors in accordance with 7.2.1.6.2 shall be permitted.
- (6) Revolving doors complying with 7.2.1.10 shall be permitted.

33.3.2.2.3 Stairs. Stairs complying with 7.2.2 shall be permitted.

33.3.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

33.3.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

33.3.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

33.3.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

33.3.2.2.8 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

33.3.2.2.9 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

33.3.2.2.10 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

the requirements contained in 32/33.3.2 are Chapter 7 provisions that require occupancy chapter permis-

CHAPTER 32 • New

sion, such as in 32/33.3.2.2.2(4), which allows the use of delayed-egress locks in accordance with 7.2.1.6.1. The limits placed on travel distance in 32/33.3.2.6 are examples of provisions for which the occupancy chapters are permitted to establish restrictions.

Facilities are prohibited from having any door locked against egress while the building is occupied per 32/33.3.2.2.2(3). This is consistent with a fundamental means of egress provision of Chapter 7. This requirement permits a door to have a locking device that allows the door to be opened from within the facility for the purpose of egress but does not allow the door to be opened from outside the facility. Ordinary double-cylinder locks and chain locks do not meet these provisions.

32.3.2.3 Capacity of Means of Egress.

32.3.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

32.3.2.3.2 Street floor exits shall be sufficient for the occupant load of the street floor plus the required capacity of stairs and ramps discharging onto the street floor.

32.3.2.3.3 The width of corridors shall be sufficient for the occupant load served but shall not be less than 1525 mm (60 in.).

32.3.2.4 Number of Exits. The minimum number of exits as required by Section 7.4 shall be provided on every story.

32.3.2.5 Arrangement of Means of Egress.

32.3.2.5.1 Access to all required exits shall be in accordance with Section 7.5.

32.3.2.5.2 Common paths of travel shall not exceed 23 m (75 ft).

32.3.2.5.3 Reserved.

32.3.2.5.4 Dead-end corridors shall not exceed 9140 mm (360 in.).

32.3.2.5.5 Any room or any suite of rooms exceeding 185 m² (2000 ft²) shall be provided with not less than two exit access doors located remotely from each other.

CHAPTER 33 • Existing

The use of delayed-egress locks that comply with 7.2.1.6.1 is permitted by 32/33.3.2.2.2(4), provided that not more than one delayed-egress device is encountered in any means of egress path. This provision requires that the building be either protected throughout by automatic sprinklers or equipped throughout with an automatic fire detection system. The 15-second or 30-second delay permitted by 7.2.1.6.1 does not affect the immediate release of the lock upon activation of the sprinklers or detectors or upon loss of power to the lock. The delayed-egress device helps provide security for infrequently used doors or stairs in board and care facilities, while doors remain available for emergency use. Chains and padlocks do not provide this feature.

33.3.2.3 Capacity of Means of Egress.

33.3.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

33.3.2.3.2 Street floor exits shall be sufficient for the occupant load of the street floor plus the required capacity of stairs and ramps discharging onto the street floor.

33.3.2.3.3 The width of corridors serving an occupant load of 50 or more shall be sufficient for the occupant load served but shall be not less than 1120 mm (44 in.).

33.3.2.3.4 Corridors serving an occupant load fewer than 50 shall be not less than 915 mm (36 in.) wide.

33.3.2.4 Number of Exits. The minimum number of exits as required by Section 7.4 shall be provided on every story.

33.3.2.5 Arrangement of Means of Egress.

33.3.2.5.1 Access to all required exits shall be in accordance with Section 7.5.

33.3.2.5.2 Common paths of travel shall not exceed 33.5 m (110 ft) in buildings not protected throughout by an automatic sprinkler system in accordance with 33.3.3.5.

33.3.2.5.3 In buildings protected throughout by automatic sprinkler systems in accordance with 33.3.3.5, common paths of travel shall not exceed 48.8 m (160 ft).

33.3.2.5.4 Dead-end corridors shall not exceed 15 m (50 ft).

CHAPTER 32 • New

32.3.2.6 Travel Distance to Exits. Travel distance from any point in a room to the nearest exit, measured in accordance with Section 7.6, shall not exceed 76 m (250 ft).

32.3.2.7 Discharge from Exits. Exit discharge shall comply with Section 7.7.

32.3.2.8 Illumination of Means of Egress. Means of egress shall be illuminated in accordance with Section 7.8.

32.3.2.9 Emergency Lighting. Emergency lighting in accordance with Section 7.9 shall be provided unless each sleeping room has a direct exit to the outside at ground level.

32.3.2.10 Marking of Means of Egress. Means of egress shall be marked in accordance with Section 7.10.

32.3.2.11 Special Means of Egress Features. (Reserved)

Street-floor egress capacity must be provided in accordance with 32/33.3.2.3.2 such that it is sufficient to accommodate the convergence of first-floor occu-

CHAPTER 33 • Existing

33.3.2.6 Travel Distance to Exits.

33.3.2.6.1 Travel distance from the door within a room, suite, or living unit to a corridor door shall not exceed 23 m (75 ft) in buildings not protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5.

33.3.2.6.2 Travel distance from the door within a room, suite, or living unit to a corridor door shall not exceed 38 m (125 ft) in buildings protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5.

33.3.2.6.3 Travel distance from the corridor door of any room to the nearest exit shall be in accordance with 33.3.2.6.3.1, 33.3.2.6.3.2, or 33.3.2.6.3.3.

33.3.2.6.3.1 Travel distance from the corridor door of any room to the nearest exit, measured in accordance with Section 7.6, shall not exceed 30 m (100 ft).

33.3.2.6.3.2 Travel distance to exits shall not exceed 61 m (200 ft) for exterior ways of exit access arranged in accordance with 7.5.3.

33.3.2.6.3.3 Travel distance to exits shall not exceed 61 m (200 ft) if the exit access and any portion of the building that is tributary to the exit access are protected throughout by approved automatic sprinkler systems in accordance with 33.3.3.5. In addition, the portion of the building in which 61-m (200-ft) travel distance is permitted shall be separated from the remainder of the building by construction having a fire resistance rating of not less than 1 hour for buildings not more than three stories in height and not less than 2 hours for buildings more than three stories in height.

33.3.2.7 Discharge from Exits. Exit discharge shall comply with Section 7.7.

33.3.2.8 Illumination of Means of Egress. Means of egress shall be illuminated in accordance with Section 7.8.

33.3.2.9 Emergency Lighting. Emergency lighting in accordance with Section 7.9 shall be provided in all buildings with more than 25 rooms, unless each sleeping room has a direct exit to the outside of the building at ground level.

33.3.2.10 Marking of Means of Egress. Means of egress shall be marked in accordance with Section 7.10.

33.3.2.11 Special Means of Egress Features. (Reserved)

pants with occupants leaving exit enclosures from the upper and lower floors and traversing areas of the first floor. This concept is common in hotel, apart-

CHAPTER 32 • New

ment, business, and mercantile occupancies. See the commentary on 28/29.2.3.2 and Exhibit 28/29.3.

The provisions of 32/33.3.2.4 are similar to those for hotels. No building or story is permitted to have a single exit. Note that 7.4.1.2 requires at least three exits for floors with more than 500 people; at least four exits are required for those with 1000 or more. This requirement will probably have minimal impact on board and care facilities, because such large floors would probably need additional exits to meet travel distance limitations.

Common path of travel in board and care facilities is measured in the usual manner outlined in A.7.5.1.5. Prior to the mid-1990s, the board and care occupancy chapters used a modified corridor common path of travel similar to that currently used in the hotel and apartment occupancy chapters.

Travel distance is addressed in 32/33.3.2.6. For new, large board and care facilities, the travel distance

CHAPTER 33 • Existing

limitation is straightforward: 76 m (250 ft) from any point to the nearest exit. For existing, large board and care facilities, the travel distance limitations of 33.3.2.6 are divided into two segments—within a room/suite and within the common corridor system or along the exterior exit access balcony.

Exhibit 32/33.9 illustrates an existing large board and care facility with three separate sections as follows. Areas B and C are nonsprinklered portions of the building, and area A is protected by an automatic sprinkler system. In the nonsprinklered areas (B and C), 33.3.2.6.1 limits the travel distance within the room/suite to 23 m (75 ft). In the sprinklered area (A), the permitted travel distance within the room/suite is 38 m (125 ft) per 33.3.2.6.2. Once outside the room/suite, 33.3.2.6.3 limits the travel distance within a nonsprinklered interior corridor to an exit to 30 m (100 ft), as in area B of the building. However, the distance is permitted to be increased to 61 m (200 ft)

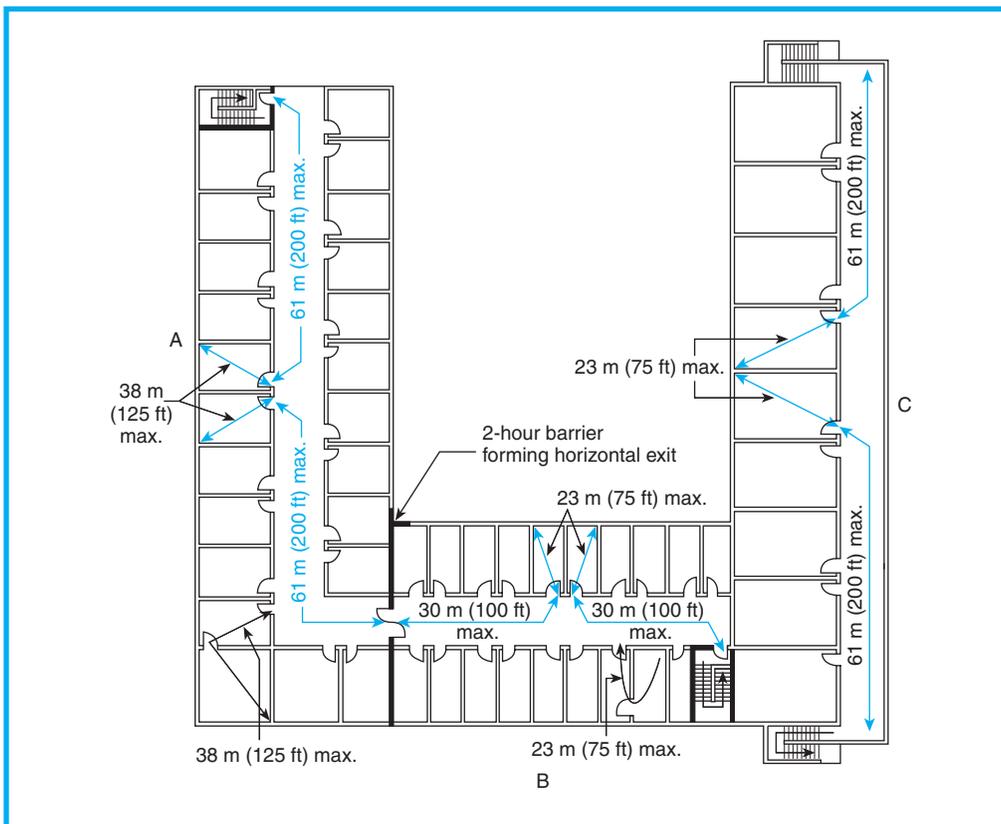

Exhibit 32/33.9 Travel distance limitations.

CHAPTER 32 • New

if the travel is an exterior exit access (area C) or if the building is protected by an automatic sprinkler system (area A), as per 33.3.2.6.3.2 and 33.3.2.6.3.3, respectively.

The provision of 32/33.3.2.9 allowing the omission

32.3.3 Protection.**32.3.3.1 Protection of Vertical Openings.**

32.3.3.1.1 Vertical openings shall be enclosed or protected in accordance with Section 8.6.

32.3.3.1.2 Unenclosed vertical openings in accordance with 8.6.8.2 shall be permitted.

32.3.3.1.3 No floor below the level of exit discharge used only for storage, heating equipment, or purposes other than residential occupancy shall have unprotected openings to floors used for residential occupancy.

Because 32.3.3.5.1 requires an automatic sprinkler system in all new, large board and care facilities, a communicating space is permitted to be separated from the remainder of the building by a smoke barrier in accordance with 8.6.6(4), rather than by a 1-hour fire barrier.

32.3.3.2 Protection from Hazards.

32.3.3.2.1 Hazardous areas shall be protected in accordance with Section 8.7.

CHAPTER 33 • Existing

of emergency lighting does not apply to facilities with exterior balconies that require travel on stairs to reach ground level; it applies only to facilities having doors opening directly at ground level.

33.3.3 Protection.**33.3.3.1 Protection of Vertical Openings.**

33.3.3.1.1 Vertical openings shall comply with 33.3.3.1.1.1, 33.3.3.1.1.2, or 33.3.3.1.1.3.

33.3.3.1.1.1 Vertical openings shall be enclosed or protected in accordance with Section 8.6.

33.3.3.1.1.2 Unprotected vertical openings not part of required egress shall be permitted to be waived by the authority having jurisdiction where such openings do not endanger required means of egress, provided that the building is protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5 and the exits and required ways of travel thereto are adequately safeguarded against fire and smoke within the building, or in which every individual room has direct access to an exterior exit without passing through a public corridor.

33.3.3.1.1.3 In buildings not more than two stories in height, unprotected vertical openings shall be permitted by the authority having jurisdiction, provided the building is protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5.

33.3.3.1.2 No floor below the level of exit discharge and used only for storage, heating equipment, or purposes other than residential occupancy shall have unprotected openings to floors used for residential occupancy.

Automatic sprinklers are not required in existing board and care facilities. However, if automatic sprinklers are installed, 33.3.3.1.1.2 and 33.3.3.1.1.3 permit the authority having jurisdiction to waive the requirements for protection of vertical openings in certain circumstances.

33.3.3.2 Protection from Hazards.

33.3.3.2.1 Rooms containing high-pressure boilers, refrigerating machinery, transformers, or other service equipment subject to possible explosion shall not be located directly under or adjacent to exits, and such rooms shall be effectively

CHAPTER 32 • New

32.3.3.2.2 The areas described in Table 32.3.3.2.2 shall be protected as indicated.

Table 32.3.3.2.2 Hazardous Area Protection

Hazardous Area Description	Separation/Protection
Boiler and fuel-fired heater rooms	1 hour
Central/bulk laundries larger than 9.3 m ² (100 ft ²)	1 hour
Paint shops employing hazardous substances and materials in quantities less than those that would be classified as a severe hazard	1 hour
Physical plant maintenance shops	1 hour
Soiled linen rooms	1 hour
Storage rooms larger than 4.6 m ² (50 ft ²) but not exceeding 9.3 m ² (100 ft ²) storing combustible material	Smoke partition
Storage rooms larger than 9.3 m ² (100 ft ²) storing combustible material	1 hour
Trash collection rooms	1 hour

The lists that appear in Table 32.3.3.2.2 and in 33.3.3.2.2 are not all-inclusive. Hazardous areas are those that contain materials that, because of their basic nature or the quantity of combustible materials involved, represent a significantly higher hazard than would otherwise be typical of the contents of a residential board and care facility.

Prior to the 2003 edition of the *Code*, most hazardous areas in new, large board and care facilities were permitted to be enclosed by only smoke partitions due to the mandatory requirement for automatic sprinklers. However, due to the revisions to Chapter

32.3.3.3* Interior Finish.

A.32.3.3.3 The provisions in 10.2.8 to allow modifications to interior finish requirements where automatic sprinklers are provided are intended to be permitted.

32.3.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

CHAPTER 33 • Existing

separated from other parts of the building as specified in Section 8.7.

33.3.3.2.2 Hazardous areas, which shall include, but shall not be limited to, the following, shall be separated from other parts of the building by construction having a fire resistance rating of not less than 1 hour, with communicating openings protected by approved self-closing fire doors, or such area shall be equipped with automatic fire extinguishing systems:

- (1) Boiler and heater rooms
- (2) Laundries
- (3) Repair shops
- (4) Rooms or spaces used for storage of combustible supplies and equipment in quantities deemed hazardous by the authority having jurisdiction

32 for the 2003 edition eliminating the requirement for evaluation of evacuation capability in new facilities, it must be assumed that facilities might contain occupants classified as impractical. As such, the hazardous area protection requirements for new, large board and care facilities mirror those in Chapter 18 for new health care occupancies (see 18.3.2.1). Other than small storage rooms, hazardous areas must be enclosed by 1-hour rated fire barriers, in addition to being protected by the automatic sprinkler system mandated by 32.3.3.5.1.

33.3.3.3 Interior Finish.

33.3.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

CHAPTER 32 • New

32.3.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be in accordance with the following:

- (1) Exit enclosures—Class A
- (2) Lobbies and corridors—Class B
- (3) Rooms and enclosed spaces—Class B

32.3.3.3.3 Interior Floor Finish.

32.3.3.3.3.1 Interior floor finish shall comply with Section 10.2.

32.3.3.3.3.2 Interior floor finish in exit enclosures and exit access corridors and spaces not separated from them by walls complying with 32.3.6 shall be not less than Class II.

32.3.3.3.3.3 Interior floor finish shall comply with 10.2.7.1 or 10.2.7.2, as applicable.

32.3.3.4 Detection, Alarm, and Communications Systems.

32.3.3.4.1 General. A fire alarm system shall be provided in accordance with Section 9.6.

32.3.3.4.2 Initiation. The required fire alarm system shall be initiated by all of the following:

- (1) Manual means in accordance with 9.6.2
- (2) A manual fire alarm box located at a convenient central control point under continuous supervision of responsible employees
- (3) Any required automatic sprinkler system
- (4) Any required detection system

32.3.3.4.3 Annunciator Panel. An annunciator panel, whose location shall be approved by the authority having jurisdiction, shall be connected to the fire alarm system.

32.3.3.4.4 Occupant Notification. Occupant notification shall be provided automatically, without delay, in accordance with 9.6.3.

32.3.3.4.5 High-rise buildings shall be provided with an approved means of voice communication in accordance with 11.8.3 or with a public address system.

CHAPTER 33 • Existing

33.3.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B.

33.3.3.3.3 Interior Floor Finish. Interior floor finish, other than approved, existing floor coverings, shall be Class I or Class II in corridors or exits.

33.3.3.4 Detection, Alarm, and Communications Systems.

33.3.3.4.1 General. A fire alarm system in accordance with Section 9.6 shall be provided, unless each sleeping room has exterior exit access in accordance with 7.5.3 and the building is not more than three stories in height.

33.3.3.4.2 Initiation. The required fire alarm system shall be initiated by all of the following means:

- (1) Manual means in accordance with 9.6.2, unless there are other effective means (such as a complete automatic sprinkler or automatic detection system) for notification of fire as required
- (2) A manual fire alarm box located at a convenient central control point under continuous supervision of responsible employees
- (3) Any automatic sprinkler system, other than those that are not required by another section of this *Code*
- (4) Any required detection system, other than sleeping room smoke alarms

33.3.3.4.3 Reserved.

33.3.3.4.4 Occupant Notification. Occupant notification shall be provided automatically, without delay, by internal audible alarm in accordance with 9.6.3.

33.3.3.4.5 Reserved.

CHAPTER 32 • New

32.3.3.4.6 Emergency Forces Notification. Emergency forces notification shall meet the following requirements:

- (1) Fire department notification shall be accomplished in accordance with 9.6.4.
- (2) Smoke detection devices or smoke detection systems equipped with reconfirmation features shall not be required to automatically notify the fire department unless the alarm condition is reconfirmed after a period not exceeding 120 seconds.

32.3.3.4.7 Smoke Alarms. Approved smoke alarms shall be installed in accordance with 9.6.2.10 inside every sleeping room, outside every sleeping area in the immediate vicinity of the bedrooms, and on all levels within a resident unit.

32.3.3.4.8 Smoke Detection Systems.

32.3.3.4.8.1 Corridors and spaces open to the corridors, other than those meeting 32.3.3.4.8.2, shall be provided with smoke detectors that comply with *NFPA 72*[®], *National Fire Alarm Code*[®], and are arranged to initiate an alarm that is audible in all sleeping areas.

32.3.3.4.8.2 Smoke detection systems shall not be required in unenclosed corridors, passageways, balconies, colonnades, or other arrangements with one or more sides along the long dimension fully or extensively open to the exterior at all times.

In addition to the normal distribution of manual fire alarm boxes (see 9.6.2), 32/33.3.3.4.2(2) requires locations such as that of the telephone operator to be equipped with a manual fire alarm box. The intent

CHAPTER 33 • Existing

33.3.3.4.6* Fire Department Notification. In case of a fire, provisions shall be made for the immediate notification of the public fire department, by either telephone or other means, or, where there is no public fire department, this notification shall be made to the private fire brigade.

A.33.3.3.4.6 See A.29.3.4.3.6.

33.3.3.4.7 Smoke Alarms. Smoke alarms shall be provided in accordance with 33.3.3.4.7.1, 33.3.3.4.7.2, or 33.3.3.4.7.3.

33.3.3.4.7.1 Each sleeping room shall be provided with an approved smoke alarm in accordance with 9.6.2.10 that is powered from the building electrical system.

33.3.3.4.7.2 Existing battery-powered smoke alarms, rather than building electrical service-powered smoke alarms, shall be accepted where, in the opinion of the authority having jurisdiction, the facility has demonstrated that testing, maintenance, and battery replacement programs ensure the reliability of power to the smoke alarms.

33.3.3.4.7.3 Sleeping room smoke alarms shall not be required in facilities having an existing corridor smoke detection system that comply with Section 9.6 and are connected to the building fire alarm system.

33.3.3.4.8 Smoke Detection Systems. All living areas as defined in 3.3.16.5 and all corridors shall be provided with smoke detectors that comply with *NFPA 72*[®], *National Fire Alarm Code*[®], and are arranged to initiate an alarm that is audible in all sleeping areas, as modified by 33.3.3.4.8.1 and 33.3.3.4.8.2.

33.3.3.4.8.1 Detectors shall not be required in living areas in facilities protected throughout by an approved automatic sprinkler system installed in accordance with 33.3.3.5.

33.3.3.4.8.2 Detectors shall not be required in unenclosed corridors, passageways, balconies, colonnades, or other arrangements with one or more sides along the long dimension fully or extensively open to the exterior at all times.

is that a manual fire alarm box is to be available at the location where residents/staff phone in an emergency.

Sleeping room smoke alarms are exempt from

CHAPTER 32 • New

activating the building fire alarm system. The smoke alarms installed in the sleeping rooms are usually single-station or multiple-station smoke alarms and are not part of a required automatic detection system. Therefore, such smoke alarms are intended to notify the occupants of the room of a smoke condition. The provision of 33.3.3.4.2(4) emphasizes this intention. The *Code*, in fact, prohibits room smoke alarms from activating the fire alarm system as stated in 9.6.2.10.4 to prevent numerous nuisance alarms, which could pose a particular problem in large board and care facilities. Because the purpose of the sleeping room smoke alarms is to warn the occupants of an individual room, the notification of the management and other occupants is the responsibility of the occupant. As such, manual alarm initiation should be emphasized in the required training for residents. See 32/33.7.2 for resident training requirements.

The location of audible alarm-notification devices in residential board and care facilities affects their audibility. In most new construction, corridor walls are of such character (soundproof) that a sounding device would be needed in each room to meet the performance criterion for alarm audibility throughout the building. If sounding devices are used only in the corridor, they might have to operate at dangerous sound levels to awaken residents in their rooms.

New, large board and care facilities must be provided with means to automatically notify the fire department of an alarm condition (see 9.6.4) per 32.3.3.4.6. In existing facilities, automatic emergency forces notification is not required by 33.3.3.4.6; however, means must be provided for staff to call the fire department at a minimum. Although direct fire alarm connection to the fire department is not required, such connection is the preferable method of providing fire department notification. If a telephone is provided, the telephone must be equipped for direct outside dial without going through a switchboard; the telephone is not permitted to be a pay phone.

The purpose of placing smoke alarms in each

CHAPTER 33 • Existing

sleeping room, as required by 32/33.3.3.4.7, is to alert the occupants of a room to the presence of smoke within that room. The alarms are not permitted to be connected to the building fire alarm system as previously discussed. When an occupant leaves a room, the door automatically closes behind the occupant, and the occupant is expected to pull a manual fire alarm box. If the occupant fails to sound the alarm manually, compensation is provided by corridor smoke detectors or by automatic sprinklers. See 32/33.3.3.4.8 and 32/33.3.3.5.

In existing board and care facilities, 33.3.3.4.7.2 applies only to existing battery-powered alarms—not to newly installed alarms in existing facilities. Battery-powered alarms are to be permitted only if they already exist and the facility can document that they are properly maintained and tested to ensure their reliability.

The provision of 33.3.3.4.7.3 recognizes that corridor smoke detection systems, rather than bedroom smoke alarms, were earlier *Code* requirements. Note that the installation of a new corridor smoke detection system does not waive the need for single-station smoke alarms in each room. However, if an existing facility already has a corridor smoke detection system, single-station smoke alarms in bedrooms are not required.

New, large board and care facilities must be provided with a corridor smoke detection system in accordance with 32.3.3.4.8.1. In existing facilities, 33.3.3.4.8 requires a system of smoke detectors in the living areas where they are not fully sprinklered. Note that 33.3.3.4.8.1 does not exempt the requirement of 33.3.3.4.7 for the provision of single-station smoke alarms in each sleeping room even when automatic sprinklers are installed. The *Code* is not equating sprinklers with smoke detectors but establishes that a fully sprinklered existing building is an adequate alternative to smoke detection in common spaces. If the facility uses exterior access corridors in the motel style, smoke detection is not required in the exterior corridors in accordance with 32/33.3.3.4.8.2.

32.3.3.5 Extinguishment Requirements.

32.3.3.5.1 All buildings shall be protected throughout by an approved automatic sprinkler system installed in accordance with 9.7.1.1(1) and provided with quick response or residential sprinklers throughout.

33.3.3.5 Extinguishment Requirements.

33.3.3.5.1* **Automatic Extinguishment Systems.** Where an automatic sprinkler system is installed for either total or partial building coverage, the system shall be installed in accordance with Section 9.7, as modified by 33.3.3.5.1.1, 33.3.3.5.1.2, and 33.3.3.5.1.3.

CHAPTER 32 • New

32.3.3.5.2 Reserved.

32.3.3.5.3 Reserved.

32.3.3.5.4 Automatic sprinkler systems shall be provided with electrical supervision in accordance with 9.7.2.

CHAPTER 33 • Existing

A.33.3.3.5.1 It is intended that this requirement apply to existing small facilities that are converted to large facilities.

Chapter 33 permits the use of NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. In some circumstances, such as those for impractical evacuation capabilities, the requirements of NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy.

33.3.3.5.1.1 In buildings not more than four stories in height, a sprinkler system complying with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, shall be permitted.

33.3.3.5.1.2 Automatic sprinklers shall not be required in closets not exceeding 2.2 m² (24 ft²) and in bathrooms not exceeding 5.1 m² (55 ft²), provided that such spaces are finished with lath and plaster or materials with a 15-minute thermal barrier.

33.3.3.5.1.3 Initiation of the fire alarm system shall not be required for existing installations in accordance with 33.3.3.5.5.

33.3.3.5.2 All high-rise buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 33.3.3.5, as modified by 33.3.3.5.3. Such systems shall initiate the fire alarm system in accordance with Section 9.6.

33.3.3.5.3 Automatic sprinklers shall not be required in small clothes closets where the smallest dimension does not exceed 915 mm (36 in.), the area does not exceed 2.2 m² (24 ft²), and the walls and ceiling are finished with noncombustible or limited-combustible materials.

33.3.3.5.4 Automatic sprinkler systems shall be supervised in accordance with Section 9.7; waterflow alarms shall not be required to be transmitted off-site.

CHAPTER 32 • New

32.3.3.5.5 Reserved.

32.3.3.5.6 Portable Fire Extinguishers. Portable fire extinguishers shall be provided in accordance with 9.7.4.1.

Automatic sprinklers are required in all new, large residential board and care facilities. Although not required, there are incentives for installing sprinklers in existing facilities. In new large facilities, sprinkler systems must meet NFPA 13, *Standard for the Installation of Sprinkler Systems*. In existing facilities having not more than four stories, 33.3.3.5.1.1 permits sprinkler systems installed in accordance with NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*.

Note that prior to the 2003 edition of the *Code*, new large facilities were permitted to be sprinklered in accordance with NFPA 13R. However, the *Code* now assumes new facilities might house residents not having the ability to evacuate or relocate without assistance. Given the potential need to use the “defend in place” strategy of occupant protection, it is important to provide complete automatic sprinkler

32.3.3.6* Corridors and Separation of Sleeping Rooms.

A.32.3.3.6 It is not intended to prohibit furniture in corridors and spaces open to corridors provided the minimum required width is maintained. Storage is not permitted in corridors or spaces open to corridors.

32.3.3.6.1 Access shall be provided from every resident use area to at least one means of egress that is separated from all sleeping rooms by walls complying with 32.3.3.6.3 through 32.3.3.6.6.

CHAPTER 33 • Existing

33.3.3.5.5 Sprinkler piping serving not more than six sprinklers for any isolated hazardous area in accordance with 9.7.1.2 shall be permitted; in new installations where more than two sprinklers are installed in a single area, waterflow detection shall be provided to initiate the fire alarm system required by 33.3.3.4.1.

33.3.3.5.6 Portable Fire Extinguishers. Portable fire extinguishers in accordance with 9.7.4.1 shall be provided near hazardous areas.

protection in accordance with NFPA 13, with quick-response or residential sprinklers throughout. This requirement recognizes the ability of quick-response and residential sprinklers to maintain tenability in the room of origin for most fire scenarios.

The provision of 33.3.3.5.1.2 applies to sprinkler systems installed in accordance with NFPA 13R and NFPA 13 in existing facilities. The requirement for wall and ceiling surfaces to provide a 15-minute thermal barrier where sprinklers are omitted includes the wall and ceiling sections behind prefabricated tub and shower enclosures. This provision helps to confine a fire that originates in a bathroom.

For existing facilities, 33.3.3.5.1 does not require quick-response or residential sprinklers. However, NFPA 13R and NFPA 13 require quick-response sprinklers if a sprinkler system is installed in the areas of a board and care facility designated as light hazard by these standards.

33.3.3.6 Corridors and Separation of Sleeping Rooms.

33.3.3.6.1 Access shall be provided from every resident use area to not less than one means of egress that is separated from all other rooms or spaces by walls complying with 33.3.3.6.3 through 33.3.3.6.6.3, unless otherwise indicated in 33.3.3.6.1.1 through 33.3.3.6.1.3.

33.3.3.6.1.1 Rooms or spaces, other than sleeping rooms, protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5 shall not be required to comply with 33.3.3.6.1.

33.3.3.6.1.2 Prompt evacuation capability facilities in buildings not over two stories in height where not less than one

CHAPTER 32 • New

32.3.3.6.2 Sleeping rooms shall be separated from corridors, living areas, and kitchens by walls complying with 32.3.3.6.3 through 32.3.3.6.6.

32.3.3.6.3 Walls required by 32.3.3.6.1 or 32.3.3.6.2 shall be smoke partitions in accordance with Section 8.4.

32.3.3.6.4 Doors protecting corridor openings shall be constructed to resist the passage of smoke.

32.3.3.6.5 Door-closing devices shall not be required on doors in corridor wall openings other than those serving required exits, smoke barriers, or enclosures of vertical openings and hazardous areas.

32.3.3.6.6 No louvers, transfer grilles, operable transoms, or other air passages, other than properly installed heating and utility installations, shall penetrate such walls or doors.

CHAPTER 33 • Existing

required means of egress from each sleeping room provides a path of travel to the outside without traversing any corridor or other spaces exposed to unprotected vertical openings, living areas, and kitchens shall not be required to comply with 33.3.3.6.1.

33.3.3.6.1.3 Rooms or spaces, other than sleeping rooms, provided with a smoke detection and alarm system connected to activate the building evacuation alarm, shall not be required to comply with 33.3.3.6.1. Furnishings, finishes, and furniture, in combination with all other combustibles within the spaces, shall be of minimum quantity and arranged so that a fully developed fire is unlikely to occur.

33.3.3.6.2 Sleeping rooms shall be separated from corridors, living areas, and kitchens by walls complying with 33.3.3.6.3 through 33.3.3.6.6.3.

33.3.3.6.3 Walls required by 33.3.3.6.1 or 33.3.3.6.2 shall comply with 33.3.3.6.3.1, 33.3.3.6.3.2, or 33.3.3.6.3.3.

33.3.3.6.3.1 Walls shall have a fire resistance rating of not less than ½ hour.

33.3.3.6.3.2 In buildings protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5, walls shall be smoke partitions in accordance with Section 8.4, and the provisions of 8.4.3.5 shall not apply.

33.3.3.6.3.3 In buildings not more than two stories in height that are classified as prompt evacuation capability and that house not more than 30 residents, walls shall be smoke partitions in accordance with Section 8.4, and the provisions of 8.4.3.5 shall not apply.

33.3.3.6.4 Doors in walls required by 33.3.3.6.1 or 33.3.3.6.2 shall comply with 33.3.3.6.4.1, 33.3.3.6.4.2, 33.3.3.6.4.3, or 33.3.3.6.4.4.

33.3.3.6.4.1 Doors shall have a fire protection rating of not less than 20 minutes.

33.3.3.6.4.2 Solid-bonded wood core doors of not less than 440 mm (1¾ in.) thickness shall be permitted to continue in use.

33.3.3.6.4.3 In buildings protected throughout by an approved automatic sprinkler system in accordance with 33.3.3.5, doors that are nonrated shall be permitted to continue in use.

33.3.3.6.4.4 Where automatic sprinkler protection is provided in the corridor in accordance with 31.3.5.6 through 31.3.5.8, the following requirements shall be met:

- (1) Doors shall not be required to have a fire protection rating but shall be in accordance with 8.4.3.
- (2) The provisions of 8.4.3.5 shall not apply.
- (3) Doors shall be equipped with latches for keeping the doors tightly closed.

33.3.3.6.5 Where walls and doors are required by 33.3.3.6.1 and 33.3.3.6.2, the following requirements shall be met:

- (1) Such walls and doors shall be constructed as smoke partitions in accordance with Section 8.4.
- (2) The provisions of 8.4.3.5 shall not apply.
- (3) No louvers, transfer grilles, operable transoms, or other air passages shall penetrate such walls or doors, except properly installed heating and utility installations.

33.3.3.6.6 Doors in walls required by 33.3.3.6.1 and 33.3.3.6.2 shall comply with 33.3.3.6.6.1, 33.3.3.6.6.2, or 33.3.3.6.6.3.

33.3.3.6.6.1 Doors shall be self-closing or automatic-closing in accordance with 7.2.1.8, and doors in walls separating sleeping rooms from corridors shall be automatic-closing in accordance with 7.2.1.8.2.

33.3.3.6.6.2 Doors to sleeping rooms that have occupant-control locks such that access is normally restricted to the occupants or staff personnel shall be permitted to be self-closing.

33.3.3.6.6.3 In buildings protected throughout by an approved automatic sprinkler system installed in accordance with 33.3.3.5, doors, other than doors to hazardous areas, vertical openings, and exit enclosures, shall not be required to be self-closing or automatic-closing.

Access to at least one exit that is separate from sleeping rooms must be provided per 32/33.3.3.6.1. For existing board and care facilities, 33.3.3.6.1 contains three provisions that address special circumstances for an access to an exit that passes through a sitting room, television room, living room, or other common use space. See 33.3.3.6.1.1 through 33.3.3.6.1.3.

Exhibit 32/33.10 illustrates arrangements requiring egress travel through furnished day rooms that would be prohibited in existing board and care facilities, unless the space is sprinklered or provided with a combination of a smoke detection and alarm system and the combustibility of furnishings is controlled.

Sleeping rooms in new, large board and care facilities must be separated from corridors by smoke partitions (see Section 8.4) in accordance with 32.3.3.6.3.

No fire resistance rating is required. Doors in corridor walls to spaces other than exits, smoke barriers, or vertical opening or hazardous area enclosures, must be smoke resistant; however, they are not required to be self-closing or automatic closing, per 32.3.3.6.5. The provision to omit self-closers on corridor doors mirrors the provisions for health care occupancies in Chapters 18 and 19.

In existing buildings, the corridor walls must have a fire resistance rating of ½ hour. The walls are permitted to be smoke partitions with no fire resistance rating if the building is protected throughout by an automatic sprinkler system (see 33.3.3.6.3.2), or if the facility is moderately sized with prompt evacuation capability (see 33.3.3.6.3.3).

The intent of 33.3.3.6.4.2 is to minimize the impact

Exhibit 32/33.10 Alternate egress arrangements.

of converting a health care facility or hotel to a board and care facility by permitting existing doors to remain in use under a variety of conditions.

Existing sleeping room doors are required to be automatic-closing in accordance with 33.3.3.6.6.1 if the building is not sprinklered. In nonsprinklered facilities in which the residents control the privacy lock on their own sleeping room doors, a self-closer (such as spring hinges or a hydraulic door check) is

acceptable. Such a device is permitted because, in practice, such doors are usually kept closed. Therefore, the likelihood that the door will be chocked or held open is minimal. If the building is sprinklered, doors to spaces other than exits, smoke barriers, or vertical opening or hazardous area enclosures do not require closers. In such case, staff should be trained to close doors in the event of a fire.

32.3.3.7 Subdivision of Building Spaces. Buildings shall be subdivided by smoke barriers in accordance with 32.3.3.7.1 through 32.3.3.7.21.

33.3.3.7 Subdivision of Building Spaces. The following requirements shall be met for all sleeping floors.

33.3.3.7.1 Every sleeping room floor shall be divided into not less than two smoke compartments of approximately the

CHAPTER 32 • New

32.3.3.7.1 Every story shall be divided into not less than two smoke compartments unless it meets 32.3.3.7.4, 32.3.3.7.5, 32.3.3.7.6, or 32.3.3.7.7.

32.3.3.7.2 Each smoke compartment shall have an area not exceeding 2100 m² (22,500 ft²).

32.3.3.7.3 The travel distance from any point to reach a door in the required smoke barrier shall be limited to a distance of 61 m (200 ft).

32.3.3.7.4 Smoke barriers shall not be required on stories that do not contain a board and care occupancy, located totally above the board and care occupancy.

32.3.3.7.5 Smoke barriers shall not be required in areas that do not contain a board and care occupancy and that are separated from the board and care occupancy by a fire barrier complying with Section 8.3.

32.3.3.7.6 Smoke barriers shall not be required on stories that do not contain a board and care occupancy and that are more than one story below the board and care occupancy.

32.3.3.7.7 Smoke barriers shall not be required in open parking structures protected throughout by an approved, supervised automatic sprinkler system in accordance with 32.3.3.5.

32.3.3.7.8 Smoke barriers shall be constructed in accordance with Section 8.3 and shall have a fire resistance rating of not less than 1 hour unless they meet 32.3.3.7.9 or 32.3.3.7.10.

32.3.3.7.9 Where an atrium is used, smoke barriers shall be permitted to terminate at an atrium wall constructed in accordance with 8.6.7(1)(c), in which case not less than two separate smoke compartments shall be provided on each floor.

32.3.3.7.10* Dampers shall not be required in duct penetrations of smoke barriers in fully ducted heating, ventilating, and air conditioning systems.

A.32.3.3.7.10 Where the smoke control system design requires dampers in order that the system functions effectively, it is not the intent of 32.3.3.7.10 to permit the damper to be omitted.

This provision is not intended to prevent the use of plenum returns where ducting is used to return air from a ceiling plenum through smoke barrier walls. Short stubs or jumper ducts are not acceptable. Ducting is required to connect at both sides of the opening and to extend into adjacent spaces away from the wall. The intent is to prohibit open-air transfers at or near the smoke barrier walls.

CHAPTER 33 • Existing

same size, with smoke barriers in accordance with Section 8.5, unless otherwise indicated in 33.3.3.7.4, 33.3.3.7.5, and 33.3.3.7.6.

33.3.3.7.2 Smoke dampers shall not be required.

33.3.3.7.3 Additional smoke barriers shall be provided such that the travel distance from a sleeping room corridor door to a smoke barrier shall not exceed 46 m (150 ft).

33.3.3.7.4 Smoke barriers shall not be required in buildings protected throughout by an approved automatic sprinkler system installed in accordance with 33.3.3.5.

33.3.3.7.5 Smoke barriers shall not be required where each sleeping room is provided with exterior ways of exit access arranged in accordance with 7.5.3.

33.3.3.7.6 Smoke barriers shall not be required where the aggregate corridor length on each floor is not more than 46 m (150 ft).

CHAPTER 32 • New

CHAPTER 33 • Existing

32.3.3.7.11 Not less than 1.4 net m² (15 net ft²) per resident shall be provided within the aggregate area of corridors, lounge or dining areas, and other low hazard areas on each side of the smoke barrier.

32.3.3.7.12 On stories not housing residents, not less than 0.56 net m² (6 net ft²) per occupant shall be provided on each side of the smoke barrier for the total number of occupants in adjoining compartments.

32.3.3.7.13* Doors in smoke barriers shall be substantial doors, such as 44-mm (1¾-in.) thick, solid-bonded wood core doors, or shall be of construction that resists fire for not less than 20 minutes.

A.32.3.3.7.13 Smoke barrier doors are intended to provide access to adjacent zones. The pair of cross-corridor doors are required to be opposite swinging. Access to both zones is required.

32.3.3.7.14 Nonrated factory- or field-applied protective plates extending not more than 1220 mm (48 in.) above the bottom of the door shall be permitted.

32.3.3.7.15 Cross-corridor openings in smoke barriers shall be protected by a pair of swinging doors or a horizontal sliding door complying with 7.2.1.14.

32.3.3.7.16 Swinging doors shall be arranged so that each door swings in a direction opposite from the other.

32.3.3.7.17* Doors in smoke barriers shall comply with 8.5.3 and shall be self-closing or automatic-closing in accordance with 7.2.1.8.

A.32.3.3.7.17 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

32.3.3.7.18* Vision panels consisting of fire-rated glazing or wire glass panels in approved frames shall be provided in each cross-corridor swinging door and in each cross-corridor horizontal sliding door in a smoke barrier.

A.32.3.3.7.18 It is not the intent to require the frame to be a listed assembly.

32.3.3.7.19 Rabbets, bevels, or astragals shall be required at the meeting edges, and stops shall be required at the head and sides of door frames in smoke barriers.

32.3.3.7.20 Positive latching hardware shall not be required.

32.3.3.7.21 Center mullions shall be prohibited.

CHAPTER 32 • New

Smoke barriers are required in new, large residential board and care facilities due to the potential for residents who might not be able to be readily evacuated to the outside. The smoke barrier provisions of 32.3.3.7 are nearly identical to those for health care occupancies, which also use the “defend in place” protection strategy for occupants. See 18.3.7 and its associated commentary for additional details.

The smoke barrier required by 33.3.3.7 for non-sprinklered existing facilities provides for horizontal movement of occupants and limits the number of rooms and, therefore, the number of occupants, exposed to a single fire that might block a corridor. Because no fire rating is required for the barrier, and because smoke dampers are not required, the provision of smoke barriers is not overly burdensome.

32.3.3.8* Cooking Facilities. Cooking facilities, other than those within individual residential units, shall be protected in accordance with 9.2.3.

A.32.3.3.8 The scope of NFPA 96 is limited to appliances that produce grease-laden vapors, and not to domestic cooking equipment used for food warming or limited cooking.

32.3.3.9 Standpipes.

32.3.3.9.1 General. Where required, standpipe and hose systems shall be installed and maintained in accordance with 9.7.4.2.

32.3.3.9.2 In High-Rise Buildings. Class I standpipe systems shall be installed throughout all high-rise buildings.

32.3.3.9.3 Roof Outlets. Roof outlets shall not be required on roofs having a slope of 3 in 12 or greater.

32.3.4 Special Provisions.

(Reserved)

32.3.5 Reserved.

32.3.6 Building Services.

32.3.6.1 Utilities. Utilities shall comply with Section 9.1.

32.3.6.2 Heating, Ventilating, and Air Conditioning.

32.3.6.2.1 Heating, ventilating, and air conditioning equipment shall comply with Section 9.2.

CHAPTER 33 • Existing

A horizontal exit is permitted to be used to comply with 33.3.3.7 and, therefore, might serve more than one function. In addition, the smoke compartment is permitted to be considered a point of safety for the purpose of determining evacuation capability under the following conditions:

- (1) The smoke barrier has at least a ½-hour fire-resistance rating.
- (2) Protection is provided by an automatic sprinkler system throughout the building.
- (3) The smoke compartment has access to an exit that does not require return to the fire area. See the definition of *point of safety* in 3.3.168.

33.3.4 Special Provisions.

(Reserved)

33.3.5 Reserved.

33.3.6 Building Services.

33.3.6.1 Utilities. Utilities shall comply with the provisions of Section 9.1.

33.3.6.2 Heating, Ventilating, and Air Conditioning.

33.3.6.2.1 Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

CHAPTER 32 • New

32.3.6.2.2 No stove or combustion heater shall be located such that it blocks escape in case of fire caused by the malfunction of the stove or heater.

32.3.6.2.3 Unvented fuel-fired heaters shall not be used in any board and care occupancy.

32.3.6.3 Elevators, Dumbwaiters, and Vertical Conveyors.

32.3.6.3.1 Elevators, dumbwaiters, and vertical conveyors shall comply with Section 9.4.

32.3.6.3.2* In high-rise buildings, one elevator shall be provided with a protected power supply and shall be available for use by the fire department in case of emergency.

A.32.3.6.3.2 “Protected power supply” means a source of electrical energy of sufficient capacity to allow proper operation of the elevator and its associated control and communications systems. The power supply’s point of origin, system of distribution, type and size of overcurrent protection, degree of isolation from other portions of the building electrical system, and degree of mechanical protection should be such that it is unlikely that the supply would be disrupted at any but the advanced stages of building fire involvement or by structural collapse.

A protected power supply might consist of, and should provide, not less than the level of reliability associated with an electrical distribution system with service equipment located and installed in accordance with 230.72(B) and 230.82(5) of NFPA 70, *National Electrical Code*[®]. The distribution system is not to have any other connection to the building electrical distribution system. A protected power supply is not required to incorporate two sources of energy or automatic transfer capability from a normal to an emergency source, for example, an alternate set of service conductors.

The number and type of elevators to be connected to a protected power supply should be limited, or the characteristics of the protected power supply should be selected to ensure conformance with 230.95 of NFPA 70, *National Electrical Code*[®], without the provision of ground fault protection for the supply.

An elevator installation supplied by a protected power supply should comply with Article 620 of NFPA 70, *National Electrical Code*[®], except that the energy absorption means required by 620.91 should always be connected on the load side of the disconnecting means. The energy absorption means should not consist of loads likely to become inoperative or disconnected under the conditions assumed to exist when the elevator is under the control of fire department personnel. Examples of such loads include light and power loads external to the elevator equipment room.

CHAPTER 33 • Existing

33.3.6.2.2 No stove or combustion heater shall be located such that it blocks escape in case of fire caused by the malfunction of the stove or heater.

33.3.6.2.3 Unvented fuel-fired heaters shall not be used in any board and care occupancy.

33.3.6.3 Elevators, Dumbwaiters, and Vertical Conveyors. Elevators, dumbwaiters, and vertical conveyors shall comply with the provisions of Section 9.4.

CHAPTER 32 • New

32.3.6.4 Rubbish Chutes, Incinerators, and Laundry Chutes. Rubbish chutes, incinerators, and laundry chutes shall comply with Section 9.5.

Section 32.4* Suitability of an Apartment Building to House a Board and Care Occupancy

A.32.4 Board and care occupancies in apartment buildings will usually be small facilities housing 16 or fewer residents. It is intended that the board and care occupancy conform to the requirements of Section 32.2 for small board and care facilities. In the unusual case where an apartment houses a large board and care facility, it would be reasonable for the authority having jurisdiction, using 4.6.1, to apply the provisions of Section 32.3 to the apartment. In addition, the apartment building in which the facility is housed needs to comply with the requirements for apartment buildings in Chapter 30 and Chapter 31 and the additional criteria presented in Section 32.4.

A board and care facility located within an apartment building is usually a small facility housing 16 or fewer residents. It is intended that the board and care facility within the apartment building conform to the requirements of Section 32/33.2 for small board and care facilities. In the unusual case where an apartment building houses a large board and care facility,

32.4.1 General.

32.4.1.1 Scope.

32.4.1.1.1 Section 32.4 shall apply to apartment buildings that have one or more individual apartments used as a board and care occupancy.

32.4.1.1.2 Section 32.4 determines the suitability of such buildings, other than those complying with 32.4.1.1.4, to house a residential board and care facility.

32.4.1.1.3 The suitability of such buildings for apartments not used for board and care occupancies is covered in Chapter 30.

32.4.1.1.4 If a new board and care occupancy is created in an existing apartment building, the suitability of such buildings for apartments not used for board and care occupancies shall be covered by Chapter 31.

CHAPTER 33 • Existing

33.3.6.4 Rubbish Chutes, Incinerators, and Laundry Chutes. Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 33.4* Suitability of an Apartment Building to House a Board and Care Occupancy

A.33.4 Board and care occupancies in apartment buildings will usually be small facilities housing 16 or fewer residents. It is intended that the board and care occupancy conform to the requirements of Section 33.2 for small board and care facilities. In the unusual case where an apartment houses a large board and care facility, it would be reasonable for the authority having jurisdiction, using 4.6.1, to apply the provisions of Section 33.3 to the apartment. In addition, the apartment building in which the facility is housed needs to comply with the requirements for apartment buildings in Chapters 30 and 31 and the additional criteria presented in Section 33.4.

it is reasonable for the authority having jurisdiction, in accordance with Section 1.4, to apply the provisions of Section 32/33.3 to the apartment unit. In addition, the apartment building in which the facility is housed is required to comply with the requirements for apartment buildings in Chapters 30 and 31 and the additional criteria provided in Section 32/33.4.

33.4.1 General.

33.4.1.1 Scope.

33.4.1.1.1 Section 33.4 shall apply to apartment buildings that have one or more individual apartments used as a board and care occupancy.

33.4.1.1.2 Section 33.4 determines the suitability of such buildings to house a residential board and care facility.

33.4.1.1.3 The suitability of such buildings for apartments not used for board and care occupancies is covered in Chapter 31.

CHAPTER 32 • New

32.4.1.2 Requirements for individual apartments used as residential board and care occupancies shall be as specified in Section 32.2. Egress from the apartment into the common building corridor shall be considered acceptable egress from the board and care facility.

32.4.1.3* Apartment buildings housing board and care facilities shall comply with the requirements of Chapter 30 and the additional requirements of Section 32.4, unless the authority having jurisdiction has determined that equivalent safety for housing a residential board and care facility is provided in accordance with Section 1.5.

A.32.4.1.3 In determining equivalency for conversions, modernizations, renovations, or unusual design concepts, the authority having jurisdiction might permit evaluations based on the residential board and care occupancies fire safety evaluation system (FSES) in NFPA 101A, *Guide on Alternative Approaches to Life Safety*.

32.4.1.4 Minimum Construction Requirements.

32.4.1.4.1 In addition to the requirements of Chapter 30, apartment buildings, other than those complying with 32.4.1.4.2, housing residential board and care facilities shall meet the construction requirements of 32.3.1.3.

32.4.1.4.2 If a new board and care occupancy is created in an existing apartment building, the construction requirements of 19.1.6 shall apply.

32.4.2 Means of Egress.

32.4.2.1 The requirements of Section 30.2 shall apply only to the parts of means of egress serving the apartment(s) used as a residential board and care occupancy, as modified by 32.4.2.2.

32.4.2.2 If a new board and care occupancy is created in an existing apartment building, the requirements of Section 31.2 shall apply to the parts of the means of egress serving the apartment(s) used as a residential board and care occupancy.

32.4.3 Protection.

32.4.3.1 Interior Finish.

CHAPTER 33 • Existing

33.4.1.2 Requirements for individual apartments used as residential board and care occupancies shall be as specified in Section 33.2. Egress from the apartment into the common building corridor shall be considered acceptable egress from the board and care facility.

33.4.1.3 Requirements Based on Evacuation Capability.

33.4.1.3.1* Apartment buildings housing board and care facilities shall comply with the requirements of Section 33.4, unless the authority having jurisdiction has determined that equivalent safety for housing a residential board and care facility is provided in accordance with Section 1.4.

A.33.4.1.3.1 In determining equivalency for existing buildings, conversions, modernizations, renovations, or unusual design concepts, the authority having jurisdiction might permit evaluations based on the residential board and care occupancies fire safety evaluation system (FSES) in NFPA 101A, *Guide on Alternative Approaches to Life Safety*.

33.4.1.3.2 All facilities shall meet the requirements of Chapter 31 and the additional requirements of Section 33.4.

33.4.1.4 Minimum Construction Requirements.

33.4.1.4.1 In addition to the requirements of Chapter 31, apartment buildings housing residential board and care facilities for groups classified as prompt or slow evacuation capability shall meet the construction requirements of 33.3.1.3, and those for groups classified as impractical evacuation capability shall meet the construction requirements of 19.1.6.

33.4.1.4.2 In applying the construction requirements of 33.4.1.4.1, the height shall be determined by the height of the residential board and care facility measured above the primary level of exit discharge.

33.4.2 Means of Egress.

The requirements of Section 31.2 shall apply only to the parts of means of egress serving the apartment(s) used as a residential board and care occupancy.

33.4.3 Protection.

33.4.3.1 Interior Finish. The requirements of 31.3.3 shall apply only to the parts of means of egress serving the apartment(s) used as a residential board and care occupancy.

CHAPTER 32 • New

32.4.3.1.1 The requirements of 30.3.3 shall apply only to the parts of means of egress serving the apartment(s) used as a residential board and care occupancy, as modified by 32.4.3.1.2.

32.4.3.1.2 If a new board and care occupancy is created in an existing apartment building, the requirements of 31.3.3 shall apply to the parts of the means of egress serving the apartment(s) used as a residential board and care occupancy.

32.4.3.2 Construction of Corridor Walls.

32.4.3.2.1 The requirements of 30.3.6 shall apply only to corridors serving the residential board and care facility, including that portion of the corridor wall separating the residential board and care facility from the common corridor, as modified by 32.4.3.2.1.

32.4.3.2.2 If a new board and care occupancy is created in an existing apartment building, the requirements of 31.3.6 shall apply to the corridor serving the residential board and care facility.

32.4.3.3 Subdivision of Building Spaces. (Reserved)

Section 32.5 Reserved

Section 32.6 Reserved

Section 32.7 Operating Features

32.7.1 Emergency Plan.

32.7.1.1 The administration of every residential board and care facility shall have, in effect and available to all supervisory personnel, written copies of a plan for protecting all persons in the event of fire, for keeping persons in place, for evacuating persons to areas of refuge, and for evacuating persons from the building when necessary.

32.7.1.2 The emergency plan shall include special staff response, including the fire protection procedures needed to ensure the safety of any resident, and shall be amended or revised whenever any resident with unusual needs is admitted to the home.

CHAPTER 33 • Existing

33.4.3.2 Construction of Corridor Walls. The requirements of 31.3.6 shall apply only to corridors serving the residential board and care facility, including that portion of the corridor wall separating the residential board and care facility from the common corridor.

33.4.3.3 Subdivision of Building Spaces. The requirements of 31.3.7 shall apply to those stories with an apartment(s) used as a residential board and care occupancy.

Section 33.5 Reserved

Section 33.6 Reserved

Section 33.7 Operating Features

33.7.1 Emergency Plan.

33.7.1.1 The administration of every residential board and care facility shall have, in effect and available to all supervisory personnel, written copies of a plan for protecting all persons in the event of fire, for keeping persons in place, for evacuating persons to areas of refuge, and for evacuating persons from the building when necessary.

33.7.1.2 The emergency plan shall include special staff response, including the fire protection procedures needed to ensure the safety of any resident, and shall be amended or revised whenever any resident with unusual needs is admitted to the home.

CHAPTER 32 • New

32.7.1.3 All employees shall be periodically instructed and kept informed with respect to their duties and responsibilities under the plan, and such instruction shall be reviewed by the staff not less than every 2 months.

32.7.1.4 A copy of the plan shall be readily available at all times within the facility.

32.7.2 Resident Training.

32.7.2.1 All residents participating in the emergency plan shall be trained in the proper actions to be taken in the event of fire.

32.7.2.2 The training required by 32.7.2.1 shall include actions to be taken if the primary escape route is blocked.

32.7.2.3 If a resident is given rehabilitation or habilitation training, training in fire prevention and the actions to be taken in the event of a fire shall be a part of the training program.

32.7.2.4 Residents shall be trained to assist each other in case of fire to the extent that their physical and mental abilities permit them to do so without additional personal risk.

32.7.3 Emergency Egress and Relocation Drills.

Emergency egress and relocation drills shall be conducted in accordance with 32.7.3.1 through 32.7.3.6.

32.7.3.1 Emergency egress and relocation drills shall be conducted not less than six times per year on a bimonthly basis, with not less than two drills conducted during the night when residents are sleeping, as modified by 32.7.3.5 and 32.7.3.6.

32.7.3.2 The drills shall be permitted to be announced in advance to the residents.

32.7.3.3 The drills shall involve the actual evacuation of all residents to an assembly point as specified in the emergency plan and shall provide residents with experience in egressing through all exits and means of escape required by the *Code*.

32.7.3.4 Exits and means of escape not used in any drill shall not be credited in meeting the requirements of this *Code* for board and care facilities.

32.7.3.5 Actual exiting from windows shall not be required to comply with 32.7.3; opening the window and signaling for help shall be an acceptable alternative.

32.7.3.6 If the board and care facility has an evacuation capability classification of impractical, those residents who

CHAPTER 33 • Existing

33.7.1.3 All employees shall be periodically instructed and kept informed with respect to their duties and responsibilities under the plan, and such instruction shall be reviewed by the staff not less than every 2 months.

33.7.1.4 A copy of the plan shall be readily available at all times within the facility.

33.7.2 Resident Training.

33.7.2.1 All residents participating in the emergency plan shall be trained in the proper actions to be taken in the event of fire.

33.7.2.2 The training required by 33.7.2.1 shall include actions to be taken if the primary escape route is blocked.

33.7.2.3 If the resident is given rehabilitation or habilitation training, training in fire prevention and the actions to be taken in the event of a fire shall be a part of the training program.

33.7.2.4 Residents shall be trained to assist each other in case of fire to the extent that their physical and mental abilities permit them to do so without additional personal risk.

33.7.3 Emergency Egress and Relocation Drills.

Emergency egress and relocation drills shall be conducted in accordance with 33.7.3.1 through 33.7.3.6.

33.7.3.1 Emergency egress and relocation drills shall be conducted not less than six times per year on a bimonthly basis, with not less than two drills conducted during the night when residents are sleeping, as modified by 33.7.3.5 and 33.7.3.6.

33.7.3.2 The emergency drills shall be permitted to be announced in advance to the residents.

33.7.3.3 The drills shall involve the actual evacuation of all residents to an assembly point as specified in the emergency plan and shall provide residents with experience in egressing through all exits and means of escape required by this *Code*.

33.7.3.4 Exits and means of escape not used in any drill shall not be credited in meeting the requirements of this *Code* for board and care facilities.

33.7.3.5 Actual exiting from windows shall not be required to comply with 33.7.3; opening the window and signaling for help shall be an acceptable alternative.

33.7.3.6 If the board and care facility has an evacuation capability classification of impractical, those residents who

CHAPTER 32 • New

cannot meaningfully assist in their own evacuation or who have special health problems shall not be required to actively participate in the drill. Section 18.7 shall apply in such instances.

32.7.4 Smoking.

32.7.4.1* Smoking regulations shall be adopted by the administration of board and care occupancies.

A.32.7.4.1 Smoking regulations should include the following:

- (1) Smoking should be prohibited in any room, compartment, or area where flammable or combustible liquids, combustible gases, or oxygen is used or stored and in any other hazardous location. Such areas should be posted with signs that read NO SMOKING or the international symbol for no smoking. In residential board and care facilities where smoking is totally prohibited and signs so indicating are placed at all major entrances, secondary signs with language that prohibits smoking are not required.
- (2) Smoking by residents classified as not responsible with regard to their ability to safely use and dispose of smoking materials should be prohibited. Where the resident is under direct supervision by staff or by a person approved by the administration, smoking might be permitted.
- (3) Smoking materials should not be provided to residents or maintained by residents without the approval of the administration.
- (4) Areas where smoking is permitted should be clearly identified.
- (5) Ashtrays of noncombustible material and safe design should be provided and required to be used in all areas where smoking is permitted.
- (6) Self-closing cover devices into which ashtrays can be emptied should be made available to all areas where smoking is permitted and should be required to be used.

32.7.4.2 Where smoking is permitted, noncombustible safety-type ashtrays or receptacles shall be provided in convenient locations.

32.7.5* Furnishings, Bedding, and Decorations.

A.32.7.5 The requirements applicable to draperies/curtains, upholstered furniture, and mattresses apply only to new draperies/curtains, new upholstered furniture, and new mattresses. The word *new* means unused, normally via procurement from the marketplace, either by purchase or donation, of items not previously used. Many board and care

CHAPTER 33 • Existing

cannot meaningfully assist in their own evacuation or who have special health problems shall not be required to actively participate in the drill. Section 19.7 shall apply in such instances.

33.7.4 Smoking.

33.7.4.1* Smoking regulations shall be adopted by the administration of board and care occupancies.

A.33.7.4.1 Smoking regulations should include the following:

- (1) Smoking should be prohibited in any room, compartment or area where flammable or combustible liquids, combustible gases, or oxygen is used or stored and in any other hazardous location. Such areas should be posted with signs that read NO SMOKING or the international symbol for no smoking. In residential board and care facilities where smoking is totally prohibited and signs so indicating are placed at all major entrances, secondary signs with language that prohibits smoking are not required.
- (2) Smoking by residents classified as not responsible with regard to their ability to safely use and dispose of smoking materials should be prohibited. Where the resident is under direct supervision by staff or by a person approved by the administration, smoking might be permitted.
- (3) Smoking materials should not be provided to residents or maintained by residents without the approval of the administration.
- (4) Areas where smoking is permitted should be clearly identified.
- (5) Ashtrays of noncombustible material and safe design should be provided and required to be used in all areas where smoking is permitted.
- (6) Self-closing cover devices into which ashtrays can be emptied should be made available to all areas where smoking is permitted and should be required to be used.

33.7.4.2 Where smoking is permitted, noncombustible safety-type ashtrays or receptacles shall be provided in convenient locations.

33.7.5* Furnishings, Bedding, and Decorations.

A.33.7.5 The requirements applicable to draperies/curtains, upholstered furniture, and mattresses apply only to new draperies/curtains, new upholstered furniture, and new mattresses. The word *new* means unused, normally via procurement from the marketplace, either by purchase or donation, of items not previously used. Many board and care

CHAPTER 32 • New

facilities allow residents to bring into the board and care home upholstered furniture items from the resident's previous residence. Such an item is not new and, thus, is not regulated. On the other hand, some of the larger board and care homes purchase contract furniture, as is done in hotels. Such new, unused furniture, whether purchased or received as a donation, is regulated by the requirements of 32.7.5.2. By federal law, mattresses manufactured and sold within the United States must pass testing per FF4-72, *Standard for the Flammability of Mattresses*.

32.7.5.1 New draperies, curtains, and other similar loosely hanging furnishings and decorations in board and care facilities shall be in accordance with the provisions of 10.3.1.

32.7.5.2* New upholstered furniture within board and care facilities shall comply with 32.7.5.2.1 or 32.7.5.2.2.

A.32.7.5.2 New upholstered furniture within board and care homes should be tested for rates of heat release in accordance with 10.3.3.

32.7.5.2.1 New upholstered furniture shall be tested in accordance with the provisions of 10.3.2(1) and 10.3.3.

32.7.5.2.2 Upholstered furniture belonging to residents in sleeping rooms shall not be required to be tested, provided that a smoke alarm is installed in such rooms; battery-powered single-station smoke alarms shall be permitted in such rooms.

32.7.5.3* New mattresses within board and care facilities shall comply with 32.7.5.3.1 or 32.7.5.3.2.

A.32.7.5.3 New mattresses within board and care homes should be tested for rates of heat release in accordance with 10.3.4.

32.7.5.3.1 New upholstered furniture shall be tested in accordance with the provisions of 10.3.2(3) and 10.3.4.

32.7.5.3.2 Mattresses belonging to residents in sleeping rooms shall not be required to be tested, provided that a smoke alarm is installed in such rooms; battery-powered single-station smoke alarms shall be permitted in such rooms.

The provisions of 32/33.7.5 extend the level of life safety provided to a residential board and care facility by further attempting to prevent room flashover. However, rather than impose these requirements retroactively on existing facilities, the requirement ap-

CHAPTER 33 • Existing

facilities allow residents to bring into the board and care home upholstered furniture items from the resident's previous residence. Such an item is not new and, thus, is not regulated. On the other hand, some of the larger board and care homes purchase contract furniture, as is done in hotels. Such new, unused furniture, whether purchased or received as a donation, is regulated by the requirements of 33.7.5.2. By federal law, mattresses manufactured and sold within the United States must pass testing per FF4-72, *Standard for the Flammability of Mattresses*.

33.7.5.1 New draperies, curtains, and other similar loosely hanging furnishings and decorations in board and care facilities shall be in accordance with the provisions of 10.3.1.

33.7.5.2* New upholstered furniture within board and care facilities shall comply with 33.7.5.2.1 or 33.7.5.2.2.

A.33.7.5.2 New upholstered furniture within board and care homes should be tested for rates of heat release in accordance with 10.3.3.

33.7.5.2.1 New upholstered furniture shall be tested in accordance with the provisions of 10.3.2(1) and 10.3.3.

33.7.5.2.2 Upholstered furniture belonging to the residents in sleeping rooms shall not be required to be tested, provided that a smoke alarm is installed in such rooms; battery-powered single-station smoke alarms shall be permitted in such rooms.

33.7.5.3* New mattresses within board and care facilities shall comply with 33.7.5.3.1 or 33.7.5.3.2.

A.33.7.5.3 New mattresses within board and care homes should be tested for rates of heat release in accordance with 10.3.4.

33.7.5.3.1 New mattresses shall be tested in accordance with the provisions of 10.3.2(3) and 10.3.4.

33.7.5.3.2 Mattresses belonging to the residents in sleeping rooms shall not be required to be tested, provided that a smoke alarm is installed in such rooms; battery-powered single-station smoke alarms shall be permitted in such rooms.

plies to new upholstered furniture and mattresses. The annex note sufficiently details the meaning of the term *new* in this context. Where the annex note references testing in accordance with FF4-72, *Standard for the Flammability of Mattresses*⁶, such testing is the

CHAPTERS 36 and 37

New and Existing Mercantile Occupancies

Mercantile occupancies include stores, markets, and other rooms, buildings, or structures used for the display and sale of merchandise. This occupancy group includes the following:

- (1) Supermarkets
- (2) 24-hour convenience stores
- (3) Department stores
- (4) Hardware stores
- (5) Video sale rental stores
- (6) Drugstores
- (7) Rental equipment centers
- (8) Automobile sales showrooms
- (9) Flea markets and craft centers
- (10) Building materials/supplies centers
- (11) Shopping centers/malls

Minor merchandising operations in buildings that house other predominant occupancies, such as a newsstand in an office building, are typically classified as incidental uses and must, therefore, meet the *Code* requirements of the predominant occupancy (see 6.1.14.1.2).

The life safety provisions for mercantile occupancies are based on their characteristic of displaying merchandise for sales purposes, which introduces significant quantities of fuel in sales areas occupied by persons who are mostly unfamiliar with the building. Mercantile occupancies are also characterized by the use of layouts of merchandise displays and store fixtures that can confuse the egress path. Fires in department stores, mall buildings, and similar mercantile occupancies that resulted in occupant fatalities were practically unheard of in the United States in the 1990s. While some serious fires have occurred in such properties, the established *Code* provisions

have served the life safety needs of the occupants very well.

As marketing techniques change to meet consumer demands—beginning in the 1960s when the first covered shopping malls were built—store design and layout also change. Consumers are offered choices that include everything from one-stop shopping to unique specialty stores. As the hypermarket, or big-box store, concept became popular in the early 1980s, the general public found itself shopping in warehouse-type surroundings. The *Code* provisions that apply to mercantile occupancies have recognized these new challenges to providing adequate life safety via a combination of flexible general requirements and specialized provisions such as those contained in 36/37.4.4 for mall buildings and 36/37.4.5 for bulk merchandising retail buildings.

The life safety measures needed for mercantile occupancies are as diverse as the types of mercantile facilities. While the nature of the actual store design—as well as the merchandise that is found in the stores—drives much of the *Code* criteria, the ongoing need to prevent the theft of merchandise also affects the protection requirements.

The features of a mercantile occupancy that determine the needed protection include the items for sale, the location of the areas occupied by the public with respect to the level of exit discharge, and the size (that is, gross area) of the facility. Guidance on establishing the appropriate subclassification for mercantile occupancies is provided by 36/37.1.4.2.

Establishing and controlling the widths of aisles that lead to exits is an important consideration. As an example, 36/37.2.5.5 establishes minimum widths, which are based on the clear width to prevent boxed

CHAPTER 36 • New

or loose merchandise from obstructing the egress path. In certain larger stores, minimum 1525-mm (60-in.) aisles might be the norm, to accommodate shopping carts as well as large numbers of occupants.

Automatic sprinkler protection and a manual fire alarm system complement the major features of the protection package for the larger Class A stores. One of the more popular options for notification of the occupants is through the use of a voice communication system as permitted in 36/37.3.4.3.1. Voice communication systems permit specific instructions to be given to the occupants if a fire occurs.

The requirements for bulk merchandising retail buildings found in 36/37.4.5 were added to the *Code* in the 1997 edition. This subsection establishes criteria that meet the special needs of such stores. The typical bulk merchandising retail store includes dis-

CHAPTER 37 • Existing

play and storage racks that are often more than 6100 mm (240 in.) high. Display merchandise is typically maintained at the lower levels, while the excess inventory of merchandise is stored on the upper tiers of the rack systems. In such cases, the range of materials in the occupancies is extensive and can include building materials, paint, electrical equipment, and indoor/outdoor power equipment and appliances. In some cases, the store inventory might consist of foodstuffs as well as household goods. Due to the cross-over nature of such occupancies—which are part warehouse and part store—36/37.4.5.2 and 36/37.4.5.3 establish requirements for providing the egress measures needed for an occupancy with a large occupant load and the fire protection measures needed for a warehouse.

Section 36.1 General Requirements

36.1.1 Application.

36.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as mercantile occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, a mercantile occupancy (*see 4.6.7 and 36.1.1.3*)
- (3) Alterations, modernizations, or renovations of existing mercantile occupancies (*see 4.6.8*)
- (4) Existing buildings or portions thereof upon change of occupancy to a mercantile occupancy (*see 4.6.12*)

36.1.1.2 This chapter establishes life safety requirements for all new mercantile buildings. Specific requirements for suboccupancy groups such as Class A, Class B, and Class C mercantile occupancies; covered malls; and bulk merchandising retail buildings are contained in paragraphs pertaining thereto.

36.1.1.3 Additions to existing buildings shall comply with 36.1.1.3.1, 36.1.1.3.2, and 36.1.1.3.3.

36.1.1.3.1 Additions to existing buildings shall conform to the requirements for new construction.

36.1.1.3.2 Existing portions of the structure are not required to be modified, provided that the new construction has not diminished the fire safety features of the facility.

Section 37.1 General Requirements

37.1.1 Application.

37.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as mercantile occupancies. (*See also 36.1.1.1.*)

37.1.1.2 This chapter establishes life safety requirements for all existing mercantile buildings. Specific requirements for suboccupancy groups such as Class A, Class B, and Class C mercantile occupancies; covered malls; and bulk merchandising retail buildings are contained in paragraphs pertaining thereto.

37.1.1.3 Additions to existing buildings shall comply with 37.1.1.3.1, 37.1.1.3.2, and 37.1.1.3.3.

37.1.1.3.1 Additions to existing buildings shall conform to the requirements for new construction.

37.1.1.3.2 Existing portions of the structure are not required to be modified, provided that the new construction has not diminished the fire safety features of the facility.

CHAPTER 36 • New

36.1.1.3.3 Existing portions shall be upgraded if the addition results in a change of mercantile subclassification. (See 36.1.4.2.)

36.1.1.4 When a mercantile occupancy changes from Class C to Class A or Class B, or from Class B to Class A, the provisions of this chapter shall apply.

To understand the full intent and scope of 37.1.1.1, it is necessary to review it concurrently with 1.3.1 and Section 1.4. Although a building code might permit existing buildings to be excluded from coverage under some form of a grandfather clause, the *Life Safety Code*, by virtue of its interest in safety to life, requires that existing building arrangements comply with the *Code* requirements that apply to existing buildings. The requirements applicable to existing mercantile occupancies are contained in Chapter 37.

If a building complies with an earlier edition of the *Code*, it is not grandfathered and, thereby, exempted from compliance with a more current edition that has been adopted as law in the building's jurisdiction. The committees on safety to life are especially careful to avoid adopting requirements for existing buildings that become more stringent from one edition of the *Code* to the next, unless the change is absolutely necessary to meet the level of safety to life intended. Thus, the old adage of "once in compliance, always in compliance" does not hold.

Commentary Table 36/37.1 summarizes the definitions of Class A, Class B, and Class C mercantile occupancies presented in 36/37.1.4.2.1 and further explained in its associated commentary.

Additions to existing mercantile occupancies must conform to the requirements for new construction in accordance with 36/37.1.1.3. However, the existing portion of the occupancy generally is permitted to continue in use if it complies with the provisions of Chapter 37. However, if the addition results in a change in the mercantile occupancy subclassification (see 36/37.1.4.2)—such as a change from Class C to Class B or from Class B to Class A—the existing portion of the enlarged, overall facility must be upgraded to meet the provisions that apply to new construction.

CHAPTER 37 • Existing

37.1.1.3.3 Existing portions shall be upgraded if the addition results in a change of mercantile subclassification. (See 37.1.4.2.)

37.1.1.4 When a change in mercantile occupancy sub-classification occurs, the following requirements shall be met:

- (1) When a mercantile occupancy changes from Class A to Class B or Class C, or from Class B to Class C, the provisions of this chapter shall apply.
- (2) When a mercantile occupancy changes from Class C to Class A or Class B, or from Class B to Class A, the provisions of Chapter 36 shall apply.

Commentary Table 36/37.1 Subclassification of Mercantile Occupancies

Store Class	Height	Aggregate Gross Area ¹ m ² (ft ²)
A	>3 Stories ²	>2800 (>30,000)
B	≤3 Stories ²	>280 (>3,000) and ≤2800 (≤30,000)
C	One story only ³	≤280 (≤3,000)

¹Sections of floors not used for sales purposes are not counted in the area classification.
²Stories not used for sales above or below sales floor are not counted in the height classification.
³A mezzanine ≤¹/₃ the area (new) or ≤¹/₂ the area (existing) of the floor below is permitted (see 8.6.9 and 36/37.1.4.2.3).

The provisions of 36/37.1.1.3 are illustrated in the following paragraphs and in Exhibit 36/37.1.

In Exhibit 36/37.1, illustration (a), the new construction, which includes 930 m² (10,000 ft²) of additional sales area and approximately 186 m² (2000 ft²) of new storage area, is added to an existing Class B mercantile occupancy with 465 m² (5000 ft²) of existing sales area. The size and placement of the new addition neither change the Class B mercantile subclassification of the enlarged overall facility nor diminish the fire safety features of the existing portion of the facility. Therefore, the addition is constructed in accordance with the requirements of Chapter 36 and the existing portion of the building is allowed to continue to be used, without upgrade, if it meets the requirements of Chapter 37. If the existing portion of the building does not meet the requirements of Chapter 37, it must be upgraded to meet those requirements.

Exhibit 36/37.1, illustration (b), depicts new con-

CHAPTER 36 • New

CHAPTER 37 • Existing

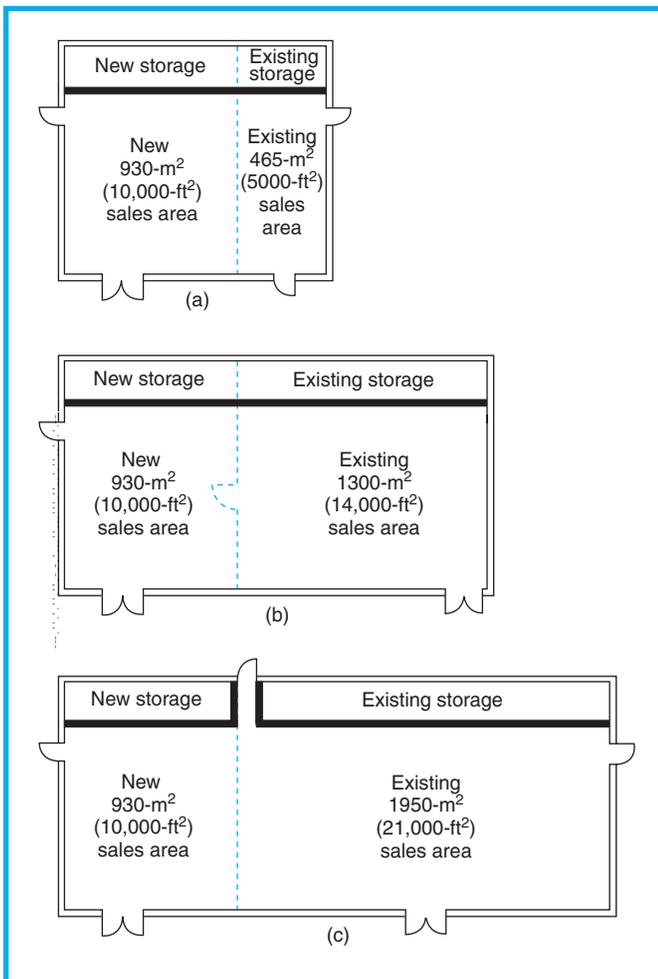

Exhibit 36/37.1 Additions to existing mercantile occupancies.

struction, identical to that of illustration (a), that is added to an existing Class B mercantile occupancy with 1300 m² (14,000 ft²) of existing sales area. Al-

though the size of the addition does not change the Class B mercantile subclassification of the overall facility, the placement of the new addition appears to have diminished the fire safety of the existing portion of the building with respect to travel distance. The broken line in illustration (b) represents what had been an exterior wall and exit door in the existing mercantile occupancy prior to construction of the addition. The door allowed occupants in the upper left portion of the existing building to reach an exit within the allowable 46-m (150-ft) travel distance specified for existing nonsprinklered mercantile occupancies in accordance with 37.2.6.2. Without the exit door, occupants of the existing portion of the building must be able to reach an exit—one of the three doors in the perimeter of the enlarged facility—within the same 46-m (150-ft) travel distance limitation. If this is not possible, an additional exit within that distance must be constructed, or the building must be sprinklered to increase the allowable travel distance to 76 m (250 ft). Because the new construction must meet the provisions of Chapter 36, the entire building—new and existing portions—must be sprinklered in accordance with 36.3.5.1, because the building exceeds 1115 m² (12,000 ft²) in gross area [see 36.3.5.1(2)].

Exhibit 36/37.1, illustration (c), depicts new construction, identical to that of illustrations (a) and (b), that is added to an existing Class B mercantile occupancy with 1950 m² (21,000 ft²) of existing sales area. The size of the new sales area, when added to that of the existing mercantile occupancy, exceeds 2800 m² (30,000 ft²) and results in a change in mercantile subclassification from Class B to Class A [see 36/37.1.4.2.1(1)]. In accordance with the provisions of 36/37.1.1.3 and the clarification of intent offered in 36/37.1.1.4, the entire building—new and existing portions—must meet the requirements for new mercantile occupancies as detailed in Chapter 36.

36.1.2 Multiple Occupancies.

36.1.2.1 General.

36.1.2.1.1 All multiple occupancies shall be in accordance with 6.1.14 and 36.1.2.

36.1.2.1.2 Where there are differences in the specific requirements in this chapter and provisions for mixed occupancies or separated occupancies as specified in 6.1.14.3 and 6.1.14.4, the requirements of this chapter shall apply.

37.1.2 Multiple Occupancies.

37.1.2.1 General.

37.1.2.1.1 All multiple occupancies shall be in accordance with 6.1.14 and 37.1.2.

37.1.2.1.2 Where there are differences in the specific requirements in this chapter and provisions for mixed occupancies or separated occupancies as specified in 6.1.14.3 and 6.1.14.4, the requirements of this chapter shall apply.

CHAPTER 36 • New

36.1.2.2 Combined Mercantile Occupancies and Parking Structures.

36.1.2.2.1 The fire barrier separating parking structures from a building classified as a mercantile occupancy shall be a fire barrier having a fire resistance rating of not less than 2 hours.

36.1.2.2.2 Openings in the fire barrier required by 36.1.2.2.1 shall not be required to be protected with fire protection-rated opening protectives in enclosed parking structures that are protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), or in open parking structures, provided all of the following conditions are met:

- (1) The openings do not exceed 25 percent of the area of the fire barrier in which they are located.
- (2) The openings are used as a public entrance and for associated sidelight functions.
- (3) The building containing the mercantile occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).
- (4)* Means are provided to prevent spilled fuel from accumulating adjacent to the openings and entering the building.

A.36.1.2.2.2(4) Means to prevent spilled fuel from accumulating and entering the mercantile occupancy building can be by curbs, scuppers, special drainage systems, sloping the floor away from the door openings, or floor elevation differences of not less than 102 mm (4 in.).

- (5) Physical means are provided to prevent vehicles from being parked or driven within 3050 mm (120 in.) of the openings.
- (6) The openings are protected as a smoke partition in accordance with Section 8.4 with no minimum fire protection rating required.

The provisions of 36/37.1.2.2 address combined mercantile occupancies and parking structures and are very similar to the requirements of 38/39.1.2.2, which address combined business occupancies and parking structures. It is common for multistory mercantile occupancies (such as department stores and shopping mall buildings) and multistory business occupancies (such as office buildings) to be attached to multistory parking garages. Such garages provide access to the mercantile or business occupancy at multiple levels. To allow flexibility in the number and type of openings and in the degree of stringency

CHAPTER 37 • Existing

37.1.2.2 Combined Mercantile Occupancies and Parking Structures.

37.1.2.2.1 The fire barrier separating parking structures from a building classified as a mercantile occupancy shall be a fire barrier having a fire resistance rating of not less than 2 hours.

37.1.2.2.2 Openings in the fire barrier required by 37.1.2.2.1 shall not be required to be protected with fire protection-rated opening protectives in enclosed parking structures that are protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), or in open parking structures, provided all of the following conditions are met:

- (1) The openings do not exceed 25 percent of the area of the fire barrier in which they are located.
- (2) The openings are used as a public entrance and for associated sidelight functions.
- (3) The building containing the mercantile occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).
- (4)* Means provided to prevent spilled fuel from accumulating adjacent to the openings and entering the building.

A.37.1.2.2.2(4) Means to prevent spilled fuel from accumulating and entering the mercantile occupancy building can be by curbs, scuppers, special drainage systems, sloping the floor away from the door openings, or elevation differences of not less than 102 mm (4 in.).

- (5) Physical means are provided to prevent vehicles from being parked or driven within 3050 mm (120 in.) of the openings.
- (6) The openings are protected as a smoke partition in accordance with Section 8.4 and with no minimum fire protection rating required.

required for opening protectives such as fire doors and fire windows, the criteria in 36/37.1.2.2.2 outline a set of provisions that, where applied in total, will safely allow a reduction in the 2-hour fire resistance rating required by 36/37.1.2.2.1. The reduction allows the use of nonrated glazing and opening protectives. This reduction permits the use of glass doors and sidelights in the barrier between the mercantile occupancy and the garage, which increase security in the garage because customers and staff can view the parking area through the glass doors or sidelights.

Note that all seven requirements mandated by

CHAPTER 36 • New

CHAPTER 37 • Existing

36/37.1.2.2.2—the sprinkler requirement for enclosed garages in the base paragraph and the six requirements of subparts (1) through (6)—must be met as a whole to apply the exception to the rule. Otherwise,

36.1.3 Definitions.

A list of terms used in this chapter follows:

- (1) **Anchor Building.** See 3.3.27.2.
- (2) **Bulk Merchandising Retail Building.** See 3.3.27.4.
- (3) **Gross Leasable Area.** See 3.3.16.3.
- (4) **Open-Air Mercantile Operation.** See 3.3.156.

In the 2003 edition of the *Code*, the term *anchor store* was replaced with *anchor building* as defined in 3.3.27.2, recognizing such a structure might contain other than mercantile occupancies. From a merchandising viewpoint, a shopping mall developer or operator might refer to any of the major tenants that have vast expanses of floor space and instant name recognition—and that are often positioned at the ends and corners of the mall building—as anchor buildings. However, the *Code* reserves the use of the term *anchor building* for those perimeter buildings with means of egress independent from the mall.

See Exhibit 36/37.2, which illustrates the difference between an anchor building and a store that, while large, is not an anchor building. Required egress from an anchor building is not permitted to pass through the mall. The store at the left of the

a continuous 2-hour fire resistance-rated separation between the mercantile occupancy and the parking structure is required.

37.1.3 Definitions.

A list of terms used in this chapter follows:

- (1) **Anchor Building.** See 3.3.27.2.
- (2) **Bulk Merchandising Retail Building.** See 3.3.27.4.
- (3) **Gross Leasable Area.** See 3.3.16.3.
- (4) **Open-Air Mercantile Operation.** See 3.3.156.

figure satisfies this requirement and, therefore, is an anchor building. The opening between the anchor building and the mall is permitted, over and above the egress width satisfied by the store's required means of egress. The store at the right of the figure relies on exits from the mall as part of its required egress capacity and, therefore, is not an anchor building.

The term *bulk merchandising retail building* (see definition in 3.3.27.4) applies to the special provisions of 36/37.4.5 for mercantile occupancies characterized by warehouse-type sales areas where merchandise is stored on pallets, in solid piles, or in racks extending far above head height. The storage arrangement and quantities of combustible materials pose challenges that differ from those typically found in department stores and supermarkets and, therefore, warrant special protection criteria.

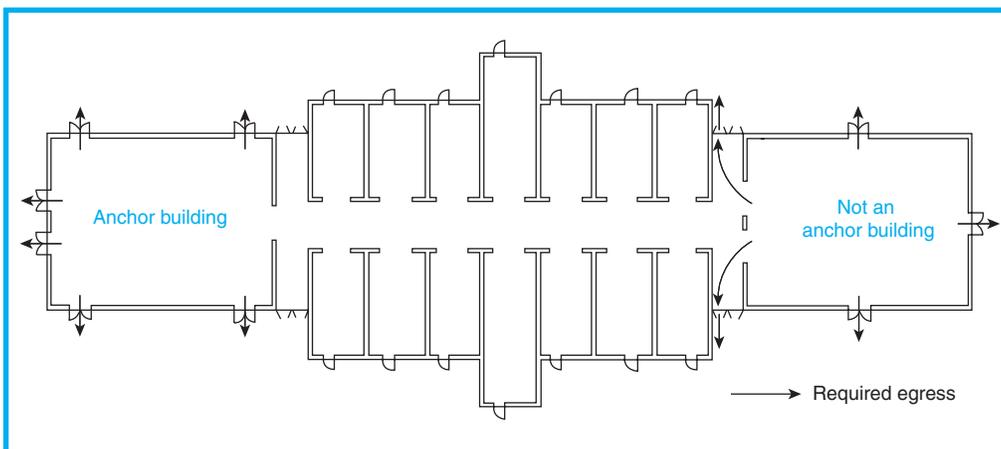

Exhibit 36/37.2 Anchor building and non-anchor building.

CHAPTER 36 • New

The terms *mall* (see definition in 3.3.133) and *mall building* (see definition in 3.3.27.9) are different from each other to permit certain requirements to apply to only the covered pedestrian way (the mall), while other requirements apply to the entire building, including all tenant spaces and common areas (the mall building). For example, the provisions of 36/37.4.4 require automatic sprinkler protection throughout the mall building but require an alarm system—and, under certain conditions, a smoke control system—only within the mall.

36.1.4 Classification of Occupancy.

36.1.4.1 General. Mercantile occupancies shall include all buildings and structures or parts thereof with occupancy as defined in 6.1.10.

36.1.4.2 Subclassification of Occupancy.

36.1.4.2.1 Mercantile occupancies shall be subclassified as follows:

- (1) *Class A*—All mercantile occupancies having an aggregate gross area of more than 2800 m² (30,000 ft²) and occupying more than three stories for sales purposes
- (2) *Class B*—All mercantile occupancies of more than 280 m² (3000 ft²), but not more than 2800 m² (30,000 ft²), aggregate gross area and occupying not more than three stories for sales purposes
- (3) *Class C*—All mercantile occupancies of not more than 280 m² (3000 ft²) gross area and used for sales purposes occupying one story only

36.1.4.2.2 For the purpose of the classification required in 36.1.4.2.1, the requirements of 36.1.4.2.2(A), 36.1.4.2.2(B), and 36.1.4.2.2(C) shall be met.

(A) The aggregate gross area shall be the total gross area of all floors used for mercantile purposes.

(B) Where a mercantile occupancy is divided into sections, regardless of fire separation, the aggregate gross area shall include the area of all sections used for sales purposes.

(C) Areas of floors not used for sales purposes, such as an area used only for storage and not open to the public, shall not be counted for the purposes of the classifications in 36.1.4.2.1(1), 36.1.4.2.1(2), and 36.1.4.2.1(3), but means of egress shall be provided for such nonsales areas in accordance with their occupancy as specified by other chapters of this *Code*.

CHAPTER 37 • Existing

The term *gross leasable area* is defined (see 3.3.16.3) to provide a criterion under which an occupant load can be calculated for use in sizing the means of egress system for the mall only. See 7.3.1.2 for details on calculating occupant load for determining required egress capacity.

Open-air mercantile operations (see definition in 3.3.156) are addressed in 36/37.4.3.

37.1.4 Classification of Occupancy.

37.1.4.1 General. Mercantile occupancies shall include all buildings and structures or parts thereof with occupancy as defined in 6.1.10.

37.1.4.2 Subclassification of Occupancy.

37.1.4.2.1 Mercantile occupancies shall be subclassified as follows:

- (1) *Class A* — All mercantile occupancies having an aggregate gross area of more than 2800 m² (30,000 ft²) and occupying more than three stories for sales purposes
- (2) *Class B* — All mercantile occupancies of more than 280 m² (3000 ft²) but not more than 2800 m² (30,000 ft²) aggregate gross area and occupying not more than three stories for sales purposes
- (3) *Class C* — All mercantile occupancies of not more than 280 m² (3000 ft²) gross area used for sales purposes and occupying one story only, excluding mezzanines

37.1.4.2.2 For the purpose of the classification required in 37.1.4.2.1, the requirements of 37.1.4.2.2(A), 37.1.4.2.2(B), and 37.1.4.2.2(C) shall be met.

(A) The aggregate gross area shall be the total gross area of all floors used for mercantile purposes.

(B) Where a mercantile occupancy is divided into sections, regardless of fire separation, the aggregate gross area shall include the area of all sections used for sales purposes.

(C) Areas of floors not used for sales purposes, such as an area used only for storage and not open to the public, shall not be counted for the purposes of the classifications in 37.1.4.2.1(1), 37.1.4.2.1(2), and 37.1.4.2.1(3), but means of egress shall be provided for such nonsales areas in accordance with their occupancy as specified by other chapters of this *Code*.

CHAPTER 36 • New

36.1.4.2.3 Mezzanines shall comply with 8.6.9.

36.1.4.2.4 Where a number of tenant spaces under different management are located in the same building, the aggregate gross area for subclassification shall be one of the following:

- (1) Where tenant spaces are not separated, the aggregate gross floor area of all such tenant spaces shall be used in determining classification per 36.1.4.2.1.
- (2) Where individual tenant spaces are separated by fire barriers with a 2-hour fire resistance rating, each tenant space shall be individually classified.
- (3) Where tenant spaces are separated by fire barriers with a 1-hour fire resistance rating and the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), each tenant space shall be individually classified.
- (4) The tenant spaces in a mall building in accordance with 36.4.4 shall be classified individually.

As noted in 36/37.1.4.1, guidance on the classification of a mercantile occupancy is provided by the definition in 6.1.10.1. Note that, per 6.1.14.1.2, minor merchandising operations in buildings that house other predominant occupancies are subject to the requirements of the predominant occupancy. For example, a newsstand located in an office building would be treated under the same business occupancy requirements (Chapters 38 and 39) as the office building.

Further clarification of the subclassification of stores as Class A, Class B, or Class C is provided by 36/37.1.4.2.1 through 36/37.1.4.2.4. Most of these provisions are included in the footnotes to Commentary Table 36/37.1. Also, the user should note the following:

- (1) The aggregate gross area is the sum of the gross areas of all floors used for mercantile (sales) purposes.
- (2) If the store is divided so that some portions are not used for sales purposes, such as shipping/receiving/storage areas, only the sales areas should be included in the aggregate gross area.
- (3) With the exception of mall buildings (see 36/37.4.4), the aggregate gross area of stores must be used in subclassifying a mercantile occupancy in accordance with 36/37.1.4.2.1 under the following conditions:

CHAPTER 37 • Existing

37.1.4.2.3 The floor area of a mezzanine, or the aggregate floor area of multiple mezzanines, shall not exceed one-half of the floor area of the room or story in which the mezzanines are located; otherwise such mezzanine or aggregated mezzanines shall be treated as floors.

37.1.4.2.4 Where a number of tenant spaces under different management are located in the same building, the aggregate gross area for subclassification shall be one of the following:

- (1) Where tenant spaces are not separated, the aggregate gross floor area of all such tenant spaces shall be used in determining classification per 37.1.4.2.1.
- (2) Where individual tenant spaces are separated by fire barriers with a 1-hour fire resistance rating, each tenant space shall be individually classified.
- (3) The tenant spaces in a mall building in accordance with 37.4.4 shall be classified individually.

- a. Where stores are contiguous to one another (even if under different ownership or management and occupying numerous buildings)
- b. Where sections or floors used for sales within any building are considered as separate stores (for example, because they are under different management)
- c. Where the contiguous or intermixed stores described in items a and b are not separated from each other by the 2-hour or 1-hour fire resistance-rated fire barriers specified in 36/37.1.4.2.4.

Mezzanines are addressed by the one-third area rule of 36.1.4.2.3 and 8.6.9 for new construction and the one-half area rule of 37.1.4.2.3 for existing mercantile occupancies. A mezzanine with an area that does not exceed the applicable one-third or one-half area rule does not constitute a story and, therefore, is not a factor in determining mercantile occupancy subclassification based on the number of floors used for sales purposes. The area of such mezzanines used for sales purposes (see 36/37.1.4.2.2) is, however, a factor in determining occupancy subclassification based on floor area devoted to sales purposes. For example, a new mercantile occupancy with a 195-m² (2100-ft²) main sales floor and a 65-m² (700-ft²) sales mezzanine has a gross area of 260 m² (2800 ft²) and

CHAPTER 36 • New

CHAPTER 37 • Existing

is, therefore, a Class C mercantile occupancy. A store with a 225-m² (2400-ft²) main sales floor and a 75-m² (800-ft²) sales mezzanine has a gross area of 300 m² (3200 ft²) and so is a Class B mercantile occupancy. In each case, the mezzanine meets the maximum one-third area rule and is not treated as a story.

Mezzanines with areas in excess of the maximum one-third area rule (or one-half area rule for existing mercantile occupancies) constitute stories and, thus, sales levels. Therefore, such mezzanines must be considered when determining mercantile occupancy subclassification. For example, a set of plans might show a proposed store with three floor levels of 740 m² (8000 ft²) each that are used for sales purposes and a single 370-m² (4000-ft²) sales mezzanine. Because the so-called mezzanine is not a mezzanine based on the maximum one-third area rule of 8.6.9 referenced by 36.1.4.2.3, the store will actually use four floor levels for sales purposes. Although its 2590-m² (28,000 ft²) sales area would seem to indicate the store is a Class B occupancy, the four floor levels used for sales purposes result in a Class A subclassification in accordance with the definition in 36/37.1.4.2.1(1).

To qualify as a Class A, Class B, or Class C mercantile occupancy, a store must meet the requirements of 36/37.1.4.2.1, which are summarized in Commentary Table 36/37.1. The classification process is important, because specific life safety requirements vary in degree of stringency for each mercantile class. A store's classification, while based directly on the size of the sales areas, is indirectly a measure of the number of occupants at risk from any given fire.

Some mercantile occupancies locate their sales and storage areas together (for example, furniture warehouse sales areas). In such cases, the mercantile occupancy subclassification should be determined using the total aggregate gross area that is open to public use. The same procedure should be followed for bulk merchandising retail buildings.

The mezzanine measurement provisions of 37.1.4.2.3 for existing mercantile occupancies use a one-half area rule, as opposed to the one-third area rule for new mercantile occupancies. The one-third rule for new mercantile occupancy mezzanines correlates with the requirements in 8.6.9.2. Because the one-half area rule was applied to mercantile occupancies long before the general provisions for mezzanines were added to Chapter 8, it has been retained only for existing (but not new) mercantile occupancies. Mezzanines in existing mercantile occupancies continue to be evaluated on the basis of the pre-

viously applicable one-half area criterion to prevent the abrupt noncompliance of existing buildings due to an issue that does not significantly lower the level of safety to life.

Examples of mezzanine arrangements to which the maximum one-third area rule can be applied are depicted in Exhibit 36/37.3, illustrations (a) through (f). Examples of mezzanine arrangements to which the maximum one-half area rule of 37.1.4.2.3 for existing mercantile occupancies can be applied are depicted in Exhibit 36/37.4, illustrations (a) through (f). For purpose of illustration, assume that all the mezzanines, as well as the entire main floor level, are used for sales purposes. Illustrations (a), (b), (c), and (d)

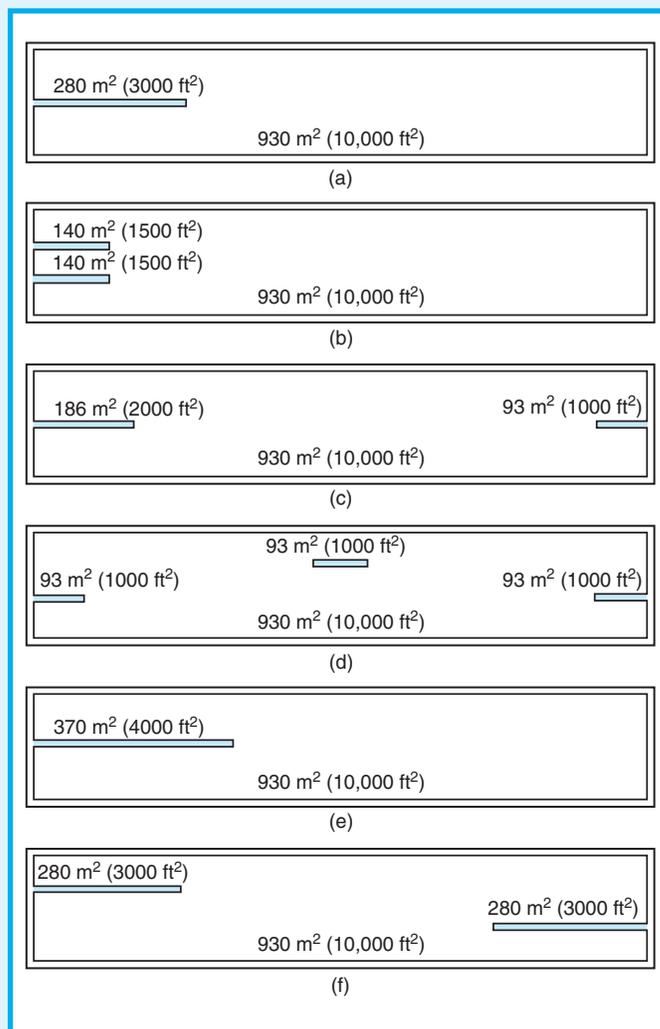

Exhibit 36/37.3 Elevation views of new mercantile occupancy mezzanine arrangements.

CHAPTER 36 • New

CHAPTER 37 • Existing

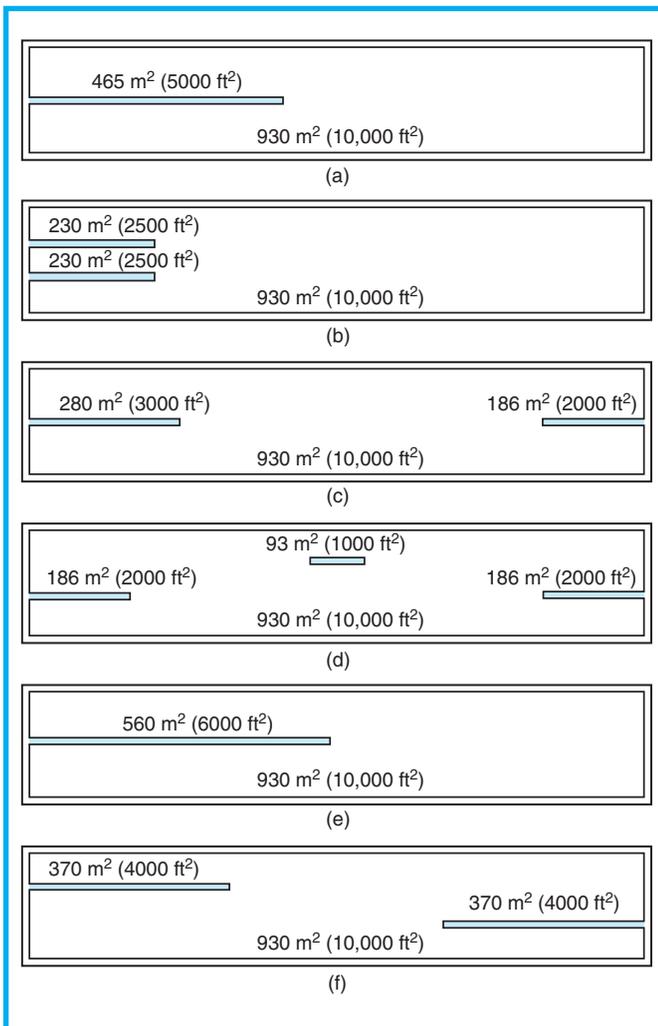

Exhibit 36/37.4 Elevation views of existing mercantile occupancy mezzanine arrangements.

of Exhibit 36/37.3 depict a new single story or single floor level with mezzanine, because the aggregate areas of the mezzanines [280 m² (3000 ft²)] do not exceed one-third of the floor area [930 m² (10,000 ft²)] of the room or story in which the mezzanine is located. Similarly, illustrations (a), (b), (c), and (d) of Exhibit 36/37.4 depict an existing single story or single floor level with mezzanine because the aggregate areas of the mezzanines [465 m² (5000 ft²)] do not exceed one-half of the floor area [930 m² (10,000 ft²)] of the room or story in which the mezzanine is located.

In illustration (e) of Exhibit 36/37.3, the new single 370-m² (4000-ft²) intermediate level referred to by oc-

cupants as a mezzanine exceeds the one-third area rule. Similarly, in illustration (e) of Exhibit 36/37.4, the existing single 560-m² (6000-ft²) intermediate level referred to by occupants as a mezzanine exceeds the one-half area rule. Therefore, in both cases, the intermediate level is not a mezzanine for *Life Safety Code* purposes but is a story by itself. Illustration (e) of Exhibit 36/37.3 and illustration (e) of Exhibit 36/37.4, therefore, depict two-story mercantile occupancies.

In illustration (f) of Exhibit 36/37.3, one of the 280-m² (3000-ft²) mezzanines fits within the maximum one-third area allowance for new mezzanines and can be called a mezzanine without constituting a floor level. Similarly, in illustration (f) of Exhibit 36/37.4, one of the 370-m² (4000-ft²) mezzanines fits within the maximum one-half area allowance for existing mercantile occupancies and can be called a mezzanine without constituting a floor level. In both cases, however, the other mezzanine, although of the same size and thus by itself not in excess of the one-third or one-half area rule, does create a story, because the sum of the areas of the two mezzanines [560 m² (6000 ft²) in Exhibit 36/37.3 and 740 m² (8000 ft²) in Exhibit 36/37.4] exceeds one-third and one-half, respectively, of the 930-m² (10,000-ft²) lower floor level. Thus, illustration (f) of Exhibit 36/37.3 and illustration (f) of Exhibit 36/37.4 each depict a two-story mercantile occupancy with a mezzanine.

Although the mezzanines in illustrations (a) through (d) of Exhibit 36/37.3 and illustrations (a) through (d) of Exhibit 36/37.4 do not establish separate stories, their areas, because they are used for sales, are included in the total gross sales area used to establish mercantile occupancy subclassification in accordance with 36/37.1.4.2.1. Illustrations (a) through (d) of Exhibit 36/37.3 show 1200 m² (13,000 ft²) of sales area and would be classified as Class B mercantile occupancies. Similarly, illustrations (a) through (d) of Exhibit 36/37.4 show 1400 m² (15,000 ft²) of sales area and would be classified as Class B mercantile occupancies.

In addition to the maximum one-third and one-half area limitations of 36/37.1.4.2.3, the provisions of 8.6.9 also apply to mezzanines. For example, a mezzanine used for sales purposes that meets the one-third or one-half area rule would not affect the mercantile occupancy subclassification with respect to number of stories used for sales purposes; however, the mezzanine would be required to be sufficiently open, in accordance with 8.6.9.3, to avoid treatment as a

CHAPTER 36 • New

CHAPTER 37 • Existing

separate floor in terms of number of means of egress (see 36/37.2.4) and the other egress arrangement requirements that apply to floors or stories.

Note that, for existing mercantile occupancies [see 37.1.4.2.4(2)], the fire resistance-rated separation

required to waive aggregate gross area is 1 hour, rather than the 2-hour rating required for new mercantile occupancies via the provision of 36.1.4.2.4(2). The same 1-hour rating applies to new construction only if the building is sprinklered [see 36.1.4.2.4(3)].

36.1.5 Classification of Hazard of Contents.

36.1.5.1 The contents of mercantile occupancies shall be classified in accordance with Section 6.2.

36.1.5.2 Mercantile occupancies classified as high hazard in accordance with Section 6.2 shall meet the following additional requirements:

- (1) Exits shall be located so that not more than 23 m (75 ft) of travel from any point is needed to reach the nearest exit.
- (2) From every point, there shall be not less than two exits accessible by travel in different directions (no common path of travel).
- (3) All vertical openings shall be enclosed.

36.1.6 Minimum Construction Requirements.

(No special requirements.)

36.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

Hazard of contents is addressed in 36/37.1.5, which refers to Section 6.2 for classification. Typically, unless an unusually hazardous situation exists, the contents of mercantile occupancies are classified as ordinary hazard.

Because the total package of life safety provided by the Chapter 36/37 requirements anticipates the display of significant quantities of combustibles, it should provide an acceptable level of safety without making it necessary to classify the typical mercantile occupancy environment as highly hazardous. Specifically, the Chapter 36/37 requirements should be adequate without imposing the stringent high hazard

37.1.5 Classification of Hazard of Contents.

37.1.5.1 The contents of mercantile occupancies shall be classified in accordance with Section 6.2.

37.1.5.2 Mercantile occupancies classified as high hazard in accordance with Section 6.2 shall meet the following additional requirements:

- (1) Exits shall be located so that not more than 23 m (75 ft) of travel from any point is needed to reach the nearest exit.
- (2) From every point, there shall be not less than two exits accessible by travel in different directions (no common path of travel).
- (3) All vertical openings shall be enclosed.

37.1.6 Minimum Construction Requirements.

(No special requirements.)

37.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

contents requirements of 36/37.1.5.2 on all but the most hazardous of mercantile occupancies.

Operations that would require classification of a mercantile occupancy as highly hazardous include dispensing gunpowder or other explosives in bulk or dispensing gasoline or flammable solvents by pouring them into open containers. The sale of flammable liquids such as camp stove fuel and rubbing alcohol should be controlled by NFPA 30, *Flammable and Combustible Liquids Code*¹, with regard to display configuration, total amount, and separation from ignition sources.

Exhibit 36/37.5 illustrates an egress arrangement

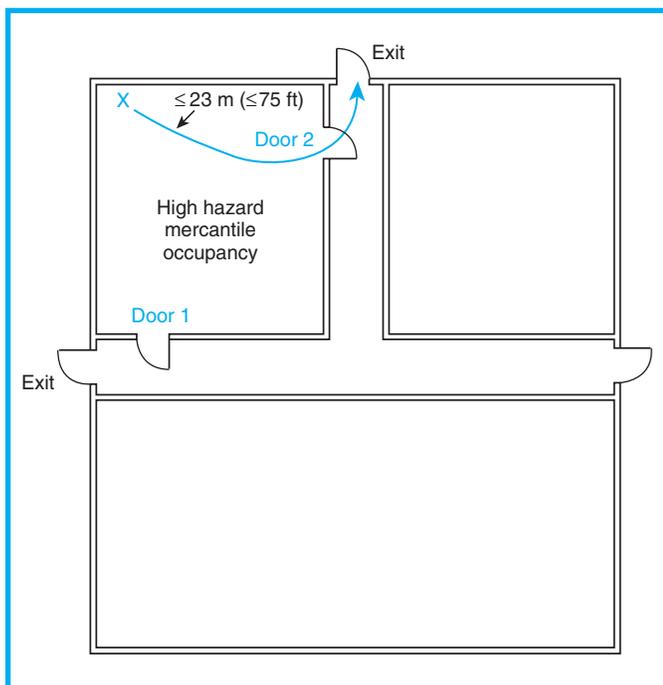

Exhibit 36/37.5 Egress arrangement from area of mercantile occupancy classified as high hazard.

from a highly hazardous area of a mercantile occupancy that meets the requirements of 36/37.1.5.2(1) and (2), which address limited travel distance and the exclusion of common path of travel. Doors 1 and 2 lead to remote corridor segments that provide access to independent and remote exits. Travel in two independent directions is possible from any point within the high hazard contents room. Travel distance from any point within the high hazard contents room to the nearest exit does not exceed 23 m (75 ft). Although mercantile occupancy requirements are generally lenient in allowing vertical openings (see 36/37.3.1), all vertical openings in high hazard mercantile occupancies are required to be fully enclosed (see Section 8.6) in accordance with 36/37.1.5.2(3).

The term *minimum construction*, as used in 36/37.1.6, describes the construction of the building housing the occupancy. Some occupancy chapters, such as Chapters 18 and 19, which address the life safety needs of nonambulatory occupants of health care occupancies, require a minimum building construction type to help ensure structural integrity for a prolonged evacuation or for safe refuge within the

building. Because mercantile occupancies characteristically are used by ambulatory customers and employees (note that mobility impaired occupants are not necessarily nonambulatory or incapable of self-preservation) and do not provide sleeping accommodations, no minimum construction requirements are imposed.

The occupant load factors for mercantile uses specified in Table 7.3.1.2 are based on the observation that, during the normal use of a mercantile occupancy, the largest number of customers usually occupy the street floor or a basement sales area. In assigning a higher occupant load to the street floor, the *Code* recognizes merchandising techniques that arrange merchandise to take advantage of the heavy flow of traffic on the street floor. Customers are attracted to merchandise displays as they walk through portions of the street floor to reach escalators, elevators, and stairs to other floors. Thus, larger numbers of occupants are expected to occupy the street floor.

The street floor, as distinguished from other sales floors, is any floor that has an entrance/exit that is directly accessible from the street with not more than three risers of ascent or descent. The term *street floor* is defined in 3.3.216. If differences in the ground level on different sides of a store create several floors of this nature, the *Code* treats them all as street floors; however, a slightly different occupant load factor is used in accordance with footnote 2 to Table 7.3.1.2. If the only access to a store from the street is by means of stairs or escalators, the principal sales floor, rather than the street level, must be considered the street floor for the purpose of choosing an occupant load factor and calculating the occupant load.

The terms *mall* and *mall building* have different meanings (see commentary following 36/37.1.3). Therefore, the intent of footnote 5 to Table 7.3.1.2 is that the egress capacity of the overall mall building is to be sized to handle an occupant load that is calculated in two steps. First, the occupant load is calculated individually for each store and tenant space using the occupant load factors of Table 7.3.1.2. Second, the required egress capacity for the mall itself (the covered pedestrian way) is calculated using the values shown in Figure 7.3.1.2. Each store or tenant space must have sufficient egress capacity for its occupant load. The egress capacity of the mall must be based on Figure 7.3.1.2, which, in effect, automatically accounts for those persons who are in the mall (the

CHAPTER 36 • New

covered pedestrian way) and those persons discharged from stores into the mall as part of the stores' means of egress.

For example, consider a mall building with 21 tenant stores located on the street floor. Each store uses 560 m² (6000 ft²) of the 700 m² (7500 ft²) of gross leasable area as sales area [assume that the other 140 m² (1500 ft²) is storage area]. Using an occupant load factor of 2.8 m² (30 ft²) per person for the sales areas and 27.9 m² (300 ft²) for the storage areas, in accordance with Table 7.3.1.2, each store must size its means of egress system to handle 205 persons [560/2.8 + 140/27.9 (6000/30 + 1500/300) = 205]. Store

CHAPTER 37 • Existing

occupants use the mall as part of the required means of egress from each store. With 21 tenant stores, each with 700 m² (7500 ft²) of gross leasable area, the mall has a gross leasable area of 14,700 m² (157,500 ft²), which is the basis on which the means of egress from the mall must be sized. Figure 7.3.1.2(a) and (b) indicate that, for a gross leasable area of 14,700 m² (157,500 ft²), the occupant load factor is 3.34 m² (36 ft²) per person. The mall must, therefore, provide a means of egress system for 14,700 m² / 3.34 m² per person (157,500 ft² / 36 ft²) per person or 4,400 persons (or 4375 persons if using inch-pound units, due to rounding error).

Section 36.2 Means of Egress Requirements

36.2.1 General.

36.2.1.1 All means of egress shall be in accordance with Chapter 7 and this chapter.

36.2.1.2 No inside open stairway or inside open ramp shall be permitted to serve as a component of the required means of egress system for more than one floor.

36.2.1.3 Where there are two or more floors below the street floor, the same stairway or other exit shall be permitted to serve all floors, but all required exits from such areas shall be independent of any open stairways between the street floor and the floor below it.

36.2.1.4 Where a level, outside exit from upper floors is possible owing to hills, either 36.2.1.4.1 or 36.2.1.4.2 shall apply:

36.2.1.4.1 Such outside exits, if not also serving as an entrance from a principal street, shall be permitted to serve instead of horizontal exits.

36.2.1.4.2 Where such outside exits from the upper floor also serve as an entrance from a principal street, the upper floor shall be classified as a street floor in accordance with the definition of *street floor* in 3.3.216 and shall be subject to the requirements of this chapter for street floors.

36.2.1.5 For special considerations for high hazard contents, see 36.1.5.2.

Section 37.2 Means of Egress Requirements

37.2.1 General.

37.2.1.1 All means of egress shall be in accordance with Chapter 7 and this chapter.

37.2.1.2 No inside open stairway, inside open escalator, or inside open ramp shall be permitted to serve as a component of the required means of egress system for more than one floor.

37.2.1.3 Where there are two or more floors below the street floor, the same stairway or other exit shall be permitted to serve all floors, but all required exits from such areas shall be independent of any open stairways between the street floor and the floor below it.

37.2.1.4 Where a level, outside exit from upper floors is possible owing to hills, either 37.2.1.4.1 or 37.2.1.4.2 shall apply.

37.2.1.4.1 Such outside exits, if not also serving as an entrance from a principal street, shall be permitted to serve instead of horizontal exits.

37.2.1.4.2 Where such outside exits from the upper floor also serve as an entrance from a principal street, the upper floor shall be classified as a street floor in accordance with the definition of *street floor* in 3.3.216 and shall be subject to the requirements of this chapter for street floors.

37.2.1.5 For special considerations for high hazard contents, see 37.1.5.2.

CHAPTER 36 • New

Even where unenclosed interior stairs or ramps are permitted by 36/37.3.1, the use of such stairs or ramps as exit access for more than one floor is prohibited by 36/37.2.1.2.

Street floors are addressed by 36/37.2.1.4. Exhibit 36/37.6 illustrates a case where two floors qualify as street floors because each has one side located at a ground level. Note, however, that each street floor has its other sides located either above or below the building's other ground level. As a result, these floors must have their exits arranged to allow horizontal travel to the exterior at one end of the floor and vertical travel (either up or down to ground level) at the other end of the floor. The egress capacity of the doors to the exterior on floor 1 must accommodate that portion of the occupant load from an upper floor that is expected to travel down to and through the exits to the exterior from floor 1. This egress capacity is in addition to the assigned portion of the floor 1 occupant load. The reverse is true for floor 2, which must increase the size of its exterior exit door capacity to accommodate occupants traveling up from floor 1 as well as those traveling down to and through the exterior exits on floor 2. The provisions of 7.3.1.5, 7.3.1.6, and 36/37.2.3.2 explain how to add egress capacity based on the number of occupants expected to discharge from floors above and below the street floor. Exhibit 36/37.10, which accompanies the com-

CHAPTER 37 • Existing

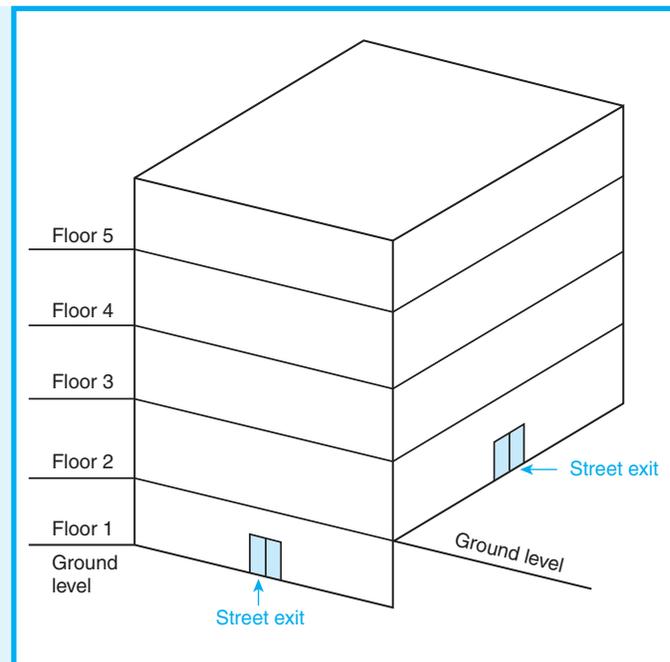

Exhibit 36/37.6 Mercantile occupancy with two street floors.

mentary associated with 36/37.2.3.2, provides an example of how to calculate exit capacity for a street floor similar to that illustrated by floor 2 in Exhibit 36/37.6.

36.2.2 Means of Egress Components.

36.2.2.1 General. Components of means of egress shall be limited to the types described in 36.2.2.2 through 36.2.2.12.

36.2.2.2 Doors.

36.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

36.2.2.2.2* Locks complying with 7.2.1.5.4 shall be permitted only on principal entrance/exit doors.

A.36.2.2.2.2 The words “principal entrance/exit doors” describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

36.2.2.2.3 Reserved.

36.2.2.2.4 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted.

37.2.2 Means of Egress Components.

37.2.2.1 General. Components of means of egress shall be limited to the types described in 37.2.2.2 through 37.2.2.12.

37.2.2.2 Doors.

37.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

37.2.2.2.2* Locks complying with 7.2.1.5.4 shall be permitted only on principal entrance/exit doors.

A.37.2.2.2.2 The words “principal entrance/exit doors” describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

37.2.2.2.3 The re-entry provisions of 7.2.1.5.7 shall not apply. (See 7.2.1.5.7.2(1).)

37.2.2.2.4 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted.

CHAPTER 36 • New

36.2.2.2.5 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted in buildings protected throughout by an approved, supervised fire detection system in accordance with Section 9.6 or an approved automatic sprinkler system in accordance with 9.7.1.1(1).

36.2.2.2.6 Where horizontal or vertical security grilles or doors are used as a part of the required means of egress from a tenant space, such grilles or doors shall comply with 7.2.1.4.1.4.

36.2.2.2.7 All doors at the foot of stairs from upper floors or at the head of stairs leading to floors below the street floor shall swing in the direction of egress travel.

36.2.2.2.8 Revolving doors complying with 7.2.1.10 shall be permitted.

36.2.2.3 Stairs.

36.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

36.2.2.3.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted.

36.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

36.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

36.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

36.2.2.7 Exit Passageways.

36.2.2.7.1 Exit passageways complying with 7.2.6 shall be permitted.

36.2.2.7.2* Exit passageways in a mall building shall be permitted to accommodate the following independently:

- (1) The portion of the occupant load assigned to the exit passageway from only the mall/pedestrian way
- (2) The largest occupant load assigned to the exit passageway from a single tenant space

A.36.2.2.7.2 To design egress from a covered mall building, the following steps should be used:

- (1) The covered mall/pedestrian way has been assigned no occupant load, but it is required to be provided with

CHAPTER 37 • Existing

37.2.2.2.5 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted in buildings protected throughout by an approved, supervised fire detection system in accordance with Section 9.6 or an approved automatic sprinkler system in accordance with 9.7.1.1(1).

37.2.2.2.6 Where horizontal or vertical security grilles or doors are used as a part of the required means of egress from a tenant space, such grilles or doors shall comply with 7.2.1.4.1.4.

37.2.2.2.7 All doors at the foot of stairs from upper floors or at the head of stairs leading to floors below the street floor shall swing in the direction of egress travel.

37.2.2.2.8 Revolving doors complying with 7.2.1.10 shall be permitted.

37.2.2.2.9 In Class C mercantile occupancies, doors shall be permitted to swing inward against the direction of egress travel where such doors serve only the street floor area.

37.2.2.3 Stairs.

37.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

37.2.2.3.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted.

37.2.2.3.3 Winders complying with 7.2.2.2.4 shall be permitted.

37.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

37.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

37.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

37.2.2.7 Exit Passageways.

37.2.2.7.1 Exit passageways complying with 7.2.6 shall be permitted.

37.2.2.7.2* Exit passageways in a mall building shall be permitted to accommodate the following independently:

- (1) The portion of the occupant load assigned to the exit passageway from only the mall/pedestrian way
- (2) The largest occupant load assigned to the exit passageway from a single tenant space

A.37.2.2.7.2 To design egress from a mall building, the following steps should be used:

- (1) The mall/pedestrian way has been assigned no occupant load, but it is required to be provided with means of

CHAPTER 36 • New

means of egress sized to accommodate the total occupant load of the covered mall building based on the gross leasable area. The exits for the covered mall/pedestrian way are permitted to be provided by a combination of exterior exit doors and exit passageways.

- (2) After completion of step (a), each tenant space is to be judged individually for occupant load and egress capacity. This step normally sends a portion or all (per 36.4.4.3.4) of the tenant space's occupant load into the covered mall. Any remaining occupants are sent through the back of the tenant space into an exit passageway that might serve multiple tenant spaces and the covered mall.
- (3) The width of the exit passageway is required to be sized for the most restrictive of the following:
 - (a) For a width of not less than 1675 mm (66 in.) per 36.4.4.2.2(3)
 - (b) For the portion of the egress capacity from the largest single tenant space being served by the exit passageway
 - (c) For the portion of the egress capacity from the covered mall being provided by the exit passageway

The concepts used in steps (a) through (c) include the following:

- (1) After proper egress capacity is provided for the covered mall/pedestrian way, each tenant space is then required to independently provide egress capacity for its occupants.
- (2) The covered mall required exit passageway width and the tenant space required exit passageway width are not required to be added together.
- (3) The required exit passageway width for a tenant space is not required to be added to that of other tenant spaces using the same exit passageway.

36.2.2.8 Reserved.**36.2.2.9 Reserved.**

36.2.2.10 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

36.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

36.2.2.12 Areas of Refuge.

36.2.2.12.1 Areas of refuge complying with 7.2.12 shall be permitted.

36.2.2.12.2 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), two rooms or spaces separated from each

CHAPTER 37 • Existing

egress sized to accommodate the total occupant load of the covered mall building based on the gross leasable area. The exits for the mall/pedestrian way are permitted to be provided by a combination of exterior exit doors and exit passageways.

- (2) After completion of step (a), each tenant space is to be judged individually for occupant load and egress capacity. This step normally sends a portion or all (per 37.4.4.3.4) of the tenant space's occupant load into the covered mall. Any remaining occupants are sent through the back of the tenant space into an exit passageway that might serve multiple tenant spaces and the covered mall.
- (3) The width of the exit passageway is required to be sized for the most restrictive of the following:
 - (a) For a width of not less than 1675 mm (66 in.) per 37.4.4.2.2(3)
 - (b) For the portion of the egress capacity from the largest single tenant space being served by the exit passageway
 - (c) For the portion of the egress capacity from the covered mall being provided by the exit passageway

The concepts used in steps (a) through (c) include the following:

- (1) After proper egress capacity is provided for the mall/pedestrian way, each tenant space is then required to independently provide egress capacity for its occupants.
- (2) The mall required exit passageway width and the tenant space required exit passageway width are not required to be added together.
- (3) The required exit passageway width for a tenant space is not required to be added to that of other tenant spaces using the same exit passageway.

37.2.2.8 Escalators and Moving Walks. Escalators and moving walks complying with 7.2.7 shall be permitted.

37.2.2.9 Fire Escape Stairs. Fire escape stairs complying with 7.2.8 shall be permitted.

37.2.2.10 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

37.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

37.2.2.12 Areas of Refuge.

37.2.2.12.1 Areas of refuge complying with 7.2.12 shall be permitted.

37.2.2.12.2 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), two rooms or spaces separated from each

CHAPTER 36 • New

other by smoke-resistant partitions in accordance with the definition of *area of refuge* in 3.3.17 shall not be required.

Only the principal entrance/exit doors of a mercantile occupancy are permitted to be equipped with the special key-operated dead bolt lock described by 7.2.1.5.4, per 36/37.2.2.2.2. See Exhibit 36/37.7. It must be easy to determine that the device is locked by using means such as a flag indicator that can be seen at a distance from the door. Other doors along the perimeter of the building are prohibited from being equipped with a key-operated dead bolt lock, because it cannot be guaranteed that these locks will be disengaged simultaneously when the principal entrance/exit door is unlocked each day at the opening of business.

Although Chapter 36 does not address stairwell re-entry, the re-entry provisions of 7.2.1.5.7 apply to new mercantile occupancies. Stairs serving five or more stories must provide either re-entry from the stairwell back onto all floors at any time, or similar re-entry following automatic release of locking devices initiated by the building fire alarm system per 7.2.1.5.7. Some stairwell doors are permitted by 7.2.1.5.7.1 to remain locked from the stairwell side of the door to provide building security, while other doors must allow re-entry. The location and number of re-entry points provide the same overall level of life safety for this type of occupancy as that intended by the base provisions of 7.2.1.5.7. Paragraph 37.2.2.2.3 exempts existing mercantile occupancies from the stairwell re-entry provisions.

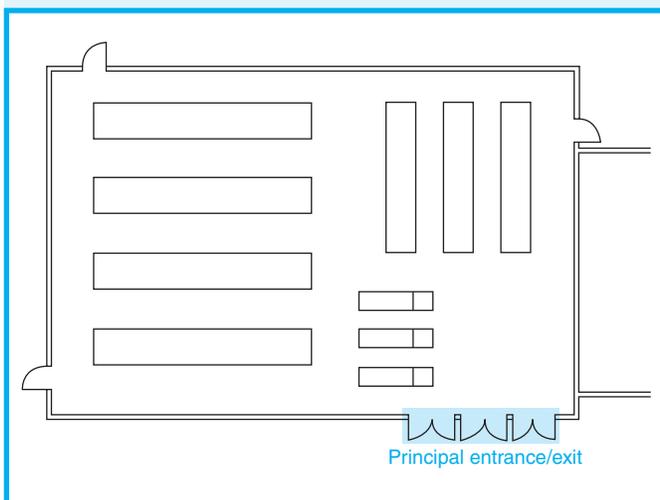

Exhibit 36/37.7 Principal entrance/exit.

CHAPTER 37 • Existing

other by smoke-resistant partitions in accordance with the definition of *area of refuge* in 3.3.17 shall not be required.

In recognition of the security needs of a mercantile occupancy, 36/37.2.2.2.4 allows the use of the delayed-egress locking device covered by 7.2.1.6.1 on any door, provided the building is protected throughout by an approved, supervised automatic sprinkler system or approved, supervised automatic fire detection system. In effect, the allowable 15- or 30-second delay will be experienced only under nonfire conditions or very early in a fire's growth, because the door must be usable immediately upon sprinkler operation, smoke or heat detection, or loss of power that controls the locking mechanism.

In mercantile occupancies with either complete sprinkler or fire detection systems, 36/37.2.2.2.5 recognizes access-controlled egress doors as security measures that do not compromise the use of the means of egress system.

Although 7.2.1.4.1.4 establishes provisions for the arrangement and use of security grilles or doors, it requires that an occupancy chapter specifically recognize the use of such measures. For mercantile occupancies, that recognition is provided by 36/37.2.2.2.6.

The provision of 36/37.2.2.2.7 supplements the door provisions of 7.2.1.4 by requiring doors that otherwise would not have to swing in the direction of egress travel to do so, based on their location. The queuing and accumulation of people at doors in locations such as at the foot of stairs from upper floors makes it difficult for occupants to step back to allow the door to swing inward.

Revolving doors are addressed by 36/37.2.2.2.8. The provisions of 7.2.1.10 specify that the use of a revolving door, regardless of whether it is permitted as part of the required means of egress, requires a conforming side-hinged swinging door to be positioned and usable within the same wall as, and to be located within 3050 mm (120 in.) of, the revolving door. This requirement helps to ensure that, once people move toward the door, if the collapsibility and other safety features of the door fail and render it unusable, egress from the vicinity would still be possible without retracing steps and traveling toward the fire. Existing revolving doors are permitted to continue to be used without having to meet some of the more stringent requirements that apply to new revolving doors. See the provisions of 7.2.1.10.1.

Paragraph 36/37.2.2.4 does not mandate the use

CHAPTER 36 • New

of smokeproof enclosures in a mercantile occupancy, but it does recognize a smokeproof enclosure as part of the means of egress system, provided the smokeproof enclosure meets the requirements of 7.2.3. (For an example of an occupancy requiring a smokeproof enclosure, see 31.2.11, in which existing nonsprinklered high-rise apartment buildings are required to be provided with smokeproof enclosures in accordance with 7.2.3.)

Exit passageways are addressed in 36/37.2.2.7. Exit passageways are frequently used within the means of egress system of mall buildings as a way of meeting the travel distance limitations or avoiding numerous exit doors along exterior walls located at the rear of tenant spaces. In effect, the exit passageway labeled A in Exhibit 36/37.8 moves the exit closer to the occupants to create a building arrangement that would otherwise require occupants to travel farther than allowable to reach an exit door in an exterior wall. The exit passageway labeled B in Exhibit 36/37.8 runs along the rear of multiple-tenant spaces and provides access to the exterior only at each end of the exit passageway for security reasons. In both cases, the exit passageway is a *Code*-complying exit in accordance with 7.2.6 and provides the same degree of safety that an exit stair enclosure would provide an occupant of an upper floor in a multistory building.

Although the provisions of 7.2.6.4 require an exit passageway to be sized to accommodate the aggregate required capacity of all means of egress discharging through the exit passageway, 36/37.2.2.7.2 allows some reduction in the required width of exit passageways in mall buildings. The provision recognizes that the sizing of the means of egress from the mall—calculated in accordance with the provisions of Figure 7.3.1.2—provides egress capacity for occupants of the mall and occupants of the adjoining tenant spaces within the mall building. Requiring an exit passageway in a mall building to be of sufficient size to accommodate both its assigned mall occupant load and the occupant load of all tenant spaces discharging

36.2.3 Capacity of Means of Egress.

36.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

36.2.3.2 In Class A and Class B mercantile occupancies, street floor exits shall be sufficient for the occupant load of

CHAPTER 37 • Existing

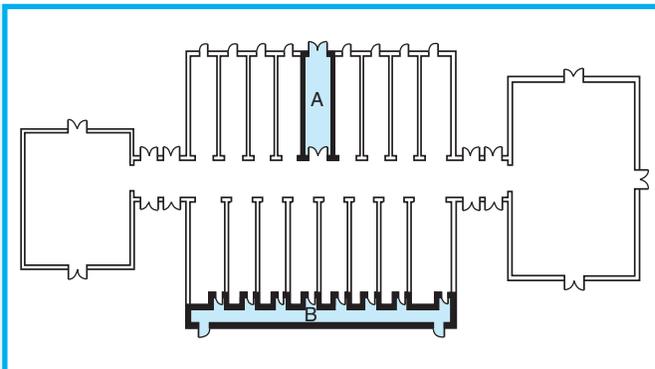

Exhibit 36/37.8 Typical uses of exit passageways in mall buildings.

through the exit passageway would be equivalent to counting a portion of the building's occupants twice and, thereby, needlessly oversizing the means of egress system.

Existing escalators and moving walks are recognized by 37.2.2.8 as part of the means of egress in accordance with 7.2.7. To qualify as exits, existing escalators and moving walks must also meet the requirements of 7.2.2.5 that address enclosure.

Existing fire escape stairs are recognized by 37.2.2.9 as part of the means of egress. Note that 7.2.8.1.2 allows only those occupancy chapters that apply to existing buildings to permit a fire escape stair within the required means of egress. Furthermore, 7.2.8.1.2.1 permits existing buildings to use fire escape stairs for no more than 50 percent of the building's required egress capacity.

In accordance with the provisions of 36/37.2.2.10 and 36/37.2.2.11, both fire escape ladders and alternating tread devices are allowed within the means of egress of mercantile occupancies, but only as permitted by the relatively narrow provisions of 7.2.9 and 7.2.11. The provisions of 7.2.11, in effect, restrict the use of alternating tread devices to locations where the *Code* recognizes the use of fire escape ladders.

37.2.3 Capacity of Means of Egress.

37.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

37.2.3.2 In Class A and Class B mercantile occupancies, street floor exits shall be sufficient for the occupant load of

CHAPTER 36 • New

CHAPTER 37 • Existing

the street floor plus the required capacity of stairs and ramps discharging through the street floor.

the street floor plus the required capacity of stairs, ramps, escalators, and moving walks discharging through the street floor.

The provisions of 7.3.1.6 mandate that any required egress capacity from a mezzanine that passes through the room below must be added to the required egress capacity of the room through which the egress passes.

Exhibit 36/37.9 illustrates a case in which a mezzanine is open to the street floor. The exits from the street floor must accommodate the following:

- (1) Occupant load of the street floor
- (2) Occupant load of the mezzanine in accordance with 7.3.1.6
- (3) Required capacity provided by the stairs from other floors discharging through the street floor in accordance with 36/37.2.3.2

To determine the egress capacity for the street floor, the occupant load of the mezzanine (1000 persons) is added to the occupant load of the street floor (2000 persons). In addition, because one-half of the exits from the upper floors discharge through the street floor, the egress capacity of the street floor must accommodate the capacity of the exit stair enclosure that discharges through that floor. The maximum occupant load on any upper floor is 2000 (second floor), and 36/37.2.7.2 permits a maximum of one-half of the exits (and one-half of the egress capacity in new

mercantile occupancies) to discharge through the street floor, provided that the building is sprinklered. Therefore, the street floor must be provided with egress capacity for 4000 persons (2000 for street floor + 1000 for mezzanine + 1000 for upper floors = 4000) or 20,000 mm (800 in.) of exit width using the factor of 5 mm (0.2 in.) per person for level egress components found in Table 7.3.3.1.

The provisions of 36/37.2.3.2 require that the exits for the street floor of a Class A or Class B mercantile occupancy have sufficient capacity to handle the occupant load of the street floor and the capacity of the exits discharging through the street floor, such as an enclosed exit stair that accommodates occupants who, when exiting the building during an emergency, must travel up from the basement sales area or down from the upper sales floors and mix with the customers already occupying the street floor.

Because people move more quickly in the horizontal direction than in the vertical direction, it is permissible to provide less door width than stair width within any given egress path. For example, in mercantile occupancies, in accordance with the egress capacity factors of Table 7.3.3.1, level components and ramps require only 5 mm (0.2 in.) of width per person, whereas stairs require 7.6 mm (0.3 in.) of width per person. As a rough approximation, for every 1120 mm (44 in.) of stair discharging through the street floor, an additional 760 mm (30 in.) of door width opening to the outside must be added to the street floor. Exhibit 36/37.10 illustrates the following example of the calculation method for determining the required exit capacity for the street floor.

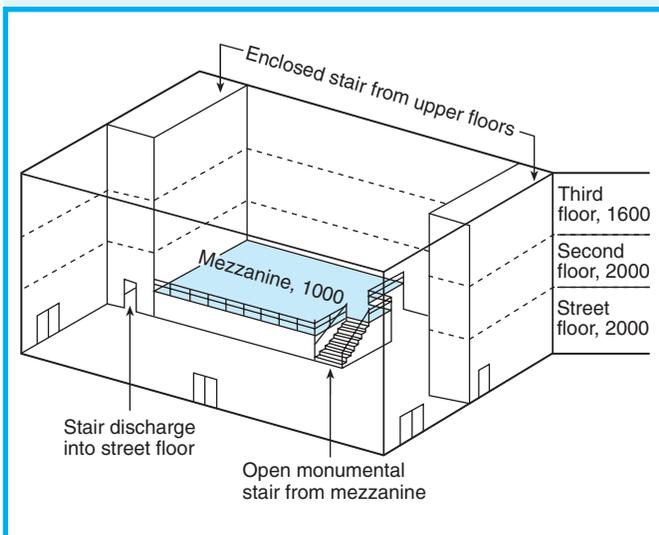

Exhibit 36/37.9 Mercantile occupancy with mezzanine open to the street floor.

Street floor occupant load alone	1000
Maximum upper floor occupant load discharging back through street floor (500/2)	+ 250
Basement occupant load discharging back through street floor (400/2)	+ 200
Total occupant load	1450

1450 persons × 5 mm (0.2 in.) per person for level exit components per 7.3.3.1 = 7250 mm (290 in.) of exit width required from the street floor egress system

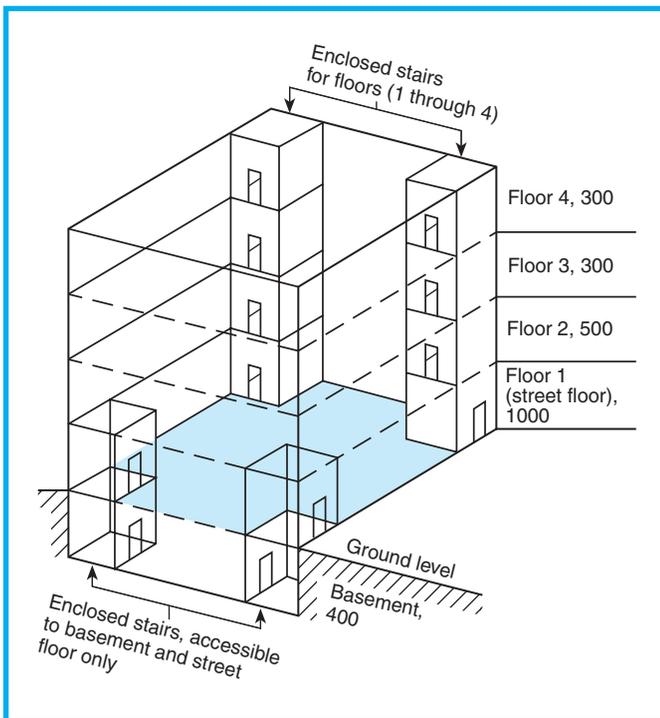

Exhibit 36/37.10 Calculation of exit capacity required for a street floor in accordance with 36/37.2.3.2.

36.2.4 Number of Exits.

36.2.4.1 Exits shall comply with the following except as otherwise permitted by 36.2.4.2 through 36.2.4.5:

- (1) The number of means of egress shall be in accordance with Section 7.4.
- (2) Not less than two separate exits shall be provided on every story.
- (3) Not less than two separate exits shall be accessible from every part of every story.

36.2.4.2 Exit access as required by 36.2.4.1(3) shall be permitted to include a single exit access path for the distances permitted as common paths of travel by 36.2.5.3.

36.2.4.3 A single means of egress shall be permitted in a Class C mercantile occupancy, provided that the travel distance to the exit or to a mall does not exceed 23 m (75 ft).

36.2.4.4 A single means of egress shall be permitted in a Class C mercantile occupancy, provided that the travel distance to the exit or to a mall does not exceed 30 m (100 ft), and the story on which the occupancy is located and all communicating levels that are traversed to reach the exit or mall are protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

37.2.4 Number of Exits.

37.2.4.1 Exits shall comply with the following except as otherwise permitted by 37.2.4.2 through 37.2.4.5:

- (1) The number of means of egress shall be in accordance with Section 7.4.
- (2) Not less than two separate exits shall be provided on every story.
- (3) Not less than two separate exits shall be accessible from every part of every story.

37.2.4.2 Exit access as required by 37.2.4.1(3) shall be permitted to include a single exit access path for the distances permitted as common paths of travel by 37.2.5.3.

37.2.4.3 A single means of egress shall be permitted in a Class C mercantile occupancy, provided that the travel distance to the exit or to a mall does not exceed 23 m (75 ft).

37.2.4.4 A single means of egress shall be permitted in a Class C mercantile occupancy, provided that the travel distance to the exit or to a mall does not exceed 30 m (100 ft), and the story on which the occupancy is located and all communicating levels that are traversed to reach the exit or mall are protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

CHAPTER 36 • New

36.2.4.5 A single means of egress to an exit or to a mall shall be permitted from a mezzanine within any Class A, Class B, or Class C mercantile occupancy, provided that the common path of travel does not exceed 23 m (75 ft), or does not exceed 30 m (100 ft) if protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

The provisions of 36/37.2.4, which apply to the required number of exits for mercantile occupancies, clarify that any level that constitutes a story must have at least two exits located on that story. This means that the occupants of the story must be able to enter two exits (such as an enclosed exit stair on an upper floor of a multistory building) without having to travel to another story to reach the entrances to the exits. Because a mezzanine that meets the maximum one-third or one-half area rule of 36/37.1.4.2.3 does not constitute a story (see the commentary associated with 36/37.1.4.2.3), two exits are not required on the mezzanine, but the criteria of 36/37.2.4.1(3) must be met with respect to providing access to two separate exits, or the provisions of 36/37.2.4.3, 36/37.2.4.4, or 36/37.2.4.5 must be met.

The provision of 36/37.2.5.3(2) allows the occupant to travel in one direction for a maximum distance (the common path allowance) before requiring exit access in two separate directions. Therefore, although the story or mezzanine must eventually provide access to two exits in accordance with 36/37.2.4.1(3), the access is required to be available only at the point where the allowable common path is expended. (See 36/37.2.5.3 for permitted common paths of travel distances.)

Although the basic requirement of 36/37.2.4 mandates that a mercantile occupancy is to be provided with at least two remotely located exits, 36/37.2.4.3 permits a single exit for Class C (small) mercantile stores, such as tobacco shops, newsstands, and small 24-hour convenience stores. If the travel distance from any point in such a store to an exit is 23 m (75 ft) or less, the likelihood that a fire might surprise and overcome the customers before they could escape is low (see Exhibit 36/37.11). The provision of 36/37.2.4.4 allows a single exit in small, sprinklered mercantile occupancies if travel to an exit is not more than 30 m (100 ft). Furthermore, a single exit is permitted in Class C occupancies where travel distance to a mall that qualifies as a pedestrian way in accordance

CHAPTER 37 • Existing

37.2.4.5 A single means of egress to an exit or to a mall shall be permitted from a mezzanine within any Class A, Class B, or Class C mercantile occupancy, provided that the common path of travel does not exceed 23 m (75 ft), or does not exceed 30 m (100 ft) if protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

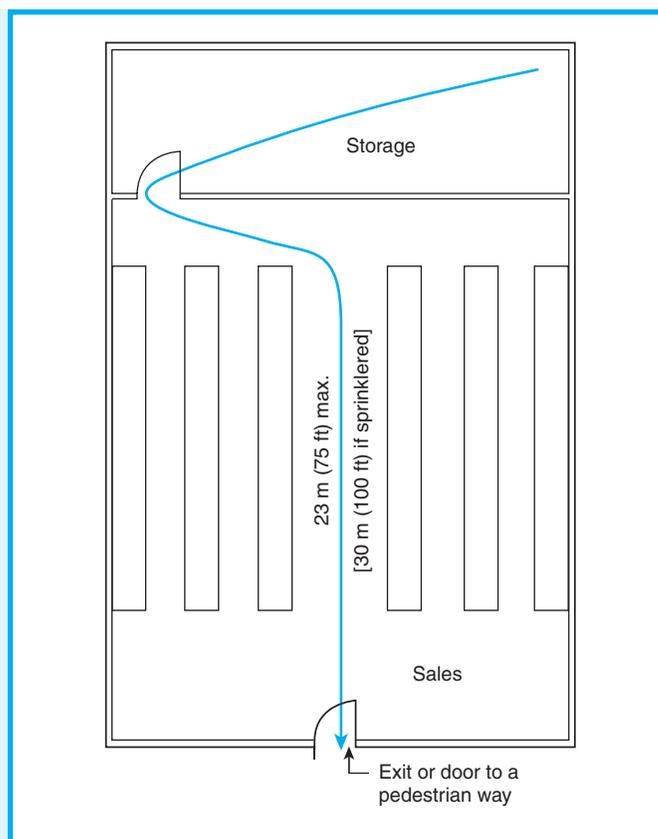

Exhibit 36/37.11 Single exit permitted in a Class C mercantile occupancy if travel distance is limited.

with 36/37.4.4.2 does not exceed 30 m (100 ft). The provisions of 36/37.4.4.2 include an automatic sprinkler system requirement for the entire mall building. Additional flexibility and a potential increase in security is provided by 36/37.2.4.4 for those small stores protected by means of automatic sprinkler installations within the store and for those portions of the overall building that occupants must traverse to reach an exit or pedestrian way.

CHAPTER 36 • New

36.2.5 Arrangement of Means of Egress.

36.2.5.1 Means of egress shall be arranged in accordance with Section 7.5.

36.2.5.2 Dead-end corridors shall comply with 36.2.5.2.1 or 36.2.5.2.2.

36.2.5.2.1 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), dead-end corridors shall not exceed 15 m (50 ft).

36.2.5.2.2 In all buildings not complying with 36.2.5.2.1, dead-end corridors shall not exceed 6100 mm (240 in.).

36.2.5.3 Common paths of travel shall be limited as follows:

- (1) Common paths of travel shall not exceed 23 m (75 ft) in mercantile occupancies classified as low or ordinary hazard.
- (2) Common paths of travel shall not exceed 30 m (100 ft) in mercantile occupancies classified as low or ordinary hazard where the building is protected throughout by an approved supervised automatic sprinkler system in accordance with 9.7.1.1(1).
- (3) Common paths of travel shall not be permitted in mercantile occupancies classified as high hazard.

36.2.5.4 Aisles leading to each exit shall be required, and the aggregate width of such aisles shall be not less than the required width of the exit.

36.2.5.5 Required aisles shall be not less than 915 mm (36 in.) in clear width.

36.2.5.6 In Class A mercantile occupancies, not less than one aisle of a 1525 mm (60 in.) minimum width shall lead directly to an exit.

CHAPTER 37 • Existing

37.2.5 Arrangement of Means of Egress.

37.2.5.1 Means of egress shall be arranged in accordance with Section 7.5.

37.2.5.2* Dead-end corridors shall not exceed 15 m (50 ft).

A.37.2.5.2 The purpose of 37.2.5.2 is to avoid pockets or dead ends of such size that they pose an undue danger of persons becoming trapped in case of fire.

It is recognized that dead ends exceeding the permitted limits exist and, in some cases, are impractical to eliminate. The authority having jurisdiction might permit such dead ends to continue to exist, taking into consideration any or all of the following:

- (1) Tenant arrangement
- (2) Automatic sprinkler protection
- (3) Smoke detection
- (4) Exit remoteness

37.2.5.3* Common paths of travel shall be limited in accordance with 37.2.5.3.1 or 37.2.5.3.2.

A.37.2.5.3 It is recognized that common paths of travel exceeding the permitted limits exist and, in some cases, are impractical to eliminate. The authority having jurisdiction might permit such paths of travel to continue to exist, taking into consideration any or all of the following:

- (1) Tenant arrangement
- (2) Automatic sprinkler protection
- (3) Smoke detection
- (4) Exit remoteness

37.2.5.3.1 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), a common path of travel shall be permitted for the first 30 m (100 ft).

37.2.5.3.2 In buildings not complying with 37.2.5.3.1, common paths of travel shall not exceed 23 m (75 ft).

37.2.5.4 Aisles leading to each exit shall be required, and the aggregate width of such aisles shall be not less than the required width of the exit.

37.2.5.5 Required aisles shall be not less than 710 mm (28 in.) in clear width.

37.2.5.6 In Class A mercantile occupancies, not less than one aisle of a 1525-mm (60-in.) minimum width shall lead directly to an exit.

CHAPTER 36 • New

36.2.5.7 In other than bulk merchandising retail buildings, if the only means of customer entrance is through one exterior wall of the building, two-thirds of the required egress width shall be located in such wall.

36.2.5.8 Not less than one-half of the required exits shall be located so as to be reached without passing through checkout stands.

36.2.5.9 Checkout stands or associated railings or barriers shall not obstruct exits, required aisles, or approaches thereto.

36.2.5.10* Where wheeled carts or buggies are used by customers, adequate provision shall be made for the transit and parking of such carts to minimize the possibility that they might obstruct means of egress.

A.36.2.5.10 To eliminate the obstruction to the means of egress of the interior exit access and the exterior exit discharge, it is the intent to provide adequate area for transit and parking of wheeled carts or buggies used by customers. This area includes corral areas adjacent to exits that are constructed to restrict the movement of wheeled carts or buggies therefrom.

36.2.5.11 Exit access in Class A and Class B mercantile occupancies that are protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), and exit access in all Class C mercantile occupancies, shall be permitted to pass through storerooms, provided that the following conditions are met:

- (1) Not more than 50 percent of exit access shall be provided through the storeroom.
- (2) The storeroom shall not be subject to locking.
- (3) The main aisle through the storeroom shall be not less than 1120 mm (44 in.) wide.
- (4) The path of travel through the storeroom, defined with fixed barriers, shall be direct and continuously maintained in an unobstructed condition.

The provision of 36.2.5.2.1 recognizes the additional level of safety to life provided by a complete automatic sprinkler system and permits added flexibility when designing the location of corridors and exits in buildings where approved sprinkler systems are installed. The provision allows dead-end corridor

CHAPTER 37 • Existing

37.2.5.7 In other than bulk merchandising retail buildings, if the only means of customer entrance is through one exterior wall of the building, two-thirds of the required egress width shall be located in such wall.

37.2.5.8 Not less than one-half of the required exits shall be located so as to be reached without passing through checkout stands.

37.2.5.9 Checkout stands or associated railings or barriers shall not obstruct exits, required aisles, or approaches thereto.

37.2.5.10* Where wheeled carts or buggies are used by customers, adequate provision shall be made for the transit and parking of such carts to minimize the possibility that they might obstruct means of egress.

A.37.2.5.10 To eliminate the obstruction to the means of egress of the interior exit access and the exterior exit discharge, it is the intent to provide adequate area for transit and parking of wheeled carts or buggies used by customers. This area includes corral areas adjacent to exits that are constructed to restrict the movement of wheeled carts or buggies therefrom.

37.2.5.11 Exit access in Class A mercantile occupancies that are protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1) and exit access in all Class B and Class C mercantile occupancies shall be permitted to pass through storerooms, provided that the following conditions are met:

- (1) Not more than 50 percent of exit access shall be provided through the storeroom.
- (2) The storeroom shall not be subject to locking.
- (3) The main aisle through the storeroom shall be not less than 1120 mm (44 in.) wide.
- (4) The path of travel through the storeroom, defined with fixed barriers, shall be direct and continuously maintained in an unobstructed condition.

pockets in new mercantile occupancies to be as long as 15 m (50 ft). Dead-end corridor pockets in existing mercantile occupancies are permitted to be 15 m (50 ft) long without any requirement for sprinklers.

Common path of travel limits are provided in 36/37.2.5.3. See the commentary following A.7.5.1.5 for

CHAPTER 36 • New

a detailed discussion on common path of travel. Also see the commentary on 36/37.2.4.2, which allows the access to a single exit or a portion of the access to multiple exits to be common.

The provisions of 36/37.2.5.4 are intended to prevent constrictions in the means of egress system that would delay egress of building occupants. The aggregate width of aisles leading to an exit is required to provide egress width equal to that required of the exit to which they lead. Without this provision, occupants could be forced to squeeze through a relatively narrow aisle or similar constriction before reaching, for example, an expansive bank of doors to the outside. The egress capacity at the doors, rather than providing simultaneous egress for the large number of occupants assigned to that exit, would not be fully utilized. Occupants would move through the doors a few at a time as they passed slowly through the constriction. The requirement of 36/37.2.5.4 is illustrated in Exhibit 36/37.12 in the upper left and right corners of the floor plan of the mercantile occupancy.

The minimum 915-mm (36-in.) aisle width required for new mercantile occupancies by 36.2.5.5, and the minimum 710-mm (28-in.) aisle width re-

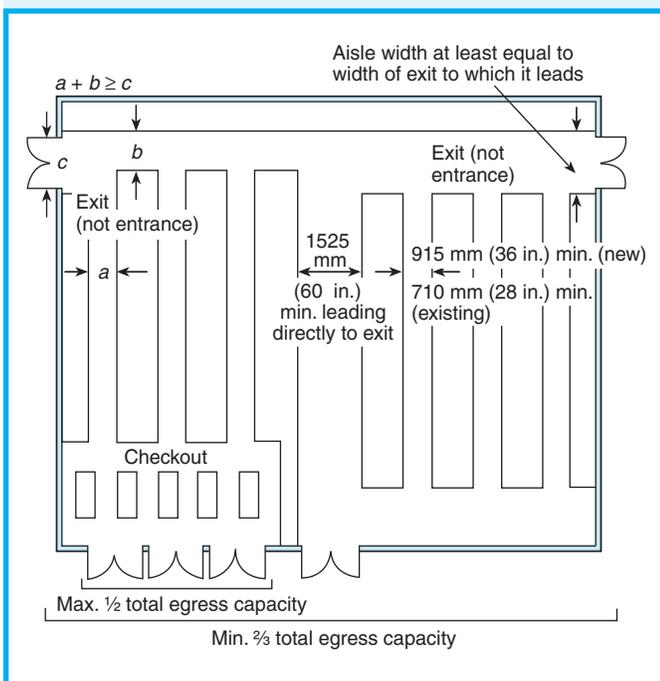

Exhibit 36/37.12 Means of egress arrangement in a Class A mercantile occupancy.

quired for existing mercantile occupancies by 37.2.5.5, are illustrated in Exhibit 36/37.12. These minimum widths are consistent with those prescribed by 7.3.4.1(2) and 7.3.4.1.2.

The intent of 36/37.2.5.4 through 36/37.2.5.6 is to ensure that the interior arrangement of counters, racks, and displays of merchandise does not block or obscure access to an exit. The arrangement illustrated in Exhibit 36/37.12 meets the requirements for a Class A store. Essentially, the width of the exit determines the minimum widths of the aisles, with the added proviso that one of the aisles must be at least 1525 mm (60 in.) wide and lead directly to an exit.

In establishing the requirements of 36/37.2.5.7, the *Code* demonstrates its concern regarding the arrangement of many discount and variety stores that have one large main exit/entrance located in the front of the store and the other exits (which cannot be used as entrances) situated at points unfamiliar to the public. In these mercantile occupancy arrangements, the wall containing the main exit/entrance must be sized to handle two-thirds of the required egress capacity of the store because the public is familiar with this entrance/exit and most customers will use it as an exit under emergency conditions. This requirement is illustrated in the lower portion of Exhibit 36/37.12.

One of the most frequently violated provisions of Chapter 36/37 is contained in 36/37.2.5.8. In many supermarkets and discount and variety stores, it is necessary to pass through checkout counters, around shopping carts, and through turnstiles to exit the facility. This process causes congestion or blockage during an emergency. The *Code* requires at least one-half of all exits to be located so that occupants can avoid passing through or around these impediments to egress. See Exhibit 36/37.12.

The potential encroachment on egress width by shopping carts is addressed by 36/37.2.5.10. In jurisdictions where returnable beverage bottle legislation has been enacted, stores and markets have had to create space for collecting empty bottles and refunding deposit charges. An area commonly used is located near the entrance/exit where wheeled shopping carts were formerly stored to be clear of the path of egress travel. The displaced carts are now often stored so that they obstruct the means of egress. This illustrates a situation where a properly designed, installed, and complying means of egress might be compromised abruptly by unexpected changes.

The provisions of 36/37.2.5.11 addresses egress

CHAPTER 36 • New

CHAPTER 37 • Existing

paths through storerooms in the following occupancies:

- (1) All Class C mercantile occupancies
- (2) Existing Class B mercantile occupancies
- (3) New Class B mercantile occupancies protected throughout, by an approved, supervised automatic sprinkler system
- (4) All Class A mercantile occupancies protected throughout by an approved, supervised automatic sprinkler system

The storeroom is limited by 36/37.2.5.11(1) to providing a maximum of 50 percent of the store's exit

access in number of exits and exit capacity. Therefore, because two exits are required, neither of the following limits can be exceeded:

- (1) Only one of the two required exits can be reached by exit access travel through the storeroom.
- (2) A maximum of one-half of the store's occupant load is permitted to egress through the storeroom.

Exhibits 36/37.13 and 36/37.14 illustrate the application of the provisions of 36/37.2.5.11. Fixed barriers, such as those formed by the ends of shelving, must define the aisle within the storeroom. The aisle must be kept unobstructed.

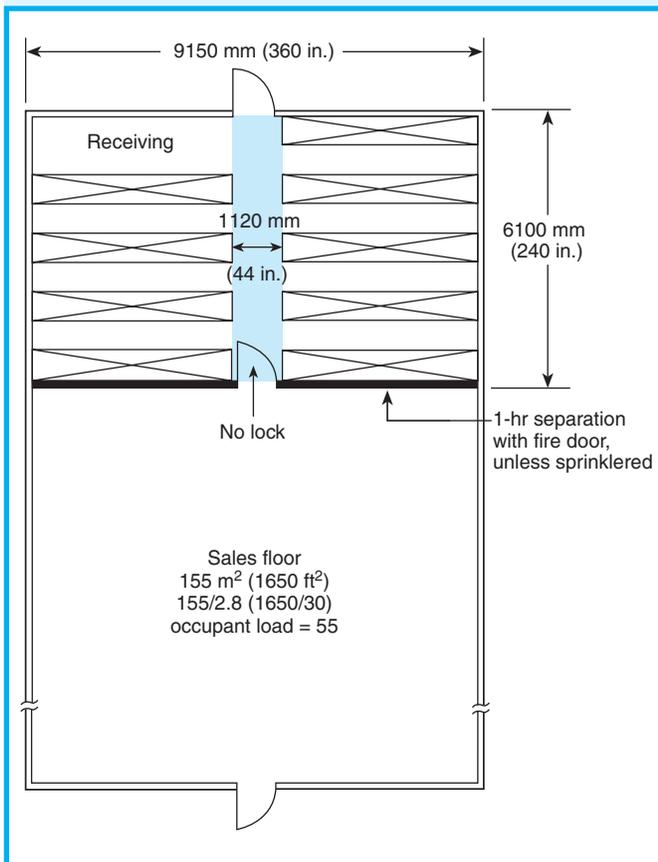

Exhibit 36/37.13 Exit access through a storeroom as permitted by 36/37.2.5.11.

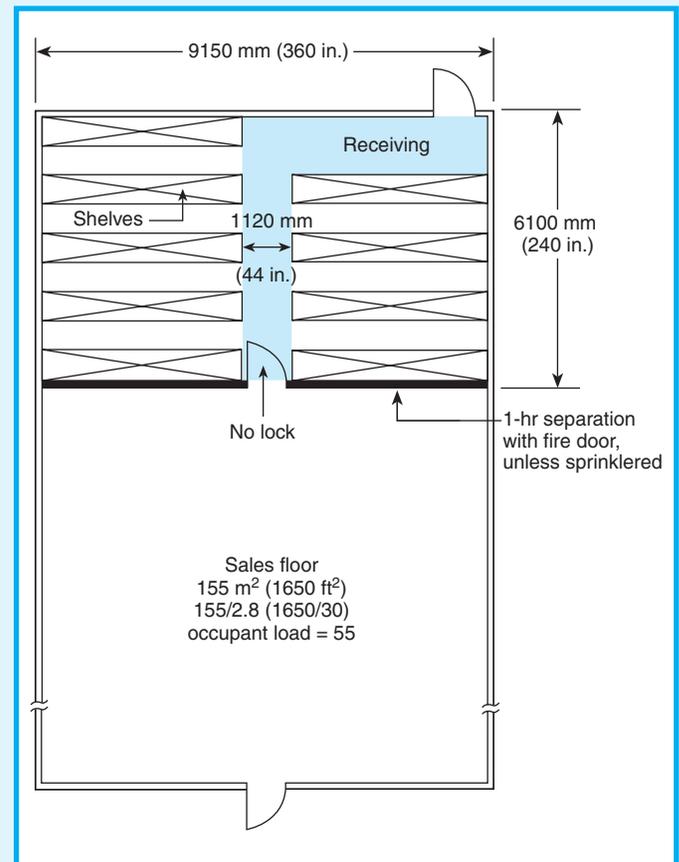

Exhibit 36/37.14 Exit access through a storeroom that is problematic because it passes through receiving area.

36.2.6 Travel Distance to Exits.

Travel distance shall be as specified in 36.2.6.1, 36.2.6.2, and 36.2.6.3 and shall be measured in accordance with Section 7.6.

37.2.6 Travel Distance to Exits.

Travel distance shall be as specified in 37.2.6.1 and 37.2.6.2 and shall be measured in accordance with Section 7.6.

CHAPTER 36 • New

36.2.6.1 In mercantile occupancies classified as ordinary hazard, travel distance shall not exceed 46 m (150 ft).

36.2.6.2 In mercantile occupancies classified as ordinary hazard in buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), travel distance shall not exceed 76 m (250 ft).

36.2.6.3 In mercantile occupancies classified as high hazard, travel distance shall not exceed 23 m (75 ft).

In accordance with Section 7.6, travel distance limitations apply to only the first (or nearest) exit from a given point in the building. In other words, the 46-m (150-ft) travel distance limit for nonsprinklered mercantile occupancies [76 m (250 ft) for sprinklered occupancies] requires that at least one exit must be located within 46 m (150 ft) [76 m (250 ft) if sprin-

36.2.7 Discharge from Exits.

36.2.7.1 Exit discharge shall comply with Section 7.7 and 36.2.7.2.

36.2.7.2* Fifty percent of the exits shall be permitted to discharge through the level of exit discharge in accordance with 7.7.2 only where the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), and the distance of travel from the termination of the exit enclosure to an outside street door shall not exceed 15 m (50 ft).

A.36.2.7.2 The basis for the exemption to the general rule on complete enclosure of exits up to their point of discharge to the outside of the building is that, with the specified safeguards, reasonable safety is maintained.

A stairway is not considered to discharge through the street floor area if it leads to the street through a fire resistance-rated enclosure (exit passageway) separating it from the main area, even though there are doors between the first floor stairway landing and the main area.

The provisions of 36.2.7.2 should not be confused with those for open stairways as permitted by 36.3.1(1).

The restriction imposed by 36/37.2.7.2 is intended to prevent more than 50 percent of the exits from any floor from discharging through the street floor. Fur-

CHAPTER 37 • Existing

37.2.6.1 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), travel distance shall not exceed 76 m (250 ft).

37.2.6.2 In buildings not complying with 37.2.6.1, the travel distance shall not exceed 46 m (150 ft).

klered] of a point in the building; it does not require that all exits must be within 46 m (150 ft) [76 m (250 ft) if sprinklered] of that same point in the building. Note that these travel distance limitations were increased from those found prior to the 2003 edition of the *Code*, recognizing the good life-loss history associated with fires in mercantile occupancies.

37.2.7 Discharge from Exits.

37.2.7.1 Exit discharge shall comply with Section 7.7 and 37.2.7.2.

37.2.7.2* Fifty percent of the exits shall be permitted to discharge through the level of exit discharge in accordance with 7.7.2 only where the building is protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1), and the distance of travel from the termination of the exit enclosure to an outside street door shall not exceed 15 m (50 ft).

A.37.2.7.2 The basis for the exemption to the general rule on complete enclosure of exits up to their point of discharge to the outside of the building is that, with the specified safeguards, reasonable safety is maintained.

A stairway is not considered to discharge through the street floor area if it leads to the street through a fire resistance-rated enclosure (exit passageway) separating it from the main area, even though there are doors between the first floor stairway landing and the main area.

The provisions of 37.2.7.2 should not be confused with those for open stairways as permitted by 37.3.1(1) and 37.3.1(2).

thermore, such exit discharge is permitted only where the building is sprinklered throughout. Note that the path of travel on the first floor from the stair enclosure

CHAPTER 36 • New

to the outside door cannot exceed 15 m (50 ft). The remaining 50 percent of the exits must discharge directly to the exterior.

The requirements of 36/37.2.7.2 are more stringent than those of 7.7.2, because they mandate automatic sprinkler protection throughout the building, set a 15-m (50-ft) interior exit discharge travel limit on the street floor, and require the street floor to have

36.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

36.2.9 Emergency Lighting.

Class A and Class B mercantile occupancies and mall buildings shall have emergency lighting facilities in accordance with Section 7.9.

36.2.10 Marking of Means of Egress.

Where an exit is not immediately apparent from all portions of the sales area, means of egress shall have signs in accordance with Section 7.10.

36.2.11 Special Means of Egress Features.

(Reserved)

Note that illumination for the means of egress, addressed in 36/37.2.8, is not the same as emergency lighting. Failure of the building power supply might cause failure of the means of egress illumination system, which is not required to have a backup, auxiliary, or secondary power supply unless mandated by 36/37.2.9, which addresses emergency lighting. Due to their small size and small occupant load, Class C mercantile occupancies are not required by the *Code* to be provided with emergency lighting.

Section 36.3 Protection

36.3.1 Protection of Vertical Openings.

Any vertical opening shall be protected in accordance with Section 8.6, except under the following conditions:

- (1) In Class A or Class B mercantile occupancies protected throughout by an approved, supervised automatic sprin-

CHAPTER 37 • Existing

an exit capacity that accommodates the occupant load of the street floor and the stairs discharging through the street floor. These requirements are not mandated by 7.7.2. The added requirements are imposed in recognition of the high combustible load of merchandise that might be on display, which is characteristic of mercantile occupancies.

37.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

37.2.9 Emergency Lighting.

Class A and Class B mercantile occupancies and mall buildings shall have emergency lighting facilities in accordance with Section 7.9.

37.2.10 Marking of Means of Egress.

Where an exit is not immediately apparent from all portions of the sales area, means of egress shall have signs in accordance with Section 7.10.

37.2.11 Special Means of Egress Features.

(Reserved)

The intent of 36/37.2.10 is to avoid requiring exit signs in small areas where the exit is readily apparent. For example, exit signs would not be required in the office of a service station, the purchase and dining areas of a small fast food restaurant, or in a Class C store where size and arrangement comply with the single-exit provisions of 36/37.2.4.3 or 36/37.2.4.4.

Section 37.3 Protection

37.3.1 Protection of Vertical Openings.

Any vertical opening shall be protected in accordance with Section 8.6, except under the following conditions:

- (1) In Class A or Class B mercantile occupancies protected throughout by an approved, supervised automatic sprin-

CHAPTER 36 • New

kler system in accordance with 9.7.1.1(1), unprotected vertical openings shall be permitted at one of the following locations:

- (a) Between any two floors
 - (b) Among the street floor, the first adjacent floor below, and adjacent floor (or mezzanine) above
- (2) In Class C mercantile occupancies, unprotected openings shall be permitted between the street floor and the mezzanine.
- (3) The draft stop and closely spaced sprinkler requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not be required for unenclosed vertical openings permitted in 36.3.1(1) and 36.3.1(2).

36.3.2 Protection from Hazards.

36.3.2.1* Hazardous areas shall be protected in accordance with 36.3.2.1.1 or 36.3.2.1.2

A.36.3.2.1 It is the intent to permit a suspended natural gas-fired unit heater that complies with the requirements of 9.2.2 to be installed and used in a mercantile occupancy without classifying the area in which it is located as hazardous.

36.3.2.1.1* Hazardous areas shall be protected in accordance with Section 8.7.

A.36.3.2.1.1 These areas can include, but are not limited to, areas used for general storage, boiler or furnace rooms, and maintenance shops that include woodworking and painting areas.

36.3.2.1.2 In general storage and stock areas protected by an automatic extinguishing system in accordance with 9.7.1.1(1) or 9.7.1.2, an enclosure shall be exempt from the provisions of 8.7.1.2.

36.3.2.2* High hazard contents areas, as classified in Section 6.2, shall meet the following criteria:

- (1) The area shall be separated from other parts of the building by fire barriers having a fire resistance rating of not less than 1 hour, with all openings therein protected by $\frac{3}{4}$ -hour fire protection-rated self-closing fire door assemblies.
- (2) The area shall be protected by an automatic extinguishing system in accordance with 9.7.1.1(1) or 9.7.1.2.
- (3) In high hazard areas, all vertical openings shall be enclosed.

A.36.3.2.2 The requirement for separating high hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

CHAPTER 37 • Existing

kler system in accordance with 9.7.1.1(1), unprotected vertical openings shall be permitted at one of the following locations:

- (a) Between any two floors
 - (b) Among the street floor, the first adjacent floor below, and adjacent floor (or mezzanine) above
- (2) In Class C mercantile occupancies, unprotected openings shall be permitted between the street floor and the mezzanine.
- (3) The draft stop and closely spaced sprinkler requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, shall not be required for unenclosed vertical openings permitted in 37.3.1(1) and 37.3.1(2).

37.3.2 Protection from Hazards.

37.3.2.1* Hazardous areas shall be protected in accordance with 37.3.2.1.1 or 37.3.2.1.2.

A.37.3.2.1 It is the intent to permit a suspended natural gas-fired unit heater that complies with the requirements of 9.2.2 to be installed and used in a mercantile occupancy without classifying the area in which it is located as hazardous.

37.3.2.1.1* Hazardous areas shall be protected in accordance with Section 8.7.

A.37.3.2.1.1 These areas can include, but are not limited to, areas used for general storage, boiler or furnace rooms, and maintenance shops that include woodworking and painting areas.

37.3.2.1.2 In general storage and stock areas protected by an automatic extinguishing system in accordance with 9.7.1.1(1) or 9.7.1.2, an enclosure shall be exempt from the provisions of 8.7.1.2.

37.3.2.2* High hazard contents areas, as classified in Section 6.2, shall meet the following criteria:

- (1) The area shall be separated from other parts of the building by fire barriers having a fire resistance rating of not less than 1 hour, with all openings therein protected by $\frac{3}{4}$ -hour fire protection-rated self-closing fire door assemblies.
- (2) The area shall be protected by an automatic extinguishing system in accordance with 9.7.1.1(1) or 9.7.1.2.

A.37.3.2.2 The requirement for separating high hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

CHAPTER 36 • New

36.3.3 Interior Finish.

36.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

36.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B.

36.3.3.3 Interior Floor Finish.

36.3.3.3.1 Interior floor finish shall comply with Section 10.2.

36.3.3.3.2 Interior finish in exit enclosures shall be Class I or Class II.

Vertical openings are addressed by 36/37.3.1. The provisions of 36/37.1.7 should be followed to assess the egress capacity for a store in which floors or mezzanines are open to the street floor. The criteria in 36/37.3.1(1) specify conditions under which such openings are permitted in sprinklered Class A and Class B mercantile occupancies.

The protection of hazardous areas is addressed by 36/37.3.2. The requirements in 8.7.1.2 normally mandate that a hazardous area protected by automatic sprinklers, rather than by enclosure with fire barriers with a 1-hour fire resistance rating and doors with a 45-minute fire protection rating, is to be enclosed by walls and doors that are at least smoke resisting. Hazardous areas composed of general storage and stock areas in a mercantile occupancy are permitted to be protected by automatic sprinklers without the need for a smoke-resisting enclosure per 36/37.3.2.1.2. In a shoe store, for example, where the

36.3.4 Detection, Alarm, and Communications Systems.

36.3.4.1 General. Class A mercantile occupancies shall be provided with a fire alarm system in accordance with Section 9.6.

36.3.4.2 Initiation. Initiation of the required fire alarm system shall be by any one of the following:

CHAPTER 37 • Existing

37.3.3 Interior Finish.

37.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

37.3.3.2 Interior Wall and Ceiling Finish.

37.3.3.2.1 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B.

37.3.3.2.2 Existing Class C interior wall and ceiling finish shall be permitted as follows:

- (1) On walls
- (2) Throughout Class C stores

37.3.3.3 Interior Floor Finish. (No requirements)

shoe storage area is sprinklered, no door would be required on the opening between the sales floor and the storage area.

Section 8.7, as referenced by 36/37.3.2.1.1, requires one of the following:

- (1) Separation of a hazardous contents area from the remainder of the occupancy by means of suitable construction
- (2) Installation of an automatic sprinkler system in a hazardous area
- (3) Both items (1) and (2) where the hazard is severe

Interior finish is addressed by 36/37.3.3. The provision of 37.3.3.2.2 states that, in existing Class C stores only, all interior finish (walls and ceilings) is permitted to be rated as Class C (flame spread as high as 200). Existing Class A and B stores are permitted to use Class C interior finish on the walls, but such finish is prohibited on the ceiling.

37.3.4 Detection, Alarm, and Communications Systems.

37.3.4.1 General. Class A mercantile occupancies shall be provided with a fire alarm system in accordance with Section 9.6.

37.3.4.2 Initiation. Initiation of the required fire alarm system shall be by one of the following:

CHAPTER 36 • New

- (1) Manual means in accordance with 9.6.2.1(1)
- (2) An approved automatic fire detection system that complies with 9.6.2.1(2) and provides protection throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5
- (3) An approved automatic sprinkler system that complies with 9.6.2.1(3) and provides protection throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5

36.3.4.3 Notification.

36.3.4.3.1 Occupant Notification. During all times that the mercantile occupancy is occupied, the required fire alarm system, once initiated, shall perform one of the following functions:

- (1) It shall activate an alarm in accordance with 9.6.3 throughout the mercantile occupancy. Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.
- (2) It shall activate an alarm signal in a continuously attended location for the purpose of initiating emergency action, by personnel trained to respond to emergencies, as follows:
 - (a) Emergency action shall be initiated by means of live voice public address system announcements originating from the attended location where the alarm signal is received.
 - (b) The live voice public address system shall be permitted to be used for other announcements, provided that the emergency action use takes precedence over any other use.

36.3.4.3.2 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying the following:

- (1) The fire department in accordance with 9.6.4
- (2) The local emergency organization, if provided

Neither Class B nor Class C mercantile occupancies are required to have a fire alarm system.

Because all new Class A stores and most existing Class A stores must be sprinklered based on gross floor area (see 36/37.3.5.1), it is logical that the sprinkler system waterflow method described in 36/37.3.4.2(3) will be used most commonly to activate the fire alarm system. The requirement for manual fire alarm boxes is waived if the sprinkler waterflow activates the fire alarm system. Nuisance alarms

CHAPTER 37 • Existing

- (1) Manual means per 9.6.2.1(1)
- (2) An approved automatic fire detection system that complies with 9.6.2.1(2) and provides protection throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5
- (3) An approved automatic sprinkler system that complies with 9.6.2.1(3) and provides protection throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5

37.3.4.3 Notification.

37.3.4.3.1 Occupant Notification. During all times that the mercantile occupancy is occupied, the required fire alarm system, once initiated, shall perform one of the following functions:

- (1) It shall activate an alarm in accordance with 9.6.3 throughout the mercantile occupancy. Positive alarm sequence in accordance with 9.6.3.4 or a presignal system in accordance with 9.6.3.3 shall be permitted.
- (2) It shall activate an alarm signal in a continuously attended location for the purpose of initiating emergency action by personnel trained to respond to emergencies, as follows:
 - (a) Emergency action shall be initiated by means of live voice public address system announcements originating from the attended location where the alarm signal is received.
 - (b) The live voice public address system shall be permitted to be used for other announcements, provided that the emergency action use takes precedence over any other use.

37.3.4.3.2 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying the following:

- (1) The fire department in accordance with 9.6.4
- (2) The local emergency organization, if provided

might be reduced by eliminating the manual fire alarm boxes and satisfying the initiation requirements by means of waterflow through the sprinkler system. However, in accordance with 9.6.2.5, at least one manual fire alarm box must be provided at a location acceptable to the authority having jurisdiction.

Positive alarm sequence, which is an updated form of a presignal system for which numerous safeguards must be provided, is recognized by 36/

CHAPTER 36 • New

37.3.4.3.1(1). Presignal systems, as recognized by 37.3.4.3.1(1), are only permitted in existing mercantile occupancies.

Note that 36/37.3.4.3.1 provides a choice between two methods of notification. Many Class A stores are provided with a continuously attended location; 36/37.3.4.3.1(2) can, therefore, be used. If such a location is not provided or not considered reliable by the au-

36.3.5 Extinguishment Requirements.

36.3.5.1 Mercantile occupancies shall be protected by an approved automatic sprinkler system in accordance with 9.7.1.1(1) as follows:

- (1) Throughout all mercantile occupancies three or more stories in height
- (2) Throughout all mercantile occupancies exceeding 1115 m² (12,000 ft²) in gross area
- (3) Throughout stories below the level of exit discharge where such stories have an area exceeding 232 m² (2500 ft²) and used for the sale, storage, or handling of combustible goods and merchandise
- (4) Throughout multiple occupancies protected as mixed occupancies in accordance with 6.1.14 where the conditions of 36.3.5.1(1), 36.3.5.1(2), or 36.3.5.1(3) apply to the mercantile occupancy

36.3.5.2 Automatic sprinkler systems in Class A mercantile occupancies shall be supervised in accordance with 9.7.2.

36.3.5.3 Portable fire extinguishers shall be provided in all mercantile occupancies in accordance with 9.7.4.1.

For information on the proper criteria for an approved automatic sprinkler system, refer to the following:

- (1) NFPA 13, *Standard for the Installation of Sprinkler Systems*²
- (2) NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*³
- (3) *Automatic Sprinkler and Standpipe Systems*⁴

All basement areas larger than 232 m² (2500 ft²) and used for sales, storage, or the handling of combustible merchandise must be sprinklered per 36/37.3.5.1(3) to avoid the potential threat to occupants of the floors above. Studies have shown that there is

CHAPTER 37 • Existing

thority having jurisdiction, 36/37.3.4.3.1(1) must be applied to provide an automatic general alarm in accordance with 9.6.3.

Where a fire alarm system is required, emergency forces notification must also be provided as specified by 36/37.3.4.3.2. Several different methods of automatically notifying the fire department are permitted by 9.6.4.

37.3.5 Extinguishment Requirements.

37.3.5.1 Mercantile occupancies, other than single-story buildings that meet the requirements of a street floor as defined in 3.3.216, shall be protected by an approved automatic sprinkler system in accordance with 9.7.1.1(1) as follows:

- (1) Throughout all mercantile occupancies with a story over 1400 m² (15,000 ft²) in area
- (2) Throughout all mercantile occupancies exceeding 2800 m² (30,000 ft²) in gross area
- (3) Throughout stories below the level of exit discharge where such stories have an area exceeding 232 m² (2500 ft²) and used for the sale, storage, or handling of combustible goods and merchandise
- (4) Throughout multiple occupancies protected as mixed occupancies in accordance with 6.1.14 where the conditions of 37.3.5.1(1), 37.3.5.1(2), or 37.3.5.1(3) apply to the mercantile occupancy

37.3.5.2 Reserved.

37.3.5.3 Portable fire extinguishers shall be provided in all mercantile occupancies in accordance with 9.7.4.1.

a higher rate of fire incidence in basements than in other areas of stores. Because smoke and heat rise, a fire in a basement can quickly render exits and exit discharges located on the street floor unusable. This danger is especially acute in mercantile occupancies, where allowances for various vertical openings in accordance with the provisions of 36/37.3.1 are more lenient than those for many other occupancies.

The sprinkler exemption in 37.3.5.1 applies to existing buildings only. It is believed that, in existing, one-story, street-floor buildings that comply with all other provisions of the *Code*, including exit travel distance limitations, adequate life safety is provided. Therefore, requiring a building to be sprinklered

CHAPTER 36 • New

retroactively is unnecessary. The term *street floor* is defined in 3.3.216 and includes a maximum of three risers of ascent or descent to reach the ground level.

36.3.6 Corridors.

36.3.6.1* Where access to exits is provided by corridors, such corridors shall be separated from use areas by walls having a fire resistance rating of not less than 1 hour in accordance with Section 8.3, except under any of the following conditions:

- (1) Where exits are available from an open floor area
- (2) Within a space occupied by a single tenant
- (3) Within buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)

A.36.3.6.1 The intent of 36.3.6.1(2) and 36.3.6.1(3) is to permit spaces within single tenant spaces, or within buildings protected throughout by an approved, supervised automatic sprinkler system, to be open to the exit access corridor without separation.

36.3.6.2 Openings in corridor walls required by 36.3.6.1 to have a fire resistance rating shall be protected in accordance with Section 8.3.

36.3.7 Subdivision of Building Spaces.

(No special requirements.)

Section 36.4 Special Provisions**36.4.1 Limited Access or Underground Buildings.**

See Section 11.7.

36.4.2 High-Rise Buildings.

High-rise buildings shall comply with the automatic sprinkler requirements of 11.8.2.1.

36.4.3 Open-Air Mercantile Operations.

36.4.3.1 Open-air mercantile operations, such as open-air markets, gasoline filling stations, roadside stands for the sale of farm produce, and other outdoor mercantile operations shall be arranged and conducted to maintain free and unobstructed ways of travel at all times.

CHAPTER 37 • Existing

The portable fire extinguishers required by 36/37.3.5.3 are to be used by properly trained employees of the mercantile occupancy as required by 36/37.7.2.

37.3.6 Corridors.

(No requirements)

37.3.7 Subdivision of Building Spaces.

(No special requirements)

Section 37.4 Special Provisions**37.4.1 Limited Access or Underground Buildings.**

See Section 11.7.

37.4.2 High-Rise Buildings.

(No additional requirements)

37.4.3 Open-Air Mercantile Operations.

37.4.3.1 Open-air mercantile operations, such as open-air markets, gasoline filling stations, roadside stands for the sale of farm produce, and other outdoor mercantile operations shall be arranged and conducted to maintain free and unobstructed ways of travel at all times.

CHAPTER 36 • New

36.4.3.2 Ways of travel shall allow prompt escape from any point of danger in case of fire or other emergency, with no dead ends in which persons might be trapped due to display stands, adjoining buildings, fences, vehicles, or other obstructions.

36.4.3.3 Mercantile operations that are conducted in roofed-over areas shall be treated as mercantile buildings, provided that canopies over individual small stands to protect merchandise from the weather are not construed as constituting buildings for the purpose of this *Code*.

The provisions of Section 11.8, whether applied singly, in various combinations, or in total, must be mandated by specific occupancy chapter requirements. In new high-rise mercantile occupancies, 36.4.2 requires only the provisions of 11.8.2.1—an approved, supervised, automatic sprinkler system with an additional sprinkler control valve and waterflow device on each floor. The new high-rise mercantile occupancy must have a sprinkler system in accordance with 36.3.5.1 and the associated system supervision requirement of 36.3.5.2 for Class A stores, regardless of the reference to 11.8.2.1.

The performance requirements of 36/37.4.3.1 and 36/37.4.3.2 are virtually open-ended provisions that provide guidance for the arrangement, use, and display of merchandise for sale in open-air mercantile operations. The phrase “ways of travel” is purposely used to avoid confusion with means of egress. The

36.4.4 Mall Buildings.

The purpose of 36.4.4 shall be to establish minimum standards of life safety for mall buildings having not more than three levels. (*See 3.3.27.9.*)

36.4.4.1 General. The mall building shall be treated as a single building for the purpose of calculation of means of egress and shall be subject to the requirements for appropriate occupancies, except as modified by the provisions of 36.4.4; and the mall shall be of a clear width not less than that needed to accommodate egress requirements as set forth in other sections of this *Code*.

36.4.4.2 Pedestrian Way. The mall shall be permitted to be considered a pedestrian way, provided the criteria of 36.4.4.2.1 through 36.4.4.2.2 are met.

36.4.4.2.1 The travel distance within a tenant space to an exit or to the mall shall not exceed 61 m (200 ft) or the

CHAPTER 37 • Existing

37.4.3.2 Ways of travel shall allow prompt escape from any point of danger in case of fire or other emergency, with no dead ends in which persons might be trapped due to display stands, adjoining buildings, fences, vehicles, or other obstructions.

37.4.3.3 Mercantile operations that are conducted in roofed-over areas shall be treated as mercantile buildings, provided that canopies over individual small stands to protect merchandise from the weather are not construed as constituting buildings for the purpose of this *Code*.

term *means of egress* (see definition in 3.3.136) is strictly defined, and its use implies the application of the minimum requirements of Chapter 7. The phrase “ways of travel” is not defined and implies no specific minimum *Code* provisions. Most open-air mercantile operations have unlimited means of entering and evacuating the areas used to display goods. For this reason, it is not necessary to provide specific *Code* requirements beyond the precautionary measures expressed in these paragraphs.

The intent of 36/37.4.3.3 is to exempt small merchandise stands with canopies from classification as mercantile buildings. All other roofed-over areas should be treated as buildings, classified by area and height as Class A, Class B, or Class C mercantile occupancies, and subject to the appropriate provisions of Chapters 36 and 37.

37.4.4 Mall Buildings.

The purpose of 37.4.4 shall be to establish minimum standards of life safety for mall buildings. (*See 3.3.27.9.*)

37.4.4.1 General. The mall building shall be treated as a single building for the purpose of calculation of means of egress and shall be subject to the requirements for appropriate occupancies, except as modified by the provisions of 37.4.4; and the mall shall be of a clear width not less than that needed to accommodate egress requirements as set forth in other sections of this *Code*.

37.4.4.2 Pedestrian Way. The mall shall be permitted to be considered a pedestrian way, provided the criteria of 37.4.4.2.1 and 37.4.4.2.2 are met.

37.4.4.2.1 The travel distance within a tenant space to an exit or to the mall shall not exceed 61 m (200 ft) or the

CHAPTER 36 • New

maximum travel distance permitted by the occupancy chapter.

36.4.4.2.2 An additional 61 m (200 ft) shall be permitted for travel through the mall space if all the following requirements are met:

- (1) The mall shall be of a clear width not less than that needed to accommodate egress requirements as set forth in other sections of this chapter but shall be not less than 6100 mm (240 in.) wide in its narrowest dimension.
- (2) On each side of the mall floor area, the mall shall be provided with an unobstructed exit access of not less than 3050 mm (120 in.) in clear width parallel to and adjacent to the mall tenant front.
- (3)* Such exit access shall lead to an exit having a width of not less than 1675 mm (66 in.).

A.36.4.4.2.2(3) The minimum requirement for terminating mall exit access in not less than 1675 mm (66 in.) of egress width relates to the minimum requirement for not less than one aisle in Class A mercantile occupancies with 2800 m² (30,000 ft²) or greater sales area to be 1525 mm (60 in.) in width.

- (4) The mall and all buildings connected thereto shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1). The system shall be installed in such a manner that any portion of the system serving tenant spaces can be taken out of service without affecting the operation of the portion of the system serving the mall.
- (5) Walls dividing tenant spaces from each other shall extend from the floor to the underside of the roof deck, floor deck above, or ceiling where the ceiling is constructed to limit the transfer of smoke. Where the tenant areas are provided with an engineered smoke control system, walls shall not be required to divide tenant spaces from each other. No separation shall be required between a tenant space and the mall.
- (6)* The mall shall be provided with a smoke control system.

A.36.4.4.2.2(6) Fire experience in covered mall shopping centers indicates that the most likely place of fire origin is in the tenant space where the combustible fire load is far greater than in the covered mall proper.

Furthermore, any fires resulting from the comparatively low fire load in the covered mall proper are more likely to be detected and extinguished in their incipient stages. Early detection is likely due to the nature of the covered mall proper as a high traffic pedestrian way. Such fires produce less smoke development in a greater volume of space than fires in the more confined adjacent tenant space.

CHAPTER 37 • Existing

maximum travel distance permitted by the occupancy chapter.

37.4.4.2.2 An additional 61 m (200 ft) shall be permitted for travel through the mall space if all the following requirements are met:

- (1) The mall shall be of a clear width not less than that needed to accommodate egress requirements as set forth in other sections of this chapter but shall be not less than 6100 mm (240 in.) wide in its narrowest dimension.
- (2) On each side of the mall floor area, the mall shall be provided with an unobstructed exit access of not less than 3050 mm (120 in.) in clear width parallel to and adjacent to the mall tenant front.
- (3)* Such exit access shall lead to an exit having a width of not less than 1675 mm (66 in.).

A.37.4.4.2.2(3) The minimum requirement for terminating mall exit access in not less than 1675 mm (66 in.) of egress width relates to the minimum requirement for not less than one aisle in Class A mercantile occupancies [2800 m² (30,000 ft²) or greater sales area] to be 1525 mm (60 in.) in width.

- (4) The mall and all buildings connected thereto shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).
- (5) Walls dividing tenant spaces from each other shall extend from the floor to the underside of the roof deck, to the floor deck above, or to the ceiling where the ceiling is constructed to limit the transfer of smoke. Where the tenant areas are provided with an engineered smoke control system, walls shall not be required to divide tenant spaces from each other. No separation shall be required between a tenant space and the mall.
- (6)* The mall shall be provided with a smoke control system.

A.37.4.4.2.2(6) Fire experience in mall shopping centers indicates that the most likely place of fire origin is in the tenant space where the combustible fire load is far greater than in the mall proper.

Furthermore, any fires resulting from the comparatively low fire load in the covered mall proper are more likely to be detected and extinguished in their incipient stages. Early detection is likely due to the nature of the covered mall proper as a high traffic pedestrian way. Such fires produce less smoke development in a greater volume of space than in the more confined adjacent tenant space.

CHAPTER 36 • New

Smoke control systems that address fire experience in covered malls are necessary in order to achieve the following:

- (1) Ensure the integrity of the covered mall as a pedestrian way by maintaining it reasonably free of the products of combustion for a duration not less than that required to evacuate the building
- (2) Confine the products of combustion to the area of origin
- (3) Remove the products of combustion with a minimum of migration of such products of combustion from one tenant to another

Systems, or combinations of systems, that can be engineered to address fires in covered malls include the following:

- (1) Separate mechanical exhaust or control systems
- (2) Mechanical exhaust or control systems in conjunction with heating, ventilating, and air conditioning systems
- (3) Automatically or manually released gravity roof vent devices, such as skylights, relief dampers, or smoke vents
- (4) Combinations of items (1), (2), and (3) in this list, or any other engineered system designed to accomplish the purpose of this section

36.4.4.3 Means of Egress Details.

36.4.4.3.1 Dead ends not exceeding a length equal to twice the width of the mall measured at the narrowest location within the dead-end portion of the mall shall be permitted.

36.4.4.3.2 Every story of a mall building shall be provided with the number of means of egress specified by Section 7.4 and as modified by 36.4.4.3.2.1 or 36.4.4.3.2.2.

36.4.4.3.2.1 Exit access travel shall be permitted to be common for the distances permitted as common paths of travel by 36.2.5.3.

36.4.4.3.2.2 A single means of egress shall be permitted in a Class C mercantile occupancy or a business occupancy, provided the travel distance to the exit or to a mall does not exceed 30 m (100 ft).

36.4.4.3.3 Every floor of a mall shall be provided with the number of means of egress specified by Section 7.4, with not less than two means of egress remotely located from each other.

36.4.4.3.4 Class A and Class B mercantile occupancies connected to a mall shall be provided with the number of means of egress required by Section 7.4, with not less than two means of egress remotely located from one another.

CHAPTER 37 • Existing

Smoke control systems that address fire experience in covered malls are necessary in order to achieve the following:

- (1) Ensure the integrity of the covered mall as a pedestrian way by maintaining it reasonably free of the products of combustion for a duration not less than that required to evacuate the building
- (2) Confine the products of combustion to the area of fire origin
- (3) Remove the products of combustion with a minimum of migration of such products of combustion from one tenant to another

Systems, or combinations of systems, that can be engineered to address fires in covered malls include the following:

- (1) Separate or mechanical exhaust or control systems
- (2) Mechanical exhaust or control systems in conjunction with heating, ventilating, and air conditioning systems
- (3) Automatically or manually released gravity roof vent devices, such as skylights, relief dampers, or smoke vents
- (4) Combinations of items (1), (2), and (3) in this list, or any other engineered system designed to accomplish the purpose of this section

37.4.4.3 Means of Egress Details.

37.4.4.3.1 Dead ends not exceeding a length equal to twice the width of the mall measured at the narrowest location within the dead-end portion of the mall shall be permitted.

37.4.4.3.2 Every story of a covered mall building shall be provided with the number of means of egress specified by Section 7.4 and as modified by 37.4.4.3.2.1 or 37.4.4.3.2.2.

37.4.4.3.2.1 Exit access travel shall be permitted to be common for the distances permitted as common paths of travel by 37.2.5.3.

37.4.4.3.2.2 A single means of egress shall be permitted in a Class C mercantile occupancy or a business occupancy, provided the travel distance to the exit or to a mall does not exceed 30 m (100 ft).

37.4.4.3.3 Every floor of a mall shall be provided with the number of means of egress specified by Section 7.4, with not less than two means of egress remotely located from each other.

37.4.4.3.4 Class A and Class B mercantile occupancies connected to a mall shall be provided with the number of means of egress required by Section 7.4, with not less than two means of egress remotely located from one another.

CHAPTER 36 • New

36.4.4.3.5* Each individual anchor building shall have means of egress independent of the mall.

A.36.4.4.3.5 It is not the intent of 36.4.4.3.5 to require that large tenant spaces be considered anchor stores. A tenant space not considered in determining the occupant load of the mall is required to be arranged so that all of its means of egress will be independent of the covered mall.

36.4.4.3.6 Every mall shall be provided with unobstructed exit access parallel to and adjacent to the mall tenant fronts and extending to each mall exit.

36.4.4.3.7* Rooms housing building service equipment, janitor closets, and service elevators shall be permitted to open directly onto exit passageways, provided that the following criteria are met:

- (1) The required fire resistance rating between such rooms or areas and the exit passageway shall be maintained in accordance with 7.1.3.2.
- (2) Such rooms or areas shall be protected by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1); however, the exceptions in NFPA 13, *Standard for the Installation of Sprinkler Systems*, that permit the omission of sprinklers from such rooms shall not be permitted.
- (3) Service elevators opening into the exit passageway shall not open into areas other than exit passageways.
- (4) Where exit stair enclosures discharge into the exit passageway, the provisions of 7.2.1.5.7 shall apply regardless of the number of stories served.

A.36.4.4.3.7 Rooms opening onto the exit passageway are intended to include building service elevators, elevator machine rooms, electrical rooms, telephone rooms, janitor closets, restrooms, and similar normally unoccupied spaces not requiring hazardous area protection in accordance with Section 8.7.

36.4.4.3.8 Emergency Lighting. See 36.2.9.

36.4.4.4 Detection, Alarm, and Communications Systems.

36.4.4.4.1 General. Malls shall be provided with a fire alarm system in accordance with Section 9.6.

36.4.4.4.2 Initiation. Initiation of the required fire alarm system shall be by means of the required automatic sprinkler system in accordance with 9.6.2.1(3).

36.4.4.4.3 Notification.

CHAPTER 37 • Existing

37.4.4.3.5* Each individual anchor building shall have means of egress independent of the mall.

A.37.4.4.3.5 It is not the intent of 37.4.4.3.5 to require that large tenant spaces be considered anchor stores. A tenant space not considered in determining the occupant load of the mall is required to be arranged so that all of its means of egress will be independent of the covered mall.

37.4.4.3.6 Every mall shall be provided with unobstructed exit access parallel to and adjacent to the mall tenant fronts and extending to each mall exit.

37.4.4.3.7* Rooms housing building service equipment, janitor closets, and service elevators shall be permitted to open directly onto exit passageways, provided that the following criteria are met:

- (1) The required fire resistance rating between such rooms or areas and the exit passageway shall be maintained in accordance with 7.1.3.2.
- (2) Such rooms or areas shall be protected by an approved automatic sprinkler system in accordance with 9.7.1.1(1); however, the exceptions in NFPA 13, *Standard for the Installation of Sprinkler Systems*, that permit the omission of sprinklers from such rooms shall not be permitted.
- (3) Service elevators opening into the exit passageway shall not open into areas other than exit passageways.
- (4) Where exit stair enclosures discharge into the exit passageway, the provisions of 7.2.1.5.7 shall apply regardless of the number of stories served.

A.37.4.4.3.7 Rooms opening onto the exit passageway are intended to include building service elevators, elevator machine rooms, electrical rooms, telephone rooms, janitor closets, restrooms, and similar normally unoccupied spaces not requiring hazardous area protection in accordance with Section 8.7.

37.4.4.3.8 Emergency Lighting. See 37.2.9.

37.4.4.4 Detection, Alarm, and Communications Systems.

37.4.4.4.1 General. Malls shall be provided with a fire alarm system in accordance with Section 9.6.

37.4.4.4.2 Initiation. Initiation of the required fire alarm system shall be by means of the required automatic sprinkler system in accordance with 9.6.2.1(3).

37.4.4.4.3 Notification.

CHAPTER 36 • New

36.4.4.4.3.1 Occupant Notification. During all times that the mall is occupied, the required fire alarm system, once initiated, shall perform one of the following functions.

- (1) It shall activate a general alarm in accordance with 9.6.3 throughout the mall.
- (2) Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.
- (3) It shall activate an alarm signal in a continuously attended location for the purpose of initiating emergency action by personnel trained to respond to emergencies. Emergency action shall be initiated by means of live voice public address system announcements originating from the attended location where the alarm signal is received. The live voice public address system shall be permitted to be used for other announcements, provided that the emergency action use takes precedence over any other use.

36.4.4.4.3.2 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying the following:

- (1) The fire department in accordance with 9.6.4
- (2) The local emergency organization, if provided

36.4.4.4.4 Emergency Control. The fire alarm system shall be arranged to automatically actuate smoke management or smoke control systems in accordance with 9.6.5.2(3).

36.4.4.5 Tenant Spaces. Each individual tenant space shall have means of egress to the outside or to the mall, based on occupant load calculated by using Table 7.3.1.2.

36.4.4.6 Exit Passageways. Exit passageways in a mall building shall be permitted to accommodate the following independently:

- (1) The portion of the occupant load assigned to the exit passageway from only the mall
- (2) The largest occupant load assigned to the exit passageway from a single tenant space

36.4.4.7 Plastic Signs. Within every store or level and from side wall to side wall of each tenant space facing the mall, plastic signs shall be limited as follows:

- (1) Plastic signs shall not exceed 20 percent of the wall area facing the mall.
- (2) Plastic signs shall not exceed a height of 915 mm (36 in.) except if the sign is vertical, in which case the height shall not exceed 2440 mm (96 in.) and the width shall not exceed 915 mm (36 in.)

CHAPTER 37 • Existing

37.4.4.4.3.1 Occupant Notification. During all times that the mall is occupied, the required fire alarm system, once initiated, shall perform one of the following functions:

- (1) It shall activate an alarm in accordance with 9.6.3 throughout the mall.
- (2) Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.
- (3) It shall activate an alarm signal in a continuously attended location for the purpose of initiating emergency action by personnel trained to respond to emergencies. Emergency action shall be initiated by means of live voice public address system announcements originating from the attended location where the alarm signal is received. The live voice public address system shall be permitted to be used for other announcements, provided that the emergency action use takes precedence over any other use.

37.4.4.4.3.2 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying the following:

- (1) The fire department in accordance with 9.6.4
- (2) The local emergency organization, if provided

37.4.4.4.4 Emergency Control. The fire alarm system shall be arranged to automatically actuate smoke management or smoke control systems in accordance with 9.6.5.2(3).

37.4.4.5 Tenant Spaces. Each individual tenant space shall have means of egress to the outside or to the mall based on occupant load calculated by using Table 7.3.1.2.

37.4.4.6 Exit Passageways. Exit passageways in a mall building shall be permitted to accommodate the following independently:

- (1) The portion of the occupant load assigned to the exit passageway from only the mall
- (2) The largest occupant load assigned to the exit passageway from a single tenant space

37.4.4.7 Plastic Signs. Within every store or level and from side wall to side wall of each tenant space facing the mall, plastic signs shall be limited as follows:

- (1) Plastic signs shall not exceed 20 percent of the wall area facing the mall.
- (2) Plastic signs shall not exceed a height of 915 mm (36 in.) except if the sign is vertical, in which case the height shall not exceed 2440 mm (96 in.) and the width shall not exceed 915 mm (36 in.)

CHAPTER 36 • New

- (3) Plastic signs shall be located a minimum distance of 455 mm (18 in.) from adjacent tenants.
- (4) Plastics, other than foam plastics, shall meet one of the following criteria:
 - (a) They shall be light-transmitting plastics.
 - (b) They shall have a self-ignition temperature of 343°C (650°F) or greater when tested in accordance with ASTM D 1929, *Standard Test Method for Ignition Determining Temperatures of Plastic*, and a flame spread index not greater than 75 and a smoke developed index not greater than 450 when tested in the manner intended for use in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.
- (5) Edges and backs of plastic signs in the mall shall be fully encased in metal.
- (6) Foam plastics shall have a maximum heat-release rate of 150 kW when tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, and shall have physical characteristics in accordance with the following:
 - (a) The minimum density of foam plastic signs shall not be less than 320 kg/m³ (20 lb/ft³).
 - (b) The thickness of foam plastic signs shall not be greater than 13 mm (½ in.).

36.4.4.8 Kiosks. Kiosks and similar structures (temporary or permanent) shall not be considered as tenant spaces and shall meet the following requirements:

- (1) Combustible kiosks and similar structures shall be constructed of any of the following materials:
 - (a) Fire retardant-treated wood complying with the requirements for fire retardant-impregnated wood in NFPA 703, *Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*
 - (b) Light-transmitting plastics complying with Chapter 47 of the *NFPA 5000™, Building Construction and Safety Code™*
 - (c) Foam plastics having a maximum heat release rate not greater than 100 kW when tested in accordance with UL 1975
 - (d) Aluminum composite material (ACM) having a Class A rating as specified in Chapter 10 when tested as an assembly in the maximum thickness intended for use
 - (e) Textiles and films determined to be flame resistant in accordance with NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*

CHAPTER 37 • Existing

- (3) Plastic signs shall be located a minimum distance of 455 mm (18 in.) from adjacent tenants.
- (4) Plastics, other than foam plastics, shall meet one of the following criteria:
 - (a) They shall be light-transmitting plastics
 - (b) They shall have a self-ignition temperature of 343°C (650°F) or greater when tested in accordance with ASTM D 1929, *Standard Test Method for Ignition Determining Temperatures of Plastic*, and a flame spread index not greater than 75 and a smoke developed index not greater than 450 when tested in the manner intended for use in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.
- (5) Edges and backs of plastic signs in the mall shall be fully encased in metal.
- (6) Foam plastics shall have a maximum heat-release rate of 150 kW when tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, and shall have physical characteristics in accordance with the following:
 - (a) The minimum density of foam plastic signs shall not be less than 320 kg/m³ (20 lb/ft³).
 - (b) The thickness of foam plastic signs shall not be greater than 13 mm (½ in.).

37.4.4.8 Kiosks. Kiosks and similar structures (temporary or permanent) shall not be considered as tenant spaces and shall meet the following requirements:

- (1) Combustible kiosks and similar structures shall be constructed of any of the following materials:
 - (a) Fire retardant-treated wood complying with the requirements for fire retardant-impregnated wood in NFPA 703, *Standard for Fire Retardant Impregnated Wood and Fire Retardant Coatings for Building Materials*
 - (b) Light-transmitting plastics complying with Chapter 47 of the *NFPA 5000™, Building Construction and Safety Code™*
 - (c) Foam plastics having a maximum heat release rate not greater than 100 kW when tested in accordance with UL 1975
 - (d) Aluminum composite material (ACM) having a Class A rating as specified in Chapter 10 when tested as an assembly in the maximum thickness intended for use
 - (e) Textiles and films determined to be flame resistant in accordance with NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*

CHAPTER 36 • New

- (2) Kiosks or similar structures located within the mall shall be protected with approved fire suppression and detection devices.
- (3) The minimum horizontal separation between kiosks or groups of kiosks and other structures within the mall shall be 6100 mm (240 in.).
- (4) Each kiosk or group of kiosks or similar structure shall have a maximum area of 27.8 m² (300 ft²).

The provisions for new mall buildings in 36.4.4 apply only to buildings up to three stories in height. For new mall buildings with more than three stories, the equivalency concept of Section 1.4 or performance-based design option of Chapter 5 should be used to engineer a unique life safety system that meets the goals and objectives of the *Code* (see Chapter 4). For existing mall buildings, the provisions of 37.4.4 apply, regardless of number of stories.

It is common for mall buildings to have food courts and areas for live performances. Such spaces with occupant loads of 50 or more are considered assembly occupancies. The provision of 36/37.4.4.1 clarifies that the requirements for the applicable occupancies need to be followed, except as modified by 36/37.4.4. One of the modifications relates to sizing the means of egress from the mall using a calculation based on gross leasable area. The use of the gross leasable area (GLA) concept for sizing the means of egress for the mall typically will result in adequate capacity, even where large assembly occupancies are located in part of the mall building.

Consider the following examples. (In these examples, it is noted that using SI values will sometimes yield results that differ from those using the traditional inch-pound values due to rounding. In these examples, for consistency with the *Code*, SI values are presented first with inch-pound values in parentheses. However, the calculations are performed using the inch-pound values. Use of either the SI or inch-pound values is deemed acceptable per Section 1.5.)

Example 1

A 5000-seat cinema complex (that is, a large assembly occupancy) is to be housed within a new mall building. The cinema seating area, lobby, and circulation space will occupy 9290 m² (100,000 ft²). The mall building will have 51,100 m² (550,000 ft²) of GLA [41,800 m² (450,000 ft²) for mercantile use and 9290 m² (100,000 ft²) for the cinema complex].

CHAPTER 37 • Existing

- (2) Kiosks or similar structures located within the mall shall be protected with approved fire suppression and detection devices.
- (3) The minimum horizontal separation between kiosks or groups of kiosks and other structures within the mall shall be 6100 mm (240 in.).
- (4) Each kiosk or group of kiosks or similar structure shall have a maximum area of 27.8 m² (300 ft²).

Using Figure 7.3.1.2, the GLA of the cinema will require that the mall have sufficient egress capacity to accommodate 2000 persons from the 5000-seat cinema. This is based on a calculation in which 9290 m² (100,000 ft²) is divided by 5.1 m² (55 ft²) per person, because the mall building's GLA exceeds 37,160 m² (400,000 ft²). Also, the mall must have adequate egress capacity for another 8180 persons due to the GLA associated with the mercantile areas. This additional capacity is based on a calculation in which 41,800 m² (450,000 ft²) is divided by 5.1 m² (55 ft²) per person. Given the main entrance/exit requirement of Chapters 12 and 13, egress for half the cinema occupant load (that is, 2500 persons) will be provided through doors leading directly to the outside or through exit passageways. If the cinema was occupied to 100 percent capacity, the other 2500 persons would be expected to use the mall as exit access. Although there might appear to be a capacity deficiency of 500 persons, the system provides safeguards as follows.

(a) Cinemas do not normally operate at 100 percent capacity. Management typically stops selling tickets at 80 percent capacity, because the larger crowds make for inefficient access to the highly profitable concession stands, thus reducing revenue. Yet the occupant load is established by counting all seats.

(b) The mall, not the mall building, is required to have a fire alarm system. This requirement considers that it is very unusual to evacuate the entire mall building due to a fire in either the mall or one of the tenant spaces. Thus, the mall egress capacity is not fully used simultaneously, although the mall has excess capacity that easily absorbs the cinema occupants not otherwise considered.

(c) If the number of persons entering the mall from the tenant space—for emergency egress—is greater than that for which the mall's egress system was sized, it doesn't mean that the additional persons

CHAPTER 36 • New

are unable to leave the building. Rather, it means that it takes longer to discharge all occupants to the outside. The requirements for sprinkler protection throughout the mall building, and for smoke control within the mall, help to maintain tenable conditions to permit a longer egress time. The mall provides for safe exit access similar to that provided within an atrium.

Example 2

A restaurant with an occupant load of 300 persons is to be located within a new mall building that has GLA of 18,580 m² (200,000 ft²). The restaurant's 300-person occupant load is derived by dividing the 418 m² (4500 ft²) of net area usable for patron standing and seating by the 1.4 m² (15 ft²) per person occupant load factor characteristic of the assembly use. However, the restaurant occupies a total GLA of 557 m² (6000 ft²).

Using Figure 7.3.1.2, the GLA of the restaurant requires the mall to provide sufficient egress capacity to accommodate 150 persons from the 300-person restaurant. This egress capacity is based on a calculation in which 557 m² (6000 ft²) is divided by 3.7 m² (40 ft²) per person because the mall building's GLA is 18,580 m² (200,000 ft²). Also, the mall must have adequate egress capacity for another 4850 persons due to the GLA associated with the mercantile areas. This additional capacity is based on a calculation in which 18,020 m² (194,000 ft²) is divided by 3.7 m² (40 ft²) per person. Given the main entrance/exit requirement of Chapters 12 and 13, egress for one-half the restaurant occupant load (that is, 150 persons) will be provided through doors leading directly to the outside or through exit passageways. The other 150 persons would be expected to use the mall as exit access. This results in a perfect match between the 150 persons who egress from the restaurant into the mall and the 150-person egress capacity imposed on the mall based on the GLA of the restaurant.

In recent years, mall shopping areas have increased in both number and size. Two approaches in addressing the life safety aspects of these complexes were developed. The first approach (described in the base paragraph of 36/37.4.4.1) treats the mall and the attached stores essentially as one large Class A store subject to all the provisions of Chapters 36 and 37. If viewed in this way, the mall would be treated as an aisle of a store.

The second approach permits the mall to be con-

CHAPTER 37 • Existing

sidered as a pedestrian way through which occupants of the attached stores are permitted to egress during a fire. The phrase "pedestrian way" is intended to convey the meaning of the term *exit access* (defined in 3.3.63).

The provisions of 36/37.4.4.2 recognize that, if the mall and all the buildings attached to the mall are protected by automatic sprinklers, occupants fleeing into the mall from a fire in a store are then moving into a space whose volume, size, and arrangement affords most of the benefits provided by an enclosed stair or a horizontal exit, as well as providing many of the benefits of an outdoor area. This criterion considers the mall to be a safe area for the occupants of the tenant spaces attached to it, despite the fact that the mall is not separated from these attached spaces by the type of construction normally provided for an exit as required by 7.1.3.2.

Where a mall is considered as a pedestrian way, the maximum travel distance to an exit or to the mall from any point within a store attached to the mall is 61 m (200 ft). The reasoning behind this provision is that use of the mall for egress is as acceptable as the use of an exit. A travel distance of up to 61 m (200 ft), in addition to the 61 m (200 ft) allowed within the store, is permitted within the mall if all of the following conditions are met.

(a) The mall building (the mall and all attached buildings) must be sprinklered. The sprinkler system must be electrically supervised. Note that, if the shopping complex is considered as one building rather than as a mall building with a complying pedestrian way, sprinkler protection most likely is also required under the 1115-m² (12,000-ft²) gross area criterion of 36/37.3.5.1(2).

(b) The clear width of the mall must be at least 6100 mm (240 in.) or wider if mandated by the egress capacity. Note that, where the mall of a shopping center is considered as a pedestrian way, an occupant load is not calculated for the mall based on its area. The required capacity of the means of egress for the mall is calculated on the basis of aggregate gross leasable area of the attached stores (excluding anchor buildings), including mid-mall kiosks and similar sales areas.

(c) At least 3050 mm (120 in.) of clear, unobstructed space must be available for exit access in front of all store fronts. This requirement is designed

CHAPTER 36 • New

CHAPTER 37 • Existing

to prohibit displays of merchandise, kiosks, or small sales stands from being located directly in front of the store fronts and ensures that the mall will have a minimum clear width of 6100 mm (240 in.).

(d) Each exit access must terminate at an exit with a minimum width of 1675 mm (66 in.).

(e) Walls separating stores must run continuously from the floor slab to the roof slab or floor slab above, but not necessarily through the roof or floor. The vertical continuity of such walls is exempted if the tenant spaces are provided with an engineered smoke control system. Walls are not required to be fire resistance rated. The intent of such separation is to resist the passage of smoke. The store front need not be separated from the mall by construction.

(f) The mall, but not the stores, must have a smoke control system. Since the individual stores are open to the mall, this requirement is essential if the mall is to be used as a safe means of egress. For detailed guidance on the design, installation, and maintenance of smoke control systems, see NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*⁵.

If the conditions of (a) through (f) are not met, the mall is still permitted to be used as part of the exit access from the mall building, but the additional travel distance to an exit would not be allowed. Therefore, from any point within the overall mall building, which includes the stores and the mall, travel distance would be limited to 46 m (150 ft) for nonsprinklered buildings or 76 m (250 ft) for sprinklered mercantile occupancies (see 36/37.2.6). In the majority of configurations, this restriction would preclude the use of the mall as an exit access.

Exhibit 36/37.15 illustrates many of the requirements necessary to qualify a mall as a pedestrian way.

The NFPA *Fire Protection Handbook*⁶ contains a discussion of the hazards to life safety associated with mall buildings.

Paragraph 36/37.4.4.3.2 reaffirms the fundamental *Code* requirement for providing at least two independent means of egress—more if the occupant load exceeds 500 persons, in accordance with 7.4.1.2.

Note that in larger stores (Class A and B mercantile occupancies), the second exit must be remote from the first exit. This requirement is usually met by evacuating occupants directly from the store to the

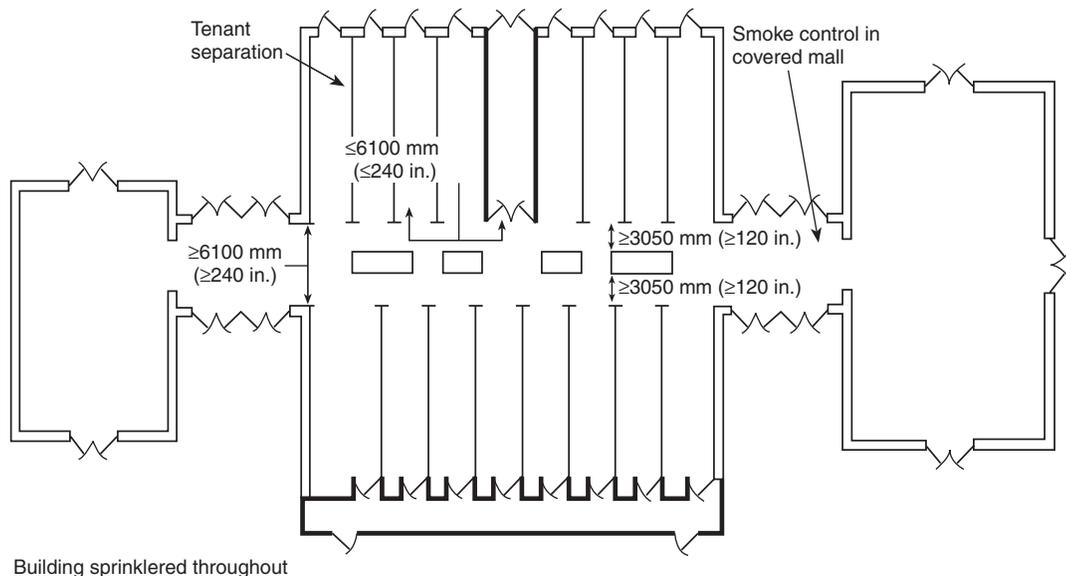

Exhibit 36/37.15 Mall meeting the requirements of a pedestrian way.

CHAPTER 36 • New

outside or directly into an exit passageway without entering the mall.

The provisions of 36/37.4.4.2(2) and (3) are echoed by 36/37.4.4.3.6, though specific measurements are not provided.

Although the requirements of Chapter 7 prohibit normally unoccupied rooms from having doors open directly into an exit enclosure, 36/37.4.4.3.7 specifically allows rooms housing building service equipment, janitor closets, and service elevators to open directly into exit passageways in mall buildings, provided that the additional criteria specified in 36/37.4.4.3.7(1) through (4) are met. The *Code* permits this allowance in recognition of operational needs and the incorporation of current design criteria in mall buildings. The conditions that are unique to this type of facility include the following:

- (1) A limitation on the number of floors (not more than three for new construction)
- (2) A main concourse for occupant movement, with specific requirements for size and smoke control, that leads to multiple points of egress
- (3) Facilities that are required to be fully protected by an automatic sprinkler system

The provision of 36/37.4.4.3.7(1) states that the exit passageway with door openings from support spaces is not to be treated as a corridor but as an exit passageway meeting the fire-rated separation requirements of 7.1.3.2.

All areas that open onto the exit passageway must be protected by an automatic sprinkler system per 36/37.4.4.3.7(2). This requirement is restated to prevent use of the provisions in NFPA 13, *Standard for the Installation of Sprinkler Systems*, which permit the omission of sprinkler protection if certain conditions are met.

The issue of communication among floors by an elevator shaft and its associated openings is addressed by 36/37.4.4.3.7(3). This requirement permits only those openings associated with an elevator that opens onto an exit passageway. This limitation would prohibit an elevator from opening to another use area, such as a storage or loading area, thereby limiting the exposure from the effects of fire from areas other than exit passageways.

The provision of 36/37.4.4.3.7(4) requires that stairwell re-entry is maintained in continuous occupant control, in accordance with 7.2.1.5.7. It prohibits the use of the exemption in 7.2.1.5.7, which permits

CHAPTER 37 • Existing

doors to be locked from the stairwell side if the building does not exceed four stories.

The annex text to 36/37.4.4.3.7 clarifies the types of spaces that are permitted to have doors that open directly onto the exit passageway. Such spaces include rooms with contents that are no more hazardous than those typically found in a mall building. These spaces are usually small and are associated with limited amounts of combustibles.

In a mall building, it is necessary to provide for services to the tenant spaces that are maintained by the mall management (for example, water, electricity, telephone, fire protection). These services must be located in a common space controlled by the mall management and, therefore, cannot be located within the tenant spaces. Frequently, these services are logically located with direct access to service corridors or exit passageways/corridors at the rear of the tenant spaces.

This common design practice has prompted many designers to seek specific approval of such designs from local authorities to allow numerous buildings to be built in this manner. There is a long history of mall buildings built in this manner with no adverse experience.

Although the provisions of 36/37.4.4 address the overall mall building, the provisions of 36/37.4.4.4.1, which apply to alarm systems, require only that the alarm system be provided for the mall (the covered pedestrian way). In addition, the provisions of 36/37.3.4.1 require that any Class A mercantile occupancy within the mall building also be provided with an alarm system. Therefore, Class B and Class C mercantile occupancies within the mall building are not required to have alarm systems.

Note that, per 36/37.4.4.4.2, manual fire alarm boxes are not required, but the sprinkler system must have a waterflow device that initiates the fire alarm system. However, in accordance with the provisions of 9.6.2.5, at least one manual fire alarm box must be provided at a location acceptable to the authority having jurisdiction.

Note that 36/37.4.4.4.3.1 provides a choice between two methods of notification. Many large shopping malls do have a continuously attended location, and 36/37.4.4.4.3.1(3) can be used. If such a location is not provided or the authority having jurisdiction does not consider the location reliable, 36/37.4.4.4.3.1(1) must be applied. Where the general alarm option is used, positive alarm sequence is per-

CHAPTER 36 • New

mitted by 36/37.4.4.4.3.1(2). In either case, the notification must be provided to the occupants of the mall but is not required to be provided within the individual stores.

36.4.5 Bulk Merchandising Retail Buildings.

New bulk merchandising retail buildings exceeding 1115 m² (12,000 ft²) in area shall comply with the requirements of this chapter as modified by 36.4.5.1 through 36.4.5.6.2.

36.4.5.1 Minimum Construction Requirements. Bulk merchandising retail buildings shall have a distance of not less than 4875 mm (192 in.) from the floor to the ceiling, from the floor to the floor above, or from the floor to the roof of any story.

36.4.5.2 Means of Egress Requirements.

36.4.5.2.1 All means of egress shall be in accordance with Chapter 7 and this chapter.

36.4.5.2.2 Not less than 50 percent of the required egress capacity shall be located independent of the main entrance/exit doors.

36.4.5.3 Storage, Arrangement, Protection, and Quantities of Hazardous Commodities.

36.4.5.3.1 The storage, arrangement, protection, and quantities of hazardous commodities shall be in accordance with the applicable portions of the following:

- (1) NFPA 13, *Standard for the Installation of Sprinkler Systems*
- (2) NFPA 30, *Flammable and Combustible Liquids Code*
- (3) NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*
- (4) NFPA 230, *Standard for the Fire Protection of Storage*
- (5) NFPA 430, *Code for the Storage of Liquid and Solid Oxidizers*
- (6) NFPA 432, *Code for the Storage of Organic Peroxide Formulations*
- (7) NFPA 434, *Code for the Storage of Pesticides*
- (8) NFPA 1124, *Code for the Manufacture, Transportation, Storage, and Retail Sales of Fireworks and Pyrotechnic Articles*

36.4.5.4 Detection, Alarm, and Communications Systems.

36.4.5.4.1 General. Bulk merchandising retail buildings shall be provided with a fire alarm system in accordance with Section 9.6.

CHAPTER 37 • Existing

Several different methods of automatically notifying the fire department are permitted by 9.6.4, as required by 36/37.4.4.4.3.2.

37.4.5 Bulk Merchandising Retail Buildings.

Existing bulk merchandising retail buildings exceeding 1400 m² (15,000 ft²) in area shall comply with the requirements of this chapter as modified by 37.4.5.1 through 37.4.5.6.2.

37.4.5.1 Minimum Construction Requirements. (No requirements)

37.4.5.2 Means of Egress Requirements.

37.4.5.2.1 All means of egress shall be in accordance with Chapter 7 and this chapter.

37.4.5.2.2 Not less than 50 percent of the required egress capacity shall be located independent of the main entrance/exit doors.

37.4.5.3 Storage, Arrangement, Protection, and Quantities of Hazardous Commodities.

37.4.5.3.1 The storage, arrangement, protection, and quantities of hazardous commodities shall be in accordance with the applicable portions of the following:

- (1) NFPA 13, *Standard for the Installation of Sprinkler Systems*
- (2) NFPA 30, *Flammable and Combustible Liquids Code*
- (3) NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*
- (4) NFPA 230, *Standard for the Fire Protection of Storage*
- (5) NFPA 430, *Code for the Storage of Liquid and Solid Oxidizers*
- (6) NFPA 432, *Code for the Storage of Organic Peroxide Formulations*
- (7) NFPA 434, *Code for the Storage of Pesticides*
- (8) NFPA 1124, *Code for the Manufacture, Transportation, Storage, and Retail Sales of Fireworks and Pyrotechnic Articles*

37.4.5.4 Detection, Alarm, and Communications Systems.

37.4.5.4.1 General. Bulk merchandising retail buildings shall be provided with a fire alarm system in accordance with Section 9.6.

CHAPTER 36 • New

36.4.5.4.2 Initiation. Initiation of the required fire alarm system shall be by means of the required approved automatic sprinkler system (*see* 36.4.5.5) in accordance with 9.6.2.1(3).

36.4.5.4.3 Occupant Notification. During all times that the mercantile occupancy is occupied, the required fire alarm system, once initiated, shall perform one of the following functions:

- (1) It shall activate an alarm in accordance with 9.6.3 throughout the mercantile occupancy. Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.
- (2) It shall activate an alarm signal in a continuously attended location for the purpose of initiating emergency action by personnel trained to respond to emergencies. Emergency action shall be initiated by means of live voice public address system announcements originating from the attended location where the alarm signal is received. The live voice public address system shall be permitted to be used for other announcements, provided that the emergency action use takes precedence over any other use.

36.4.5.4.4 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying the following:

- (1) The fire department in accordance with 9.6.4
- (2) The local emergency organization, if provided

36.4.5.5 Extinguishing Requirements. Bulk merchandising retail buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1) and the applicable provisions of the following:

- (1) NFPA 13, *Standard for the Installation of Sprinkler Systems*
- (2) NFPA 30, *Flammable and Combustible Liquids Code*
- (3) NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*
- (4) NFPA 230, *Standard for the Fire Protection of Storage*

36.4.5.6 Emergency Plan and Employee Training.

36.4.5.6.1 There shall be in effect an approved written plan for the emergency egress and relocation of occupants.

36.4.5.6.2 All employees shall be instructed and periodically drilled with respect to their duties under the plan.

CHAPTER 37 • Existing

37.4.5.4.2 Initiation. Initiation of the required fire alarm system shall be by means of the required approved automatic sprinkler system (*see* 37.4.5.5) in accordance with 9.6.2.1(3).

37.4.5.4.3 Occupant Notification. During all times that the mercantile occupancy is occupied, the required fire alarm system, once initiated, shall perform one of the following functions:

- (1) It shall activate an alarm in accordance with 9.6.3 throughout the mercantile occupancy. Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.
- (2) It shall activate an alarm signal in a continuously attended location for the purpose of initiating emergency action by personnel trained to respond to emergencies. Emergency action shall be initiated by means of live voice public address system announcements originating from the attended location where the alarm signal is received. The live voice public address system shall be permitted to be used for other announcements, provided that the emergency action use takes precedence over any other use.

37.4.5.4.4 Emergency Forces Notification. Emergency forces notification shall be provided and shall include notifying the following:

- (1) The fire department in accordance with 9.6.4
- (2) The local emergency organization, if provided

37.4.5.5 Extinguishing Requirements. Bulk merchandising retail buildings shall be protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1) and the applicable provisions of the following:

- (1) NFPA 13, *Standard for the Installation of Sprinkler Systems*
- (2) NFPA 30, *Flammable and Combustible Liquids Code*
- (3) NFPA 30B, *Code for the Manufacture and Storage of Aerosol Products*
- (4) NFPA 230, *Standard for the Fire Protection of Storage*

37.4.5.6 Emergency Plan and Employee Training.

37.4.5.6.1 There shall be in effect an approved written plan for the emergency egress and relocation of occupants.

37.4.5.6.2 All employees shall be instructed and periodically drilled with respect to their duties under the plan.

CHAPTER 36 • New

CHAPTER 37 • Existing

Bulk merchandising retail buildings provide life safety challenges that differ from typical mercantile occupancies. Fires in bulk merchandising retail buildings demonstrate the need for specific requirements to help ensure adequate life safety of building occupants. The provisions of 36/37.4.5 codify a package of requirements that, in conjunction with those of the remainder of Chapters 36 and 37, help fill a void in earlier editions of the *Code*. The provisions of 36/37.4.5 apply to new bulk merchandising retail buildings exceeding 1115 m² (12,000 ft²) and existing facilities exceeding 1400 m² (15,000 ft²).

The term *bulk merchandising retail building* (see definition in 3.3.27.4) refers to occupancies with storage height in excess of 3660 mm (144 in.), which differentiates it from typical mercantile occupancies. Where the storage and display of combustible materials exceed 3660 mm (144 in.) in height, the requirements of 36/37.4.5 are to be applied.

The minimum 4875 mm (192 in.) ceiling height requirement for new construction (see 36.4.5.1) is intended to provide a full 3050 mm (120 in.) of clearance above the heads of building occupants to allow for smoke accumulation early in the fire while building evacuation takes place.

The requirement that not less than 50 percent of the required egress capacity be located independent of the main entrance/exit doors (see 36/37.4.5.2.2) will help to provide for a better distribution of egress capacity around the perimeter of the building, thus providing occupants with multiple, independent routes for egress.

Bulk merchandising retail buildings are characterized by the storage and display of significant quantities of hazardous commodities. Thus, reference is made to numerous NFPA documents that address hazardous materials (see 36/37.4.5.3.1). Some of the documents include specific requirements that address the display of such materials.

The extinguishing requirements refer to Section 9.7 (see 36/37.4.5.5) and, therefore, adopt the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*. In addition, the companion specialized storage standards are mandatorily referenced.

As the history of fires in bulk merchandising retail buildings has shown, it is important to have an approved, written emergency evacuation plan with employees instructed and periodically drilled in their duties (see 36/37.4.5.6, 36/37.7.1, and 36/37.7.2).

Section 36.5 Building Services

36.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

36.5.2 Heating, Ventilating, and Air Conditioning.

Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

36.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

36.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 37.5 Building Services

37.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

37.5.2 Heating, Ventilating, and Air Conditioning.

Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

37.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

37.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

CHAPTER 36 • New

Section 36.6 Reserved**Section 36.7 Operating Features****36.7.1 Drills.**

In every Class A or Class B mercantile occupancy, employees shall be periodically trained in accordance with Section 4.7.

36.7.2 Extinguisher Training.

Employees of mercantile occupancies shall be periodically instructed in the use of portable fire extinguishers.

36.7.3 Food service operations shall comply with 12.7.1.

The authority having jurisdiction determines the extent of the extinguisher training required by 36/37.7.2 (for example, instruction only or instruction and hands-on use).

CHAPTERS 38 and 39

New and Existing Business Occupancies

Business occupancies are typically occupied by persons who are awake and ready to begin emergency egress or relocation, with little or no staff assistance, as soon as the occupants become aware of a fire. Historical evidence validates that the package of life safety features imposed on business occupancies by the *Code* doesn't need to be very extensive. At the time that this commentary was written early in 2003, 2000 was the last year in which a multiple-death business occupancy fire occurred in the United States (the term *multiple-death* means three or more fatalities, for the purpose of fire data analysis). That fire took place in a three-story (with a basement) partially sprinklered building in Newton, Massachusetts, and resulted in five deaths. The fire, of undetermined cause, started in a second floor nonsprinklered office. Smoke spread quickly throughout the building, making escape impossible for those victims who perished. Another noteworthy fire resulting in five deaths took place in an Atlanta, Georgia, high-rise office building in 1989. One of the fire victims was intimate with the fire source in an electrical vault; the other four victims were occupying their areas on the same floor when the fire began. This was the first office building fire in 17 years to result in more than three fatalities.

The bombing of the Alfred Murrah Federal Office Building in Oklahoma City, Oklahoma, in 1995 killed 168 people and injured 475. The bomb caused about one-third of the floor area of the nine-story building

to collapse. The September 11, 2001, attacks on the World Trade Center in New York City and the Pentagon in Arlington, Virginia, killed some 2600 and 125 people respectively (including 403 emergency responders at the World Trade Center, but excluding the passengers on the three aircraft used as weapons and a fourth that crashed in a field in Pennsylvania). Thousands more were injured. The *Code* cannot protect against the effects of terrorist attacks such as the bombing of, or the intentional collision of a jet airliner into, a building. Such incidents will, however, continue to be discussed by code development organizations for many years to come.

It is common for business occupancies to occupy high-rise buildings. Where business occupancies are located in new high-rise buildings, the complete protection package detailed in Section 11.8 is mandated; for existing business occupancies in high-rise buildings, either sprinkler protection or an engineered life safety system that provides protection equivalent to that of sprinklers is required.

The life safety features in Chapters 38 and 39 center on arrangement of the means of egress as well as alarm and occupant notification provisions. The travel distance and common path of travel allowances are generous. Fire resistance-rated corridor walls or other mitigating features, such as sprinkler protection, are required in an effort to keep the means of egress system usable.

CHAPTER 38 • New

Section 38.1 General Requirements**38.1.1 Application.**

38.1.1.1 The requirements of this chapter shall apply to the following:

- (1) New buildings or portions thereof used as business occupancies (*see 1.3.1*)
- (2) Additions made to, or used as, a business occupancy (*see 4.6.7 and 38.1.1.3*)
- (3) Alterations, modernizations, or renovations of existing business occupancies (*see 4.6.8*)
- (4) Existing buildings or portions thereof upon change of occupancy to a business occupancy (*see 4.6.12*)

38.1.1.2 This chapter establishes life safety requirements for all new business buildings.

38.1.1.3 Additions to existing buildings shall conform to the requirements for new construction. Existing portions of the structure shall not be required to be modified, provided that the new construction has not diminished the fire safety features of the facility.

To understand the full intent and scope of 39.1.1.1 for existing buildings, it is necessary to review it concurrently with Sections 1.2, 1.3, and 1.4. Although a building code might exclude existing buildings from coverage under some form of a grandfather clause, the *Life Safety Code*, by virtue of its interest in safety to life, does not condone existing building arrangements that do not comply with the *Code* requirements that apply to existing buildings. The requirements that apply to existing business occupancies are contained in Chapter 39.

If a building complies with an earlier edition of the *Code*, it is not “grandfathered” and, thereby, exempted from compliance with a more current edition of the *Code* that has been adopted as law in the building’s jurisdiction. The committees on safety to life are especially careful to avoid adopting requirements for existing buildings that become more stringent from one edition of the *Code* to the next, unless the change is absolutely necessary to enhance the overall package of safety to life intended by the *Code*. Thus, the old adage of “once in compliance, always in compliance” does not hold.

The provisions of Chapter 39 are intended to be

CHAPTER 39 • Existing

Section 39.1 General Requirements**39.1.1 Application.**

39.1.1.1 The requirements of this chapter shall apply to existing buildings or portions thereof currently occupied as business occupancies. (*See also 38.1.1.1.*)

39.1.1.2 This chapter establishes life safety requirements for existing business buildings. Specific requirements for high-rise buildings (*see definition in 3.3.27.7*) are contained in paragraphs pertaining thereto.

applied retroactively. Due consideration has been given to the practical difficulties of making alterations in existing, functioning facilities. The specified provisions, viewed as a whole, establish minimum, acceptable criteria for safety to life that reasonably minimize the likelihood of a life-threatening fire.

The requirements of Chapter 39 are permitted to be modified in instances where compliance is impractical or where alternate but equal provisions are proposed. The modifications must provide a level of protection equivalent to that achieved by compliance with the corresponding *Code* provisions. Note that Section 1.4 permits alternatives to literal *Code* compliance that maintain a building design as *Code*-conforming. However, the authority having jurisdiction ultimately determines whether equivalent safety has been provided.

The *Code* does not limit the methods that an authority having jurisdiction might use to determine equivalency. However, NFPA 101A, *Guide on Alternative Approaches to Life Safety*¹, provides an equivalency system that uses numerical values to analyze the fire safety effectiveness of a building design. This system, known as the Fire Safety Evaluation System (FSES),

provides a method by which alternative designs can be evaluated as options to literal *Code* compliance.

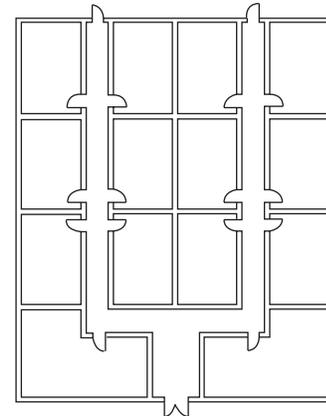

The 2004 edition of NFPA 101A, although published one year after this 2003 edition of the *Life Safety Code*, is the proper edition of NFPA 101A to consult for one potential equivalency system for business occupancies. Its measurement system has been calibrated against the requirements of the 2003 edition of the *Code*, whereas the fire safety evaluation systems contained in the 2001 edition of NFPA 101A were calibrated against the requirements of the 2000 edition of the *Code*.

In providing the equivalency concept, the *Code* does not limit equivalency evaluations to those based solely on the system presented for business occupancies in NFPA 101A. The AHJ retains the power to evaluate and approve alternative designs on the basis of appropriate supporting data. The FSES is permitted to be used to aid in this evaluation. Use of the FSES is in no way mandated, nor is the AHJ required to accept the results of an evaluation using the NFPA 101A equivalency system.

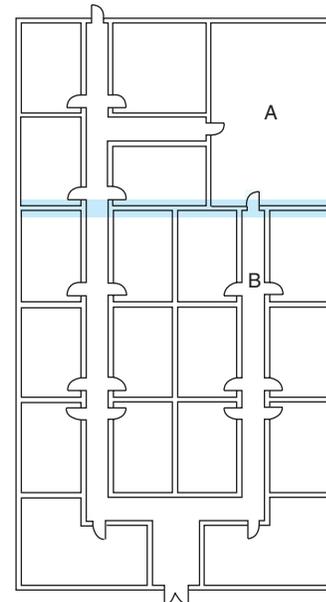

Although the FSES was primarily developed to evaluate alternative designs in existing buildings, it is particularly useful for determining equivalency for conversions, modernizations, renovations, or unusual design concepts—all of which are considered new construction. However, the FSES is only a tool to help determine equivalency—it should not be used to circumvent *Code* requirements. *Code* requirements must be met, or equivalent safety must be provided by alternative means approved by the authority having jurisdiction.

Additions to existing buildings are addressed by 38.1.1.3. Although construction of an addition generally does not require existing portions of the building to be modified, Exhibit 38/39.1 illustrates a case where the planned new construction would diminish the fire safety features of the existing building and thus necessitate corrective action within the existing portion of the building. The location of new room A creates an excessively long dead-end corridor, B, which must be corrected.

In Exhibit 38/39.1, in addition to creating an unacceptable dead-end corridor, the construction of room A diminishes the fire safety features in two other ways; however, both are negligible and do not warrant correction. The door from corridor B into room A was formerly an exit door to the outside. Thus, with the new addition, the number of exits has been

Existing Building

Existing Building and Planned Addition

Exhibit 38/39.1 An addition that diminishes existing life safety features.

decreased from three to two; also, the travel distance for occupants in some of the rooms off corridor B has been increased, because the nearest exit for those occupants becomes the pair of doors at the front of the building (that is, at the bottom of the figure). If the occupant load of the floor doesn't exceed 500 persons, only two exits are required (see 7.4.1.2), and the loss of one of the three exits is permitted without further correction. Also, if the maximum allowable

CHAPTER 38 • New

travel distance [61 m (200 ft) where the building is not sprinklered or 91 m (300 ft) where the building is sprinklered, in accordance with 38/39.2.6] is not exceeded, the travel distance increase caused by the

38.1.2 Multiple Occupancies.

38.1.2.1 General.

38.1.2.1.1 All multiple occupancies shall be in accordance with 6.1.14 and 38.1.2.

38.1.2.1.2 Where there are differences in the specific requirements in this chapter and provisions for mixed occupancies or separated occupancies as specified in 6.1.14.3 and 6.1.14.4, the requirements of this chapter shall apply.

38.1.2.2 Combined Business Occupancies and Parking Structures.

38.1.2.2.1 The fire barrier separating parking structures from a building classified as a business occupancy shall be a fire barrier having a fire resistance rating of not less than 2 hours.

38.1.2.2.2 Openings in the fire barrier required by 38.1.2.2.1 shall not be required to be protected with fire protection-rated opening protectives in enclosed parking structures that are protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), or in open parking structures, provided all of the following conditions are met:

- (1) The openings do not exceed 25 percent of the area of the fire barrier in which they are located.
- (2) The openings are used as a public entrance and for associated sidelight functions.
- (3) The building containing the business occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).
- (4)* Means are provided to prevent spilled fuel from accumulating adjacent to the openings and entering the building.

A.38.1.2.2.2(4) Means to prevent spilled fuel from accumulating and entering the business occupancy building can be by curbs, scuppers, special drainage systems, sloping the floor away from the door openings, or elevation differences not less than 102 mm (4 in.).

- (5) Physical means are provided to prevent vehicles from being parked or driven within 3050 mm (120 in.) of the openings.

CHAPTER 39 • Existing

addition of room A is permitted without further correction. Thus, only the newly created, excessively long dead-end corridor needs to be corrected.

39.1.2 Multiple Occupancies.

39.1.2.1 General.

39.1.2.1.1 All multiple occupancies shall be in accordance with 6.1.14 and 39.1.2.

39.1.2.1.2 Where there are differences in the specific requirements in this chapter and provisions for mixed occupancies or separated occupancies as specified in 6.1.14.3 and 6.1.14.4, the requirements of this chapter shall apply.

39.1.2.2 Combined Business Occupancies and Parking Structures.

39.1.2.2.1 The fire barrier separating parking structures from a building classified as a business occupancy shall be a fire barrier having a fire resistance rating of not less than 2 hours.

39.1.2.2.2 Openings in the fire barrier required by 39.1.2.2.1 shall not be required to be protected with fire protection-rated opening protectives in enclosed parking structures that are protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), or in open parking structures, provided all of the following conditions are met:

- (1) The openings do not exceed 25 percent of the area of the fire barrier in which they are located.
- (2) The openings are used as a public entrance and for associated sidelight functions.
- (3) The building containing the business occupancy is protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).
- (4)* Means are provided to prevent spilled fuel from accumulating adjacent to the openings and entering the building.

A.39.1.2.2.2(4) Means to prevent spilled fuel from accumulating and entering the business occupancy building can be by curbs, scuppers, special drainage systems, sloping the floor away from the door openings, or elevation differences not less than 102 mm (4 in.).

- (5) Physical means are provided to prevent vehicles from being parked or driven within 3050 mm (120 in.) of the openings.

CHAPTER 38 • New

- (6) The openings are protected as a smoke partition in accordance with Section 8.4, with no minimum fire protection rating required.

Minor office occupancies that are incidental to operations in another occupancy are considered part of the predominant occupancy, rather than part of a mixed occupancy, and are subject to the *Code* provisions that apply to the predominant occupancy. The commentary associated with 38/39.1.4 discusses classification of business occupancies in more detail.

The determination of those criteria that constitute a minor or incidental office area cannot be based solely on percentage of business area in comparison to overall building area. For example, a 19-m² (200-ft²) office area in a 370-m² (4000-ft²) warehouse can reasonably be judged as incidental to the storage operations and result in the building being classified as a storage occupancy. However, an 1860-m² (20,000-ft²) office area in a 37,200-m² (400,000-ft²) distribution warehouse represents the same proportion of business use but cannot be judged as incidental (see Exhibit 38/39.2). The 1860-m² (20,000-ft²) office area probably has an occupant load of approximately 200 persons. The *Code* requirements that apply to business occupancies, which are more stringent than those that apply to storage occupancies, are needed to protect the occupants of the office area adequately. The distribution warehouse is classified as a multiple occupancy that is part storage occupancy and part business occupancy. If packaging operations take place in the warehouse, it might also be classified as part industrial occupancy. Consequently, the requirements of 6.1.14 for either mixed or separated multiple occupancies apply.

Where certain accessory occupancies, including offices and clerical- and administrative-use areas, are determined to be nonincidental per 6.1.14.1.2, they must be treated as part of a multiple occupancy. However, 6.1.14.1.3 permits such areas to be considered “separated” with no physical fire barrier separation provided the total area of the accessory use spaces does not exceed 25 percent of the principal occupancy’s area. This provision would permit a multiple occupancy that is part warehouse (storage) and part office (business) to have the requirements for storage occupancies in Chapter 42 applied to the warehouse space, and the requirements for business occupancies in Chapter 38 or Chapter 39 applied to the office space with no separation as normally required by

CHAPTER 39 • Existing

- (6) The openings are protected as a smoke partition in accordance with Section 8.4, with no minimum fire protection rating required.

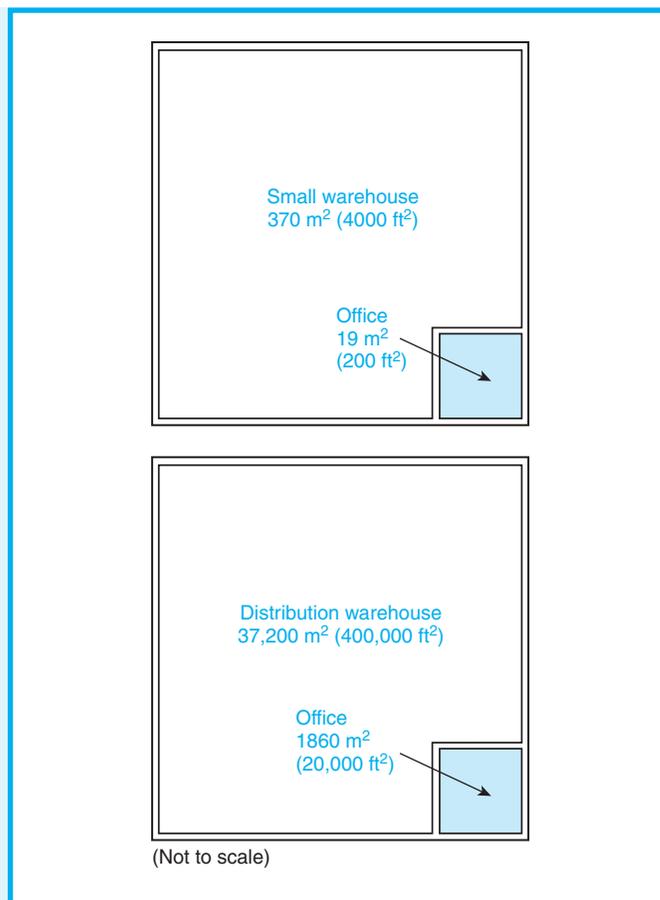

Exhibit 38/39.2 Incidental and nonincidental office use.

Table 6.1.14.4.1, and with the additional limitations that the office area does not exceed 25 percent of the storage area and the storage area contains no high-hazard contents. Without this provision, the *Code* would require the more stringent requirements to be applied throughout the building as is required for mixed occupancies (see 6.1.14.3).

The provisions of 38/39.1.2.2 address combined business occupancies and parking structures and are very similar to the requirements of 36/37.1.2.2, which address combined mercantile occupancies and parking structures. It is very common for multistory business occupancies, such as office buildings, and multistory mercantile occupancies, such as depart-

CHAPTER 38 • New

ment stores and shopping mall buildings, to be attached to multistory parking garages. These garages provide access to the business or mercantile occupancy at multiple levels. The provisions of 38/39.1.2.2.2 outline a set of provisions that, where applied in total, will safely allow a reduction in the 2-hour fire resistance-rated separation requirement of 38/39.1.2.2.1. This reduction allows flexibility in the number and type of openings and considers the stringent requirements for opening protectives such as fire doors and windows. The reduction also permits the use of nonrated glazing and opening protectives, which allows the use of glass doors and sidelights in

38.1.3 Definitions.

See Chapter 3.

38.1.4 Classification of Occupancy.

Business occupancies shall include all buildings and structures or parts thereof with occupancy as defined in 6.1.11.

38.1.5 Classification of Hazard of Contents.

38.1.5.1 The contents of business occupancies shall be classified as ordinary hazard in accordance with Section 6.2.

38.1.5.2 For purposes of automatic sprinkler system design, a business occupancy shall be classified as a light hazard occupancy in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

38.1.6 Minimum Construction Requirements.

(No requirements)

38.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

Classification of occupancy is addressed in 38/39.1.4.

Per the *Code's* definition of a business occupancy (see 6.1.11.1), the following constitute business occupancies; they are therefore covered by the provisions of Chapters 38 and 39:

CHAPTER 39 • Existing

the barrier between the business occupancy and the garage. Security in the garage is thereby increased, because occupants can view the area through the glass doors or sidelights. This feature, in turn, helps to meet the security concerns of office building managers and tenants.

Note that all seven requirements mandated by 38/39.1.2.2.2—the sprinkler requirement for enclosed garages per the base paragraph and its six subparts—must be met as a whole to apply the exception to the rule. Otherwise a 2-hour fire resistance-rated separation between the business occupancy and the parking structure is required.

39.1.3 Definitions.

See Chapter 3.

39.1.4 Classification of Occupancy.

Business occupancies shall include all buildings and structures or parts thereof with occupancy as defined in 6.1.11.

39.1.5 Classification of Hazard of Contents.

39.1.5.1 The contents of business occupancies shall be classified as ordinary hazard in accordance with Section 6.2.

39.1.5.2 For purposes of automatic sprinkler system design, a business occupancy shall be classified as a light hazard occupancy in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*.

39.1.6 Minimum Construction Requirements.

(No requirements)

39.1.7 Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

- (1) Occupancies used for the transaction of business (other than those classified as mercantile occupancies)
- (2) Occupancies used for keeping accounts and records and for similar purposes

CHAPTER 38 • New

CHAPTER 39 • Existing

Business occupancies include doctors' offices, dentists' offices (see Chapter 20/21 for ambulatory health care centers), and general offices, as well as city halls, town halls, and courthouses, all of which have areas for keeping books and records and transacting public business. Other occupancies included under the definition of business occupancies are service facilities common to office buildings, such as newsstands, lunch counters (with a seating area for fewer than 50 people), barber shops, and beauty parlors.

Birth centers occupied by fewer than four patients, not including infants, at any one time should be classified as business occupancies in accordance with the guidelines of A.6.1.11.1 and the definition of the term *birth center* in 3.3.24 and its corresponding annex text in A.3.3.24.

Note that the *Code's* definition of a business occupancy does not include types of stores that, although considered businesses, are covered under the provisions of Chapters 36 and 37. For example, supermarkets, department stores, and other occupancies that display and sell merchandise would not be considered business occupancies. Neither would the assembly portions of city halls, town halls, and courthouses, which are covered by Chapters 12 and 13.

Classification of hazard of contents is addressed in 38/39.1.5. Most occupancy chapters refer to Section 6.2 for classification of hazard of contents. However, the requirement of 38/39.1.5.1 emphasizes that, unless an extraordinarily hazardous situation exists, the contents of business occupancies are to be classified as ordinary hazard. This requirement is intended to prevent the user from classifying the hazard of contents as high hazard, except where a combustible load far in excess of the usual, yet considerable, quantity of boxed records and paper files exists. Isolated hazardous contents areas within the overall ordinary hazard business occupancy, such as storage rooms, must be protected or separated in accordance with the requirements of 38/39.3.2.

The intent of 38/39.1.5.2 is to clarify that contents

classified by the *Code* as ordinary for the purpose of life safety are not always classified as ordinary under NFPA 13, *Standard for the Installation of Sprinkler Systems*². For purposes of sprinkler design, the anticipated fuel load of business occupancies in Chapters 38 and 39 is classified as light hazard.

There are no construction requirements for business occupancies; therefore, 38/39.1.6 serves as a placeholder. Some occupancy chapters, such as Chapters 18 and 19, which address the life safety needs of nonambulatory health care occupants, require a minimum building construction type to help ensure the structural integrity required for a lengthy evacuation or for safe refuge within the building. Because business occupancies are normally occupied by those who are ambulatory, and because they do not provide sleeping accommodations, there are no minimum construction requirements imposed.

Subsection 38/39.1.7 references Table 7.3.1.2 for determining the occupant load factors that apply to the use areas of a business occupancy. Because the number of people expected to occupy certain types of office buildings can be determined with a great degree of accuracy (such as by means of a company's detailed account of its office space), it might be beneficial to compare that occupant load with one calculated on the basis of one person per 9.3 m² (100 ft²) of gross floor area (see Table 7.3.1.2). In office occupancies where people work in highly concentrated groups (such as a customer-service call center or secretarial pool area), the actual number of people occupying a space might exceed the figure calculated by gross area. As emphasized in Section 7.3, where this is the case, the egress capacity must be designed to accommodate the actual (larger) occupant load. Note that the converse is not true; that is, if the actual occupant load is less than the gross area calculation, the *Code* still requires that the gross area calculation (that is, the larger occupant load) be used to determine the occupant load for which the egress capacity must be provided.

Section 38.2 Means of Egress Requirements

38.2.1 General.

38.2.1.1 All means of egress shall be in accordance with Chapter 7 and this chapter.

Section 39.2 Means of Egress Requirements

39.2.1 General.

39.2.1.1 All means of egress shall be in accordance with Chapter 7 and this chapter.

CHAPTER 38 • New

38.2.1.2 If, owing to differences in grade, any street floor exits are at points above or below the street or ground level, such exits shall comply with the provisions for exits from upper floors or floors below the street floor.

38.2.1.3 Stairs and ramps serving two or more floors below a street floor occupied for business use shall be permitted in accordance with 38.2.1.3.1 and 38.2.1.3.2.

38.2.1.3.1 Where two or more floors below the street floor are occupied for business use, the same stairs or ramps shall be permitted to serve each.

38.2.1.3.2 An inside open stairway or inside open ramp shall be permitted to serve as a required egress facility from not more than one floor level below the street floor.

38.2.1.4 Floor levels that are below the street floor; are used only for storage, heating, and other service equipment; and are not subject to business occupancy shall have means of egress in accordance with Chapter 42.

Exhibit 38/39.3 illustrates a case where two floors qualify as street floors in accordance with 38/39.2.1.2, because each floor has one side located at a ground level. Note, however, that each of the two floors has

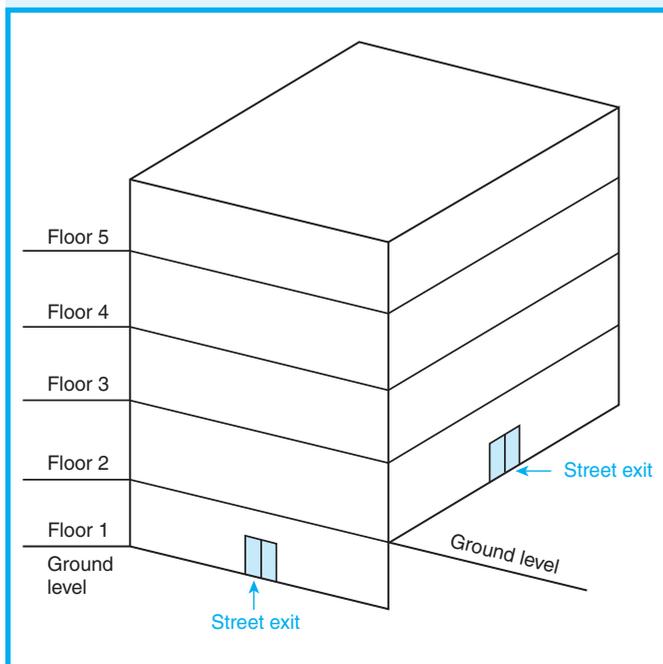

Exhibit 38/39.3 Business occupancy with two street floors.

CHAPTER 39 • Existing

39.2.1.2 If, owing to differences in grade, any street floor exits are at points above or below the street or ground level, such exits shall comply with the provisions for exits from upper floors or floors below the street floor.

39.2.1.3 Stairs and ramps serving two or more floors below a street floor occupied for business use shall be permitted in accordance with 39.2.1.3.1 and 39.2.1.3.2.

39.2.1.3.1 Where two or more floors below the street floor are occupied for business use, the same stairs, escalators, or ramps shall be permitted to serve each.

39.2.1.3.2 An inside open stairway, inside open escalator, or inside open ramp shall be permitted to serve as a required egress facility from not more than one floor level below the street floor.

39.2.1.4 Floor levels that are below the street floor; are used only for storage, heating, and other service equipment; and are not subject to business occupancy shall have means of egress in accordance with Chapter 42.

its other sides located either above or below the building's other ground level. As a result, floors 1 and 2 must have their exits arranged to allow horizontal travel to the exterior at one end of the floor and vertical travel (either up or down to ground level) at the other end of the floor. The egress capacity of the doors to the exterior on floor 1 must accommodate that portion of the occupant load from an upper floor that is expected to travel down to and through the exits to the exterior from floor 1. This portion of the occupant load is to be added to the portion of the floor 1 occupant load assigned to a given exit. The reverse is true for floor 2, which must increase the size of its exterior exit capacity to accommodate occupants traveling up from floor 1, as well as those traveling down to and through the exterior exits on floor 2. The provisions of 7.3.1.5, 7.3.1.6, and 38/39.2.3.3 explain how to add egress capacity based on the number of occupants expected to discharge from floors above and below the street floor. Exhibit 38/39.7 provides an example of how to calculate exit capacity for a street floor such as that illustrated by floor 2 in Exhibit 38/39.3.

The use of unenclosed interior stairs or unenclosed interior ramps as exit access for more than one floor below the street floor is prohibited by 38/39.2.1.3.2; it does not establish permission for the presence of an open stairway or open ramp. See 38/

CHAPTER 38 • New

39.3.1, which addresses the protection of business occupancy vertical openings, to determine if the stair or ramp is permitted to be unenclosed. The required width of the stair or ramp serving multiple floors is determined by the floor with the largest occupant load. This requirement ensures that a stair or other component of a means of egress will accommodate its assigned portion of the population of any floor it serves.

The implementation of 38/39.2.1.4 results in a sig-

38.2.2 Means of Egress Components.

38.2.2.1 General. Means of egress components shall be limited to the types described in 38.2.2.2 through 38.2.2.12.

38.2.2.2 Doors.

38.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

38.2.2.2.2* Locks complying with 7.2.1.5.4 shall be permitted only on principal entrance/exit doors.

A.38.2.2.2.2 The words “principal entrance/exit doors” describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

38.2.2.2.3 Reserved.

38.2.2.2.4 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted.

38.2.2.2.5 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

38.2.2.2.6 Where horizontal or vertical security grilles or doors are used as part of the required means of egress from a tenant space, such grilles or doors shall comply with 7.2.1.4.1.4.

38.2.2.2.7 Reserved.

CHAPTER 39 • Existing

nificant reduction in the number and size of exits for floors located below the street floor that are used only for storage or for heating and service equipment and that are not subject to business occupancy use. These reductions are permitted because the expected population of such floors will be well below that of a floor used as a typical business occupancy. Also see Section 7.12, which specifically regulates boiler rooms and similar spaces.

39.2.2 Means of Egress Components.

39.2.2.1 General. Means of egress components shall be limited to the types described in 39.2.2.2 through 39.2.2.12.

39.2.2.2 Doors.

39.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

39.2.2.2.2* Locks complying with 7.2.1.5.4 shall be permitted only on principal entrance/exit doors.

A.39.2.2.2.2 The words “principal entrance/exit doors” describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

39.2.2.2.3 The re-entry provisions of 7.2.1.5.7 shall not apply. [See 7.2.1.5.7.2(1).]

39.2.2.2.4 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted.

39.2.2.2.5 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

39.2.2.2.6 Where horizontal or vertical security grilles or doors are used as part of the required means of egress from a tenant space, such grilles or doors shall comply with 7.2.1.4.1.4.

39.2.2.2.7 Approved existing horizontal-sliding or vertical-rolling fire doors shall be permitted in means of egress under the following conditions:

- (1) They are held open by fusible links.
- (2) The fusible links are rated at not less than 74°C (165°F).
- (3) The fusible links are located not more than 3050 mm (120 in.) above the floor.
- (4) The fusible links are in immediate proximity to the door opening.
- (5) The fusible links are not located above a ceiling.

CHAPTER 38 • New

38.2.2.2.8 Revolving doors complying with 7.2.1.10 shall be permitted.

Only the principal entrance/exit doors of a business occupancy are permitted by 38/39.2.2.2.2 to be equipped with the special key-operated dead bolt lock described by the provisions of 7.2.1.5.4. It must be easy to determine that the device is locked by using means such as a flag indicator that can be seen at a distance from the door. Other doors along the perimeter of the building are prohibited from being equipped with a key-operated dead bolt lock, because it cannot be guaranteed that these locks will be disengaged simultaneously when the principal entrance/exit door is unlocked each day at the opening of business. See Exhibit 38/39.4 for an example of the principal entrance/exit in a business occupancy.

Note that, per 39.2.2.2.3, existing business occupancies are exempt from the re-entry provisions of 7.2.1.5.7, which apply to exit stair enclosure doors. Such exemption is not provided for new business occupancies; thus 38.2.2.2.3 is reserved as a placeholder.

The use of the delayed-egress lock covered by 7.2.1.6.1 is permitted by 38/39.2.2.2.4 on any door in recognition of the security needs of a business occupancy. Per 7.2.1.6.1, the building must be protected throughout by an approved, supervised automatic

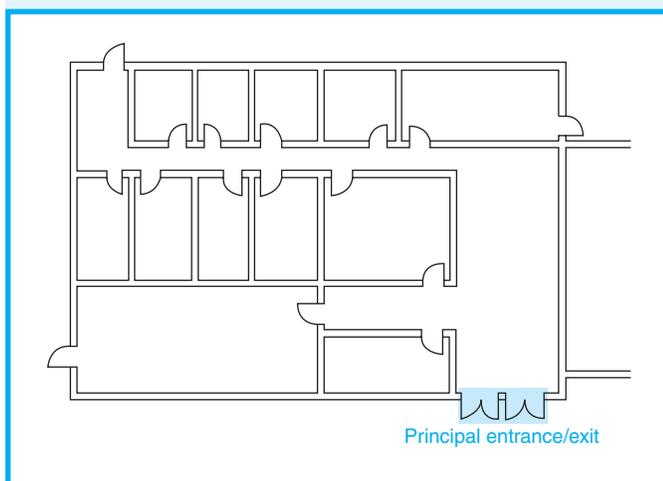

Exhibit 38/39.4 Principal entrance/exit.

CHAPTER 39 • Existing

(6) The door is not credited with providing any protection under this *Code*.

39.2.2.2.8 Revolving doors complying with 7.2.1.10 shall be permitted.

sprinkler system or an approved, supervised automatic fire detection system. In effect, the allowable 15- or 30-second delay will be experienced only under nonfire conditions or very early in a fire's growth, because the door must be usable immediately upon sprinkler operation, smoke or heat detection, or loss of power that controls the locking mechanism.

Access-controlled egress doors in business occupancies are recognized by 38/39.2.2.2.5 as security measures that do not compromise the use of the means of egress system, provided they meet the criteria specified in 7.2.1.6.2.

Paragraph 7.2.1.4.1.4 establishes provisions for the arrangement and use of horizontal or vertical security grilles or doors if such features are specifically recognized by an occupancy chapter. For business occupancies, such recognition is provided by 38/39.2.2.2.6.

Horizontal-sliding or vertical-rolling fire doors exist in many business occupancies for purposes of property protection. Although the *Code* normally does not recognize these doors within the required means of egress, 39.2.2.2.7 provides a special exemption for existing horizontal-sliding or vertical-rolling fire doors. By requiring the fusible link to be positioned in immediate proximity to the door opening, rated 74°C (165°F) or higher, and located not more than 3050 mm (120 in.) above the floor, the *Code* helps to ensure that the door will remain open until rising temperatures make it unsafe to pass through the door opening. The door will not close early in the fire development; therefore, it cannot be credited as a fire door for life safety purposes. However, the door might serve for property protection. See Exhibit 38/39.5 for an example of an existing vertical-rolling fire door as permitted by 39.2.2.2.7.

Revolving doors are addressed by 38/39.2.2.2.8. The provisions of 7.2.1.10 specify that the use of a revolving door, regardless of whether it is permitted as part of the required means of egress, requires a conforming side-hinged swinging door to be positioned and usable within the same wall as, and to be located within 3050 mm (120 in.) of, the revolving door. This requirement helps to ensure that, once

CHAPTER 38 • New

people move toward the door, if the collapsibility and other safety features of the door fail and render it unusable, egress from the vicinity would still be possible without retracing steps and requiring travel toward the fire.

CHAPTER 39 • Existing

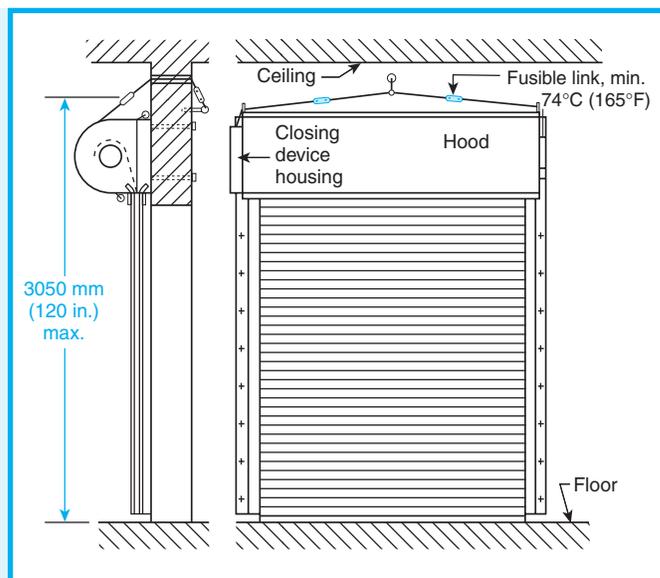

Exhibit 38/39.5 Existing vertical-rolling fire door in accordance with 39.2.2.2.7.

38.2.2.3 Stairs.

38.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

38.2.2.3.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted.

38.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

38.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

38.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

38.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

38.2.2.8 Reserved.

38.2.2.9 Reserved.

38.2.2.10 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

39.2.2.3 Stairs.

39.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

39.2.2.3.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted.

39.2.2.3.3 Winders complying with 7.2.2.2.4 shall be permitted.

39.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

39.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

39.2.2.6 Ramps. Ramps complying with 7.2.5 shall be permitted.

39.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

39.2.2.8 Escalators and Moving Walks. Escalators and moving walks complying with 7.2.7 shall be permitted.

39.2.2.9 Fire Escape Stairs. Fire escape stairs complying with 7.2.8 shall be permitted.

39.2.2.10 Fire Escape Ladders. Fire escape ladders complying with 7.2.9 shall be permitted.

CHAPTER 38 • New

38.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

38.2.2.12 Areas of Refuge.

38.2.2.12.1 Areas of refuge complying with 7.2.12 shall be permitted.

38.2.2.12.2 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), two rooms or spaces separated from each other by smoke-resistant partitions in accordance with the definition of area of refuge in 3.3.17 shall not be required.

The use of smokeproof enclosures is not mandated by 38/39.2.2.4. However, smokeproof enclosures are recognized as part of the means of egress system in business occupancies if they meet the requirements of 7.2.3. For an example of an occupancy requiring a smokeproof enclosure, see 31.2.11, which specifies that existing, nonsprinklered, high-rise apartment buildings are required to be provided with smokeproof enclosures in accordance with 7.2.3.

Existing escalators and moving walks are permitted to serve within the means of egress of existing business occupancies per 39.2.2.8. Note that 7.2.7 allows escalators and moving walks to continue to be permitted within the required means of egress if permitted by an occupancy chapter. In earlier editions of the *Code*, such escalators and moving walks might have been permitted and credited with providing egress capacity for 75 persons. To qualify as exits, existing escalators and moving walks must also meet the requirements of 7.1.3.2, which addresses exit enclosures. Escalators protected using the sprinkler-vent, spray nozzle, rolling shutter, or partial enclosure method do not constitute acceptable exits but could continue to serve as exit access if previously approved as such.

Existing fire escape stairs are permitted to serve within the means of egress of existing business occupancies per 39.2.2.9. Note that 7.2.8.1.2.1 permits ex-

38.2.3 Capacity of Means of Egress.

38.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

38.2.3.2* The clear width of any corridor or passageway serving an occupant load of 50 or more shall be not less than 1120 mm (44 in.).

CHAPTER 39 • Existing

39.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

39.2.2.12 Areas of Refuge.

39.2.2.12.1 Areas of refuge complying with 7.2.12 shall be permitted.

39.2.2.12.2 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), two rooms or spaces separated from each other by smoke-resistant partitions in accordance with the definition of area of refuge in 3.3.17 shall not be required.

isting buildings to continue to use fire escape stairs for no more than 50 percent of their required egress capacity.

Alternating tread devices are addressed in 38/39.2.2.11. The provisions of 7.2.11, in effect, restrict the use of alternating tread devices to locations where the *Code* recognizes the use of fire escape ladders. See 38/39.2.2.10, 7.2.9, and 7.2.11.

Areas of refuge are addressed in 38/39.2.2.12. Areas accessible to persons with severe mobility impairment in new buildings must be provided with accessible means of egress in accordance with 7.5.4.1. Existing business occupancies are exempt from the provisions of 7.5.4.1. For the stories above the level of exit discharge, where providing ramps is usually not feasible, areas of refuge (see 7.2.12) will typically be used to meet the requirements for accessible means of egress in new construction. The provision of 38/39.2.2.12.2 permits a sprinklered story of a business occupancy to be considered an area of refuge, even if an occupant does not have access to any of the tenant spaces. The effectiveness of sprinkler systems should allow an occupant with mobility impairment to remain on the floor of fire origin without experiencing untenable conditions. Doors to tenant spaces that are locked create inaccessibility to spaces other than the corridor, so the corridor effectively serves as the area of refuge.

39.2.3 Capacity of Means of Egress.

39.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

39.2.3.2 The clear width of any corridor or passageway serving an occupant load of 50 or more shall be not less than 1120 mm (44 in.).

CHAPTER 38 • New

A.38.2.3.2 It is not the intent that this provision apply to noncorridor or nonpassageway areas of exit access, such as the spaces between rows of desks created by office layout or low-height partitions.

38.2.3.3 Street floor exits shall be sufficient for the occupant load of the street floor plus the required capacity of stairs and ramps discharging through the street floor.

Chapter 7 mandates that any required egress capacity from a mezzanine that passes through the room below must be added to the required egress capacity of the room through which the egress passes.

Exhibit 38/39.6 illustrates a case in which a mezzanine is open to the street floor. The exits from the street floor must accommodate the following:

- (1) Occupant load of the street floor
- (2) Occupant load of the mezzanine in accordance with 7.3.1.6
- (3) Required capacity provided by the stairs from other floors discharging through the street floor in accordance with 38/39.2.3.3

The exits for the street floor of a business occupancy must have sufficient capacity to handle the occupant load of the street floor and the capacity of the exits discharging through the street floor per 38/

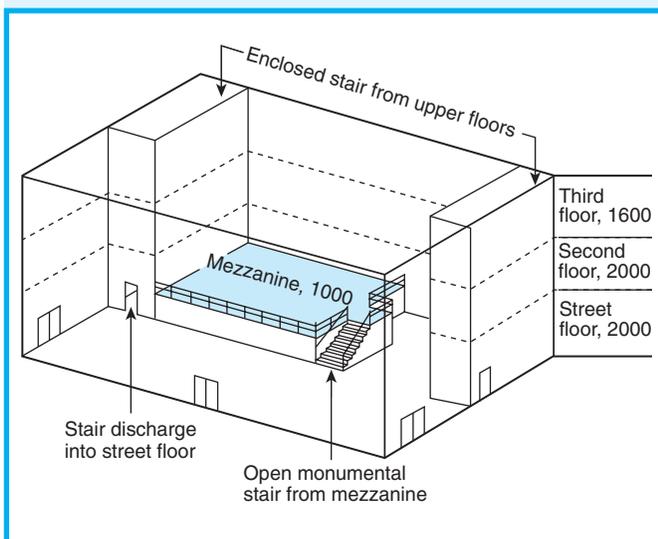

Exhibit 38/39.6 Business occupancy with a mezzanine open to the street floor.

CHAPTER 39 • Existing

39.2.3.3 Street floor exits shall be sufficient for the occupant load of the street floor plus the required capacity of stairs, ramps, escalators, and moving walks discharging through the street floor.

39.2.3.3. An example is an enclosed exit stair that accommodates occupants who, when exiting the building during an emergency, must travel up from the basement area or down from the upper floors and mix with the occupants already occupying the street floor.

To determine the exit capacity for the street floor, the occupant load of the mezzanine (1000 persons) is added to the occupant load of the street floor (2000 persons). In addition, because one-half of the exits from the upper floors discharge through the street floor, the egress capacity of the street floor must accommodate the capacity of the exit stair enclosure that discharges through that floor. The maximum occupant load of any upper floor is 2000 (second floor); and 38/39.2.7, in accordance with its reference to Section 7.7, permits a maximum of one-half of the exits (and one-half of the exit capacity for new business occupancies) to discharge through the street floor, provided that the requirements of 7.7.2 are met. Those requirements most typically involve the sprinkling of the level of exit discharge. Therefore, the street floor must be provided with egress capacity for 4000 persons or 20,000 mm (800 in.) of exit width using the factor of 5 mm (0.2 in.) per person for level exit components found in Table 7.3.3.1 (2000 for street floor + 1000 for mezzanine + 1000 for upper floors = 4000).

Corridors in business occupancies must be at least 1120 mm (44 in.) only if serving an occupant load of 50 or more persons per 38/39.2.3.2. If a corridor serves fewer than 50 persons, the minimum 915-mm (36-in.) width—mandated by 7.3.4.1 for egress components in general—would apply.

A corridor with the minimum 1120-mm (44-in.) width required by 38/39.2.3.2 has sufficient egress capacity, where calculated using the 5 mm (0.2 in.) per person capacity factor of Table 7.3.3.1 for level components, for approximately 220 persons; that is, 1120 mm/5 mm per person (44 in./0.2 in. per person).

For example, in a corridor that runs from one end of a building to the other end with an exit stair located at each end, 220 persons can travel from the midpoint of that corridor to the exit enclosure at one end. Another 220 persons can travel to the exit enclosure at the other end. Therefore, in this example, the occu-

pany load of the floor would have to exceed 440 persons before the minimum 1120 mm (44-in.) corridor width must be increased.

Because people move more quickly in the horizontal direction than in the vertical direction, it is permissible to provide less door width than stair width within any given egress path for a given number of occupants. For example, in business occupancies, in accordance with the egress capacity factors of Table 7.3.3.1, level components and ramps require only 5 mm (0.2 in.) of width per person, whereas stairs require 7.6 mm (0.3 in.) of width per person. As a rough approximation, for every 1120 mm (44 in.) of stair discharging through the street floor, an additional 760 mm (30 in.) of door width opening to the outside must be added for the street floor. Exhibit 38/39.7 provides an example of the calculation method for determining the required exit capacity for the street floor.

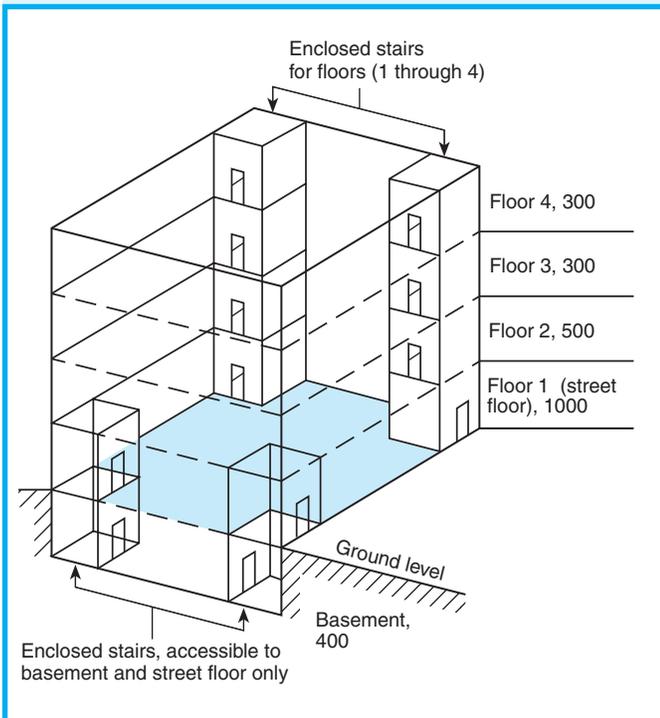

Exhibit 38/39.7 Calculation of exit capacity required for a street floor in accordance with 38/39.2.3.3.

Street floor occupant load	1000
Maximum upper floor occupant load discharging back through street floor (500/2)	+ 250
Basement occupant load discharging back through street floor (400/2)	+ 200
Total occupant load	1450

1450 persons × 5 mm (0.2 in.) per person for level exit components per 7.3.3.1 = 7250 mm (290 in.) of exit width required from the street floor egress system

38.2.4 Number of Exits.

38.2.4.1 Exits shall comply with the following except as otherwise permitted by 38.2.4.2 through 38.2.4.6:

- (1) The number of means of egress shall be in accordance with Section 7.4.
- (2) Not less than two separate exits shall be provided on every story.
- (3) Not less than two separate exits shall be accessible from every part of every story.

38.2.4.2 Exit access as required by 38.2.4.1(3) shall be permitted to include a single exit access path for the distances permitted as common paths of travel by 38.2.5.3.

39.2.4 Number of Exits.

39.2.4.1 Exits shall comply with the following except as otherwise permitted by 39.2.4.2 through 39.2.4.6:

- (1) The number of means of egress shall be in accordance with 7.4.1.1 and 7.4.1.3 through 7.4.1.6.
- (2) Not less than two separate exits shall be provided on every story.
- (3) Not less than two separate exits shall be accessible from every part of every story.

39.2.4.2 Exit access as required by 39.2.4.1(3) shall be permitted to include a single exit access path for the distances permitted as common paths of travel by 39.2.5.3.

CHAPTER 38 • New

38.2.4.3 A single exit shall be permitted for a room or area with a total occupant load of fewer than 100 persons, provided that the following criteria are met:

- (1) The exit shall discharge directly to the outside at the level of exit discharge for the building.
- (2) The total distance of travel from any point, including travel within the exit, shall not exceed 30 m (100 ft).
- (3) Such travel shall be on the same floor level or, if traversing of stairs is necessary, such stairs shall not exceed 4570 mm (180 in.) in height, and the stairs shall be provided with complete enclosures to separate them from any other part of the building, with no door openings therein.
- (4) A single outside stair in accordance with 7.2.2 shall be permitted to serve all floors permitted within the 4570-mm (180-in.) vertical travel limitation.

38.2.4.4 Any business occupancy not exceeding three stories, and not exceeding an occupant load of 30 people per floor, shall be permitted a single separate exit to each floor, provided the following criteria are met:

- (1) This arrangement shall be permitted only where the total travel distance to the outside of the building does not exceed 30 m (100 ft) and where the exit is enclosed in accordance with 7.1.3.2, serves no other levels, and discharges directly to the outside.
- (2) A single outside stair in accordance with 7.2.2 shall be permitted to serve all floors.

38.2.4.5 A single means of egress shall be permitted from a mezzanine within a business occupancy, provided that the common path of travel does not exceed 23 m (75 ft), or 30 m (100 ft) if protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

38.2.4.6 A single exit shall be permitted for a maximum two-story, single-tenant space/building that is protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1) and where the total travel to the outside does not exceed 30 m (100 ft).

A minimum of two exits are required by 38/39.2.4.1. For new business occupancies, see 7.4.1.2, which requires a minimum of three means of egress or a minimum of four means of egress where the occupant load exceeds 500 and 1000, respectively.

The provisions of 38/39.2.4.1(2), which apply to the required number of exits for business occupancies, clarify that any level that constitutes a story must have at least two exits located on that story. The occu-

CHAPTER 39 • Existing

39.2.4.3 A single exit shall be permitted for a room or area with a total occupant load of fewer than 100 persons, provided that the following criteria are met:

- (1) The exit shall discharge directly to the outside at the level of exit discharge for the building.
- (2) The total distance of travel from any point, including travel within the exit, shall not exceed 30 m (100 ft).
- (3) Such travel shall be on the same floor level or, if traversing of stairs is necessary, such stairs shall not exceed 4570 mm (180 in.) in height, and the stairs shall be provided with complete enclosures to separate them from any other part of the building, with no door openings therein.
- (4) A single outside stair in accordance with 7.2.2 shall be permitted to serve all floors permitted within the 4570-mm (180-in.) vertical travel limitation.

39.2.4.4 Any business occupancy not exceeding three stories, and not exceeding an occupant load of 30 people per floor, shall be permitted a single separate exit to each floor, provided the following criteria are met:

- (1) This arrangement shall be permitted only where the total travel distance to the outside of the building does not exceed 30 m (100 ft) and where the exit is enclosed in accordance with 7.1.3.2, serves no other levels, and discharges directly to the outside.
- (2) A single outside stair in accordance with 7.2.2 shall be permitted to serve all floors.

39.2.4.5 A single means of egress shall be permitted from a mezzanine within a business occupancy, provided that the common path of travel does not exceed 23 m (75 ft), or 30 m (100 ft) if protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1).

39.2.4.6 A single exit shall be permitted for a maximum two-story, single-tenant space/building that is protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1) and where the total travel to the outside does not exceed 30 m (100 ft).

pants of the story must be able to enter an exit (such as an enclosed exit stair on an upper floor of a multistory building) without having to travel to another story to reach the entrance to the exit. Because a mezzanine that meets the maximum one-third area rule of 8.6.9 does not constitute a story (see 8.6.9.1.1), two exits are not required on the mezzanine. However, the criteria of 38/39.2.4.1(3) must be met with respect to providing access to two separate exits, or the provi-

CHAPTER 38 • New

sions for common path of travel in 38/39.2.4.2 or 38/39.2.4.5 must be met.

The provision for common path of travel in 38/39.2.4.2 applies only to 38/39.2.4.1(3), which requires access to two separate exits from every part of every level (story or mezzanine). Occupants are allowed to travel in one direction for a maximum distance (the common path allowance) before requiring access in two separate directions. Therefore, although the story or mezzanine must eventually provide access to two exits in accordance with 38/39.2.4.1(3), that access is required to be available only at the point where the allowable common path is expended.

Exhibits 38/39.8 and 38/39.9 illustrate two cases where a single exit from a room or area in a business occupancy is allowed in accordance with 38/39.2.4.3. In the first case, the travel distance from the area is located on the same floor level as the exit. In the second case, stairs must be traversed.

The criteria for allowing the single exit in accordance with 38/39.2.4.3 follow:

- (1) Occupant load fewer than 100 persons
- (2) Direct exit to a street or to an open exterior area at ground level
- (3) Total distance of not more than 30 m (100 ft) from any point in the room to the exterior [note that this is total distance from any point to the exterior, not travel distance as measured in Section 7.6;

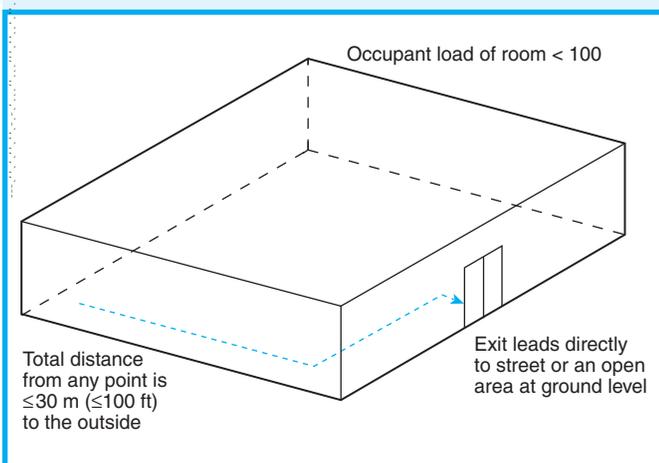

Exhibit 38/39.8 Single exit from area or room in business occupancy in accordance with 38/39.2.4.3—travel from area to exit without stairs.

CHAPTER 39 • Existing

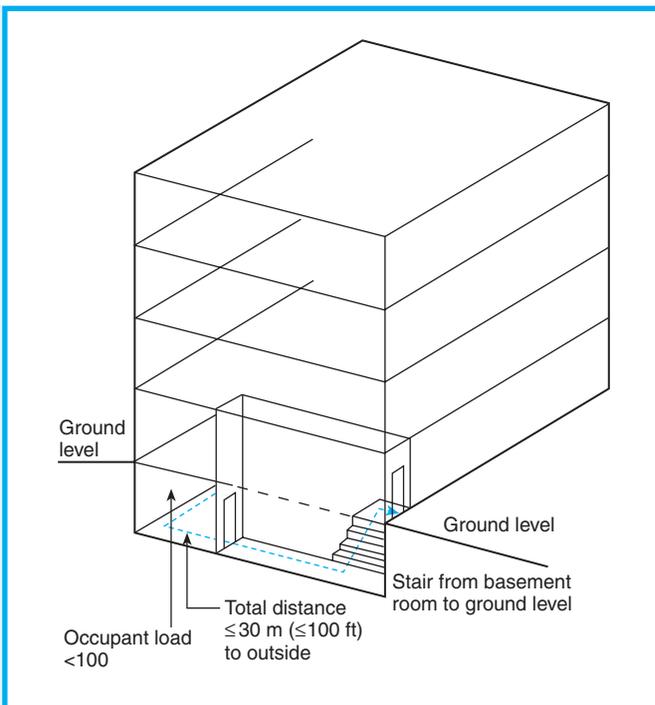

Exhibit 38/39.9 Single exit from area or room in business occupancy in accordance with 38/39.2.4.3—stairs traversed in traveling from the area to the exit.

therefore, total distance includes the distance traveled on enclosed stairs (exit)]

- (4) Stairs not more than 4570 mm (180 in.) in height
- (5) Stairs completely enclosed with no door openings between the stair enclosure and the rest of the building, or stairs meet requirements applicable to outside stairs (see 7.2.2.6.3)

To use this single-exit provision, all five criteria must be met.

Exhibit 38/39.10 illustrates a single exit from the third floor of a business occupancy in accordance with 38/39.2.4.4. The stair is totally enclosed, has an opening onto a building floor only at the third floor, and discharges directly to the street with no communication at the second and first floors. A similar, but separate, arrangement could be provided for the second floor of the same building.

The criteria for allowing a single exit in accordance with 38/39.2.4.4 follow:

- (1) Building height not more than 3 stories
- (2) Occupant load of each floor not more than 30

CHAPTER 38 • New

CHAPTER 39 • Existing

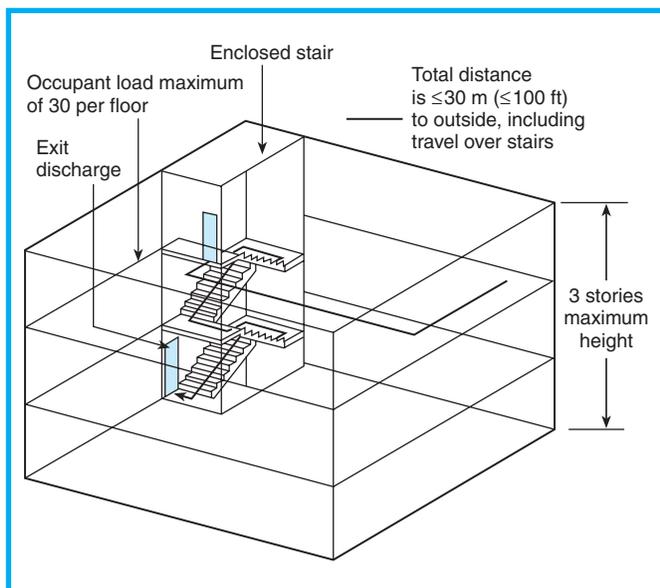

Exhibit 38/39.10 Single exit from third floor of a business occupancy in accordance with 38/39.2.4.4.

- (3) Total distance from any point on any floor to exterior at ground level not more than 30 m (100 ft), including travel over stairs [note that this is total distance from any point to the exterior, not travel distance as measured in Section 7.6; therefore, total distance includes the distance traveled on enclosed stairs (exit)]
- (4) Stair is not used by, nor has an opening to, any other floor

- (5) Stair is totally enclosed or meets the requirements applicable to outside stairs (see 7.2.2.6.3)

To use this single-exit provision, all five criteria must be met.

Although 38/39.2.4.2 allows common access to the two required means of egress for limited distances, 38/39.2.4.5 exempts a mezzanine in a business occupancy from providing a point where access to two exits is available if the single means of egress leads to an exit within the same limited distances as those allowed for common path of travel.

The provision of 38/39.2.4.6 provides some relief from the requirement that mandates two separate exits on every story, which affects town house-type, sprinklered business occupancies. These town house-type business occupancies typically have two stories with an open interior stair and are of such limited size that, if a second stair were added, little usable space would remain, and the two stairs would, in effect, be located side by side. The provision offers any single-tenant space in a fully sprinklered building with a maximum of two stories, or any sprinklered single-tenant building with a maximum of two stories, the option of providing only one exit if the total travel distance to the outside does not exceed 30 m (100 ft). Note that a companion provision in 38/39.3.1.1(2) that addresses vertical opening protection allows the open interior stair in town house-style business occupancies addressed here.

38.2.5 Arrangement of Means of Egress.

38.2.5.1 Means of egress shall be arranged in accordance with Section 7.5.

38.2.5.2 Dead-end corridors shall be permitted in accordance with 38.2.5.2.1 or 38.2.5.2.2.

38.2.5.2.1 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), dead-end corridors shall not exceed 15 m (50 ft).

38.2.5.2.2 In buildings other than those complying with 38.2.5.2.1, dead-end corridors shall not exceed 6100 mm (240 in.).

39.2.5 Arrangement of Means of Egress.

39.2.5.1 Means of egress shall be arranged in accordance with Section 7.5.

39.2.5.2* Dead-end corridors shall not exceed 15 m (50 ft).

A.39.2.5.2 It is recognized that dead ends exceeding the permitted limits exist and, in some cases, are impractical to eliminate. The authority having jurisdiction might permit such dead ends to continue to exist, taking into consideration any or all of the following:

- (1) Tenant arrangement
- (2) Automatic sprinkler protection
- (3) Smoke detection
- (4) Exit remoteness

CHAPTER 38 • New

38.2.5.3 Limitations on common path of travel shall be in accordance with 38.2.5.3.1, 38.2.5.3.2, and 38.2.5.3.3.

38.2.5.3.1 Common path of travel shall not exceed first 30 m (100 ft) in a building protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1).

38.2.5.3.2 Common path of travel shall not exceed first 30 m (100 ft) within a single tenant space having an occupant load not exceeding 30 persons.

38.2.5.3.3 In buildings other than those complying with 38.2.5.3.1 or 38.2.5.3.2, common path of travel shall not exceed 23 m (75 ft).

Because they have separate and distinct requirements, the *Code* separates dead-end corridors and common path of travel into two distinct and separate paragraphs. Dead-end corridors are limited to 6100 mm (240 in.) in new business occupancy buildings that are not protected throughout by an approved, supervised automatic sprinkler system. The provision of 38.2.5.2.1 recognizes the additional level of safety to life that a complete automatic sprinkler system provides; it, therefore, allows added flexibility when designing the location of corridors and exits in buildings where approved sprinkler systems are installed by permitting the dead-end corridor pocket to be as long as 15 m (50 ft). Existing business occupancies are permitted a 15-m (50-ft) dead-end corridor, regardless of the presence of sprinklers.

Three typical dead-end corridors are illustrated in Exhibit 38/39.11. Dead-end pockets are located in the corridor between points B and C, F and G, and H and I. They are limited to a maximum length of 6100 mm (240 in.) [15 m (50 ft) for existing business occupancies or sprinklered new business occupancies].

See the commentary associated with A.7.5.1.5 for

CHAPTER 39 • Existing

39.2.5.3* Limitation on common path of travel shall be in accordance with 39.2.5.3.1, 39.2.5.3.2, and 39.2.5.3.3.

A.39.2.5.3 It is recognized that common paths of travel exceeding the permitted limits exist and, in some cases, are impractical to eliminate. The authority having jurisdiction might permit such common paths of travel to continue to exist, taking into consideration any or all of the following:

- (1) Tenant arrangement
- (2) Automatic sprinkler protection
- (3) Smoke detection
- (4) Exit remoteness

39.2.5.3.1 Common path of travel shall not exceed 30 m (100 ft) on a story protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1).

39.2.5.3.2 Common path of travel shall not be limited in a single-tenant space with an occupant load not exceeding 30 people.

39.2.5.3.3 In buildings other than those complying with 39.2.5.3.1 or 39.2.5.3.2, common path of travel shall not exceed 23 m (75 ft).

a detailed discussion on common path of travel. Also see the commentary associated with 38/39.2.4.2, which allows a portion of the access to a single exit or multiple exits to be common.

The restriction on common path of travel is separate and distinct from the restriction on dead-end corridors. A common path of travel might sometimes involve a dead-end corridor, and dead ends might involve common path of travel, but not in every case. For an example, the elevator lobby shown in Exhibit 38/39.11 is a dead-end corridor but not a common path of travel.

Common path of travel is measured similarly to travel distance (see Section 7.6). The starting point for measurement of common path of travel is the same as the starting point for travel distance measurement—the most remote point. The difference is that, instead of terminating at the entrance to an exit, common path of travel measurement often ends before the exit's entrance, because it terminates at the point where the occupant has a choice of two distinct and separate paths to an exit (see the definition of the term *common path of travel* in 3.3.34). See rooms 1, 2, and 3 in Exhibit 38/39.11, where common paths

CHAPTER 38 • New

CHAPTER 39 • Existing

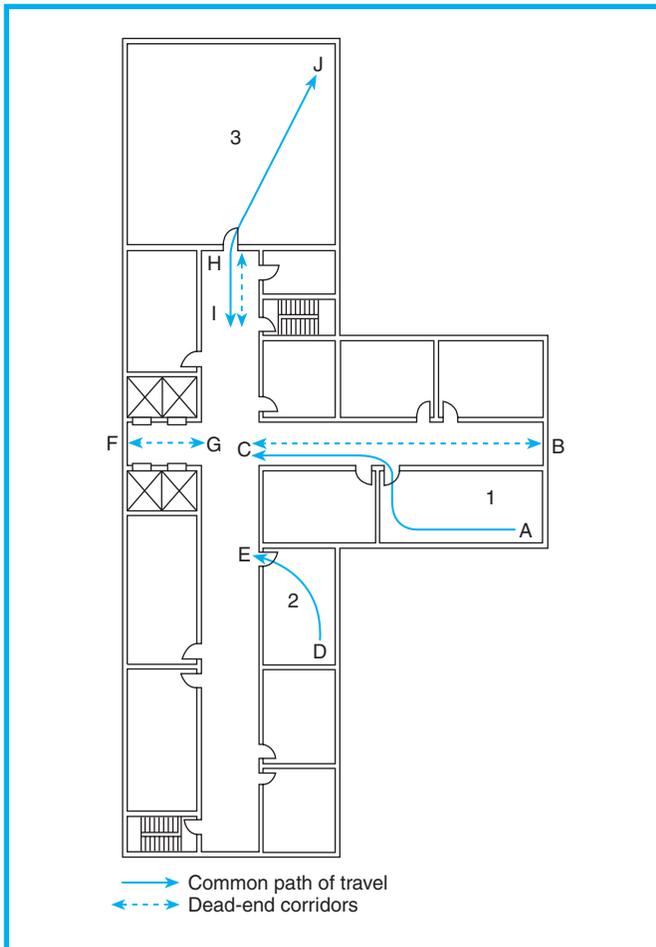

Exhibit 38/39.11 Dead-end corridor pockets and common paths of travel.

of travel occur between points A and C, D and E, and J and I.

The provision of 38/39.2.5.3.1 allows the common path of travel to be extended from 23 m (75 ft) to 30 m (100 ft) if sprinklers are provided. For new business occupancies, the building must be protected throughout by an approved, supervised automatic sprinkler system; for existing business occupancies, the sprinkler system is not required to be supervised and is not required to protect the entire building but only the floor on which the increased common path is located. This provision recognizes the additional level of safety to life that automatic sprinkler protection provides and allows added flexibility when designing the location of corridors and exits in buildings where approved sprinkler systems are installed.

The provision of 38.2.5.3.2 permits common path of travel in a new business occupancy to be extended from 23 m (75 ft) to 30 m (100 ft), without requiring the sprinkler protection addressed in 38.2.5.3.1, if the common path of travel occurs wholly within a maximum 30-person [normally, approximately 279 m² (3000 ft²), based on the business occupant load factor of 9.3 m² (100 ft²) per person] single-tenant space, with no additional common path encountered once the common space, such as the corridor, is reached. In Exhibit 38/39.11, 38.2.5.3.2 could be applied to room 2 but not to room 1 or room 3 because, upon leaving those rooms, additional common path of travel is encountered within the corridor.

The criteria addressed by 38.2.5.3.2 are not included in Chapter 39, because an existing business occupancy is offered the 7-m (25-ft) extension in allowable common path of travel—to 30 m (100 ft) as specified in 39.2.5.3.1—which is easier to meet. The criterion in 39.2.5.3.2 exempts a single-tenant space with a maximum occupant load of not more than 30 people from the common path of travel requirement. The tenant space would normally have an area of approximately 279 m² (3000 ft²), based on the business occupant load factor of 9.3 m² (100 ft²) per person. This provision can be used only if the single door from that tenant space leads to a corridor that does not have a dead end in excess of 15 m (50 ft). For an existing business occupancy, 39.2.5.3.2 might permit the common path of travel indicated between points J and I in Exhibit 38/39.11.

Exhibit 38/39.12 is an additional example of common path of travel in a business occupancy. Also see the commentary associated with Section 7.5 on arrangement of means of egress.

In Suite A of Exhibit 38/39.12, the travel from point X to point A is a common path of travel; although there are two routes to reach the corridor, they both merge at common point A. In Suite B, the travel from point X to point B is common path of travel, and does not appear to exceed the 23-m (75-ft) maximum; if it were in excess of 23 m (75 ft) but no more than 30 m (100 ft), it would be permitted by either 38/39.2.5.3.1 (involving sprinkler protection) or 38/39.2.5.3.2 (involving single tenant space). Although Suites C and D do not have common paths of travel, the remoteness of the two exit access doors from each suite is questionable. See 7.5.1.3 for details on means of egress remoteness.

The common path of travel restriction regulates

where an office space requires two exit access doors. If the common path of travel is exceeded, a second door from the office space is required. The door must be positioned so that any resulting common path of travel complies with the allowable distances. In addition, the second door must be remotely located from the first door (see 7.5.1.3), and each door must lead to remote exits by means of remote paths. Therefore, in a single requirement, the *Code* regulates not only the number of exit access doors required from an office area but also the arrangement of those doors.

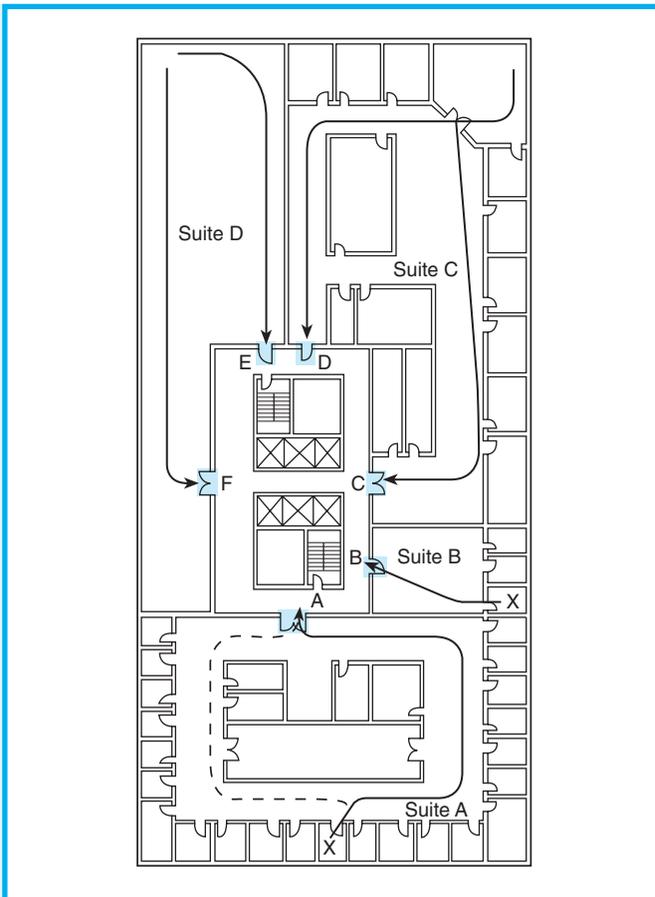

Exhibit 38/39.12 Common path of travel.

38.2.6 Travel Distance to Exits.

38.2.6.1 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), the travel distance shall not exceed 91 m (300 ft).

38.2.6.2 In buildings other than those complying with 38.2.6.1, the travel distance, measured in accordance with Section 7.6, shall not exceed 61 m (200 ft).

38.2.7 Discharge from Exits.

Exit discharge shall comply with Section 7.7.

38.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

39.2.6 Travel Distance to Exits.

39.2.6.1 In buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1), the travel distance shall not exceed 91 m (300 ft).

39.2.6.2 In all buildings other than those complying with 39.2.6.1, the travel distance, measured in accordance with Section 7.6, shall not exceed 61 m (200 ft).

39.2.7 Discharge from Exits.

Exit discharge shall comply with Section 7.7.

39.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8.

CHAPTER 38 • New

38.2.9 Emergency Lighting.

38.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9 in any building where any one of the following conditions exists:

- (1) The building is two or more stories in height above the level of exit discharge.
- (2) The occupancy is subject to 50 or more occupants above or below the level of exit discharge.
- (3) The occupancy is subject to 300 or more total occupants.

38.2.9.2 Emergency lighting in accordance with Section 7.9 shall be provided for all underground and limited access structures as defined in 3.3.217.11 and 3.3.217.3.

38.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

38.2.11 Special Means of Egress Features.

(Reserved)

Travel distance is addressed in 38/39.2.6. In accordance with Section 7.6, travel distance requirements apply to only the first (or nearest) exit from a given point in a building. In other words, the 61-m (200-ft) travel distance limit requires that at least one exit is to be located within 61 m (200 ft) of any point in the building; it does not require that all exits be within 61 m (200 ft) of any point in the building.

The provision of 38/39.2.6.1 allows the travel distance to be increased to 91 m (300 ft) if the building is protected throughout by an approved, electrically

CHAPTER 39 • Existing

39.2.9 Emergency Lighting.

39.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9 in any building where any one of the following conditions exists:

- (1) The building is two or more stories in height above the level of exit discharge.
- (2) The occupancy is subject to 100 or more occupants above or below the level of exit discharge.
- (3) The occupancy is subject to 1000 or more total occupants.

39.2.9.2 Emergency lighting in accordance with Section 7.9 shall be provided for all underground and limited access structures as defined in 3.3.217.11 and 3.3.217.3.

39.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

39.2.11 Special Means of Egress Features.

(Reserved)

supervised automatic sprinkler system. This provision recognizes the additional level of safety to life that a complete automatic sprinkler system provides and allows added flexibility in the design and arrangement of the means of egress.

If any of the three conditions of 38/39.2.9.1 exist, emergency lighting as specified in Section 7.9 is required for the business occupancy. Note that 38/39.2.9.1(1) specifically mentions buildings that have two or more stories located above the level of exit discharge, or a minimum of three stories.

Section 38.3 Protection**38.3.1 Protection of Vertical Openings.**

38.3.1.1 Vertical openings shall be enclosed or protected in accordance with Section 8.6, unless otherwise permitted by the following:

- (1) Unenclosed vertical openings in accordance with 8.6.8.2 shall be permitted.
- (2) Exit access stairs shall be permitted to be unenclosed in two-story, single-tenant spaces that are provided with a single exit in accordance with 38.2.4.2(5).

Section 39.3 Protection**39.3.1 Protection of Vertical Openings.**

39.3.1.1 Vertical openings, shall be enclosed or protected in accordance with Section 8.6 unless otherwise permitted by the following:

- (1) Unenclosed vertical openings in accordance with 8.6.8.2 shall be permitted.
- (2) Exit access stairs shall be permitted to be unenclosed in two-story, single-tenant spaces that are provided with a single exit in accordance with 39.2.4.2(5).

CHAPTER 38 • New

38.3.1.2 Floors that are below the street floor and are used for storage or other than a business occupancy shall have no unprotected openings to business occupancy floors.

The provisions for vertical openings in 38/39.3.1.1 reference Section 8.6. Paragraph 8.6.6 permits the three-story communicating space (sometimes referred to as a “mini-atrium”) unless there is a prohibition on such use in the applicable occupancy chapter. Neither Chapter 38 nor Chapter 39 prohibits the use of 8.6.6. Note that 8.6.6 requires that, if the communicating space (the vertical opening and all areas open to it) contains ordinary hazard contents, it must be protected by automatic sprinklers. In accordance with 38/39.1.5, business occupancies are classified as ordinary hazard.

The provision of 38/39.3.1.1(1)—via its reference to 8.6.8.2—permits, for example, a two-level office or a reference library in an office building to have an unenclosed convenience stair.

The provision of 38/39.3.1.1(2) completes the single-exit package for town house-type and similarly arranged business occupancies by allowing the single means of egress to include an unenclosed stair. See the commentary associated with 38/39.2.4.6.

38.3.2 Protection from Hazards.

38.3.2.1* Hazardous areas including, but not limited to, areas used for general storage, boiler or furnace rooms, and maintenance shops that include woodworking and painting areas shall be protected in accordance with Section 8.7.

A.38.3.2.1 It is not the intent of this provision that rooms inside individual tenant spaces, used to store routine office supplies for that tenant, be required to be either separated or sprinklered.

CHAPTER 39 • Existing

- (3) Unprotected vertical openings shall be permitted in buildings complying with all of the following:
- Where protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1)
 - Where no unprotected vertical opening serves as any part of any required means of egress
 - Where required exits consist of exit doors that discharge directly to grade in accordance with 7.2.1, outside stairs in accordance with 7.2.2, smokeproof enclosures in accordance with 7.2.3, or horizontal exits in accordance with 7.2.4

39.3.1.2 Floors that are below the street floor and are used for storage or other than a business occupancy shall have no unprotected openings to business occupancy floors.

Application of 39.3.1.1(3) requires not only that the building housing the existing business occupancy be protected with complete automatic sprinkler protection, but also that all building exits be either smokeproof enclosures, outside stairs, horizontal exits, or doors leading directly to the outside at ground level. Otherwise, the unprotected vertical openings must be suitably enclosed.

The separation requirement of 38/39.3.1.2 prevents the possibility that a fire in a basement housing a hazardous area with a high fuel load (such as areas used for workshops, repairs, or storage of maintenance supplies, files, and records) might directly expose the floor of exit discharge through an unprotected vertical opening. A fire in a basement can quickly cause exits and exit discharges located on the street floor to become unusable when smoke and heat rise.

39.3.2 Protection from Hazards.

39.3.2.1* Hazardous areas including, but not limited to, areas used for general storage, boiler or furnace rooms, and maintenance shops that include woodworking and painting areas shall be protected in accordance with Section 8.7.

A.39.3.2.1 It is not the intent of this provision that rooms inside individual tenant spaces, used to store routine office supplies for that tenant, be required to be separated or sprinklered.

CHAPTER 38 • New

38.3.2.2* High hazard contents areas, as classified in Section 6.2, shall meet the following criteria:

- (1) The area shall be separated from other parts of the building by fire barriers having a fire resistance rating of not less than 1 hour, with all openings therein protected by $\frac{3}{4}$ -hour fire protection-rated self-closing fire doors assemblies.
- (2) The area shall be protected by an automatic extinguishing system in accordance with 9.7.1.1(1) or 9.7.1.2.

A.38.3.2.2 The requirement for separating high hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

The provisions of 38/39.3.2 reflect the intent of Section 8.4, which requires one of the following:

- (1) Separation of a hazardous area from the remainder of the occupancy by means of suitable construction
- (2) Installation of automatic sprinklers in the hazardous area

38.3.3 Interior Finish.

38.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

38.3.3.2 Interior Wall and Ceiling Finish.

38.3.3.2.1 Interior wall and ceiling finish material complying with Section 10.2 shall be Class A or Class B in exits and in exit access corridors.

38.3.3.2.2 Interior wall and ceiling finishes shall be Class A, Class B, or Class C in all other areas.

38.3.3.3 Interior Floor Finish.

38.3.3.3.1 Interior floor finish shall comply with Section 10.2.

38.3.3.3.2 Interior finish in exit enclosures shall be Class I or Class II.

The requirement that interior floor finish be Class I or Class II (see Section 10.2) applies only to exits, such as enclosed stairs, in new business occupancies. The intent is that the interior floor finish materials used in exits are to resist the spread of fire if exposed to the radiant energy from a fully developed room

CHAPTER 39 • Existing

39.3.2.2* High hazard contents areas, as classified in Section 6.2, shall meet the following criteria:

- (1) The area shall be separated from other parts of the building by fire barriers having a fire resistance rating of not less than 1 hour, with all openings therein protected by $\frac{3}{4}$ -hour fire protection-rated self-closing fire door assemblies.
- (2) The area shall be protected by an automatic extinguishing system in accordance with 9.7.1.1(1) or 9.7.1.2.

A.39.3.2.2 The requirement for separating high hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

- (3) Protection by both items (1) and (2) where the hazard is severe

Where a hazardous area in a new business occupancy is protected by automatic sprinklers, that area is required to be enclosed by walls and doors meeting the requirements of smoke partitions in Section 8.4. See 8.7.1.2.

39.3.3 Interior Finish.

39.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

39.3.3.2 Interior Wall and Ceiling Finish.

39.3.3.2.1 Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A or Class B in exits and in exit access corridors.

39.3.3.2.2 Interior wall and ceiling finishes shall be Class A, Class B, or Class C in all other areas.

39.3.3.3 Interior Floor Finish. (No requirements)

fire by means of an open door. A provision in 10.2.8 allows for a reduction of one class of interior floor finish (that is, from Class I to Class II, or from Class II to no classification required) in sprinklered buildings.

In all cases, regardless of sprinkler protection,

CHAPTER 38 • New

carpet and carpet-like floor finishes must comply with ASTM D 2859, *Standard Test Method for Flammability of Finished Textile Floor Covering Materials*³, as referenced in 10.2.7.1. Other floor finish materials

38.3.4 Detection, Alarm, and Communications Systems.

38.3.4.1 General. A fire alarm system in accordance with Section 9.6 shall be provided in all business occupancies where any one of the following conditions exists:

- (1) The building is two or more stories in height above the level of exit discharge.
- (2) The occupancy is subject to 50 or more occupants above or below the level of exit discharge.
- (3) The occupancy is subject to 300 or more total occupants.

38.3.4.2 Initiation. Initiation of the required fire alarm system shall be by one of the following:

- (1) By manual means in accordance with 9.6.2.1(1)
- (2) By means of an approved automatic fire detection system that complies with 9.6.2.1(2) and provides protection throughout the building
- (3) By means of an approved automatic sprinkler system that complies with 9.6.2.1(3) and provides protection throughout the building

38.3.4.3 Occupant Notification. During all times that the building is occupied, the required fire alarm system, once initiated, shall perform one of the following functions:

- (1) It shall activate a general alarm in accordance with 9.6.3 throughout the building; positive alarm sequence in accordance with 9.6.3.4 shall be permitted.
- (2) It shall activate an alarm signal in a continuously attended location for the purpose of initiating emergency action by personnel trained to respond to emergencies. Emergency action shall be initiated by means of live voice public address system announcements originating from the attended location where the alarm signal is received. The live voice public address system shall be permitted to be used for other announcements, provided that the emergency action use takes precedence over any other use.

CHAPTER 39 • Existing

must have a minimum critical radiant flux of 0.1 W/cm² per 10.2.7.2. Existing business occupancies have no interior floor finish requirements (see 39.3.3.3).

39.3.4 Detection, Alarm, and Communications Systems.

39.3.4.1 General. A fire alarm system in accordance with Section 9.6 shall be provided in all business occupancies where any one of the following conditions exists:

- (1) The building is two or more stories in height above the level of exit discharge.
- (2) The occupancy is subject to 100 or more occupants above or below the level of exit discharge.
- (3) The occupancy is subject to 1000 or more total occupants.

39.3.4.2 Initiation. Initiation of the required fire alarm system shall be by one of the following:

- (1) By manual means in accordance with 9.6.2.1(1)
- (2) By means of an approved automatic fire detection system that complies with 9.6.2.1(2) and provides protection throughout the building
- (3) By means of an approved automatic sprinkler system that complies with 9.6.2.1(3) and provides protection throughout the building

39.3.4.3 Occupant Notification. During all times that the building is occupied (*see 7.2.1.1.3*), the required fire alarm system, once initiated, shall perform one of the following functions:

- (1) It shall activate a general alarm in accordance with 9.6.3 throughout the building.
 - (a) Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.
 - (b) A presignal system in accordance with 9.6.3.3 shall be permitted.
- (2) It shall activate an alarm signal in a continuously attended location for the purpose of initiating emergency action by personnel trained to respond to emergencies. Emergency action shall be initiated by means of live voice public address system announcements originating from the attended location where the alarm signal is received. The live voice public address system shall be permitted to be used for other announcements, provided that the emergency action use takes precedence over any other use.

CHAPTER 38 • New

CHAPTER 39 • Existing

A fire alarm system is required in a business occupancy under the same conditions as those under which emergency lighting is required (see 38/39.2.9.1). If any one of the three conditions of 38/39.3.4.1 exists, a fire alarm system must be provided. Note that, in 38/39.3.4.1(1), “two or more stories in height above the level of exit discharge” usually describes a building with three or more stories.

A required fire alarm system must have initiation means per 38/39.3.4.2, but the requirement for manual fire alarm boxes is waived if the system is initiated by either an automatic fire detection system providing protection throughout the building or an automatic sprinkler system providing protection throughout the building. This waiver does not exempt the fire alarm system but only the manual fire alarm boxes. However, 9.6.2.5 requires at least one manual fire alarm box to be provided at a location acceptable to the authority having jurisdiction.

38.3.5 Extinguishment Requirements.

Portable fire extinguishers shall be provided in every business occupancy in accordance with 9.7.4.1.

Although no requirements for automatic sprinkler systems are provided in 38/39.3.5, 38.4.2 has the effect of requiring new high-rise office buildings to be protected by automatic sprinklers, because the referenced provisions of Section 11.8 require sprinklers. Also, if the atrium provisions of 8.6.7 are used, a sprinkler system is required throughout the building. Additional incentives with respect to the following features are provided to encourage sprinkler installation:

- (1) Nonrated openings to attached parking structures (38/39.1.2.2)
- (2) Delayed-egress locks (38/39.2.2.4)

38.3.6 Corridors.

38.3.6.1* Where access to exits is provided by corridors, such corridors shall be separated from use areas by walls having a fire resistance rating of not less than 1 hour in accordance with Section 8.3, unless one of the following conditions exists:

When the required fire alarm system is initiated by one of the means specified in 38/39.3.4.2, the system must either automatically sound a general alarm throughout the building, or, if a continuously attended location is provided (as is often the case in high-rise or other large office buildings), the alarm is permitted to sound at that location only, with the appropriate emergency action initiated at that location. See 38/39.3.4.3 for details on occupant notification requirements.

Note that presignal systems are permitted in existing business occupancies only [see 39.3.4.3(1)]; the better, fail-safe feature, positive alarm sequence, is permitted for both new and existing business occupancies. See 9.6.3.3, 9.6.3.4 and *NFPA 72*,[®] *National Fire Alarm Code*^{®4}, for details on presignal and positive alarm sequence systems.

39.3.5 Extinguishment Requirements.

Portable fire extinguishers shall be provided in every business occupancy in accordance with 9.7.4.1.

- (3) Stories constituting areas of refuge (38/39.2.2.12)
- (4) Number of exits (38/39.2.4)
- (5) Dead-end corridors (38/39.2.5.2)
- (6) Common path of travel (38/39.2.5.3)
- (7) Travel distance to exits (38/39.2.6)
- (8) Discharge of exits through the level of exit discharge (38/39.2.7 per Section 7.7)
- (9) Protection from hazards (38/39.3.2)
- (10) Interior finish (38/39.3.3 per Section 10.2)
- (11) Elimination of manual fire alarm boxes (38/39.3.4.2)
- (12) Nonrated corridors (38.3.6.1)

39.3.6 Corridors.

(No requirements)

CHAPTER 38 • New

CHAPTER 39 • Existing

(1)* Where exits are available from an open floor area

A.38.3.6.1(1) Where exits are available from an open floor area, such as open plan buildings, corridors are not required to be separated. An example of an open plan building is a building in which the work spaces and accesses to exits are delineated by the use of tables, desks, bookcases, or counters or by partitions that are less than floor-to-ceiling height.

(2)* Within a space occupied by a single tenant

A.38.3.6.1(2) It is the intent of this provision that a single tenant be limited to an area occupied under a single management and work the same hours. The concept is that people under the same employ working the same hours would likely be familiar with their entire tenant space. It is not the intent to apply this provision simply because tenants are owned by the same organization. For example, in a government-owned office building, the offices of different federal agencies would be considered multiple tenants because an employee normally works for one agency. The agencies might work various hours. Another example of multiple tenancy would be a classroom building of a university because some classrooms might be in use at times when other classrooms are not being used.

(3) Within buildings protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)

A.38.3.6.1 The intent of 38.3.6(1) through 38.3.6(3) is to permit spaces to be open to the exit access corridor without separation.

38.3.6.2 Unenclosed exits available from an open floor area, or unenclosed exits that serve a space occupied by a single tenant, shall not be required to be protected in accordance with 38.3.6.1.

38.3.6.3 Openings in corridor walls required by 38.3.6.1 to have a fire resistance rating shall be protected in accordance with Section 8.3.

Corridors in new business occupancies are addressed in 38.3.6; no corridor requirements are specified for existing business occupancies.

The provision of 38.3.6.1(1) provides for the popular “office landscape” or “open office” arrangement. If there is direct access to exits from the open area, it is not necessary to provide corridors. This provision recognizes that a fire in an open space is subject to more rapid observation and response than a fire in an enclosed room or office.

The provision of 38.3.6.1(2) recognizes that, in

areas occupied by a single tenant, there is a high level of familiarity with the area, and the partitioned offices or spaces are occupied by the same people on a regular basis. Such spaces are exempt from corridor requirements.

The provision of 38.3.6.1(3) recognizes the value of automatic sprinklers as a life safety feature that helps to control fire growth and, thus, maintains the exit access usable for a longer time. Such sprinklered buildings are exempt from all corridor requirements.

CHAPTER 38 • New

38.3.7 Subdivision of Building Spaces.

(No special requirements)

Section 38.4 Special Provisions**38.4.1 Limited Access or Underground Buildings.**

See Section 11.7.

38.4.2* High-Rise Buildings.

High-rise buildings shall comply with Section 11.8.

A.38.4.2 In the design of high-rise buildings, special consideration should also be given to a life safety system including, but not limited to, the following features:

- (1) Movement of occupants to safety
- (2) Control of fire and smoke
- (3) Psychological features
- (4) Communications systems
- (5) Elevators
- (6) Emergency planning
- (7) Overall system reliability

CHAPTER 39 • Existing

39.3.7 Subdivision of Building Spaces.

(No special requirements)

Section 39.4 Special Provisions**39.4.1 Limited Access or Underground Buildings.**

See Section 11.7.

39.4.2 High-Rise Buildings.

39.4.2.1 All high-rise business occupancy buildings shall be provided with a reasonable degree of safety from fire, and such degree of safety shall be accomplished by one of the following:

- (1) The installation of a complete, approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)
- (2) The installation of an engineered life safety system which shall comply with the following:
 - (a) The engineered life safety system shall be developed by a registered professional engineer experienced in fire and life safety systems design
 - (b) The life safety system shall be approved by the authority having jurisdiction and might include any or all of the following systems:
 - i. Partial automatic sprinkler protection
 - ii. Smoke detection alarms
 - iii. Smoke control
 - iv. Compartmentation
 - v. Other approved systems

39.4.2.2* A limited but reasonable time shall be permitted for compliance with any part of 39.4.2.1, commensurate with the magnitude of expenditure and the disruption of services.

A.39.4.2.2 In some cases, appreciable cost might be involved in bringing an existing occupancy into compliance. Where this is true, it would be appropriate for the authority having jurisdiction to prescribe a schedule determined jointly with the facility, allowing suitable periods of time for the correction of the various deficiencies and giving due weight to the ability of the owner to secure the necessary funds.

39.4.2.3 In addition to the requirements of 39.4.2.1 and 39.4.2.2, all buildings, regardless of height, shall comply with all other applicable provisions of this chapter.

CHAPTER 38 • New

Section 38.5 Building Services**38.5.1 Utilities.**

Utilities shall comply with the provisions of Section 9.1.

38.5.2 Heating, Ventilating, and Air Conditioning.

Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

38.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

38.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 38.6 Reserved**Section 38.7 Operating Features****38.7.1 Drills.**

In all business occupancy buildings occupied by more than 500 persons, or by more than 100 persons above or below the street level, employees and supervisory personnel shall be periodically instructed in accordance with Section 4.7 and shall hold drills periodically where practicable.

38.7.2 Extinguisher Training.

Designated employees of business occupancies shall be periodically instructed in the use of portable fire extinguishers.

38.7.3 Food service operations shall comply with 12.7.1.

The extent of the portable fire extinguisher training required by 38/39.7.2 (for example, instruction only, or instruction and hands-on use) is determined by the authority having jurisdiction.

CHAPTER 39 • Existing

Section 39.5 Building Services**39.5.1 Utilities.**

Utilities shall comply with the provisions of Section 9.1.

39.5.2 Heating, Ventilating, and Air Conditioning.

Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

39.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

39.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 39.6 Reserved**Section 39.7 Operating Features****39.7.1 Drills.**

In all business occupancy buildings occupied by more than 500 persons, or by more than 100 persons above or below the street level, employees and supervisory personnel shall be periodically instructed in accordance with Section 4.7 and shall hold drills periodically where practicable.

39.7.2 Extinguisher Training.

Designated employees of business occupancies shall be periodically instructed in the use of portable fire extinguishers.

39.7.3 Food service operations shall comply with 13.7.1.

CHAPTER 40

Industrial Occupancies

Industrial occupancy is a broad classification. The following are examples of industrial occupancies:

- (1) Factories of all kinds
- (2) Pumping stations
- (3) Telephone exchanges
- (4) Gas plants
- (5) Laundries
- (6) Laboratories
- (7) Recycling plants
- (8) Refineries
- (9) Food processing plants
- (10) Dry cleaning plants
- (11) Autobody and repair shops
- (12) Sawmills
- (13) Hangars (for servicing aircraft)
- (14) Power plants
- (15) Post office central sorting/maintenance facilities

The range of facilities that are classified as industrial occupancies is diverse. Industrial occupancies comprise a wide variety of building configurations, uses, and equipment types. Some industrial occupancies might be considered innocuous with respect to the threat of fire hazard, such as a factory that manufactures concrete blocks. An industrial occupancy subject to the threat of serious fire hazard might be a petroleum processing and refining plant, where the threat of explosion is always present. The subclassification system used in 40.1.4.1 is intended to assist the user in establishing the level of hazard to the occupants of an industrial occupancy.

The requirements of Chapter 40 were written to provide adequate life safety without unduly restricting the functional operations of a facility. For example, 40.2.2.10 and 40.2.2.11 permit fire escape ladders and slide escapes as part of an occupant pro-

tection package that balances the need for rapid escape from platforms and other industrial structures with the ability of the occupants to use such egress devices. By permitting the use of fire escape ladders and slide escapes, Chapter 40 recognizes that functional requirements necessitate occupant access to unusual spaces within the industrial facility and that efficient egress from these spaces is important.

A unique life safety consideration addressed in Chapter 40 involves egress for occupants of ancillary facilities. Paragraph 40.2.5.1 recognizes that some types of industrial processes and equipment cannot be immediately abandoned if the building fire alarm sounds. If workers do not remain in the building long enough to effect orderly shutdown during a fire emergency, dangers greater than fire might result. The protection measures required by 40.2.5.1 provide for the safety of occupants who must remain while others leave the building.

Another unique feature that the *Code* addresses for industrial occupancies is the equipment access dimensional criteria of Table 40.2.5.2.1. These dimensional criteria, although more lenient than those of Chapter 7, provide adequate egress paths for the small number of occupants using any of those routes to reach major aisles that lead to exits.

The statistics provided by the national fire incident databases demonstrate that the potential loss of life from fire in an industrial occupancy is directly related to the hazard of the industrial operation or process. Most multiple-death industrial fires are the result of flash fires caused by highly combustible material or explosions involving combustible dusts, flammable liquids, or gases.

Although industrial fire losses constitute a high percentage of the annual property loss from fire, such fires have not, as a general rule, resulted in extensive

loss of life. A number of operating features common to industrial occupancies have contributed to this favorable record. Continued emphasis on proper egress design and maintenance and day-to-day attention to industrial safety and training programs can help to perpetuate this trend.

One of the major features to be considered in the design of an industrial building's life safety system is the widespread use of automatic sprinkler protection. Originally developed for industrial property protection, the automatic sprinkler has also been largely responsible for an excellent life safety record in industrial occupancies—limiting the size of a fire by means of sprinklers provides sufficient time for the safe evacuation of occupants. This record has been recognized by the fire protection community, as evidenced by the widespread use of automatic sprinkler systems in buildings with significant hazards to life. The contribution of the automatic sprinkler to safety to life can be fully appreciated only when the wide range of fire risks associated with the many processes used in an industrial facility are recognized.

Employees and other occupants of industrial buildings are generally ambulatory and capable of quick response to fires. They are also able to exit rapidly once properly alerted. To capitalize on this employee capability, many industrial facilities include life safety measures in their emergency preplanning. A well-conceived plan provides a valuable tool in preventing loss of life. Provisions that should be part of the emergency preplan include the following:

- (1) Measures for alerting employees
- (2) Identification and posting of exit access routes
- (3) Establishment of group assembly areas for occupants once they have evacuated the building
- (4) Procedures for determining that all employees have safely evacuated

Responsibilities are usually established and assigned in the preplan to ensure that the tasks necessary to facilitate safe evacuation of the building are performed. The preplan should routinely be evaluated through simulated fire exercises and drills. Only through the execution of such drills can flaws in the preplan be recognized and modified.

Although the life safety record in industry has been good, the trend toward constructing large industrial plants that house hazardous operations might prove problematic. The introduction of combustible materials, such as extensive quantities of plastics, has increased the need for additional measures to help protect employees from fire. Compared

with the industrial buildings of the early twentieth century, the modern industrial complex has placed a larger number of employees in a more complex and increasingly hazardous environment. This trend has increased the need for industrial management to concentrate on life safety principles not only during the design stage but also during day-to-day plant operations.

As part of their employee training programs, most industrial firms include education in the use of first aid fire-fighting equipment, such as in-plant standpipes, hose, and portable fire extinguishers. Although first aid fire-fighting measures are primarily a property protection measure, they also provide a significant life safety benefit. Industrial training of this type, where fully utilized, has resulted in a major reduction in property loss and life loss.

Section 40.1 General Requirements

40.1.1 Application.

40.1.1.1 The requirements of this chapter shall apply to both new and existing industrial occupancies.

40.1.1.2 Industrial occupancies shall include factories making products of all kinds and properties used for operations such as processing, assembling, mixing, packaging, finishing or decorating, repairing, and similar operations.

40.1.1.3 Incidental high hazard operations protected in accordance with Section 8.7 and 40.3.2 in occupancies containing low or ordinary hazard contents shall not be the basis for high hazard industrial occupancy classification.

Unlike most occupancies covered in the *Code*, both new and existing industrial occupancies are covered in one chapter. Where requirements vary, exemptions that apply to existing industrial occupancies are often provided, or additional requirements that are limited to new industrial occupancies are specified.

40.1.2 Multiple Occupancies.

All multiple occupancies shall be in accordance with 6.1.14.

Subsection 40.1.2 directs the user to the multiple occupancies provisions of 6.1.14, which permit protecting multiple occupancies either as mixed occupancies or as separated occupancies. Where the multiple occupancy is protected via the provisions

of 6.1.14.4 for separated occupancies, the required number of hours of fire-rated separation is specified by Table 6.1.14.4.1.

40.1.3 Definitions.

See Chapter 3.

Although no definitions are listed in 40.1.3, industrial occupancies are subclassified and defined in 40.1.4.1, under the labels *general industrial occupancy*, *special purpose industrial occupancy*, and *high hazard industrial occupancy*. See also 3.3.152.8, 3.3.152.8.1, 3.3.152.8.2, and 3.3.152.8.3.

40.1.4 Classification of Occupancy.

See 6.1.12.

The method for determining the degree of hazard to life safety posed by an industrial occupancy is, at best, a matter of personal judgment and not science. The authority having jurisdiction must use judgment based on past experience, a review of reference materials, and full discussion with third parties to evaluate the life safety measures in an industrial occupancy. The *Code* establishes broad categories of occupancy classification so that the relative risks to life safety posed by various types of buildings can be assessed.

A common error made when classifying industrial occupancies is the use of hazard categories for automatic sprinklers contained in NFPA 13, *Standard for the Installation of Sprinkler Systems*¹, to determine the hazard to life safety. While the guidelines in NFPA 13 might not differ greatly from those of the *Life Safety Code* where classifying occupancies with high hazards, the remaining categories specified in NFPA 13 are usually not suitable for the general industrial occupancy classification of the *Code*. (The use of NFPA 13 is particularly inappropriate where classifying low hazard occupancies, which are classified as light hazard by NFPA 13.) The distinction is that the life safety industrial occupancy classification is concerned with determining the overall hazard to occupants in a manufacturing building for purposes of implementing an adequate means of egress system, while the NFPA 13 classification system is concerned with defining the hazard so that a sprinkler system can be designed to meet the challenge of the hazard.

To examine the conflicts between life safety occupancy classification and classifications in other fire

codes, consider a metalworking plant using a flammable solvent in a dip tank coating operation. From a life safety standpoint, the normally ordinary hazard classification of the metalworking plant should not be changed to high hazard solely because of the presence of a dip tank coater. An adequate means of safe egress leading away from the coater is required to ensure the safety of the occupants. However, additional exits and a reduction in travel distance to an exit, as specified for a high hazard contents area, are not required. Nevertheless, if the coater is the principal piece of equipment in a separately enclosed area, that area might be considered as a high hazard industrial occupancy.

When determining the life safety hazard classification for an industrial occupancy, the authority having jurisdiction should carefully analyze the nature of that industrial operation to ensure an accurate evaluation of the hazard to occupants. A number of resources are available for properly determining the degree of risk to life safety. One resource that should not be overlooked is the expertise of the industrial plant operator, who can provide a wealth of hazard information, although some such information might be treated as confidential to prevent competitors from learning the details of an industrial process. In such a case, the enforcing authority must handle that information with discretion; once an enforcing authority is known to be an outside source of data on industrial secrets, further cooperation will be difficult to obtain.

Another resource is the engineering department of the company responsible for a facility's insurance coverage. In addition, discussions with officials who oversee jurisdictions where similar facilities exist and a review of NFPA literature will provide further information on a particular process and its associated hazards.

To assess the risk to life safety in an industrial occupancy, a number of factors should be considered. It should be determined if the manufacturing process includes the handling of flammable, reactive, or explosive materials in quantities that could directly expose occupants to a fire or explosion. If so, the occupancy is a strong candidate for a high hazard classification.

It should also be determined whether the manufacturing process requires a large number of people or whether it is basically a large collection of machines or equipment occasionally attended by operators. In some instances, operators might be clustered in one location, such as a control room. If a building is predominantly occupied by machinery or equipment and is used by few employees, the building can be

classified as a special purpose industrial occupancy. See 40.1.4.1(2).

If an industrial building is used mostly for storage of materials (such as preparatory stock for assembly or finished goods), it might meet the requirements for classification as a storage occupancy. See Chapter 42.

Occupancy classification is based on the burning and explosive characteristics of the materials contained in a building, not on the quantity of combustibles. For example, there is no reason to classify a building as high hazard simply because it is associated with a manufacturing process that requires extensive quantities of ordinary combustible materials to be distributed in such a manner that the process involves a high combustible load.

The classification of an industrial occupancy, for life safety purposes, is not based on the type of structure housing the industrial process. The basic purpose of the hazard classification in Section 6.2 is to evaluate the risk of contents. The classification is determined by an evaluation of the contents and other factors in a fire's development that affect the time available for safe evacuation of the occupants. Once employees are evacuated to a safe location, the extent of fire spread in the structure becomes a threat to property. As long as life safety measures are met, the threat of heavy fire damage to a building is beyond the scope of the *Life Safety Code*. Also see the commentary following 40.1.4.1(2) and 40.1.4.1(3).

40.1.4.1 Subclassification of Industrial Occupancies.

Each industrial occupancy shall be subclassified according to its use as follows:

- (1) *General Industrial Occupancy*. A general industrial occupancy conducts ordinary and low hazard industrial operations in buildings of conventional design suitable for various types of industrial processes. Also included are multistory buildings where floors are occupied by different tenants or buildings suitable for such occupancy and, therefore, subject to possible use for types of industrial processes with a high density of employee population.
- (2) *Special Purpose Industrial Occupancy*. A special purpose industrial occupancy conducts ordinary and low hazard industrial operations in buildings designed for, and suitable only for, particular types of operations. Such occupancy is characterized by a relatively low density of employee population, with much of the area occupied by machinery or equipment.

It can be difficult to determine if a building qualifies as a special purpose industrial occupancy. For example, a structure is often erected to protect a large machine or equipment from weather. Once constructed, authorities might try to impose exit requirements applicable to a general industrial occupancy, despite the fact that only a handful of personnel are to occupy the building. Steel mills, paper plants, power-generating plants, and other operations with large machines are examples of the types of industrial occupancies requiring massive structures for process control and weather protection. These structures often represent minimum hazards to life safety and should be classified as special purpose industrial occupancies. In many of the more modern operations, all process control is conducted from a control room by remote means, which further reduces the number of occupants likely to be exposed to a fire in the equipment areas.

The special purpose industrial occupancy classification must not be applied to a building simply to reduce egress requirements. Economic considerations, or staffing limitations that result in occupancy by fewer employees than usual, cannot be used as justification for reducing life safety features; the full number and arrangement of exits required for a general industrial occupancy should be maintained. A reduction in aisles, doors, stairways, and other components of the means of egress cannot be justified by the temporary classification of a building as a special purpose industrial occupancy.

- (3)* *High Hazard Industrial Occupancy*. A high hazard industrial occupancy conducts industrial operations that use high hazard materials or processes or houses high hazard contents. Incidental high hazard operations in low or ordinary occupancies that are protected in accordance with Section 8.4 and 40.3.2 shall not be the basis for overall occupancy classification.

A.40.1.4.1(3) Additional information can be found in the annex for the definition of *High Hazard Industrial Occupancy* in A.3.3.152.8.2.

A high hazard occupancy classification is limited to those industrial buildings housing extremely hazardous operations. Incidental use of restricted quantities of flammable liquids in a building does not constitute a high hazard, although some additional life safety precautions might be required during the limited pe-

riod of use. Refer to NFPA 30, *Flammable and Combustible Liquids Code*², for guidance. Storage of flammable liquids, such as paint, in sealed containers does not require a high hazard occupancy classification, unless the operation includes mixing or blending operations that require the containers to be opened. Mixing and blending of flammable liquids is permitted to be conducted in a separate room with a fire barrier between the storage and mixing areas. The mixing and blending room would be considered a high hazard industrial occupancy, while the adjacent, fire-separated storage area would be considered a general-purpose industrial occupancy or possibly a storage occupancy subject to the requirements of Chapter 42.

Combustible dusts released from an industrial or manufacturing process constitute a significant threat to life safety and might justify a high hazard classification. Major loss of life has occurred in industrial occupancies that release extensive quantities of combustible dusts. Opportunity for the rapid escape of employees who work in operations that release combustible dust should be provided to prevent injury or loss of life if a dust explosion occurs. In high hazard occupancies that are subject to explosions, the provisions of 40.3.2 require special consideration of the techniques for explosion suppression or venting to ensure the life safety of occupants. Full use of fire protection engineering techniques should be employed in these occupancies to minimize the risk to life safety.

The industrial occupancies that clearly require classification as high hazard are those associated with the production of explosives or highly reactive chemicals. In some especially hazardous operations, additional exits will be necessary to ensure rapid egress to prevent loss of life in the event of an explosion or fire. Where the installation of the preventive or protective measures specified in 40.3.2 is not possible due to the nature of the industrial operation, consideration should be given to operating procedures that restrict access to a limited number of people during the hazardous portion of the operation. The operating procedures would limit the potential threat to those trained personnel who are fully aware of the extent of the hazard. Procedures should also include a record of personnel who have signed in or out. This procedure ensures prompt determination of the number of personnel exposed to a hazardous operation and, thus, the number who might require rescue.

40.1.4.2 Change of Industrial Occupancy Subclassification. Changing from one subclassification of industrial oc-

cupancy to another shall be permitted only if the structure, building, or portion thereof conforms to the requirements of this chapter that apply to new construction for the new use.

Paragraph 4.6.12 requires that upon change of occupancy (for example, an industrial occupancy factory building that is renovated to become a residential occupancy apartment building), the building is to meet the requirements that apply to new construction for the new occupancy classification. Paragraph 40.1.4.2 expands the concept to include changes in industrial occupancy subclassification. In each of the following examples, the industrial occupancy that results from a change in subclassification must meet the requirements of Chapter 40 that apply to new industrial occupancies:

- (1) A general industrial occupancy is reclassified as a high hazard industrial occupancy based on the introduction of flammable liquids throughout the various processes used to manufacture the product.
- (2) A high hazard industrial occupancy is reclassified as a general industrial occupancy based on replacing flammable solvents, which had been used throughout the various manufacturing processes, with noncombustible materials.
- (3) A special purpose industrial occupancy with an automated, metal-casting line is reclassified as a general industrial occupancy following the removal of the line equipment and the introduction of metal-machining lathes and skilled operators.

40.1.5 Classification of Hazard of Contents.

Classification of hazard of contents shall be in accordance with Section 6.2.

40.1.6 Minimum Construction Requirements.

(No requirements)

Some occupancy chapters, such as Chapters 18 and 19, which address the life safety needs of nonambulatory health care occupants, specify minimum building construction type requirements to ensure structural integrity for the time needed for a lengthy evacuation or for safe refuge within the building. No minimum construction requirements are imposed in Chapter 40, because industrial occupancies charac-

teristically have ambulatory occupants and do not provide sleeping accommodations. Occupants should be able to egress the building quickly before the fire-resisting qualities of the building construction become an issue.

40.1.7* Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the occupant load factors of Table 7.3.1.2 that are characteristic of the use of the space or shall be determined as the maximum probable population of the space under consideration, whichever is greater.

A.40.1.7 In most cases, the requirements for maximum travel distance to exits will be the determining factor rather than numbers of occupants because exits provided to satisfy travel distance requirements will be sufficient to provide egress capacity for all occupants, except in cases of unusual arrangement of buildings or high occupant load of a general manufacturing occupancy.

The occupant load of an industrial building is based on an average of 9.3 m² (100 ft²) of gross floor area per occupant in accordance with Table 7.3.1.2. Many industrial users of the *Code* confuse this concept with the actual number of employees who use the facility. The usual complaint is that the number of potential employees calculated for egress purposes in accordance with the 9.3-m² (100-ft²) criterion far exceeds the anticipated or actual number of employees. Many industrial managers argue that using the larger number as a basis for egress design requires more exits, wider doors, and more passageways than are needed for emergency egress purposes, reducing productive work space and resulting in increased cost.

The concept of determining occupant load by using an occupant load factor is useful, although it does not necessarily relate directly to the actual number of building occupants. The occupant load factor is used as a means of calculating the minimum egress requirements, based on the needs of an average industrial occupancy. Although actual conditions might vary in an individual location, the egress width determined by the occupant load calculation will normally provide the necessary, adequate, and required means of egress for a typical industrial building with little or no penalty to the building's owner/operator.

See Exhibit 40.1 for examples of occupant load determination using the occupant load factor for

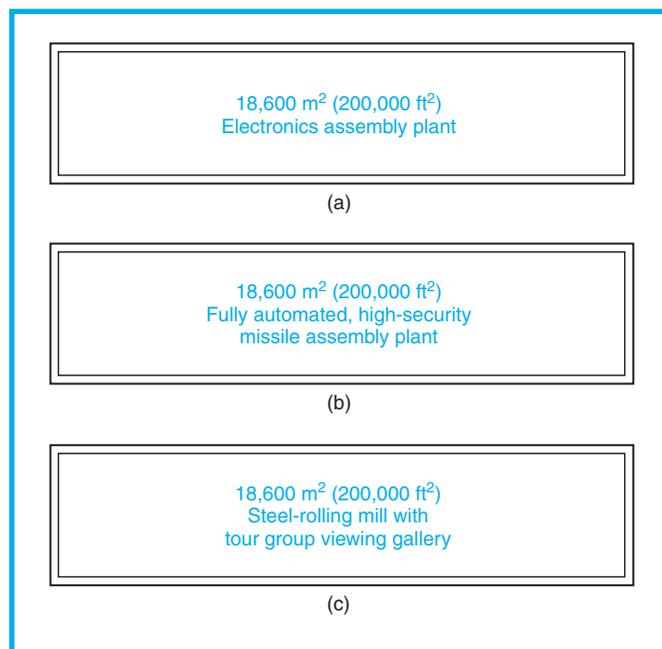

Exhibit 40.1 Determination of occupant load of industrial occupancies.

a general industrial occupancy and using the probable number of occupants for a special purpose industrial occupancy.

In Exhibit 40.1, illustration (a), the general industrial occupancy must provide a means of egress for at least 2000 persons based on use of an occupant load factor of 1 person per 9.3 m² (100 ft²).

In Exhibit 40.1, illustration (b), a special purpose industrial occupancy can size its means of egress for the maximum 20 persons (actual anticipated employee population) who are expected to occupy the facility under any probable condition.

In Exhibit 40.1, illustration (c), the 200-person tour groups that visit this special purpose industrial occupancy on the first Monday of each month must be added to the 45 employees (actual employee population) who are normally present, for a total occupant load of 245 persons.

Section 40.2 Means of Egress Requirements

40.2.1 General.

Each required means of egress shall be in accordance with the applicable portions of Chapter 7.

40.2.2 Means of Egress Components.

40.2.2.1 General. Components of means of egress shall be limited to the types described in 40.2.2.2 through 40.2.2.13.

40.2.2.2 Doors.

40.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

40.2.2.2.2 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted.

Use of the delayed-egress locking device covered by 7.2.1.6.1 is allowed on any door in recognition of the security needs of some industrial occupancies. In effect, the allowable 15- or 30-second delay will be experienced only under nonfire conditions or very early in a fire's growth, because the door must be usable immediately upon sprinkler operation, smoke or heat detection, or loss of power that controls the locking mechanism. The building must be protected throughout by an approved, supervised automatic sprinkler system or an approved, supervised automatic fire detection system.

40.2.2.2.3 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

Paragraph 40.2.2.2.3 recognizes access-controlled egress doors in industrial occupancies as security measures that do not compromise the use of the means of egress system.

40.2.2.2.4 Approved existing horizontal-sliding fire doors shall be permitted in the means of egress under the following conditions:

- (1) They are held open by fusible links.
- (2) The fusible links are rated at not less than 74°C (165°F).
- (3) The fusible links are located not more than 3050 mm (120 in.) above the floor.
- (4) The fusible links are in immediate proximity to the door opening.
- (5) The fusible links are not located above a ceiling.
- (6) The door is not credited with providing any protection under this *Code*.

Horizontal-sliding fire doors exist in many industrial occupancies for property protection purposes. Although the *Code* normally does not recognize these doors within the required means of egress, 40.2.2.2.4 makes a special exemption for existing horizontal-

sliding fire doors. By requiring the fusible link to be positioned in immediate proximity to the door opening, rated 74°C (165°F) or higher, and located not more than 3050 mm (120 in.) above the floor, the *Code* helps to ensure that the door will remain open until rising temperatures make it unsafe to pass through the door opening. Because the door will not close early in the fire development, the door cannot be credited as a fire door for life safety purposes. However, the door might serve as a means of property protection. See Exhibit 40.2.

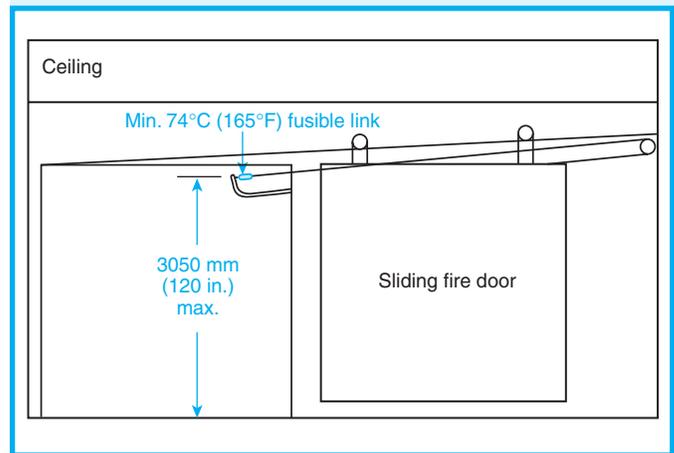

Exhibit 40.2 Existing horizontal-sliding fire door in accordance with 40.2.2.2.4.

40.2.2.3 Stairs.

40.2.2.3.1 Stairs shall comply with 7.2.2 and be permitted to be modified by 40.2.2.3.1(1) and 40.2.2.3.1(2).

- (1) Noncombustible, grated stair treads and noncombustible, grated landing floors shall be permitted.
- (2) Industrial equipment access stairs in accordance with 40.2.5.2 shall be permitted.

40.2.2.3.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted.

40.2.2.3.3 Existing winders complying with 7.2.2.2.4 shall be permitted.

Paragraph 40.2.2.3.1(1) exempts stair treads and landings in industrial occupancies from the provisions of 7.2.2.3.3.1, which would otherwise require that all stair treads and stair landing floors be solid. Although the requirement for solid treads and landing floors is intended to prevent occupants from avoiding the

use of the stairs because they become afraid when they are able to see through the openings to the floor or ground below, occupants of industrial occupancies are usually more familiar, and thus more comfortable, with grated or expanded metal treads and landings. The grated walking surfaces provide slip resistance in what can sometimes be greasy and slippery surroundings. For consistency, 7.2.2.3.3.4(3) alerts the user that industrial occupancies, in accordance with Chapter 40, are exempt from the solid tread and landing provisions.

Paragraph 40.2.2.3.1(2) serves to remind the user that 40.2.5.2 has special provisions for industrial equipment access stairs that differ from the requirements of Chapter 7. See the commentary following 40.2.5.2.

40.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

Paragraph 40.2.2.4 does not mandate the use of smokeproof enclosures. It does, however, recognize such an enclosure as part of the means of egress system in an industrial occupancy only if that enclosure meets the requirements of 7.2.3. For an example of an occupancy requiring a smokeproof enclosure, see 31.2.11, which specifies that existing, nonsprinklered high-rise apartment buildings are required to be provided with smokeproof enclosures in accordance with 7.2.3. See 40.2.2.1.

40.2.2.5 Horizontal Exits.

40.2.2.5.1 Horizontal exits complying with 7.2.4 shall be permitted.

40.2.2.5.2* In horizontal exits where the opening is protected by a fire door assembly on each side of the wall in which it is located, one fire door shall be of the swinging type as provided in 7.2.4.3.6, and the other shall be permitted to be an automatic-sliding fire door that shall be kept open whenever the building is occupied.

A.40.2.2.5.2 The customary building code requirement for fire doors on both sides of an opening in a fire wall is permitted to be met by having an automatic-sliding fire door on one side, and a self-closing fire door swinging out from the other side of the wall. This arrangement qualifies only as a horizontal exit from the side of the sliding door. For further information, see A.7.2.4.3.9.

Paragraph 40.2.2.5.1 does not mandate the use of horizontal exits. It does, however, recognize a horizontal exit as part of the means of egress system in an industrial occupancy if that exit meets the requirements of 7.2.4, as modified by 40.2.2.5.2.

Paragraph 40.2.2.5.2 and A.40.2.2.5.2 recognize the common practice of combining a horizontal exit that is used for life safety with a fire barrier having a significant fire resistance rating that is used for property protection. Opening protectives for such a fire barrier can require the use of a set of doors to achieve the required fire protection rating. It is impractical for both doors to swing in the same direction without interfering with each other; yet, operation of two doors that swing in opposite directions is cumbersome for daily or frequent use. One swinging and one sliding door, as shown in Exhibit 40.3, provide an acceptable arrangement for day-to-day functioning of the building. The open sliding door does not compromise life safety, because by the time its fusible link mechanism releases the door and allows it to close, temperatures in the vicinity of the door opening render use of the door impractical. See also the commentary following 40.2.2.2.4(6). The provisions of 40.2.2.2.4 also permit an existing horizontal-sliding door (as depicted in Exhibit 40.2) to serve within the means of egress.

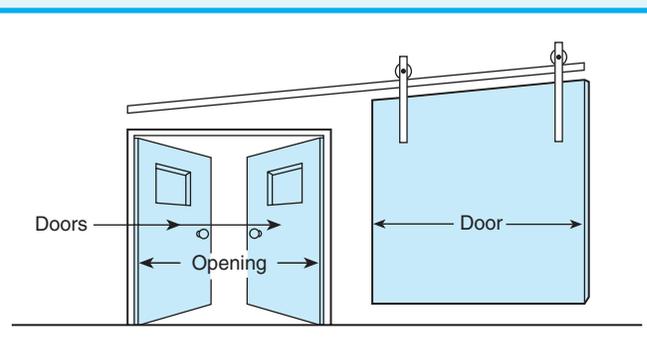

Exhibit 40.3 Combination swinging and sliding doors permitted by 40.2.2.5.2.

40.2.2.6 Ramps. Ramps shall comply with 7.2.5, except that industrial equipment access ramps shall be permitted to be in accordance with 40.2.5.2.

Paragraph 40.2.2.6 does not mandate the use of ramps in industrial occupancies. It does, however, recognize

a ramp as part of the means of egress system if that ramp meets the requirements of 7.2.5. See 40.2.2.1.

Paragraph 40.2.2.6 also serves to remind the user that 40.2.5.2 has special provisions for industrial equipment access ramps that differ from the requirements of Chapter 7. See the commentary following 40.2.5.2.

40.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

Paragraph 40.2.2.7 does not mandate the use of exit passageways in industrial occupancies. It does, however, recognize an exit passageway as part of the means of egress system if that exit passageway meets the requirements of 7.2.6. See 40.2.2.1.

40.2.2.8 Escalators and Moving Walks. Existing, previously approved escalators and moving walks complying with 7.2.7 and located within the required means of egress shall be permitted.

Note that 7.2.7 permits existing escalators and moving walks to continue to be recognized within the required means of egress if permitted by an occupancy chapter. In earlier editions of the *Code*, such escalators and moving walks were recognized as providing egress capacity for 75 persons. To qualify as exits (as opposed to exit access), escalators and moving walks must also meet the requirements of 7.1.3.2, which addresses exit enclosures.

Note that escalators protected in accordance with the sprinkler-vent, spray nozzle, rolling shutter, or partial enclosure method do not constitute acceptable exits but can continue to serve as exit access if previously approved as such.

40.2.2.9 Fire Escape Stairs. Existing fire escape stairs complying with 7.2.8 shall be permitted.

40.2.2.10 Fire Escape Ladders.

40.2.2.10.1 Fire escape ladders complying with 7.2.9 shall be permitted.

40.2.2.10.2 Fixed industrial stairs in accordance with the minimum requirements for fixed stairs in ANSI A1264.1, *Safety Requirements for Workplace Floor and Wall Openings, Stairs and Railings Systems*, shall be permitted where fire escape ladders are permitted in accordance with 7.2.9.1.

The geometry associated with the incline angle and the size and shape of surfaces intended for foot placement on fire escape ladders falls within the range permitted for fixed industrial stairs. However, most fixed industrial stairs meet criteria that result in a safer arrangement than that provided by the fire escape ladder detailed in 7.2.9. Therefore, 40.2.2.10.2 recognizes fixed industrial stairs as a substitute for fire escape ladders.

40.2.2.11 Slide Escapes.

40.2.2.11.1 Approved slide escapes complying with 7.2.10 shall be permitted as components in 100 percent of the required means of egress for both new and existing high hazard industrial occupancies.

40.2.2.11.2 Slide escapes permitted by 40.2.2.11.1 shall be counted as means of egress only where regularly used in emergency egress drills, to ensure that occupants are familiar with their use through practice.

The intent of 40.2.2.11 is to allow the use of slide escapes, which are a common means of egress from areas that house explosives or other highly hazardous materials in chemical industry buildings. This provision allows consideration of slide escapes as part of the required means of egress from both new and existing high hazard industrial occupancies. In many high hazard industrial occupancies, slide escapes are the only practical means of ensuring safe egress prior to an explosion or flash fire. As required by 40.2.2.11.2, occupants must drill in the use of the slide escapes to help ensure sufficient familiarity to permit quick egress under emergency conditions.

40.2.2.12 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

The provisions of 7.2.11, in effect, limit the use of alternating tread devices to those locations where the *Code* recognizes the use of fire escape ladders (and fixed industrial stairs). See 40.2.2.10.1, 40.2.2.10.2, 7.2.9, and 7.2.11.

40.2.2.13 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

40.2.3 Capacity of Means of Egress.

Capacity of means of egress shall comply with either of 40.2.3.1 or 40.2.3.2.

40.2.3.1 The capacity of means of egress shall be in accordance with Section 7.3.

40.2.3.2 In only special purpose industrial occupancies, means of egress shall be sized to accommodate the occupant load as determined in accordance with Table 7.3.1.2; spaces not subject to human occupancy because of the presence of machinery or equipment shall not be included in the computation.

Prior to 1991, the *Code* required a minimum 1120-mm (44-in.) width for corridors and passageways within the required means of egress of industrial occupancies. A corridor or passageway of that minimum width would have provided egress capacity for 220 persons [that is, 1120 mm/5 mm (approximately 44 in./0.2 in.) per person in accordance with Table 7.3.3.1 for level travel components]. That minimum requirement produced artificially large egress systems, relative to the occupant load, in many industrial occupancies. Therefore, the requirement was eliminated and the minimum 915-mm (36-in.) width requirement of 7.3.4.1(2), which addresses the minimum width of any exit access, was made applicable to industrial occupancies. Exit access is required to be wider than 915 mm (36 in.) only if a corridor or passageway in an industrial occupancy is to provide capacity for more than 180 persons [that is, 915 mm/5 mm (approximately 36 in./0.2 in.) per person]. See the commentary following A.40.1.7.

Paragraph 40.2.3.2 imposes practical limits on the number of required means of egress and on the arrangement of the means of egress in a special purpose industrial occupancy. No life safety purpose is served by providing exits from the center of a large machine or equipment installation that is unoccupied under normal operating conditions. A number of industries provide weather shelter for large processes and equipment. Typical examples include steel-rolling mills, paper extruders, and metalworking machines, all of which occupy a majority of the floor space in the sheltered building. In many of the more sophisticated operations, full process control is conducted from a remotely located control room. Personnel normally occupy the building only for maintenance and adjustment purposes, and then only on a limited basis. The provision of exits from these special purpose industrial occupancies serves no useful purpose and could unjustly impose an economic penalty in the name of safety.

The large areas normally enclosed by special purpose structures would require excessive egress width if the occupant load were calculated on the basis of

the 9.3 m² (100 ft²) per person specified for general industrial occupancies. Such arrangements might actually require exits from the interior of machinery and equipment installations, which would be incompatible with the equipment's design. In many cases, these exits would originate from locations that, even under normal operating conditions, would be considered dangerous for humans. Poorly conceived exit facilities serve no life safety purpose and detract from an otherwise well-designed exit system.

40.2.4 Number of Means of Egress.

See also Section 7.4.

40.2.4.1 The number of means of egress shall comply with either 40.2.4.1.1 or 40.2.4.1.2.

40.2.4.1.1 Not less than two means of egress shall be provided from every story or section, and not less than one exit shall be reached without traversing another story.

40.2.4.1.2 A single means of egress shall be permitted from any story or section in low and ordinary hazard industrial occupancies, provided that the exit can be reached within the distance permitted as a common path of travel.

40.2.4.2 In new buildings, floors or portions thereof with an occupant load of more than 500 shall have the minimum number of separate and remote means of egress specified by 7.4.1.2.

40.2.4.3 Areas with high hazard contents shall comply with Section 7.11.

The provisions of 40.2.4.1.1, which apply to the minimum required number of means of egress for industrial occupancies, clarify that, in addition to providing every story or section with access to at least two means of egress, one of the exits must be located on each floor so that the entrance to that exit (for example, a door that opens into an enclosed exit stair) can be reached without traveling to another floor.

Paragraph 40.2.4.1.2 recognizes that there are small floors or areas in low and ordinary hazard industrial occupancies that, if provided with access to only a single exit, are no less safe than larger areas of a building that have access to two exits where an occupant must first travel through the maximum allowable common path. Where a single exit is provided, the occupant travels the 15 m (50 ft) [or 30 m (100 ft) in sprinklered buildings] of common path allowed by Table 40.2.5, enters the exit, and is judged to have reached a point of safety (see Exhibit 40.4).

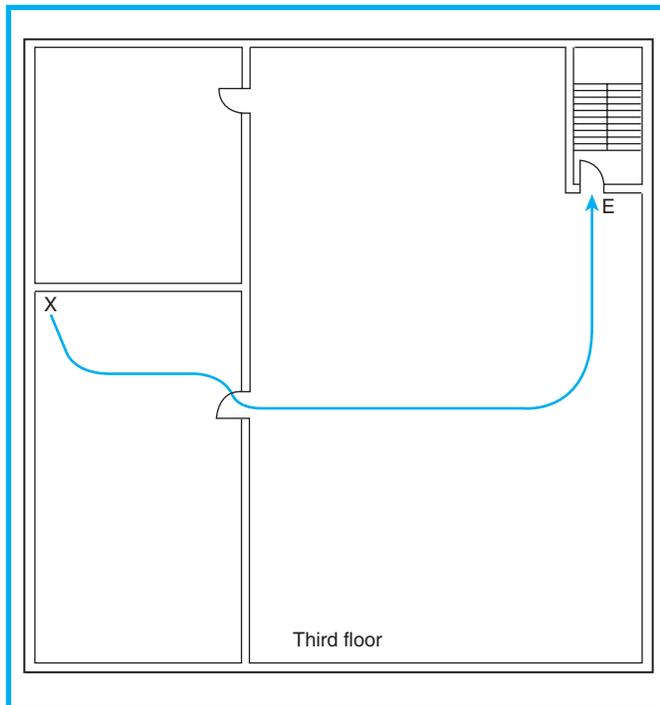

Exhibit 40.4 Single means of egress from story of low or ordinary hazard industrial occupancy.

In larger buildings and larger building areas that do not meet the limited travel distance for a single exit, a minimum of two exits must be provided. By traveling to the nearer of the two exits, the occupant is permitted to travel the same 15 m (50 ft) [or 30 m (100 ft) in sprinklered buildings] of common path that the occupant of the single-exit building traveled to reach the one exit before reaching the point where travel to the two exits in different directions is possible. Although the occupant of the single-exit building has reached an exit by this point, the occupant of the multiple-exit building is then allowed an additional 46 m (150 ft) [61 m (200 ft) if building is sprinklered] of exit access travel before the safety of an exit must be reached. Therefore, the single-exit exemption provides a level of life safety that is at least equivalent to that of the multiple-exit building.

Historically, the *Code* has required more than two exits based on occupant load for assembly occupancies only. Third, fourth, and subsequent exits were provided in industrial occupancies to meet travel distance requirements or as a convenience for day-to-day use. Paragraph 7.4.1.2 expands the concept of requiring three or four exits based on occupant load to apply to all occupancies. Paragraph 40.2.4.2, in compliance with the option offered by 7.4.1.2, exempts existing buildings from the requirement for

third and fourth exits to avoid unnecessarily forcing existing, previously complying means of egress systems into noncompliance.

Section 7.11 includes an adequate set of provisions for high hazard areas and is referenced by 40.2.4.3 to provide commensurate protection to industrial occupancies that contain high hazard areas. The provisions of Section 7.11 are vital to life safety in high hazard occupancies. The requirement for two means of egress for all high hazard occupancies recognizes the possibility that a fire or explosion might block or destroy one of the two exits. Two separate and equal means of egress from high hazard areas provide a necessary redundancy to ensure the evacuation of occupants under fire or explosion conditions and to minimize the potential for injury or loss of life. Subsection 7.11.4 recognizes that it is not necessary to require two means of egress from very small high hazard areas [maximum 18.6 m² (200 ft²)] with limited occupant load (maximum three persons) if the room door can be reached within 7620 mm (300 in.) of travel.

40.2.5 Arrangement of Means of Egress.

Means of egress, arranged in accordance with Section 7.5, shall not exceed that provided by Table 40.2.5.

See the discussion of dead-end corridor pockets and common path of travel in A.7.5.1.5 and its associated commentary.

40.2.5.1 Ancillary Facilities.

40.2.5.1.1* New ancillary facilities shall be arranged to allow travel in independent directions after leaving the ancillary facility so that both means of egress paths do not become compromised by the same fire or similar emergency.

A.40.2.5.1.1 Ancillary facilities located within industrial occupancies might include administrative office, laboratory, control, and employee service facilities that are incidental to the predominant industrial function and are of such size that separate occupancy classification is not warranted.

40.2.5.1.2* New ancillary facilities in special purpose industrial occupancies where delayed evacuation is anticipated shall have not less than a 2-hour fire resistance-rated separation from the predominant industrial occupancy and shall have one means of egress that is separated from the predominant industrial occupancy by 2-hour fire resistance-rated construction.

A.40.2.5.1.2 Occupants of ancillary facilities located within special-purpose industrial occupancies might be required by administrative controls to remain in the facility when a fire

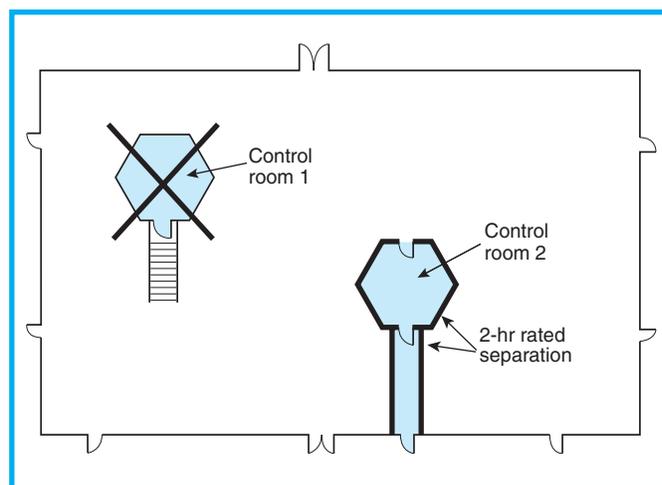

Table 40.2.5 Arrangements of Means of Egress

Level of Protection	General Industrial Occupancy	Special Purpose Industrial Occupancy	High Hazard Industrial Occupancy
Dead-End Corridor			
Protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	15 m (50 ft)	15 m (50 ft)	Prohibited except as permitted by 7.11.4.
Not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	15 m (50 ft)	15 m (50 ft)	Prohibited except as permitted by 7.11.4.
Common Path of Travel			
Protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	30 m (100 ft)	30 m (100 ft)	Prohibited except as permitted by 7.11.4.
Not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	15 m (50 ft)	15 m (50 ft)	Prohibited except as permitted by 7.11.4.

occurs in the predominant industrial area so that they can perform an orderly shutdown of process equipment to control the spread of the fire and minimize damage to important equipment.

The presence of ancillary facilities within an industrial occupancy can create unusual challenges to life safety. For example, the means of egress for factory office workers, who might have little knowledge of the industrial processes and operations and their respective hazards, might require leaving the safety of an office area and traveling across the factory production floor. In other cases, safe egress is not assured to employees assigned to a control room who might have to perform orderly shutdown of certain processes to control the spread of fire before evacuating a building. The requirements of 40.2.5.1.1 and 40.2.5.1.2 are illustrated in Exhibit 40.5.

In Exhibit 40.5, an occupant of control room 1, which is elevated and has a single means of egress via a stair leading down to the main production floor, is forced to travel in one direction only into the open manufacturing area. This arrangement does not meet the requirement of 40.2.5.1.1, which mandates that egress be arranged to allow travel in independent directions after leaving the ancillary facility so that both means of egress paths are not compromised by

**Exhibit 40.5** Ancillary facilities.

the same fire or similar emergency. Control room 1 requires a second exit access door and stair remotely located from the first.

Control room 2 in Exhibit 40.5 meets the requirements of both 40.2.5.1.1 and 40.2.5.1.2. Control room 2 permits egress travel in independent directions, so that both means of egress paths are not compromised by the same fire or similar emergency. Further, it provides one of the two means of egress via an exit

passageway-like arrangement separated from the predominant industrial occupancy by 2-hour fire resistance-rated construction. Also, control room 2 itself is surrounded by 2-hour fire resistance-rated construction. This protection permits occupants charged with special emergency duties to delay their egress and still be afforded adequate life safety.

The requirements of 40.2.5.1 for ancillary facilities were added to the *Code* in 1997 and are not retroactively applied to existing facilities.

40.2.5.2 Industrial Equipment Access.

40.2.5.2.1 Industrial equipment access walkways, platforms, ramps, and stairs that serve as a component of the means of egress from the involved equipment shall be permitted in accordance with the applicable provisions of Chapter 7 as modified by Table 40.2.5.2.1.

Table 40.2.5.2.1 Industrial Equipment Access Dimensional Criteria

Minimum horizontal dimension of any walkway, landing, or platform	560 mm (22 in.) clear
Minimum stair or ramp width	560 mm (22 in.) clear between rails
Minimum tread width	560 mm (22 in.) clear
Minimum tread depth	255 mm (10 in.)
Maximum riser height	230 mm (9 in.)
Handrails shall be permitted to terminate, at the required height, at a point directly above the top and bottom risers.	
Maximum height between landings	3660 mm (144 in.)
Minimum headroom	2030 mm (80 in.)

40.2.5.2.2 Any means of egress component permitted by 40.2.5.2.1 shall serve not more than 20 people.

Paragraph 40.2.5.2 permits industrial equipment access walkways, platforms, ramps, and stairs serving not more than 20 persons to deviate from some of the usual dimensional criteria specified by Chapter 7. The dimensional criteria detailed in Table 40.2.5.2.1 are illustrated in Exhibit 40.6.

40.2.6 Travel Distance to Exits.

Travel distance, measured in accordance with Section 7.6, shall not exceed that provided by Table 40.2.6.

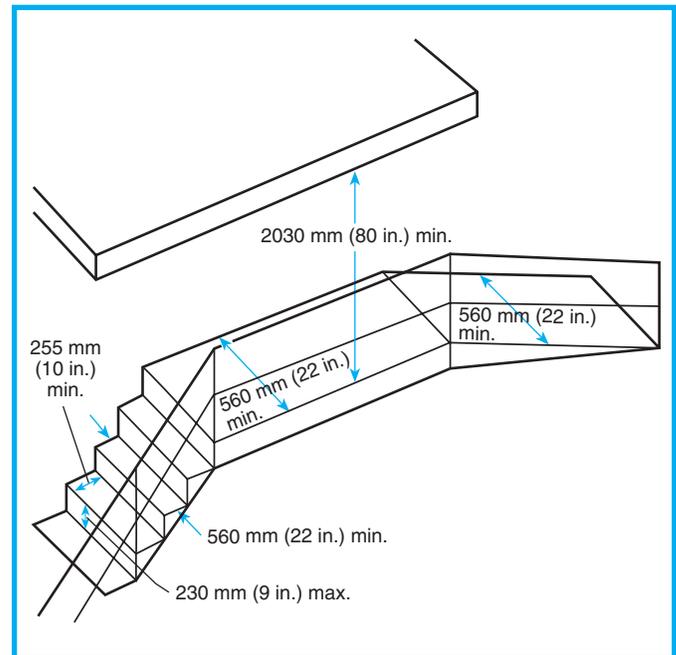

Exhibit 40.6 Industrial equipment access dimensional criteria.

The travel distance exemption permitted by the note to Table 40.2.6 is meant to provide flexibility in determining the layout of the means of egress system in a single-story industrial building with a large floor area that houses a low or ordinary hazard general industrial occupancy. It is limited to use in one-story buildings. Any stairs or other impediments to the rapid movement of occupants would result in slower evacuation of the building and increase the possibility of exposure to smoke or fire. The exemption requires a performance-based analysis to demonstrate that safe egress can be accomplished. NFPA 204, *Standard for Smoke and Heat Venting*³, might be of assistance. In addition, NFPA 92B, *Guide for Smoke Management Systems in Malls, Atria, and Large Areas*⁴, can be consulted when designing buildings with ceilings of heights that approximate those of covered mall buildings and atria. Also, see Chapter 5.

The construction of tunnels and elevated means of egress that originate from the center of an industrial building with an extensive floor area is rarely attempted. Only a handful of buildings have ever been provided with such egress facilities, and most were World War II airframe manufacturing buildings of massive size. In most industrial buildings, it is not practicable or economical to construct exit tunnels or overhead passageways. These special types of means of egress are not easily altered if modifications are necessary to adjust to changes in the layout of the

Table 40.2.6 Maximum Travel Distance to Exits

Level of Protection	General Industrial Occupancy	Special Purpose Industrial Occupancy	High Hazard Industrial Occupancy
Protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	76 m (250 ft)†	122 m (400 ft)	23 m (75 ft)
Not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	61 m (200 ft)	91 m (300 ft)	Not permitted

†In single-story buildings, a travel distance of 122 m (400 ft) shall be permitted, provided that a performance based analysis demonstrates that safe egress can be accomplished.

facility. In addition, the construction costs for tunnels and elevated passageways are high due to the special design features required to ensure their safety, including fire resistance-rated supports for the elevated passageways, waterproofing, and other features necessary to maintain the integrity of underground tunnels. Another negative factor in such construction is the confining nature of a tunnel or elevated passage, which tends to discourage the use of these means of egress.

The use of horizontal exits that pass through fire walls is common in many industrial occupancies. The provisions in Chapter 7 are required to be fully considered to ensure the safe use of horizontal exits. A common violation of the provisions of Chapter 7 is the failure to provide the proper type of fire door in a fire wall. A horizontal-sliding fire door cannot be considered as an acceptable life safety feature. Such a door is permitted in existing installations in accordance with 40.2.2.2.4, but, even then, the door is not credited with protecting the opening. If the horizontal exit is to be used from both sides of a fire wall, careful consideration of the direction of door swing is necessary to ensure that the Code will recognize this use. In many instances, two doors swinging in opposite directions will be required so that the exit is permitted to be used as a means of egress from both sides of the fire wall. See 7.2.1.4, 7.2.4.3.6, and 40.2.2.5.

Low and ordinary hazard special purpose industrial occupancies, which are characterized by large, specialized equipment and low occupant load, are permitted an increase in travel distance beyond that allowed for low and ordinary general industrial occupancies. Table 40.2.6 permits an increase to 91 m (300 ft) if the building is not sprinklered, and an increase to 122 m (400 ft) if the building is protected throughout by a supervised sprinkler system.

For a summary of the various travel distance allowances for industrial occupancies, see Exhibit 40.7.

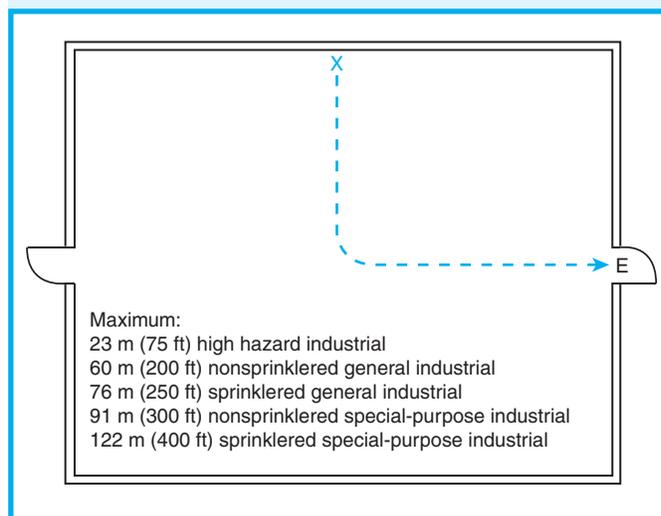

Exhibit 40.7 Summary of industrial occupancy travel distance options permitted by Table 40.2.6.

40.2.7 Discharge from Exits.

Discharge from exits shall be in accordance with Section 7.7.

The purpose of the requirement of 7.7.2 is to control the arrangement of exits from upper stories that discharge to the outside through the level of exit discharge. Subsection 7.7.2 modifies the general rule for complete enclosure of exits up to their point of discharge to the outside of the building, because the safeguards specified in 7.7.2—especially those for automatic sprinkler protection of the level of exit dis-

charge—maintain reasonable safety. When the arrangement of exits is evaluated, a stairway is not considered as discharging through the level of discharge if it leads to the outside through an exit passageway in accordance with 7.2.6. This evaluation is valid, despite the fact that doors are located in the exit passageway walls between the base of the enclosed stairway and the door to the outside on the level of exit discharge.

40.2.8 Illumination of Means of Egress.

Means of egress shall be illuminated in accordance with Section 7.8 or with natural lighting that provides the required level of illumination in structures occupied only during daylight hours.

40.2.9* Emergency Lighting.

A.40.2.9 The authority having jurisdiction should review the facility and designate the stairs, aisles, corridors, ramps, and passageways that should be required to be provided with emergency lighting. In large locker rooms or laboratories using hazardous chemicals, for example, the authority having jurisdiction should determine that emergency lighting is needed in the major aisles leading through those spaces.

40.2.9.1 Emergency lighting shall be provided in accordance with Section 7.9, except as otherwise exempted by 40.2.9.2.

40.2.9.2 Emergency lighting shall not be required for the following:

- (1) Special purpose industrial occupancies without routine human habitation
- (2) Structures occupied only during daylight hours, with skylights or windows arranged to provide the required level of illumination on all portions of the means of egress during such hours

The intent of 40.2.8 is not to require the installation of extensive and unneeded illumination systems in industrial occupancies. Illumination is required for the exit access, which is limited to designated aisles, corridors, and passageways that lead to an exit. No requirement is specified for the provision of illumination throughout the building, which in many industrial occupancies would involve lighting an extensive floor area. The purpose of the lighting system is to ensure that occupants are able to see the means of egress, not to illuminate the operation of production facilities.

In addition, the *Code* does not require illumination of the means of egress if the building is occupied

during the daylight hours only. To meet the daylight hours exemption of 40.2.8, the building, including stairways, must have sufficient windows and skylights to ensure natural illumination. The authority having jurisdiction should make certain that the building is not occupied after daylight hours.

The exemptions of 40.2.9.2 for emergency lighting are included for the same reasons that illumination of the means of egress is not required (see 40.2.8). Paragraph 40.2.9.2(1) addresses special-purpose industrial occupancies that are not routinely occupied. There is no need to install an extensive and costly emergency lighting system in an unoccupied building.

40.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

40.2.11 Special Means of Egress Features.

(Reserved)

Section 40.3 Protection

40.3.1 Protection of Vertical Openings.

Any vertical opening shall be protected in accordance with Section 8.6 unless otherwise permitted by one of the following:

- (1) In special purpose industrial and high hazard industrial occupancies where unprotected vertical openings exist and are necessary to manufacturing operations, such openings shall be permitted beyond the specified limits, provided that every floor level has direct access to one or more enclosed stairs or other exits protected against obstruction by any fire or smoke in the open areas connected by the unprotected vertical openings.
- (2) Approved, existing open stairs, existing open ramps, and existing escalators shall be permitted where connecting only two floor levels.
- (3) Approved existing unprotected vertical openings in buildings with low or ordinary hazard contents that are protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1) shall be permitted, provided that the following conditions exist:
 - (a) The vertical opening does not serve as a required exit.
 - (b) All required exits consist of outside stairs in accordance with 7.2.2, smokeproof enclosures in accordance with 7.2.3, or horizontal exits in accordance with 7.2.4.

- (4) Vertical openings in accordance with 8.6.8.2 shall be permitted.

Paragraph 40.3.1(1) strictly limits the use of unprotected vertical openings in high hazard and special purpose industrial occupancies. Direct access to one or more enclosed stairways or to other exits is required from any areas connected by unprotected vertical openings. This provision recognizes that many high hazard and special purpose industrial occupancies require openings between floor levels to accommodate piping, conveyors, and other devices and equipment essential to the orderly operation of the facility. In most of these situations, full enclosure is not practical or feasible. In high hazard occupancies, the provision of two means of egress will, in most situations, be sufficient to comply with this exception. In special-purpose industrial occupancies, additional exits or other special arrangements will normally be required for compliance with the provision that stairways and exits be protected against obstruction from fire and smoke in open areas connected by unprotected vertical openings.

Paragraph 40.3.1(2) limits the use of existing open stairways, existing open ramps, and existing escalators that are unenclosed or unprotected by permitting them to connect only two floors. An existing open stairway connecting three floors would have to be enclosed, protected, or permitted by another of the exemptions to 40.3.1.

Paragraph 40.3.1(3) recognizes that an existing industrial occupancy might contain unprotected vertical openings and still provide a reasonable level of safety to life if the building houses only low or ordinary hazard contents and is protected by a complete automatic sprinkler system. Smokeproof enclosures and outside stairways (the only types of vertical exits permitted by this exemption) must be fully enclosed or protected against vertical fire spread and must meet the requirements of Chapter 7. The unenclosed vertical openings are not permitted to serve as part of the means of egress, although they can remain as convenience openings and stairways to be used for normal operations.

Although the major reason for allowing this provision is economic (enclosing all vertical openings in existing buildings is expensive), there is actually little effect on the life safety of occupants where a building houses low or ordinary hazard contents. However, some difficulties in fire control are created, because unprotected vertical openings can contribute to fire spread and result in extensive property damage and

potential impact on occupants prior to evacuation; therefore, a complete automatic sprinkler system is required.

40.3.2* Protection from Hazards.

A.40.3.2 Emergency lighting should be considered where operations require lighting to perform orderly manual emergency operation or shutdown, maintain critical services, or provide safe start-up after a power failure.

40.3.2.1 All high hazard industrial occupancies, operations, or processes shall have approved, supervised automatic extinguishing systems in accordance with Section 9.7 or other protection appropriate to the particular hazard, such as explosion venting or suppression.

40.3.2.2 Protection in accordance with 40.3.2.1 shall be provided for any area subject to an explosion hazard in order to minimize danger to occupants in case of fire or other emergency before they have time to use exits to escape.

40.3.2.3 Activation of the fire extinguishing or suppression system required by 40.3.2.1 shall initiate the required building fire alarm system in accordance with 40.3.4.3.4.

40.3.2.4 Hazardous areas in industrial occupancies protected by approved automatic extinguishing systems in accordance with Section 9.7 shall be exempt from the smoke-resisting enclosure requirement of 8.7.1.2.

The intent of 40.3.2 is to provide for the life safety of the occupants of industrial buildings by controlling the risk associated with hazardous operations. The alternatives offered in 40.3.2 are not all-inclusive, and a proper fire protection engineering solution might not incorporate the listed provisions. The *Code* intends to allow for engineering judgment in a wide range of potentially hazardous situations including some where protection might be limited. The intent of the subsection is also broad in application, because, in many highly hazardous operations, an explosion might be immediately preceded by a fire or other emergency, such as an overheated reactor vessel, an exothermic reaction, or increased pressure. Because such conditions might initiate an explosion, depending on the process and arrangement of the equipment, immediate egress from the facility might be necessary. If fire or other emergencies are likely to develop rapidly into an explosion, adequate precautions are necessary for life safety. Where a sprinkler system is used to provide the protection required by 40.3.2.1, it must be supervised.

In many modern facilities, provisions that prove adequate for the life safety of occupants might already be included for process control and property protection, and any additional measures will not increase the life safety of operators to an appreciable degree.

The NFPA *Fire Protection Handbook*⁵ discusses the basic principles of explosion prevention, venting, and suppression. The applicable chapters also contain an extensive bibliography on the subject. Recommendations for the design and use of vents to limit pressures developed by explosions are specified in NFPA 68, *Guide for Venting of Deflagrations*⁶. Standards for explosion prevention systems are found in NFPA 69, *Standard on Explosion Prevention Systems*⁷.

Paragraph 8.7.1.2 requires that, where a hazardous area is protected by automatic sprinklers, the hazardous area must be enclosed by smoke partitions rather than with fire barriers with a 1-hour fire resistance rating and doors with a 45-minute fire protection rating. Paragraph 40.3.2.4 exempts hazardous areas in industrial occupancies from the requirement for smoke partitions if those areas are protected by automatic sprinklers. For consistency, similar wording appears in 8.7.1.2(2).

40.3.3 Interior Finish.

40.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

40.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A, Class B, or Class C in operating areas and shall be as required by 7.1.4 in exit enclosures.

40.3.3.3 Interior Floor Finish. (No requirements.)

40.3.4 Detection, Alarm, and Communications Systems.

40.3.4.1 General. A fire alarm system shall be required in accordance with Section 9.6 for industrial occupancies, unless the total capacity of the building is under 100 persons and of these fewer than 25 persons are above or below the level of exit discharge.

40.3.4.2 Initiation. Initiation of the required fire alarm system shall be by any of the following means:

- (1) Manual means in accordance with 9.6.2.1(1)
- (2) An approved automatic fire detection system in accordance with 9.6.2.1(2) throughout the building; plus a

minimum of one manual fire alarm box in accordance with 9.6.2.5

- (3) An approved, supervised automatic sprinkler system in accordance with 9.6.2.1(3) throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5

40.3.4.3 Notification.

40.3.4.3.1 The required fire alarm system shall meet one of the following criteria:

- (1) It shall provide occupant notification in accordance with 9.6.3.
- (2) It shall sound an audible and visible signal in a constantly attended location for the purposes of initiating emergency action.

40.3.4.3.2 Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.

40.3.4.3.3 Existing presignal systems in accordance with 9.6.3.3 shall be permitted.

40.3.4.3.4 In high hazard industrial occupancies as described in 40.1.4.1(3), the required fire alarm system shall automatically initiate an occupant evacuation alarm signal in accordance with 9.6.3.

The requirements of 40.3.4.3.1 and 40.3.4.3.4 specify two separate and distinct provisions for audible alarms activated by the fire alarm system required by 40.3.4.1. In low and ordinary hazard industrial occupancies, the system is permitted to activate an evacuation alarm or to sound an alarm in a constantly attended location for the purpose of initiating emergency action (see 40.3.4.3.1). This provision allows an interface between the alarm system and the plant's emergency organization. The alarm system is permitted to be controlled from a central security console or a similar location. The key feature is that the location from which the alarm sounds must be constantly staffed. This requirement is not intended to mandate the installation of supervisory service, such as that connected to a central station, but the location must be fully attended at all times when the building is occupied.

In high hazard occupancies, the alarm must be arranged to provide evacuation signals (see 40.3.4.3.4), because the safety of the occupants of these areas depends on their immediate notification of a fire.

Note that 40.3.4.3.3 recognizes existing presignal systems but not new presignal systems. If an auto-

matic form of delay is desired for an existing alarm system that doesn't already have a presignal feature, or for a new alarm system, the more reliable system feature known as *positive alarm sequence* is permitted by 40.3.4.2.2. The positive alarm sequence option might be applied to the high hazard industrial occupancies addressed in 40.3.4.3.4 for which an automatic form of occupant notification is needed. Also, positive alarm sequence might be used in industrial occupancies, other than those that are high hazard, where the provisions of 40.3.4.3.1(1) are used instead of those of 40.3.4.3.1(2).

40.3.5 Extinguishment Requirements.

(None)

40.3.6 Corridors.

The provisions of 7.1.3.1 shall not apply.

Without the exemption to the requirements of 7.1.3.1 provided by 40.3.6, all new industrial occupancy corridors serving more than 30 persons would be required to have a 1-hour fire resistance rating, with openings protected by 20-minute fire protection-rated door assemblies. The exemption to 7.1.3.1 was adopted because of the ambulatory nature of occupants of industrial occupancies and the operational need for openings, even where corridors are provided.

Section 40.4 Special Provisions: High-Rise Buildings

Automatic sprinkler requirements of 11.8.2.1 shall be required for new high-rise industrial occupancies, except for general low hazard or special purpose industrial occupancies.

Section 40.4 references a portion of the high-rise building provisions of Section 11.8 that were written to allow an occupancy chapter to mandate their use. New, high-rise, general-purpose industrial occupancy buildings that are classified as ordinary hazard and new high-rise industrial occupancy buildings that are classified as high hazard are required to be protected throughout by an approved, supervised automatic sprinkler system in accordance with 11.8.2.1. The remainder of Section 11.8 is not mandated for high-rise industrial occupancy buildings.

Section 40.5 Building Services

40.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

40.5.2 Heating, Ventilating, and Air Conditioning.

Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

40.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

40.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 40.6* Special Provisions for Aircraft Servicing Hangars

A.40.6 For further information on aircraft hangars, see NFPA 409, *Standard on Aircraft Hangars*.

40.6.1 The requirements of Section 40.1 through Section 40.5 shall be met, except as modified by 40.6.1.1 through 40.6.1.4.

40.6.1.1 There shall be not less than two means of egress from each aircraft servicing area.

40.6.1.2 Exits from aircraft servicing areas shall be provided at intervals not exceeding 46 m (150 ft) on all exterior walls.

40.6.1.3 Where horizontal exits are provided, doors shall be provided in the horizontal exit fire barrier at intervals not exceeding 30 m (100 ft).

40.6.1.4 Where dwarf, or "smash," doors are provided in doors that accommodate aircraft, such doors shall be permitted for compliance with 40.6.1.1 through 40.6.1.3.

40.6.2 Means of egress from mezzanine floors in aircraft servicing areas shall be arranged so that the travel distance to the nearest exit from any point on the mezzanine does not exceed 23 m (75 ft), and such means of egress shall lead directly to a properly enclosed stair discharging directly to the exterior, to a suitable cutoff area, or to outside stairs.

40.6.3 Dead ends shall not exceed 15 m (50 ft) for other than high hazard contents areas and shall not be permitted for high hazard contents areas.

Section 40.6, which addresses aircraft servicing hangars, is nearly identical to Section 42.6, which addresses aircraft storage hangars. Because aircraft hangars are used for both storage and repair, corresponding requirements can be found in both Chapters 40 and 42.

CHAPTER 41

Reserved

Typically, the occupancy chapters are paired so that the even-numbered chapter in the pair addresses new facilities of the occupancy type and the odd-numbered chapter addresses existing facilities of the occupancy type. Chapter 40, which precedes this chapter, addresses both new and existing industrial occupancies in a single chapter. Chapter 41 has been reserved to permit the chapter on storage occupancies to be assigned an even number (that is, Chapter 42). The reserved chapter number might be used at a future date if the requirements for industrial occupancies are split into a pair of chapters—one for new construction and one for existing buildings.

CHAPTER 42

Storage Occupancies

Storage occupancies include all buildings or structures used primarily for the storage or sheltering of goods, merchandise, products, vehicles, or animals. The following are examples of storage occupancies:

- (1) Barns
- (2) Stables
- (3) Hangars (for aircraft storage only)
- (4) Freight terminals
- (5) Bulk oil storage
- (6) Truck and marine terminals
- (7) Parking garages
- (8) Cold storage
- (9) Grain elevators
- (10) Warehouses

This final chapter of the *Code* covers a range of facilities used for storage of a wide variety of commodities. While the same life safety philosophy that prevails in the other occupancy chapters applies to storage occupancies, the protection scheme is less complicated, given the relatively small number of people who characteristically occupy a storage occupancy. Although some warehouse facilities are substantially larger than buildings housing other occupancies, they are typically occupied by few people.

Once the basic characteristics of a given storage occupancy are determined, the general protection measures of Section 42.2 and Section 42.3 can be applied. In addition to these measures, the supplementary provisions that are specific to a particular type of storage occupancy can be applied. These provisions include those for aircraft storage hangars (Section 42.6), grain and other bulk storage elevators (Section 42.7), and parking structures (Section 42.8).

Section 42.1 General Requirements

42.1.1 Application.

42.1.1.1 The requirements of this chapter shall apply to both new and existing storage occupancies.

42.1.1.2 Storage occupancies shall include all buildings or structures used primarily for the storage or sheltering of goods, merchandise, products, vehicles, or animals.

Note that Chapter 42 applies to both new and existing storage occupancies. Where the requirements vary, exemptions that apply to existing storage occupancies are often provided, or additional requirements that are limited to new storage occupancies are specified.

Minor storage that is incidental to another occupancy is treated as part of the other occupancy. See 6.1.14.1.2(1).

42.1.2 Multiple Occupancies.

All multiple occupancies shall be in accordance with 6.1.14.

Subsection 42.1.2 directs the user to the multiple occupancies provisions of 6.1.14, which permit protecting the multiple occupancies either as mixed occupancies or as separated occupancies. Where the multiple occupancy is protected via the provisions of 6.1.14.4 for separated occupancies, the required number of hours of fire-rated separation is specified by Table 6.1.14.4.1.

42.1.3 Definitions.

See Chapter 3.

Life safety provisions for storage locations are not extensive, because the number of occupants is generally low and many of those who occupy such a structure are present for only short periods of time. Furthermore, employees of storage occupancies normally do not remain in one location; instead, their assignments require that they move about and perform activities of a short-term nature.

Due to the special characteristics of storage occupancies, a number of provisions are included in the *Code* to modify, as required, those provisions that normally apply to occupancies with larger populations.

The purpose of 42.1.4.3 is to provide suitable egress facilities for storage occupancies, or portions of storage occupancies, where a storage building has a population greater than normally expected. It is common practice to employ large numbers of people in a storage building for industrial types of operations, such as labeling, sorting, or packaging. Such operations require additional egress in accordance with the provisions of Chapter 40 for industrial occupancies.

42.1.4 Classification of Occupancy.

42.1.4.1 Storage occupancies shall include all buildings and structures or parts thereof with occupancy as defined in 6.1.13.

42.1.4.2 Incidental storage in another occupancy shall not be the basis for overall occupancy classification.

42.1.4.3 Storage occupancies or areas of storage occupancies that are used for the purpose of packaging, labeling, sorting, special handling, or other operations requiring an occupant load greater than that normally contemplated for storage shall be classified as industrial occupancies. (*See Chapter 40.*)

42.1.5 Classification of Hazard of Contents.

Contents of storage occupancies shall be classified as low hazard, ordinary hazard, or high hazard, in accordance with Section 6.2, depending on the character of the materials stored, their packaging, and other factors.

No basis for comparison exists between the hazard categories for storage facilities in NFPA 13, *Standard for the Installation of Sprinkler Systems*¹, and those of

the *Life Safety Code*. The hazard categories for storage facilities contained in NFPA 13 are established for the design of automatic sprinkler systems.

There is a strong inclination to use the potential for rapid fire growth associated with high-piled or racked storage as justification for establishing strict life safety provisions. However, the arrangement of buildings typical for this type of storage is adequate to allow safe and rapid egress at the first notification or discovery of fire. If a building is not protected by automatic sprinklers, the *Code* provides adequate provisions—such as those for travel distance to an exit—to help ensure the survival of the occupants.

42.1.6 Minimum Construction Requirements.

(No requirements)

Some occupancy chapters, such as Chapters 18 and 19, which address the life safety needs of nonambulatory health care occupants, specify minimum building construction type requirements to ensure structural integrity for the time needed for a lengthy evacuation or for safe refuge within the building. No minimum construction requirements are imposed in Chapter 42, because characteristically storage occupancies have few occupants and those few occupants are ambulatory.

42.1.7* Occupant Load.

The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined on the basis of the maximum probable population of the space under consideration.

A.42.1.7 There is no occupant load factor specified for storage occupancies. Rather, the actual probable maximum number of persons present needs to be considered in determining the occupant load.

Although 42.1.7 and Table 7.3.1.2 do not provide a required occupant load factor for calculating a minimum occupant load to size a means of egress system in a storage occupancy, it is necessary to establish an occupant load. The occupant load is determined on the basis of the maximum number of persons expected to occupy the storage occupancy under any anticipated facility operation. Due to the low occupant load characteristic of storage occupancies, compliance with other *Code* provisions—such as minimum widths for doors, corridors, or passage-

ways; minimum number of exits; and travel distance allowances—generally provides a means of egress system capable of handling the actual occupant load, without specifically considering the occupant load when the means of egress is designed.

Section 42.2 Means of Egress Requirements

42.2.1 General.

Each required means of egress shall be in accordance with the applicable portions of Chapter 7.

42.2.2 Means of Egress Components.

42.2.2.1 General. Components of means of egress shall be limited to the types described in 42.2.2.2 through 42.2.2.12.

42.2.2.2 Doors.

42.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

42.2.2.2.2 Delayed-egress locks complying with 7.2.1.6.1 shall be permitted.

42.2.2.2.3 Access-controlled egress doors complying with 7.2.1.6.2 shall be permitted.

42.2.2.2.4 Approved existing horizontal-sliding fire doors shall be permitted in the means of egress under the following conditions:

- (1) They are held open by fusible links.
- (2) The fusible links are rated at not less than 74°C (165°F).
- (3) The fusible links are located not more than 3050 mm (120 in.) above the floor.
- (4) The fusible links are in immediate proximity to the door opening.
- (5) The fusible links are not located above a ceiling.
- (6) The door is not credited with providing any protection under this *Code*.

Use of the delayed-egress locking device in accordance with all criteria of 7.2.1.6.1 is allowed on any door in recognition of the security needs of some storage occupancies. In effect, the allowable 15- or 30-second delay will be experienced only under non-fire conditions or very early in a fire's growth, because the door must be usable immediately upon sprinkler operation, smoke or heat detection, and loss of power that controls the locking mechanism. The building must be protected throughout by an approved, super-

vised automatic sprinkler system or an approved, supervised automatic fire detection system.

Paragraph 42.2.2.2.3 recognizes access-controlled egress doors in storage occupancies as security measures that do not compromise the use of the means of egress.

Horizontal-sliding doors exist in many storage occupancies for property protection purposes. Although the *Code* normally does not recognize these doors within the required means of egress, 42.2.2.2.4 makes an exemption for existing horizontal-sliding fire doors. See Exhibit 42.1. By requiring the fusible link to be positioned in immediate proximity to the door opening, rated 74°C (165°F) or higher, and located not more than 3050 mm (120 in.) above the floor, the *Code* helps to ensure that the door will remain open until rising temperatures make it unsafe to pass through the door opening. Because the door will not close early in the fire development, the door cannot be credited as a fire door for life safety purposes. However, the door might serve as a means of property protection.

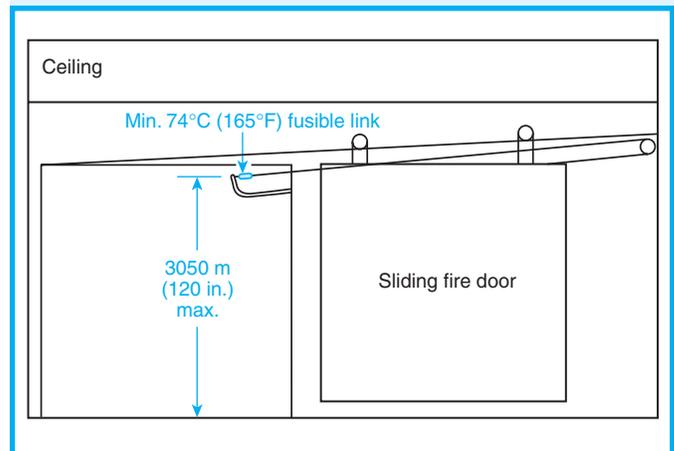

Exhibit 42.1 Existing horizontal sliding fire door in accordance with 42.2.2.2.4.

42.2.2.3 Stairs.

42.2.2.3.1 Stairs shall comply with 7.2.2 and shall be permitted to be modified by as follows:

- (1) Noncombustible, grated stair treads and noncombustible, grated landing floors shall be permitted.
- (2) Industrial equipment access stairs in accordance with 40.2.5.2 shall be permitted.

42.2.2.3.2 Spiral stairs complying with 7.2.2.2.3 shall be permitted.

42.2.2.3.3 Existing winders complying with 7.2.2.2.4 shall be permitted.

Paragraph 42.2.2.3.1(1) exempts stair treads and landings in storage occupancies from the provisions of 7.2.2.3.3.1, which would otherwise require that all stair treads and stair landing floors be solid. Although the requirement for solid treads and landing floors is intended to prevent occupants from avoiding the use of the stairs because they become afraid when they are able to see through the openings to the floor or ground below, occupants of storage occupancies are usually more familiar, and thus more comfortable, with grated or expanded metal treads and landings. The grated walking surfaces provide slip resistance in what can sometimes be greasy and slippery surroundings. The exemption from 7.2.2.3.3.1 for storage occupancies is new to the 2003 edition of the *Code*, but a similar exemption has been allowed for many years for industrial occupancies. In future editions, 7.2.2.3.3.4 will be updated to cross-reference the exemption, just the way that 7.2.2.3.3.4(3) currently does for industrial occupancies.

Paragraph 42.2.2.3.1(2) serves to remind the user that the special provisions for industrial equipment access stairs in 40.2.5.2 are permitted to be used in storage occupancies. The provisions of 40.2.5.2 differ from the requirements of Chapter 7. See the commentary following 40.2.5.2.

42.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

Paragraph 42.2.2.4 does not mandate the use of smokeproof enclosures. However, it does recognize a smokeproof enclosure as part of the means of egress system in a storage occupancy if that smokeproof enclosure meets the requirements of 7.2.3. See 42.2.2.1. For an example of an occupancy requiring a smokeproof enclosure, see 31.2.11, which specifies that existing nonsprinklered, high-rise apartment buildings are required to be provided with smokeproof enclosures in accordance with 7.2.3.

42.2.2.5 Horizontal Exits.

42.2.2.5.1 Horizontal exits complying with 7.2.4 shall be permitted.

42.2.2.5.2* In horizontal exits where the opening is protected by a fire door assembly on each side of the wall in which it is located, one fire door shall be of the swinging

type as provided in 7.2.4.3.6, and the other shall be permitted to be an automatic-sliding fire door that shall be kept open whenever the building is occupied.

A.42.2.2.5.2 The customary building code requirement for fire doors on both sides of an opening in a fire wall is permitted to be met by having an automatic-sliding fire door on one side and a self-closing fire door swinging out from the other side of the wall. This arrangement qualifies only as a horizontal exit from the side of the sliding door. For further information, see A.7.2.4.3.9.

Paragraph 42.2.2.5.1 does not mandate the use of horizontal exits. However, it does recognize a horizontal exit as part of the means of egress system in a storage occupancy if that horizontal exit meets the requirements of 7.2.4, as modified by 42.2.2.5.2.

Paragraphs 42.2.2.5.2 and A.42.2.2.5.2 recognize the common practice of combining a horizontal exit that is used for life safety with a fire barrier of a significant fire resistance rating that is used for property protection. Opening protectives for such a fire barrier can require the use of a set of two doors to achieve the required fire protection rating. It is impractical for both doors to swing in the same direction without interfering with each other; yet, operation of two doors that swing in opposite directions is cumbersome for daily or frequent use. One swinging and one sliding door, as shown in Exhibit 42.2, provide an acceptable arrangement for day-to-day functioning of the building. The open sliding door does not compromise life safety, because by the time its fusible link mechanism releases the door and allows it to close, temperatures in the vicinity of the door opening render use of the door impractical.

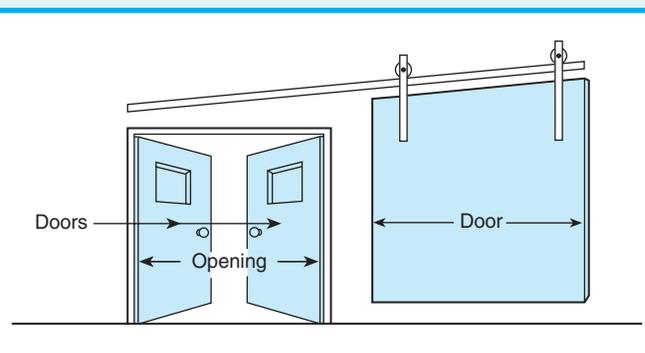

Exhibit 42.2 Combination swinging and sliding doors permitted by 42.2.2.5.2.

42.2.2.6 Ramps.

42.2.2.6.1 Ramps complying with 7.2.5 shall be permitted.

42.2.2.6.2 Industrial equipment access ramps in accordance with 40.2.5.2 shall be permitted.

Paragraph 42.2.2.6.1 does not mandate the use of ramps in storage occupancies. However, it does recognize a ramp as part of the means of egress system if that ramp meets the requirements of 7.2.5. See 42.2.2.1.

Paragraph 42.2.2.6.2 recognizes the industrial access ramp provisions of 40.2.5.2, which are a relaxation of the ramp provisions of 7.2.5. For example, Table 40.2.5.2.1 permits a minimum ramp width of 560 mm (22 in.) instead of the 1120 mm (44 in.) minimum of Table 7.2.5.2(a). However, the industrial equipment access provisions of 40.2.5.2 have the restriction that the egress component, in this case a ramp, serve not more than 20 persons.

42.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

Paragraph 42.2.2.7 does not mandate the use of exit passageways in storage occupancies. However, it does recognize an exit passageway as part of the means of egress system if that exit passageway meets the requirements of 7.2.6. See 42.2.2.1.

42.2.2.8 Fire Escape Stairs. Existing fire escape stairs complying with 7.2.8 shall be permitted.

42.2.2.9 Fire Escape Ladders.

42.2.2.9.1 Fire escape ladders complying with 7.2.9 shall be permitted.

42.2.2.9.2 Fixed industrial stairs in accordance with the minimum requirements for fixed stairs in ANSI A1264.1, *Safety Requirements for Workplace Floor and Wall Openings, Stairs, and Railing Systems*, shall be permitted where fire escape ladders are permitted in accordance with 7.2.9.1.

The geometry associated with the incline angle and the size and shape of surfaces intended for foot placement on fire escape ladders falls within the range permitted for fixed industrial stairs. However, most fixed industrial stairs meet criteria that result in a safer arrangement than that provided by the fire escape ladder detailed in 7.2.9. Therefore, 42.2.2.9.2 recognizes fixed industrial stairs as a substitute for fire escape ladders.

42.2.2.10 Slide Escapes. Existing slide escapes complying with 7.2.10 shall be permitted.

The intent of 42.2.2.10 is to allow the continued use of existing slide escapes, which are a common means of egress from areas that house explosives or other highly hazardous materials in warehouses associated with the chemical industry. The provision allows slide escapes to be considered as part of the required means of egress from existing storage occupancies only if the slide escape meets the requirements of 7.2.10.

42.2.2.11 Alternating Tread Devices. Alternating tread devices complying with 7.2.11 shall be permitted.

The provisions of 7.2.11, in effect, limit the use of alternating tread devices to those locations where the *Code* recognizes the use of fire escape ladders. See 42.2.2.9.1, 7.2.9, and 7.2.11.

42.2.2.12 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

42.2.3 Capacity of Means of Egress.

The capacity of means of egress shall be in accordance with Section 7.3.

Prior to 1991, the *Code* required a minimum 112-cm (44-in.) width for corridors and passageways within the required means of egress of storage occupancies. A corridor or passageway of that minimum width would have provided egress capacity for 220 persons [that is, 1120 mm/5 mm (44 in./0.2 in.) per person in accordance with Table 7.3.3.1 for level travel components]. That requirement produced artificially large egress systems, relative to the occupant load, in many storage occupancies. The requirement was eliminated, and the minimum 915-mm (36-in.) width requirement of 7.3.4.1(2), which addresses the minimum width of any exit access, was made applicable to storage occupancies. Exit access is required to be wider than 915 mm (36 in.) only if a corridor or passageway in a storage occupancy is to provide capacity for more than 180 persons [that is, 915 mm/5 mm (36 in./0.2 in.) per person].

See the commentary following A.42.1.7.

42.2.4 Number of Means of Egress.

See also Section 7.4.

42.2.4.1 The number of means of egress shall comply with 42.2.4.1(1), 42.2.4.1(2), or 42.2.4.1(3).

- (1) In low hazard storage occupancies, a single means of egress shall be permitted from any story or section.
- (2) In ordinary hazard storage occupancies, a single means of egress shall be permitted from any story or section, provided that the exit can be reached within the distance permitted as a common path of travel.
- (3) All buildings or structures not complying with 42.2.4.1(1) or 42.2.4.1(2) and used for storage, and every section thereof considered separately, shall have not less than two separate means of egress as remotely located from each other as practicable.

42.2.4.2 In new buildings, floors or portions thereof with an occupant load of more than 500 persons shall have the minimum number of separate and remote means of egress specified by 7.4.1.2.

42.2.4.3 Areas with high hazard contents shall comply with Section 7.11.

Paragraphs 42.2.4.1(1) and 42.2.4.1(2) modify the requirement for two, separate, remotely located means of egress due in part to the small number of employees typically found in a storage occupancy and the exemplary life safety fire record of such facilities. Paragraph 42.2.4.1(1) recognizes that a low hazard storage occupancy is not subject to a self-propagating fire, and, therefore, considers a single means of egress to be safe. Paragraph 42.2.4.1(2) allows a single means of egress in an ordinary hazard storage occupancy if the total travel distance to the single exit does not exceed the 15-m (50-ft) or 30-m (100-ft) common path of travel allowance for nonsprinklered and sprinklered buildings, respectively (see Table 42.2.5.1). This allowance is made because such a single-exit arrangement is equivalent or superior to a two-exit arrangement that applies the maximum common path of travel allowance and subsequently requires additional travel distance to reach an exit.

In Exhibit 42.3, a single exit is depicted in illustration (a). It is located within the distance permitted for common path of travel (see Table 42.2.5.1), as addressed by 42.2.4.1(2) for ordinary hazard storage occupancies, and creates a situation no more dangerous than the common path of travel shown as X1–C1 in the two-exit building depicted in illustration (b).

42.2.5 Arrangement of Means of Egress.

42.2.5.1 Means of egress, arranged in accordance with Section 7.5, shall not exceed that provided by Table 42.2.5.1.

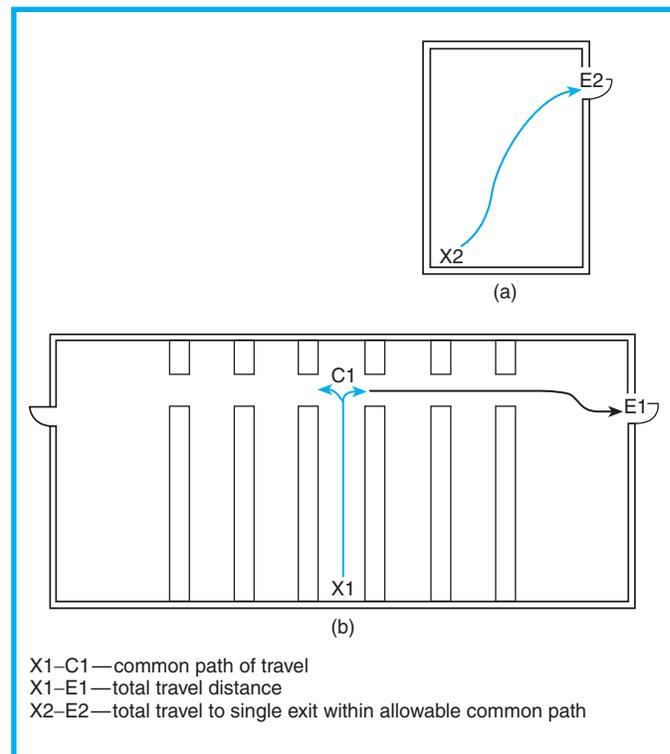

Exhibit 42.3 Common path of travel in single-exit building compared to that in two-exit building.

By definition, no self-propagating fire can occur in low hazard contents. If a fire will not spread or continue to burn, building occupants will not be subject to an emergent need to egress the building by means of paths that avoid the fire. Therefore, the *Code* establishes no maximum dead-end corridor and no maximum common path of travel for storage occupancies with low hazard contents. See Section 6.2.

An ordinary hazard storage occupancy, despite its characteristically low occupant load, is not permitted to provide a common path of travel that forces an occupant to travel in one direction only for more than 15 m (50 ft) [30 m (100 ft) in a sprinklered building] without providing a route to a second, remotely located exit.

By definition, an extremely rapid-developing fire or the potential for explosion are characteristics of high hazard contents. If a fire spreads with extreme rapidity, building occupants will have an emergent need to egress the building by means of paths that avoid the fire. Therefore, the *Code* permits no dead-end corridors and no common path of travel for storage occupancies with high hazard contents except as allowed by 7.11.4. See Section 6.2 and 7.11.4.

42.2.6* Travel Distance to Exits.

Travel distance, measured in accordance with Section 7.6, shall not exceed that provided by Table 42.2.6.

A.42.2.6 The travel distance to exits specified recognizes a low population density. Consideration should be given to locating areas that have a relatively high population, such as lunchrooms, meeting rooms, packaging areas, and offices, near the outside wall of the building to keep the travel distance to a minimum.

Subsection 42.2.6 establishes limitations on travel distance for storage occupancies. Note that the provisions create a direct relationship between the level of hazard of contents housed within a building and its life safety requirements. Therefore, in low hazard storage occupancies, no limitation is imposed on travel distance.

As the level of hazard of contents increases, travel distance limitations are imposed. Storage buildings housing ordinary hazards and lacking sprinkler protection are limited to 61 m (200 ft) of travel distance to an exit. A distance of 122 m (400 ft) is permitted if complete automatic sprinkler protection is provided. For the first printing of the 2003 edition of the *Code*,

the 61 m (200 ft) and 122 m (400 ft) values were inadvertently transposed. The subject was corrected via issuance of errata and in subsequent printings.

In high hazard storage occupancies, travel distance is restricted to a maximum of 23 m (75 ft) in nonsprinklered buildings and 30 m (100 ft) if the building is equipped with a complete automatic sprinkler system.

The absence of travel distance restrictions for low hazard storage occupancies is reasonable, because the small fire risk posed by low hazard materials, coupled with the low number of occupants, provides a minimal risk to life safety. The imposition of restrictive provisions would not be consistent with good fire protection and reasonable life safety requirements, because the possibility of fire is very low, and occupants are not expected to experience difficulty in evacuating the building. See Section 6.2 for guidelines on low hazard contents.

The last entry in Table 42.2.6 addresses an increase in travel distance for storage occupancies where flammable and combustible liquid products are stored and protected in accordance with NFPA 30, *Flammable and Combustible Liquids Code*². Since 1996, NFPA 30 has had adequate safeguards to permit increasing the travel distance allowance from 23 m

Table 42.2.5.1 Arrangements of Means of Egress

Level of Protection	Low Hazard Storage Occupancy	Ordinary Hazard Storage Occupancy	High Hazard Storage Occupancy
Dead-End Corridor			
Protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	No limits	30 m (100 ft)	Prohibited except as permitted by 7.11.4.
Not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	No limits	15 m (50 ft)	Prohibited except as permitted by 7.11.4.
Common Path of Travel			
Protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	No limits	30 m (100 ft)	Prohibited except as permitted by 7.11.4.
Not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	No limits	15 m (50 ft)	Prohibited except as permitted by 7.11.4.

Table 42.2.6 Maximum Travel Distance to Exits

Level of Protection	Low Hazard Storage Occupancy	Ordinary Hazard Storage Occupancy	High Hazard Storage Occupancy
Protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	No limits	122 m (400 ft)	30 m (100 ft)
Not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	No limits	61 m (200 ft)	23 m (75 ft)
Flammable and combustible liquid products stored and protected in accordance with NFPA 30, <i>Flammable and Combustible Liquids Code</i>	Not applicable	Not applicable	46 m (150 ft)

(75 ft) to 46 m (150 ft). Flammable and combustible liquids storage facilities not in compliance with the 1996, 2000, or 2003 edition of NFPA 30 should not make use of the travel distance increase.

42.2.7 Discharge from Exits.

Discharge from exits shall be in accordance with Section 7.7.

42.2.8 Illumination of Means of Egress.

42.2.8.1 Means of egress shall be illuminated in accordance with Section 7.8.

42.2.8.2 In structures occupied only during daylight hours, means of egress shall be permitted to be illuminated with windows arranged to provide the required level of illumination on all portions of the means of egress during such hours when approved by the authority having jurisdiction.

The intent of 42.2.8 is not to require the installation of extensive and unneeded exit illumination systems in storage occupancies. Illumination is required for the exit and for the exit access, which is limited to designated aisles, corridors, and passageways that lead to an exit. Limiting the extent of the lighting system to egress areas eliminates the necessity for installing specialized lighting systems throughout storage areas, a practice that might be extremely costly while providing little or no return in safety to life.

Paragraph 42.2.8.2 waives the requirement for il-

lumination systems if a building, including the stairways, is sufficiently lit during periods of occupancy by means of natural lighting. The term *windows*, as used in the text of the exemption, should not be interpreted literally. The term is meant to include skylights, open wall sections, and similar means of illumination by natural sources. The provisions are based on the fact that there is no need for a lighting system if the building is unoccupied during nondaylight hours.

42.2.9 Emergency Lighting.

Emergency lighting shall be provided in normally occupied storage occupancies in accordance with Section 7.9, except for spaces occupied only during daylight hours with natural illumination in accordance with 42.2.8.2.

Emergency lighting is exempted in storage occupancies that are naturally illuminated when occupied for the reasons stated in the commentary following 42.2.8.2. The exemption allows circuit arrangements that disconnect power from emergency lighting systems when the building is unoccupied. In many warehouses, power is turned off during periods when the building is unoccupied. This power disconnection serves fire prevention, energy conservation, and security purposes.

42.2.10 Marking of Means of Egress.

Means of egress shall have signs in accordance with Section 7.10.

42.2.11 Special Means of Egress Features.

(Reserved)

Section 42.3 Protection**42.3.1 Protection of Vertical Openings.**

Any vertical opening shall be protected in accordance with Section 8.6 unless otherwise permitted by one of the following:

- (1) Existing open stairs, existing open ramps, and existing open escalators shall be permitted when connecting only two floor levels.
- (2) Existing, unprotected vertical openings in buildings with low or ordinary hazard contents and protected throughout by an approved automatic sprinkler system in accordance with 9.7.1.1(1) shall be permitted where they do not serve as required exits. All required exits shall consist of outside stairs in accordance with 7.2.2, smokeproof enclosures in accordance with 7.2.3, or horizontal exits in accordance with 7.2.4.

Paragraph 42.3.1(2) recognizes that an existing storage occupancy might contain unprotected vertical openings and still provide a reasonable level of safety to life if the building houses only low or ordinary hazard contents and is protected by a complete automatic sprinkler system. Smokeproof enclosures and outside stairways (the only types of vertical exits permitted by this exemption) must be fully enclosed or protected against vertical fire spread and must meet the requirements of Chapter 7. The unenclosed vertical openings are not permitted to serve as part of the means of egress, although they can remain as convenience openings and stairways to be used for normal operations.

Although the major reason for allowing this provision is economic (enclosing all vertical openings in existing buildings is expensive), there is actually little effect on the life safety of occupants where a building houses low or ordinary hazard contents. However, some difficulties in fire control are created, because unprotected vertical openings can contribute to fire spread in buildings and result in extensive property damage and potential impact on occupants prior to evacuation; therefore, a complete automatic sprinkler system is required.

42.3.2 Protection from Hazards.

(No requirements.) (See also Section 8.7.)

42.3.3 Interior Finish.

42.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

42.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A, Class B, or Class C in storage areas and shall be as required by 7.1.4 in exit enclosures.

42.3.3.3 Interior Floor Finish. (No requirements.)

42.3.4 Detection, Alarm, and Communications Systems.

42.3.4.1 General. A fire alarm system shall be required in accordance with Section 9.6 for storage occupancies except as modified by 42.3.4.1.1, 42.3.4.1.2, and 42.3.4.1.3.

42.3.4.1.1 Storage occupancies limited to low hazard contents shall not be required to have a fire alarm system.

42.3.4.1.2 Storage occupancies with ordinary or high hazard contents not exceeding an aggregate floor area of 9300 m² (100,000 ft²) shall not be required to have a fire alarm system.

42.3.4.1.3 Storage occupancies protected throughout by approved automatic sprinkler system in accordance with Section 9.7 shall not be required to have a fire alarm system.

42.3.4.2 Initiation. Initiation of the required fire alarm system shall be by any of the following means:

- (1) Manual means in accordance with 9.6.2.1(1).
- (2) An approved automatic fire detection system in accordance with 9.6.2.1(2) throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5.
- (3) An approved, supervised automatic sprinkler system in accordance with 9.6.2.1(3) throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5.

42.3.4.3 Notification.

42.3.4.3.1 The required fire alarm system shall meet one of the following criteria:

- (1) It shall provide occupant notification in accordance with 9.6.3.
- (2) It shall sound an audible and visible signal in a constantly attended location for the purposes of initiating emergency action.

42.3.4.3.2 Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.

42.3.4.3.3 Existing presignal systems in accordance with 9.6.3.3 shall be permitted.

42.3.4.3.4 In high hazard storage occupancies, the required fire alarm system shall automatically initiate an occupant evacuation alarm signal in accordance with 9.6.3.

Subsection 42.3.4 requires the installation of a fire alarm system in nonsprinklered storage occupancies with an aggregate floor area of over 9300 m² (100,000 ft²). An alarm system is not required in a storage occupancy limited to housing low hazard contents, regardless of its size, nor is one required in a sprinklered storage occupancy, regardless of size. Storage placement limits visibility in buildings with large floor areas. As a result, personnel who work in storage areas might be unaware of the occurrence of fire for a long period. If fire spreads, which is highly possible in an unprotected storage building, means of exit access could be blocked. An alarm system provides a means of alerting all occupants to the presence of fire and allows for timely egress.

The requirements of 42.3.4.3.1 and 42.3.4.3.4 specify two separate and distinct provisions for audible alarms activated by the fire alarm system required by 42.3.4.1. In low and ordinary hazard storage occupancies (see 42.3.4.3.1), the system is permitted to activate an evacuation alarm or sound an alarm in a constantly attended location for the purpose of initiating emergency action. This provision allows an interface between the alarm system and the building's emergency organization. The alarm system is permitted to be controlled from a central security console or a similar location. The key feature is that the location from which the alarm sounds must be constantly staffed. This requirement is not intended to mandate the installation of supervisory service, such as that connected to a central station, but the location must be fully attended at all times when the building is occupied.

In high hazard storage occupancies (see 42.3.4.3.4), the alarm must be arranged to provide evacuation signals, because the safety of the occupants of these areas depends on their immediate notification of a fire.

Note that 42.3.4.3.3 recognizes existing presignal systems but not new presignal systems. If an automatic form of delay is desired for an existing alarm system that doesn't already have a presignal feature, or for a new alarm system, the more reliable system feature known as *positive alarm sequence* is permitted. The positive alarm sequence option permitted by 42.3.4.3.2 might be applied to the high hazard storage occupancies addressed in 42.3.4.3.4 for which an

automatic form of occupant notification is needed. Also, positive alarm sequence might be used in storage occupancies, other than those that are high hazard, where the provisions of 42.3.4.3.1(1) are used instead of those of 42.3.4.3.1(2).

The *Code* does not specify an alarm system as a property protection requirement, although the probability of property loss is reduced in any occupancy where an alarm system is installed.

42.3.5 Extinguishment Requirements.

(None)

42.3.6 Corridors.

The provisions of 7.1.3.1 shall not apply.

Without the exemption to the requirements of 7.1.3.1 provided by 42.3.6, all new storage occupancy corridors serving more than 30 persons would be required to have a 1-hour fire resistance rating, with openings protected by 20-minute fire protection-rated door assemblies. The exemption to 7.1.3.1 was adopted because of the ambulatory nature of occupants of storage occupancies; the operational need for openings, even where corridors are provided; and the functional need served by open floor areas.

Section 42.4 Special Provisions

In all new high-rise buildings, all storage occupancies except for low hazard occupancies shall meet the automatic sprinkler requirements of 11.8.2.1.

42.4.1 High-Rise Buildings.

Automatic sprinkler requirements of 11.8.2.1 shall be required for new high-rise storage occupancies, except for low hazard storage occupancies.

The provisions of 42.4.1, which apply to high-rise storage occupancy buildings, reference a portion of the high-rise building provisions of Section 11.8 that were written to allow an occupancy chapter to mandate their use. New high-rise storage occupancy buildings that are classified as ordinary hazard or high hazard are required to be protected throughout by an approved, supervised automatic sprinkler system in ac-

cordance with 11.8.2.1. The remainder of Section 11.8 is not mandated for high-rise storage occupancy buildings.

Section 42.5 Building Services

42.5.1 Utilities.

Utilities shall comply with the provisions of Section 9.1.

42.5.2 Heating, Ventilating, and Air Conditioning.

Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

42.5.3 Elevators, Escalators, and Conveyors.

Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

42.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes.

Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

Section 42.6* Special Provisions for Aircraft Storage Hangars

A.42.6 For further information on aircraft hangars, see NFPA 409, *Standard on Aircraft Hangars*.

42.6.1 The requirements of Section 42.1 through Section 42.5 shall be met, except as modified by 42.6.1.1 through 42.6.1.4.

42.6.1.1 There shall be not less than two means of egress from each aircraft servicing area.

42.6.1.2 Exits from aircraft servicing areas shall be provided at intervals not exceeding 46 m (150 ft) on all exterior walls.

42.6.1.3 Where horizontal exits are provided, doors shall be provided in the horizontal exit fire barrier at intervals not exceeding 30 m (100 ft).

42.6.1.4 Where dwarf, or “smash,” doors are provided in doors that accommodate aircraft, such doors shall be permitted for compliance with 42.6.1.1, 42.6.1.2, and 42.6.1.3.

42.6.2 Means of egress from mezzanine floors in aircraft storage areas shall be arranged so that the travel distance to

the nearest exit from any point on the mezzanine does not exceed 23 m (75 ft), and such means of egress shall lead directly to a properly enclosed stair discharging directly to the exterior, to a suitable cutoff area, or to outside stairs.

42.6.3 Dead ends shall not exceed 15 m (50 ft) for other than high hazard contents areas and shall not be permitted for high hazard contents areas.

For provisions that apply to aircraft servicing hangars, see Section 40.6.

Section 42.6 specifies two alternate methods of providing egress from aircraft storage hangars. Where egress is possible through the outside wall, a distance of 46 m (150 ft) between exit doors is adequate. In larger hangars, the storage bay might have offices and other rooms located along one or more sides, with the walls constructed of fire resistance-rated materials. In those cases where the wall has a fire resistance rating so as to qualify as a horizontal exit, exit spacing of up to 30 m (100 ft) is specified. If the wall is nonrated, access to the outside is required. During inclement weather, large hangar doors are typically closed, so it is common procedure to provide small access doors for personnel in the larger aircraft hangar door. The small door can be considered a normal means of egress from an aircraft hangar. If possible, the door should swing in the direction of egress; however, this might not be possible due to the design of the aircraft door. For further information on aircraft hangars, see NFPA 409, *Standard on Aircraft Hangars*³.

Section 42.7* Special Provisions for Grain or Other Bulk Storage Elevators

A.42.7 For further information, see NFPA 61, *Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Processing Facilities*. The egress requirements for storage elevators are based on the possibility of fire and are not based on the possibility of grain dust explosions.

42.7.1 General.

The requirements of Section 42.1 through Section 42.5 shall be met, except as modified by 42.7.2 through 42.7.4.2.

42.7.2 Number of Means of Egress.

There shall be not less than two means of egress from all working levels of the head house as modified by 42.7.2.1, 42.7.2.2, and 42.7.2.3.

42.7.2.1 One of the two means of egress shall be a stair to the level of exit discharge that is enclosed by a dust-resistant 1-hour fire resistance-rated enclosure in accordance with 7.1.3.2.

42.7.2.2 The second means of egress shall be one of the following:

- (1) An exterior stair or basket ladder-type fire escape that is accessible from all working levels of the head house and provides a passage to ground level
- (2) An exterior stair or basket ladder-type fire escape that is accessible from all working levels of the head house, provides access to the top of adjoining structures, and provides a continuous path to the means of egress described in 42.7.3.

42.7.2.3 Existing Stair Enclosures. Stair enclosures in existing structures shall be permitted to have non-fire-rated dust resistant enclosures.

42.7.3 Fire Escapes.

An exterior stair or basket ladder-type fire escape shall provide passage to ground level from the top of the end of an adjoining structure, such as a silo, conveyor, gallery, or gantry.

42.7.4 Underground Spaces.

42.7.4.1 Number of Means of Egress. Underground spaces shall have not less than two means of egress, one of which shall be permitted to be a means of escape that shall be arranged to eliminate dead ends.

42.7.4.2 Travel Distance to Exits. Travel distance, measured in accordance with Section 7.6, shall not exceed that provided by Table 42.7.4.2.

Table 42.7.4.2 Maximum Travel Distance to Means of Escape or Exits

Level of Protection	Travel Distance
Protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	122 m (400 ft)
Not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	61 m (200 ft)
Existing structures	Unlimited

It is not the intent of 42.7.2.1 to require a fully dust-tight shaft, because the door will allow passage of limited amounts of dust during the normal course

of daily operations. However, the shaft should be separated from the operating areas by fire resistance-rated construction and should be as free of dust as possible.

Section 42.7 establishes the following three basic requirements:

- (1) Two means of egress from all working levels of the head house
- (2) A means of egress at the end of all galleries and similar spaces, thereby eliminating dead ends
- (3) A means of escape provided to eliminate dead ends in underground areas

Subsection 42.7.2 requires that one means of egress from the head house must be an enclosed stair. The alternate means of egress can be either an outside stair or a basket ladder-type fire escape connecting all working levels and leading to either the ground or the top of an adjoining structure that complies with 42.7.3.

The principal hazard of elevator storage structures that handle combustible materials is dust explosion. A dust explosion can be violent enough to damage or destroy the primary means of egress required in 42.7.2.

Section 42.8 Special Provisions for Parking Structures

42.8.1 General Requirements.

42.8.1.1 Application. The provisions of 42.8.1 through 42.8.5.4 shall apply to parking structures of the closed or open type, above or below ground, but shall not apply to mechanical or exclusively attendant-type parking facilities that are not occupied by customers. The requirements of Section 42.1 through Section 42.7 shall not apply.

The intent of the special provisions for parking structures is to provide adequate life safety for the patrons, who probably will be unfamiliar with the parking structure and its arrangement. Where parking attendants are the only occupants that enter the parking area, the Code’s intent is to provide exits in accordance with the previous sections of Chapter 42. In such instances, the provisions for ordinary hazard contents storage occupancies apply.

Section 42.8 is self-contained and, therefore, independent of Sections 42.1 through 42.7, which apply to other storage occupancies. However, Section 42.8

does reference other portions of the *Code*, mainly the core Chapters 1 through 7.

For further information on garages, see NFPA 88A, *Standard for Parking Structures*⁴.

42.8.1.2 Multiple Occupancies.

42.8.1.2.1 Where both parking and repair operations are conducted in the same building, the entire building shall comply with Chapter 40 except as modified by 42.8.1.2.2.

42.8.1.2.2 Where the parking and repair sections are separated by not less than 1-hour fire-rated construction, the parking and repair sections shall be permitted to be treated separately.

42.8.1.2.3 In areas where repair operations are conducted, the means of egress shall comply with Chapter 40.

Paragraph 42.8.1.2.2 allows a building to house parking and repair operations simultaneously and permits such operations to be treated independently if they are separated by 1-hour fire resistance-rated construction. The repair operation would be governed by the provisions of Chapter 40 and the parking facilities by those of Section 42.8.

42.8.1.3 Definition: Open Parking Structure. See 3.3.217.7.

The definition of the term *open parking structure* (see 3.3.217.7) specifies the degree to which the structure's exterior walls must have openings. Parking structures that meet the definition of open parking structure provide sufficient area in exterior walls to vent the products of combustion to a greater degree than an enclosed parking structure. Open parking structures—as contrasted with enclosed parking structures—are permitted to use vehicle ramps as a second means of egress, have longer travel distance allowances, and are exempt from the alarm system requirement. See 42.8.2.2.6.1(2), Table 42.8.2.6, and 42.8.3.4.1.2.

42.8.1.4 Classification of Occupancy. Incidental vehicle parking in another occupancy shall not be the basis for overall occupancy classification.

42.8.1.5 Classification of Hazard of Contents. Parking structures used only for the storage of vehicles shall be classified as ordinary hazard in accordance with Section 6.2.

Paragraph 42.8.1.5 appropriately classifies the hazard of contents as ordinary hazard for garages used only for the storage of vehicles. With the increased use of combustible materials in vehicle bodies and interiors, a garage presents a hazard greater than that of low hazard contents as defined by the hazard of contents classifications specified in Section 6.2.

42.8.1.6 Minimum Construction Requirements. (No requirements)

42.8.1.7 Occupant Load. (No requirements)

42.8.2 Means of Egress Requirements.

42.8.2.1 General. Means of egress shall be in accordance with Chapter 7 and this section.

42.8.2.2 Means of Egress Components.

42.8.2.2.1 General. Components of means of egress shall be limited to the types described in 42.8.2.2.2 through 42.8.2.2.9.

42.8.2.2.2 Doors.

42.8.2.2.2.1 Doors complying with 7.2.1 shall be permitted.

42.8.2.2.2.2 Special locking arrangements complying with 7.2.1.6 shall be permitted.

42.8.2.2.2.3 An opening for the passage of automobiles shall be permitted to serve as an exit from a street floor, provided that no door or shutter is installed therein.

42.8.2.2.3 Stairs.

42.8.2.2.3.1 Stairs complying with 7.2.2 shall be permitted.

42.8.2.2.3.2 Existing winders complying with 7.2.2.2.4 shall be permitted.

42.8.2.2.3.3 Paragraph 7.2.2.4.5.3(2) shall not apply to guards for parking garages that are accessible to the general public.

42.8.2.2.4 Smokeproof Enclosures. Smokeproof enclosures complying with 7.2.3 shall be permitted.

42.8.2.2.5 Horizontal Exits. Horizontal exits complying with 7.2.4 shall be permitted.

42.8.2.2.6 Ramps.

42.8.2.2.6.1 Ramps shall be permitted in accordance with any of the following conditions:

- (1) Ramps complying with 7.2.5 shall be permitted and shall not be subject to normal vehicular traffic where used as an exit.

- (2) In a ramp-type open parking structure with open vehicle ramps not subject to closure, the ramp shall be permitted to serve in lieu of the second means of egress from floors above the level of exit discharge, provided that the ramp discharges directly outside at the street level.
- (3) For parking structures extending only one floor level below the level of exit discharge, a vehicle ramp leading directly to the outside shall be permitted to serve in lieu of the second means of egress, provided that not door or shutter is installed therein.

42.8.2.2.6.2 Paragraph 7.2.2.4.5.3(2) shall not apply to guards for parking garages that are accessible to the general public.

Paragraphs 42.8.2.2.6.1(2) and 42.8.2.2.6.1(3) permit the use of vehicle ramps as part of the means of egress. Properly arranged ramps can facilitate safe egress to a degree well in excess of that required for the given number of occupants.

Paragraph 42.8.2.2.6.1(2) allows consideration of ramps in open-air parking structures as a secondary means of egress from floors located above the street level where they are arranged to provide clear and unobstructed discharge to the street level. Ramps from floors located above the street level are required to be open and must not be enclosed by walls or other means that will confine smoke and heat in the ramp structure. Ramps located in enclosed garages—except those addressed by 42.8.2.2.6.1(3)—cannot be considered as part of the egress system, and normal means of egress (specified in 42.8.2.2) needs to be provided.

Paragraph 42.8.2.2.6.1(3) allows a ramp to be used as a secondary means of egress in a garage that extends not more than one floor level below the level of exit discharge. The ramp must not have a door or a shutter and must lead directly outside.

42.8.2.2.7 Exit Passageways. Exit passageways complying with 7.2.6 shall be permitted.

42.8.2.2.8 Fire Escape Stairs. Fire escape stairs complying with 7.2.8 shall be permitted for existing parking structures only.

42.8.2.2.9 Areas of Refuge. Areas of refuge complying with 7.2.12 shall be permitted.

42.8.2.3 Capacity of Means of Egress. See also 42.8.2.4 and 42.8.2.5.

42.8.2.4 Number of Means of Egress. See also Section 7.4.

42.8.2.4.1 Not less than two means of egress shall be provided from every floor or section of every parking structure.

42.8.2.4.2 In new buildings, floors or portions thereof with an occupant load of more than 500 persons shall have the minimum number of separate and remote means of egress specified by 7.4.1.2.

Note that there is no single-exit exception to the two-exit rule for parking garages.

42.8.2.5 Arrangement of Means of Egress. See also Section 7.5.

42.8.2.5.1 A common path of travel shall be permitted for the first 15 m (50 ft) from any point in the parking structure.

42.8.2.5.2 Dead ends shall not exceed 15 m (50 ft).

42.8.2.5.3 Where fuel-dispensing devices are located within a parking structure, 42.8.2.5.3.1 and 42.8.2.5.3.2 shall apply.

42.8.2.5.3.1 Travel away from the fuel-dispensing device in any direction shall lead to an exit with no dead end in which occupants might be trapped by fire.

42.8.2.5.3.2 Within closed parking structures containing fuel-dispensing devices, exits shall be arranged and located to meet the following additional requirements:

- (1) Exits shall lead to the outside of the building on the same level or to stairs; no upward travel shall be permitted unless direct outside exits are available from that floor.
- (2) Any story below that story at which fuel is being dispensed shall have exits leading directly to the outside via outside stairs or doors at ground level.

Paragraph 42.8.2.5.3 specifies the conditions required for protection of the occupants of parking garages from fires that might be caused by gasoline-dispensing operations located inside the building. Additional provisions apply where gasoline dispensing takes place in enclosed parking structures. Paragraph 42.8.2.5.3.2(2) requires that direct access to the outside be provided from floors located below those on which gasoline is dispensed. This requirement prevents gasoline vapors, which are heavier than air, from accumulating in enclosed portions of a means of egress, such as inside exit stairways.

The hazards associated with dispensing gasoline inside buildings are avoided by dispensing fuel outdoors, as in the case of ordinary gasoline filling stations. See NFPA 30A, *Code for Motor Fuel Dispensing*

Facilities and Repair Garages⁵, for requirements on dispensing gasoline indoors.

42.8.2.6 Travel Distance to Exits. Travel distance, measured in accordance with Section 7.6, shall not exceed that provided by Table 42.8.2.6.

42.8.2.7 Discharge from Exits. Exit discharge shall comply with Section 7.7.

42.8.2.8 Illumination of Means of Egress. Means of egress shall be illuminated in accordance with Section 7.8 or with natural lighting that provides the required level of illumination in structures occupied only during daylight hours.

42.8.2.9 Emergency Lighting. Parking structures shall be provided with emergency lighting in accordance with Section 7.9, except for structures occupied only during daylight hours and arranged to provide the required level of illumination of all portions of the means of egress by natural means.

42.8.2.10 Marking of Means of Egress. Means of egress shall have signs in accordance with Section 7.10.

42.8.2.11 Special Means of Egress Features. (Reserved)

42.8.3 Protection.

42.8.3.1 Protection of Vertical Openings.

42.8.3.1.1 Vertical Openings in Enclosed Parking Structures.

42.8.3.1.1.1 Vertical openings through floors in buildings four stories or more in height shall be enclosed with walls or partitions having a fire resistance rating of not less than 2 hours.

42.8.3.1.1.2 For buildings less than four stories, the walls or partitions required by 42.8.3.1.1.1 shall have a fire resistance rating of not less than 1 hour.

42.8.3.1.1.3 Ramps in enclosed parking structures shall not be required to be enclosed when either of the following safeguards is provided:

- (1) An approved, automatic sprinkler system fully protecting the parking structure
- (2) An approved, automatic, supervised fire detection system installed throughout the parking structure using detectors sensing products of combustion other than heat and mechanical ventilation system

42.8.3.2 Protection from Hazards. (No requirements)

42.8.3.3 Interior Finish.

42.8.3.3.1 General. Interior finish shall be in accordance with Section 10.2.

42.8.3.3.2 Interior Wall and Ceiling Finish. Interior wall and ceiling finish materials complying with Section 10.2 shall be Class A, Class B, or Class C in parking structures and shall be as required by 7.1.4 in exit enclosures.

42.8.3.3.3 Interior Floor Finish. (No requirements)

42.8.3.4 Detection, Alarm, and Communications Systems.

42.8.3.4.1 General. A fire alarm system shall be required in accordance with Section 9.6 for parking structures except as modified by 42.3.4.1.1, 42.3.4.1.2, and 42.3.4.1.3.

42.8.3.4.1.1 Parking structures not exceeding an aggregate floor area of 9300 m² (100,000 ft²) shall not be required to have a fire alarm system.

42.8.3.4.1.2 Open parking structures shall not be required to have a fire alarm system.

42.8.3.4.1.3 Parking structures protected throughout by an approved automatic sprinkler system in accordance with Section 9.7 shall not be required to have a fire alarm system.

Table 42.8.2.6 Maximum Travel Distance to Exits

Level of Protection	Enclosed Parking Structure	Open Parking Structure	Parking Structure Open Not Less Than 50% On All Sides
Protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	61 m (200 ft)	122 m (400 ft)	122 m (400 ft)
Not protected throughout by an approved, supervised automatic sprinkler system in accordance with 9.7.1.1(1)	46 m (150 ft)	91 m (300 ft)	122 m (400 ft)

42.8.3.4.2 Initiation. Initiation of the required fire alarm system shall be by one of the following:

- (1) Manual means in accordance with 9.6.2.1(1).
- (2) An approved automatic fire detection system in accordance with 9.6.2.1(2) throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5.
- (3) An approved supervised automatic sprinkler system in accordance with 9.6.2.1(3) throughout the building; plus a minimum of one manual fire alarm box in accordance with 9.6.2.5.

42.8.3.4.3 Notification.

42.8.3.4.3.1 The required fire alarm system shall sound an audible alarm in a continuously attended location for purposes of initiating emergency action.

42.8.3.4.3.2 Positive alarm sequence in accordance with 9.6.3.4 shall be permitted.

42.8.3.4.3.3 Existing presignal systems in accordance with 9.6.3.3 shall be permitted.

42.8.3.5 Extinguishing Requirements. (None)

42.8.3.6 Corridors. The provisions of 7.1.3.1 shall not apply.

42.8.4 Special Provisions: High-Rise Buildings.

(No requirements)

42.8.5 Building Services.

42.8.5.1 Utilities. Utilities shall comply with the provisions of Section 9.1.

42.8.5.2 Heating, Ventilating, and Air Conditioning. Heating, ventilating, and air conditioning equipment shall comply with the provisions of Section 9.2.

42.8.5.3 Elevators, Escalators, and Conveyors. Elevators, escalators, and conveyors shall comply with the provisions of Section 9.4.

42.8.5.4 Rubbish Chutes, Incinerators, and Laundry Chutes. Rubbish chutes, incinerators, and laundry chutes shall comply with the provisions of Section 9.5.

ANNEX A

Explanatory Material

The material contained in Annex A of the 2003 edition of the *Life Safety Code* is not a part of the requirements of the *Code* but is included with the *Code* for informational purposes only. For the convenience of readers, in this handbook the Annex A material is interspersed among the verbiage of Chapters 1 through 42 and, therefore, is not repeated here.

Annex B

Informational References

Note that the mandatory referenced publications appear in Chapter 2. Many of the documents shown in Annex B also appear in Chapter 2, and although shown here for advisory purposes, they remain mandatory in the body of the *Code* (Chapters 1 through 42).

B.1

The following documents or portions thereof are referenced within this *Code* for informational purposes only and are thus not considered part of the requirements of this *Code* unless also listed in Chapter 2. The edition indicated here for each reference is the current edition as of the date of the NFPA issuance of this *Code*.

B.2 References for Extracts.

A reference in brackets [] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, Annex B lists the complete title and edition of the source documents for both mandatory and nonmandatory extracts. Editorial changes to extracted material consist of revising references to an appropriate division in this document or the inclusion of the document number with the division number when the reference is to the original document. Requests for interpretations or revisions of extracted text [shall, should] be sent to the technical committee responsible for the source document.

PART TWO

Supplements

The seven supplements collected in Part Two of this handbook were written by recognized experts in the fields they cover. Printed in black within a green box, these supplements are not part of the *Code* or the commentary. They present additional, useful information about specialized subjects in more depth than is allowed by the *Code*-and-commentary format of this handbook. The supplements give case histories of fires that influenced the *Life Safety Code*; provide an overview of how fire alarm, sprinkler, elevator, and fire test requirements interact with the requirements found in NFPA 101; guide the user in adopting the *Life Safety Code* into law; and bring the reader up to date on the issue of building security versus life safety. Much like the commentary, the supplements are intended to provide useful guidance for *Code* users.

- 1 Case Histories: Fires Influencing the *Life Safety Code*
- 2 Fire Alarm Systems for *Life Safety Code* Users
- 3 A Brief Introduction to Sprinkler Systems for *Life Safety Code* Users
- 4 Extracts from ASME *Elevator Code and Handbook*
- 5 Fire Tests for *Life Safety Code* Users
- 6 Home Security and Fire Safety
- 7 The Application of Performance-Based Design Concepts for Fire and Life Safety

S U P P L E M E N T 1

Case Histories: Fires Influencing the *Life Safety Code*

Paul E. Teague, M.A.

Editor's Note: This supplement illustrates how historically significant fires have led to improvements in the Life Safety Code.

Paul E. Teague, former editor of Fire Journal magazine, is a veteran award-winning engineering journalist. Currently, he is the national editor and supplements director for Design News magazine, the largest mechanical engineering magazine in the United States.

Codes and standards are living documents. Born of the efforts of men and women to make their environment safer, codes and standards grow into maturity based on fire experience and the observations and research of those responsible for them. The best codes and standards, such as those produced by NFPA, never age, as they are continually updated with new information that allows them to adapt to an ever-changing world.

Such is the case with NFPA 101, *Life Safety Code*. Originally known as the *Building Exits Code*, it had its origins in the effort to make factories safer for workers in the early days of the twentieth century. Its first focus was on the hazards of stairways and fire escapes, the need for fire drills in various occupancies, and the construction and arrangement of exits.

However, as American society changed, technology blossomed, and fire experience accumulated, the *Code* grew in scope. It began to include provisions for sprinklers, alarm and detection systems, protection of interior finish, and other important features. Of the thousands of fires whose lessons are reflected in the latest edition of the *Code*, probably none has had a bigger impact than the Triangle Shirtwaist fire of March 25, 1911. It was that fire that prompted creation of NFPA's Committee on Safety to Life and, ultimately, development of the *Code* itself.

TRIANGLE SHIRTTWAIST FIRE

Since its founding in 1896, the NFPA has always placed special importance on its life safety work. NFPA's original objectives, "establishing proper safeguards against loss of life and property by fire," placed life safety ahead of property protection. Yet, until the Triangle Shirtwaist fire, there was not one technical committee devoted exclusively to life safety concerns.

The Triangle Shirtwaist Company was located on the 8th, 9th, and 10th floors of the Asch Building at the intersection of Washington Place and Green Street in New York City's Washington Square. The building was a "loft," typical of many in its day. The Triangle Company, with more than 500 employees, was reportedly the largest business of its kind in the city. Most of the employees were young women, many of them recent immigrants, who worked six days a week in cramped and dirty quarters.

Numerous Fire Hazards

New York City law at the time required buildings 11 stories and higher to have stone floors and metal window frames. The Asch Building was only 10 stories high and was constructed with wood floors, wood trim, and wood window frames. Unsafe as they were,

these features of the building's construction were only part of the fire danger that workers unwittingly faced every day.

Buildings with 10,000 ft² of floor space per floor were required to have three staircases per floor. The Asch Building had two. The building's architect had pleaded for approval of two staircases, because there was also an outside fire escape that could be reached by windows on each floor. The fire escape terminated at the second floor, not at the ground.

Labor laws in effect at the time required that factory doors open outward, *if practical*. The architect claimed it was not practical in the Asch Building, because each landing was only one stair width from the door. All doors had to open inward.

Those same labor laws required that factory doors be kept unlocked during the workday. Doors at the Triangle Company reportedly were usually locked during the workday to keep track of the workers and prevent them from stealing material.

Rags consisting of cutaway cloth materials regularly accumulated on the floors. When last collected, an accumulation of 2252 pounds of rags had been removed. At the time of the fire, the rags had not been removed for about two months.

The Triangle workers were crowded together on the top three floors of the Asch Building. Aisles leading to exits were narrow and obstructed. Partitions were placed in front of doors and elevators. A fire insurance inspector had recommended in 1909 that the company keep the doors unlocked during the workday and conduct fire drills. The owners took no action on those recommendations.

Fire Begins in the Rags. No NFPA investigative report was written on the Triangle Shirtwaist fire, but two books describe the horror that took place: *The Triangle Shirtwaist Fire* (Franklin Watts, Inc., 1971), by Corinne Naden; and *The Triangle Fire*, by Leon Stein (J. B. Lippincott, 1962). The descriptions of the building and the fire reported here are summarized from these two books.

It was near quitting time on March 25, 1911, when one of the workers on the 8th floor noticed smoke coming from one of the rag bins. A fire in a rag bin was reportedly not unusual, but this fire spread with astonishing speed, despite the attempts of supervisors to extinguish it using pails of water. The fire spread from the rags to cutting tables and then to cloth patterns hanging on wire above the tables. In no time, flames consumed the wood floor trim, the sewing tables, and partitions, then spread to the ceiling.

Workers on the 8th floor rushed for the doors.

One door was locked. When workers finally got it unlocked, it opened inward. The panicked workers piled up against the door, making it difficult for those who arrived first to open it. Eventually, they were able to open the door, and workers rushed into the stairway. However, some fell at the 7th floor level, and those behind piled up until there was no more room in the stairway. A policeman, who had seen the fire from the street, saw the pile-up as he ran up the stairs to help. He untangled the pile-up, and about 125 workers escaped down that stairway.

Someone used a telephone connection to the 10th-floor executive offices to report the fire. Other workers frantically rang for the elevators. Because the elevators had been summoned to the 10th floor, at first, they didn't stop on the 8th floor. When they did stop, workers crowded into them, one on top of another. The elevators made so many trips to save workers on the 8th and 10th floors that the operators were overcome by smoke and exhaustion.

Some workers on the 8th floor climbed out the windows to the narrow fire escape. At least one worker fell down the fire escape to the courtyard below. Others climbed down to the 6th floor, went back into the building through a window, and walked down the inside staircase.

Many of the workers on the 10th floor escaped to the roof of the building, where they were rescued by law students from an adjacent building. Of the approximately 70 workers on the 10th floor, only one died. That death occurred because the victim jumped from a window.

The only telephone communication to the 9th floor was through the 10th-floor switchboard. No one on the 10th floor notified the 9th-floor workers of the fire.

Ninth-Floor Workers Were the Last to Be Informed. There were about 260 workers on the ninth floor. There were also eight double rows of sewing machines on 75-ft-long tables that took up nearly the entire floor. The only way to leave the tables was to walk to the north end of the building. Workers sitting at the south end had to walk the entire length of the rows of tables to reach the area where the exits were located. Along the way, they had to negotiate around chairs, wicker baskets, and other items that obstructed the passageways.

When the quitting bell rang, one worker walked down one of the stairways to go home. When he reached the 8th floor, he saw it was in flames. He was the first 9th-floor worker to learn of the fire. Confused, he simply continued moving. By the time he thought of running back up the stairs to warn his

coworkers, it was too late. He was unable to get back up the stairway.

The rest of the workers on the 9th floor learned of the fire when flames leaped through the windows. About 150 people raced for the Green Street exit, and more than 100 of them made it down to the sidewalk. Others ran to the Washington Place exit, but it was locked. Some rushed for the fire escape. Jammed with people and hot from the fire, the fire escape pulled away from the building and partially collapsed, sending bodies flying to the courtyard below.

Many workers, including those who found the Washington Place exit locked, congregated at the elevators and summoned them. However, the elevators were already packed with people from the 8th and 10th floors. Some of the workers jumped or were pushed into the elevator shafts. A few slid down the cables, some landing on the roofs of the elevators.

To escape the searing heat and suffocating smoke, many of the workers climbed out to the window ledge and jumped to their deaths. The impact of their bodies was so great that it not only broke the fire department nets, but also smashed holes in the concrete and glass pavement.

The fire department arrived at the scene early but could do little except cool the exterior of the building. Its equipment was good for fighting fires only up to seven stories. In total, about 147 people died in the Triangle Shirtwaist fire.

Move for Reform

The Asch Building was a fire trap, but it was not the worst one in the city. In 1910, a public agency investigated conditions in 1243 coat and suit shops. Nine days before the Triangle Shirtwaist fire, a local New York City newspaper published excerpts from the agency's report. The report stated that 99 percent of the shops were deficient in safety. Many had only one exit, many others had locked doors during the workday, and 94 percent had doors that opened inward rather than outward.

Whether that report by itself would have generated remedial action is open to question. The dismal record of previous attempts by unions and others to mobilize action indicates that improvements would not likely have been made. The Triangle Shirtwaist fire, however, illustrated more than a report ever could the dangers lurking in lofts and other types of buildings.

In fact, the Triangle Shirtwaist fire aroused the nation and eventually revolutionized an industry. Unions, particularly the garment workers' union, intensified their activities to bring about improvements

in working conditions for their members. Citizens of all economic classes in New York City banded together to work for safer factories, and politicians passed new laws to protect workers.

Almost immediately after the fire, New York City residents formed the Committee on Safety. Among its members was Frances Perkins, who later became U.S. Secretary of Labor. The chairman was Henry Stimson, who soon left that position to become Secretary of War. He was succeeded as chairman by Henry Morgenthau. The committee became a focus for efforts to pass laws mandating improvements in factories and other buildings.

In June 1911, New York Governor John Alden Dix created the New York State Factory Investigating Commission to look into conditions in all factories and allocated the commission a \$10,000 budget. Chairman of the commission was Robert Wagner, Sr., then a state senator. Samuel Gompers was also on the commission.

In October of the same year, the Sullivan-Hoey Law was passed, which established the New York City Fire Prevention Bureau, the first in the country, and expanded the powers of the fire commissioner.

NFPA Broadens Its Focus to Include Life Safety. NFPA members were shocked but not surprised by the fire. For years, they had warned of many of the dangers present in buildings like the Asch Building. In particular, they had warned about the problems of fire escapes. The April 1911 *NFPA Quarterly* stated that it had long been recognized that fire escapes were a "delusion." For a quarter of a century, it continued, fire escapes had "contributed the principal element of tragedy to all fires where panic resulted. Iron is quickly heated and expansion of the bolts, stays, and fastenings soon pulls the frame loose so that the weight of a single body may precipitate it into a street or alley."

At the NFPA Annual Meeting in May 1911, R. H. Newbern presented a paper on private fire departments and fire drills and referred to the value of drills in educating factory workers in procedures that help avoid panic and promote survival. A year later, Mr. Newbern's recommendations were published in a pamphlet titled "Exit Drills in Factories, Schools, Department Stores, and Theatres." This was the first safety-to-life publication produced by NFPA. However, there was still no specific NFPA committee devoted exclusively to life safety.

Formation of the Safety to Life Committee. At the 1913 NFPA Annual Meeting, President H. L. Phillips suggested to members that they could include "a

section or committee having for its object the consideration of safety of life against accidents of every description." Later during that meeting, members listened to a speech titled "The Social and Human Cost of Fire" by Frances Perkins of the New York Committee on Safety. She urged them to study hazardous industries, publish the results, and publish rules that would make people in factories safe.

Perkins had witnessed the Triangle Shirtwaist fire. She saw workers leap from the ninth floor to the street below, and she was horrified. She told NFPA members that when she counted the social, human, and economic cost of that fire, she found it was enormous. "We lost not only those workers in the Triangle Shirtwaist fire," she said, "we lost their valuable services to society as economic factors. . . . It is because that social and human loss is to the entire community that this problem of fire deserves the closest attention of all people who are interested in the general progress and welfare of humanity. . . . Nothing is so important as human health and happiness . . . and if it costs dollars and cents to procure . . . then we must pay . . . and if it reduces profits we must reduce those profits. . . . You who are more or less technical . . . must help us by giving . . . the correct information . . . which we will be only too glad to use."

On June 23, 1913, NFPA's Executive Committee formed the Committee on Safety to Life and left it to this new committee to suggest the scope of its work. The July 1913 *Quarterly* stated that the formation of the committee was "the crystalization of a latent feeling which has for some time existed in the membership" for focusing attention on life safety.

The new committee, headed by H. W. Forster, spent the first few years studying fires involving loss of life and attempting to analyze the cause of that loss of life. At the 1914 Annual Meeting, the committee delivered its first report, which included a special section on egress, a statement that sprinklers can save lives, and preliminary specifications for outside fire escapes.

The committee said its studies showed that existing laws "are exceedingly deficient in this very important matter of egress. A number of states report frankly that they have no real legislation upon the subject."

The preliminary specifications for outside fire escapes were controversial and received a great deal of attention from the membership. The committee members did not like outside fire escapes, and many felt they were a delusion, as stated in the 1911 *Quarterly*. Nevertheless, the committee felt they had to face the fact that fire escapes existed and would be used.

"Admitting . . . that a fire escape on a building is usually an admission that life is not safe in it, the fact remains that the outside fire escape is the commonest special provision for escape . . . [and] this Association should determine upon proper precautions for such escapes, and use its influence to have them adopted and enforced," the committee wrote.

At the 1915 Annual Meeting, the NFPA adopted revised specifications for fire escapes. In 1916, the committee's work was published in a pamphlet, "Outside Stairs for Fire Exits." In 1918, another committee report was published in a pamphlet titled "Safeguarding Factory Workers from Fire." The pamphlets were widely circulated, put into general use, and, with other documents, form the basis of the present *Life Safety Code*.

In 1921, the Committee on Safety to Life was enlarged to include representation from interested groups not previously participating in its work. Work was started on the further development and integration of previous committee publications to provide a comprehensive guide to exits and related features of life safety from fires in all classes of occupancy. This work resulted in the publication in 1927 of the first edition of NFPA's *Building Exits Code*.

COCOANUT GROVE FIRE

As anyone involved in any safety endeavor will attest, it often takes a tragedy to alert society to dangers that must be addressed. The Triangle Shirtwaist fire moved the nation toward the prevention of many fire hazards. However, as time passes, the public forgets the lessons it learned and is forced to learn them once again through another tragedy. Thirty-one years after the Triangle Shirtwaist fire, in which locked exits trapped and doomed many workers, the United States witnessed another major fire in a building with locked exits.

The fire occurred in 1942 at the Coconut Grove, one of the most popular night clubs in Boston. It was a one-story-and-basement structure built in 1916. The original property was of reinforced concrete construction. Several additions had been made to the building, and a rolling roof had been installed over the dance floor.

State of Fire Protection: 1911 to 1942

There are many differences between the fires at the Triangle Shirtwaist Company and the Coconut Grove. One building was a high-rise factory, and the other was a single-story nightclub. The biggest difference lies in the state of the art of fire protection at

the time. In 1911, when the Triangle Shirtwaist fire erupted, there were no universally recognized standards for exits. In 1942, when the Cocoanut Grove burned, those standards existed and were part of NFPA's *Building Exits Code*. Evidently, they were ignored. As a result, 492 people died.

Virtually all the hazards at the Cocoanut Grove were covered by the 1942 edition of the *Building Exits Code*. The main problems appear to have been the chaotic condition of Boston's building regulations and lax enforcement.

As the *Christian Science Monitor* said in an editorial after the fire, "action will be taken to prevent another Cocoanut Grove, and somebody could have taken action to prevent this one."

The late Robert S. Moulton, long-time NFPA Technical Secretary and Secretary to the Committee on Safety to Life, wrote a report on the fire that was widely circulated. Much of the information that follows comes from that report.

Fire Hazards in the Popular Night Spot

In 1942, the Broadway Cocktail Lounge was added to the Cocoanut Grove night club. The lounge was installed in a group of old brick-joisted buildings varying in height from two stories to three and one-half stories and was connected to the main property by a passageway and doorways leading to dressing rooms for entertainers.

The basement of the original structure contained the Melody Lounge, another cocktail area. The Melody Lounge had false walls made of light wooden frame covered with light wallboard. Decorations in the lounge included colorful fabrics, artificial leather on the walls, and cloth on the ceiling. In addition, there were imitation coconut palm trees in the lounge and in the main dining/dancing hall. Light fixtures were made from coconut shells, with the wiring concealed in the "foliage." These decorations had reportedly been flame-proofed.

No Easy Way Out. There was only one obvious exit from the Melody Lounge. It was a door at the top of the stairway that led to a narrow hallway on the first floor, then to a foyer and the main entrance. Another door, leading to an outside alley, was concealed behind the false walls of the lounge. It was locked. A door leading to the street from the narrow hallway at the head of the stairs to the Melody Lounge was equipped with panic hardware. This door was locked, however.

According to writer Paul Benzaquin in his book, *Holocaust* (Henry Holt and Company, 1959), there was also a passageway from the Melody Lounge to the

kitchen, but it seems that only employees knew of this passageway. That door was painted and draped and unlikely to be seen by those who didn't know it was there. Nevertheless, it was counted as an exit by the city's fire commissioner in his post-fire report.

Many other doors were locked as well, and some opened inward. Many of the windows were obscured by the false walls, and the main doorway of the Cocoanut Grove was blocked by a revolving door.

A Capacity Crowd That Kept Getting Bigger. The official seating capacity of the nightclub was about 600 persons. No one knows exactly how many patrons were there the night of November 28, but unofficial estimates indicate that there were about 1000 people. Benzaquin reports that waiters were setting up more tables to accommodate additional patrons.

Overcrowding was not (and probably is still not) unusual in nightclubs. They are businesses established to make a profit, and the more patrons served, the greater the profit. Moulton said he was told the club was often congested, particularly on Saturday evenings.

According to Benzaquin, the club's application for a new license requested permission to install an additional 30 fixed stools for the new cocktail lounge. He writes that the stools were installed *before* permission was granted, on the assumption that there would be no objection.

That was probably a reasonable assumption. A member of the city's licensing board testified at the fire commissioner's hearing that the Cocoanut Grove got its original license and several renewals without any hearings to determine whether it complied with regulations.

The 12-Minute Fire. Benzaquin states in his book that the fire lasted about 12 minutes. It started in the Melody Lounge and was possibly ignited accidentally by a match held by a bus boy who was replacing a light bulb in one of the fake palm trees. As Moulton reported, however, the exact source of ignition was of less importance than the inadequacy of the exits and the extensive use of combustible decorations.

According to the fire commissioner's report, the fire immediately spread throughout the Melody Lounge along the underside of the false ceiling. Feeding on the combustible decorations, the fire reached and ascended the stairway and passed through the connecting passageway into the foyer, past the main entrance, and into the dining room and other areas of the club.

When the fire began to spread rapidly, panic ensued. Most of the patrons in the Melody Lounge raced

for the stairway, their only obvious exit. Many died on those stairs. Those who escaped the basement lounge through the stairway piled up in the corridor while attempting to reach the main entrance. If the door from that corridor to the outside had been unlocked, many might have been saved.

Led by a few quick-thinking employees, a few patrons made their escape from the lounge by going through the concealed door to the kitchen area, and some of them escaped through a door to an alley outside. Others tried to get to the main floor but could not because of the heat. A few escaped through a basement window into a courtyard, and a few others survived the fire by seeking refuge in a large refrigerator.

Moulton wrote that about 100 people died at the Broadway entrance to the club, more than 190 ft from the stairway leading from the Melody Lounge, where the fire started. He reported that about 200 were trapped behind the revolving door at the main entrance. That revolving door, which under the best of conditions would slow exit travel, jammed and blocked the exit.

Lessons Learned

There were few “new” lessons to be learned from the Cocoanut Grove fire. Even before the Triangle Shirtwaist fire in 1911, the danger of locked, blocked, and concealed exits was known. The NFPA had publicized its views on exits and means of egress in pamphlet form after the Triangle Shirtwaist fire.

The 1942 *Building Exits Code* prohibited revolving doors as exits in places of assembly and required that other occupancies that used revolving doors must have swinging doors immediately adjacent or within 20 ft.

That same edition of the *Code* required that “decorations of theatres and assembly halls shall be of fire resistive or nonflammable materials. Fabrics and papers used for such purposes shall be treated with an effective flame-proofing material.” A cautionary note warned, “Paper and cloth decorative materials should be kept to a minimum in places of assembly since such flimsy materials increase the hazard of the kindling and spread of fire.”

The decorative materials in the Cocoanut Grove were supposedly flameproofed, but, if this were true, the flameproofing was ineffective. The fire did demonstrate, once again, that “fireproof” buildings, which was the status of the Cocoanut Grove when first erected, can still be death traps due to their contents. It also proved that fire inspections should be conducted when facilities are in operation. Ac-

ording to Moulton, the Boston building inspector reported that he had inspected the building and found the exits adequate. This might have been true when the building was not crowded with 1000 people and the doors were unlocked.

“There is a real danger in attempting to remedy conditions such as were responsible for the Cocoanut Grove tragedy by the enactment of more laws,” wrote Moulton. “In our opinion, building and fire officials can now do practically everything that is necessary to assure public safety from fire without any more laws.”

Six months after the fire, at the 1943 NFPA Annual Meeting, Moulton reported to the membership that, due to the war, the Safety to Life Committee had been unable to meet. The committee members did exchange correspondence, however, and Moulton said they believed “our existing recommendations, that date back to 1913, are adequate.”

Code Changes. There was one change involving the *Building Exits Code* that did come about immediately after and as a direct result of the Cocoanut Grove fire: The *Code* was adopted by many more jurisdictions across the country, due in large part to the efforts of the fire service. The Committee on Safety to Life reported on that increased usage at the 1945 NFPA Annual Meeting.

It was during the 1945 NFPA Annual Meeting that the Committee recommended a change in the method of exit measurement, clarification of the need for stairway enclosure, provisions covering loose chairs in nightclubs, and changes in lighting and signs. Those changes were incorporated into the 1946 edition of the *Code*, as was a special note on interior finish.

Interior Finish. While combustible decorations were a factor in the Cocoanut Grove fire, interior finish was becoming more and more of a fire problem in the 1940s. In 1946, the nation witnessed the LaSalle and Winecoff hotel fires. The latter, with 119 fatalities, was the largest multiple-death hotel fire up to that time during the twentieth century.

The Committee on Safety to Life was concerned about the dangers of combustible interior finish. Therefore, it recommended, and the full membership approved, a caution in the 1946 *Code*, which stated that “where interior finish materials are used having a higher combustibility, greater rate of fire spread, or potentialities of greater generation of smoke or fumes than wood, the exits specified in the *Code* may not be sufficient to provide adequate life safety from fire.”

The lack of a standard way to measure the combustibility of interior finish hampered the committee. In the July 1943 *Quarterly*, A. J. Steiner of Underwriters Laboratories described a new method he was developing to test the combustibility of interior finish. The Steiner Tunnel Test was recommended for adoption at the 1953 NFPA Annual Meeting by the NFPA Building Construction Committee. It was eventually incorporated into the *Building Exits Code*.

OUR LADY OF ANGELS SCHOOL FIRE

Combustible interior finish was one of the factors that led to fire spread at the Our Lady of Angels School in Chicago in December 1958. Wood trim in one corridor and combustible ceiling tile in classrooms in one wing (and perhaps in other areas of the building) provided fuel for this fire.

Avoidable Problem

The primary cause of loss of life, according to the NFPA investigative report of the fire, was *the inadequacy of the exit facilities*. As a result of this completely avoidable problem, 90 pupils and 3 nuns died.

Adequacy of exits, as determined by proper enclosure, provision of at least two exits remote from each other, and sufficient exit capacity, were well-established fundamentals of fire protection by 1958. The Triangle Shirtwaist fire, the Coconut Grove fire, and hundreds of other fires had demonstrated the consequences of exits that were neglected. The 1958 edition of the *Building Exits Code* specified exact requirements for adequate exits and for other elements of school fire safety.

Chester I. Babcock, then manager of the NFPA fire records department, and Rex Wilson, then an NFPA engineer and currently a consultant, investigated the fire for the NFPA. A year later, Babcock wrote, "We know now and have known since before most of today's schools were built how to design and protect a school so that the lives of the pupils and teachers will be safe from fire. Refinements and improvements are needed and undoubtedly will come, but this does not mean that fire protection engineering has been groping for an answer. Practical methods of assuring life safety from fire that have stood the test of time and are based on sound fire protection engineering principles have been available for years."

One Fire Area. In 1953, the two-story school building was connected to another old, two-story, brick, wood-joisted building by a two-story, brick-joisted annex. The NFPA report of the fire stated that the building

constituted one fire area, due to open stairways and the fact that the masonry division wall between the north wing and the annex had substandard doorway protection.

The stairways in the school were open except for two located in the front of the north wing. Those stairs were enclosed at the second-story level by substandard doors that were held open at the time of the fire. Because the three stairways from the second floor corridor of the north wing were connected through a common corridor, pupils in second-story classrooms, in effect, had no way out.

Origin of the Fire. About 2:25 p.m., one half-hour before school was normally dismissed, fire broke out in combustible materials at the bottom of the rear stairway of the north wing. Pupils from one of the second-floor classrooms had taken trash to the boiler room incinerator, as was their routine, returned to the classroom at 2:30 p.m., and reported that they had smelled smoke. Their teacher informed a teacher in a nearby room, who went to find the principal. When the principal could not be found, both teachers led their classes out of the building to the parish church. Smoke was already at head level in the second-floor corridor. Only after they had their classes settled in the church did one of the teachers run back to the school and operate the fire alarm signal.

The school's janitor noticed smoke and ran to the parish house to tell the housekeeper to call the fire department. Apparently, the housekeeper waited a few minutes before placing the call. The fire department reported that at about 2:42 p.m. it received the first of some 15 calls reporting the fire.

Hot fire gases and smoke billowed up the chimney-like stairwell and mushroomed through the second-story corridor. Eventually the hot gases and combustible interior finish in the corridor ignited. The heat broke the large glass transoms over the classroom doors, and the hot gases and flames entered the rooms.

Those Who Escaped and Those Who Did Not. As soon as the fire alarm rang, occupants of the first floor left the building by means of the five available stairways, according to the NFPA report. The evacuation of pupils in the second-floor annex and south wing was hampered by smoke that came through an open door in the division wall at that level. Either the janitor or a fire fighter closed the door.

Pupils in the second-floor north wing did not escape as easily. Their travel through the corridor to the stairways was blocked by heavy smoke and heat. Some jumped from their classroom windows. Others

were taken down fire department ladders. Many died in their classrooms, some at their desks.

Aftermath of the Fire

One immediate effect of the Our Lady of Angels fire was a public awakening to the hazards in the nation's schools. According to Babcock's follow-up report, within a year after the fire, hazardous conditions had been eliminated in thousands of schools across the country.

Throughout this country's history, major improvements in safety have been made after terrible fires. The Iroquois Theater fire brought about improvements in theater safety; the Triangle Shirtwaist fire brought about improvements in factories; the Coconut Grove fire resulted in improvements in nightclubs; and the LaSalle, Winecoff, MGM Grand, Stouffer's, and DuPont Plaza fires resulted in improvements in hotels.

In 1959, NFPA sampled more than 2000 fire departments to analyze the level of improvements made in school safety. Many had been made. Nearly every community had acted on such issues as frequent and improved exit drills, tighter control of waste disposal, inspections, and proper storage of combustible supplies. However, that same survey revealed that needed improvements had not been made in about 30,000 schools.

The NFPA conducted an informal telephone survey in 1978, 20 years after the fire. The consensus from that informal survey was that schools were safer. (Indeed, one respondent said they couldn't help but be safer than they were in 1958, when they were the "lousiest-constructed buildings in existence!") Unfortunately, they were not as safe as fire professionals had hoped. The passage of time and the growing concern with vandalism and security had blocked out the memories of the Our Lady of Angels tragedy.

LA School Fire Tests. The most publicized result of the fire was the fire test program conducted by the Los Angeles Fire Department. The tests, conducted in 1959 and 1960 under the direction of then Los Angeles Fire Marshal Raymond M. Hill, were designed to investigate methods of protecting multi-story, open-stairway school buildings. One of the conclusions drawn from the tests was that complete automatic sprinkler protection offered the best chance for escape.

The 1958 edition of the *Building Exits Code* provided for sprinklers in schools. The 1960 edition retained those provisions and totally reorganized the section of the *Code* covering educational occupancies. That edition classified schools as follows:

Group A: One-story buildings with exterior or interior access, or multistory buildings with access only by exterior balconies and outside stairs

Group B: Buildings of two stories or more with egress through corridors and interior stairways

Group C: Sprinklered buildings

Group D: Open-plan schools

Group E: Existing buildings

There were somewhat different requirements for each group.

A great deal of discussion took place among members of the Committee on Safety to Life in 1960 regarding whether they should recommend permitting open stairways in two-story sprinklered schools. The committee decided not to make this recommendation that year. The 1961 edition of the *Code*, however, did permit open stairs in sprinklered two-story schools. One reason for this decision was that committee members noted that, in two-story buildings, pupils constantly pass through the doors anyway.

In 1966, the year the *Building Exits Code* was reorganized and renamed the *Life Safety Code*, a provision was added that required all parts of school buildings below grade to be sprinklered. In addition, the allowable travel distance to the nearest exit was increased from 100 ft to 150 ft, under normal conditions, and up to 200 ft in sprinklered school buildings.

BEVERLY HILLS SUPPER CLUB FIRE

Those who study fires can't help but have a feeling of *déjà vu*. It seems that the same fire problems return to haunt us time and again. Inadequate means of egress, lack of employee preparedness and training, and a general noncompliance with proven provisions of the *Life Safety Code* were all factors in the Triangle, Coconut Grove, and Our Lady of Angels fires, as well as in countless others.

These problems were critical factors again on May 28, 1977, at the Beverly Hills Supper Club. In a fire at the club, a public assembly occupancy that billed itself as "The Showplace of the Nation," 164 people died. The NFPA conducted an in-depth investigation of the fire, and much of what follows was taken from the investigative report prepared by Richard L. Best.

Fire Conditions in the Showplace of the Nation

The Beverly Hills was a glamorous nightclub in Southgate, Kentucky, just outside Cincinnati, Ohio. Banquets, dinner dances, balls, floor shows, fashion shows, weddings, wedding receptions, and business

meetings were all held in the club's "18" function rooms.

The quotation marks around the number 18 represent the advertised number of function rooms. There were actually five main dining rooms, the large "Cabaret Room," a small function room called the "Zebra Room," and the main bar. Three of the large dining rooms could be subdivided into smaller rooms by the use of folding partitions.

There had been a wedding reception in the Zebra Room on the day of the fire. The wedding party had left at approximately 8 p.m. Performers were scheduled to entertain guests in the Cabaret Room around 8:30 p.m. There were an estimated 1200 to 1300 guests in the Cabaret Room, about triple the number that could be accommodated safely. Numerous patrons later said that tables were squeezed together and the narrow aisles were obstructed with chairs. There were about 2400 to 2800 patrons in the club altogether.

Delayed Notification. The fire was discovered by employees between 8:45 and 8:50 p.m. in the empty Zebra Room. It started in a concealed space, and the origin was presumed by investigators to have been electrical in nature.

Employees alerted the club's hostess, while other employees ran around looking for the management. Two managers tried to fight the fire with portable fire extinguishers. Busboys and waiters helped them, but their efforts were to no avail. One of the managers eventually ran to the hostess and told her to evacuate the patrons. By that time, it was about 9:00. Someone notified the fire department about a minute later.

As this general description of events indicates, about 15 minutes might have elapsed between discovery of the fire and notification of employees. That delay was a critical factor in evacuation efforts. Also, it seems that there was some degree of staff confusion regarding evacuation procedures, since employees had not been trained.

Once notification of patrons started, an interesting phenomenon took place. According to interviews conducted by the Kentucky State Police after the fire, waiters and waitresses instinctively took responsibility for the safety of the patrons they were serving. They went directly to those guests and to other guests in those rooms and told them to leave. They did not, however, necessarily take responsibility for guests they were not serving who were in different parts of the building.

The Cabaret Room was isolated from the rest of the club once the show was in progress. There were no waiters, waitresses, busboys, or hostesses traveling to and from the kitchen or standing in the service

halls between dining room seatings. This indicates that employees serving the Cabaret Room did not see other employees rushing around notifying patrons and the management of the fire, so they were totally unaware of the danger. However, one busboy, who had just left the Cabaret Room to work in another room, learned of the fire and decided to take action.

Quick Thinking. In a display of courage, calmness, and good sense, the busboy took upon himself the responsibility of evacuating patrons in the Cabaret Room. He was walking down one of the main corridors from the Cabaret Room to the Viennese Room when he learned of the fire. He looked toward the Zebra Room and saw smoke coming through the top edge of the closed doors. He quickly told a bartender to leave, then spun around and ran back to the Cabaret Room.

When he arrived there, he told the host to open the doors of the room. The host also moved the rope divider and reservations stand from the corridor and instructed people waiting in line to walk toward the Garden Room area in another part of the building.

The busboy then walked into the Cabaret Room, calmly climbed up onto the stage where a performance was taking place, took the microphone, and spoke to the guests in the room. This is what he told the post-fire investigators:

The first thing I did was . . . ask them to look at the exit sign . . . "I want you to all notice that exit sign and I want you to look at the other corner of the room and there will be another exit sign . . . I want the left side of my room to go out of the exit sign behind that I'm pointing to now . . . I want my right half of the room to go out of the other exit sign . . . There is a fire in the small room on the other side of the building . . . I don't think there is any reason to panic or rush . . . you should leave."

Although he later said that some people looked at him as if he were crazy, people did begin to leave. Of the 164 fatalities in the fire, most occurred in the Cabaret Room. There is no way of knowing how many more would have died if the busboy had not taken charge.

Once he was back in the hallway, the busboy saw smoke billowing toward him, so he went to an exit. "There were just three doors, and one was locked," he said. "I tried to bang it open with my shoulder [but] I couldn't."

The Human Factor. Post-fire interviews showed, not surprisingly, that people, in general, did not take the

fire threat too seriously at first. Much of the evacuation in the early stages of the fire was without difficulty, partly because people proceeded calmly and deliberately, some perhaps not even believing there was a serious fire in the making.

When heavy smoke and intense heat descended on patrons trying to leave the Cabaret Room, those people suddenly did realize the seriousness of the situation. Some began to rush and push, and some stumbled and fell, blocking exits with their bodies. One fire fighter reported seeing people stacked two and three high.

One bartender told of a young woman who had fallen near an exit. Other people fell on top of her. The bartender and one of his coworkers tried to pull her out, but they were unable to move her. "And there was a man that was on top," the bartender said. "He was a heavy guy and he was reaching up his arms and so I thought he was all right . . . the first thought was to get him off the top so you can do something with the bottom ones . . . I had him wrap his arms around my neck and I pushed up against this door as hard as I could . . . and I didn't have enough strength to lift him and he just looked at me and shook his head . . . there was nothing I could do."

Familiar Factors Contributed to Deaths

The rapid fire spread along the main corridor of the club, delay in notifying patrons in the Cabaret Room, insufficient exit capacity, and an excessive number of people in the Cabaret Room were all major factors that resulted in employees and guests having insufficient time to escape this fire. Virtually all of these factors were covered in the *Life Safety Code* in existence at that time. Some specific factors are examined below.

Construction. Previous editions of the *Code* defined Class A places of assembly as those having a capacity of 1000 people or more. The Beverly Hills Supper Club's total occupant load was 2375. Unprotected, noncombustible construction such as that of the Beverly Hills Supper Club was not permitted for Class A assembly occupancies. That construction was permitted for Class C occupancies, which were restricted to 300 people or less. (It is now permitted, but only if the building is fully sprinklered.)

Number of Exits. The number of exits, based on 100 persons per unit of exit width and on square footage, should have been 27.5 exit units. The actual number was 16.5. The second floor had no exits with components permitted by the *Code*. (The Melody Lounge

at the Cocoanut Grove was also overcrowded.) The Cabaret Room should have had four exits, since it was itself a Class A place of assembly. It had only three. (The Cocoanut Grove's Melody Lounge had only one obvious exit.) There was evidence of locked doors and chains and locks on panic hardware. (The same was true at the Cocoanut Grove.) Exits were not well marked. A door to the corridor, for example, appeared to be part of the wall paneling, and it was not marked as an exit. (The Cocoanut Grove's Melody Lounge had a door that was painted and draped and not likely to be seen by patrons. In addition, some windows were concealed by false walls.)

Obstructions. There was seating in the aisles in the Cabaret Room. Tables were placed too close together, and there were too many chairs and other items restricting the aisles. There also were chairs and tables stored on the platform outside the Viennese Room that led to steps to double doors. (Chairs and tables also blocked aisles at the Cocoanut Grove.)

Enclosures. Vertical openings should be enclosed. The curved stairway in the club's "Hallway of Mirrors" was neither enclosed nor protected.

Interior Finish. The 1976 *Code* required interior finish in all means of egress in all places of assembly to be Class A, that is, with a flame spread rating of 0–25. The interior finish in the Hallway of Mirrors and the main north–south corridor had a flame spread rating greater than 25. It is interesting to note how many of these factors were present in the Cocoanut Grove fire 35 years before.

Alarm Systems. One of the factors that made it difficult for patrons to escape was a delay in notification of the fire. An alarm system would have avoided that delay. The *Code* required alarm systems in all occupancies except storage facilities and places of assembly. Committee members had discussed the importance of alarm systems for a long time, but many felt an alarm system could cause panic. The Beverly Hills Supper Club fire demonstrated the need for an alarm system, however, and so the requirement was added for public assembly occupancies in the next edition of the *Code*, which was published in 1981. Still concerned with the potential for panic and aware of tests showing the value of voice alarms, the committee added an interesting note to its alarm requirements.

Manual pull stations were required to alert occupants. The pull stations send an alarm to a central office or other location on the property that is continuously staffed while the occupancy is in use. The

central office must have a way of then notifying occupants, either through a voice alarm over a public address system or a vocal fire alarm system. The alarm notification requirement was made retroactive to apply to new and existing buildings.

Sprinklers. Historically, the *Code* had required sprinklers in assembly occupancies used as exhibit halls. Cost was a perceived prohibitive factor in efforts to spread that requirement to other public assembly occupancies. After the Beverly Hills Supper Club fire, however, the committee said, in effect, that cost is important, but lives are more important.

The committee approached sprinkler requirements in the following two ways. Members reassessed construction requirements for all classes of assembly occupancies, consolidated them, and required sprinklers based on construction type and location of assembly occupancy within the building. It was decided that even fire-resistive buildings having four or more stories above the exit discharge should be sprinklered. These provisions applied to new buildings, and some were made retroactive for existing buildings.

In addition, every Class A and Class B occupancy was required to be sprinklered throughout. This requirement applied only to new construction. There were some exceptions, but none applied to facilities such as the Beverly Hills Supper Club.

Discussion of the value of sprinklering all places of assembly was ongoing after the Beverly Hills Supper Club fire. Numerous fires, including the Gulliver's Discotheque fire in New York and the Upstairs Lounge fire in New Orleans, both of which took place during the 1970s and involved a fire blocking a means of egress, highlighted similar problems and emphasized the need for sprinklers.

ONGOING CHALLENGE

The story of fire protection is one that continues. Fire protection professionals study history and conduct research to determine code requirements that are needed to protect lives. They continuously use their influence to ensure that those requirements are adopted and enforced. Unfortunately, it often takes a tragedy to bolster their efforts, and, even then, if action isn't taken immediately, people forget. Even

as this handbook goes to press, the *Code* is being revised through the tentative interim amendment process as a result of the February 2003 Station nightclub fire in West Warwick, Rhode Island, caused by illegal pyrotechnics, in which 100 people perished.

In Nevada, momentum toward tighter codes had slowed down a year after the 1980 MGM Grand fire. Subsequent fires brought back memories of that tragedy. Today, the Ballys Las Vegas (formerly the MGM) has installed about 30,000 sprinklers, 8000 loud speakers, and other fire protection equipment. In addition, the American Automobile Association (AAA) now includes fire protection among the factors it considers when rating hotels in its travel guides.

Sometimes fires demonstrate the wisdom of committee members. For example, the 1987 Dupont Plaza Hotel fire illustrated that the Committee on Safety to Life was correct in requiring corridors and lobbies to be separated from assembly areas by 1-hour walls, unless the building is sprinklered or 50 percent of the egress is independent of the lobby.

The Las Vegas Hilton fire in 1981, which resulted in 8 deaths, illustrated that committee members were correct in restricting carpeting on walls. That fire saw flames leap-frogging up the side of the building, entering windows, and spreading along carpeting on the walls and ceilings. The committee had been convinced of the dangers of carpeting on walls by fire tests sponsored by the carpeting industry, which had pushed for regulation of its own products.

It is always tempting to concentrate on the tragedies, because they are so obvious. However, there are positive results to consider even if they are not as well documented.

It is impossible to know the number of lives saved because vertical openings were enclosed, exits were adequate and unlocked, and alarm, detection, and sprinkler systems were in place, since fires in such buildings don't get out of hand.

The key, once requirements are put into codes and the codes are adopted, is enforcement. The challenge for everyone who reads this handbook is to make certain that the codes, which contain the accumulated fire protection knowledge of generations, are enforced. To paraphrase Frances Perkins' speech to the 1913 NFPA Annual Meeting, People are not always their own masters. "It is necessary for organizations like yours . . . to insist on safety for them." That is our job.

Fire Alarm Systems for *Life Safety Code* Users

Robert P. Schifiliti, P.E.

Editor's Note: This supplement is an introduction to fire alarm systems. It explains the various types of systems addressed by the Life Safety Code and describes their components in detail. In this supplement, the term 'fire alarm' is intended to include detection systems and systems that provide control functions, such as elevator recall, and alarm information or notification to occupants and emergency forces.

Robert P. Schifiliti is the founder of R.P. Schifiliti Associates, Inc., and is chair of the Technical Committee on Notification Appliances for Fire Alarm Systems. Mr. Schifiliti serves as one of several faculty for the NFPA Fire Alarm Workshop and is a licensed Fire Protection Engineer. He received his Master of Science in Fire Protection Engineering from Worcester Polytechnic Institute.

INTRODUCTION

This supplement starts with an overview that describes how NFPA codes and standards categorize the various types of fire detection and alarm systems. A section on fire signatures reviews the physical and environmental changes that take place during a fire that may be sensible or detectable. A review of fire detection devices emphasizes proper selection to meet fire safety goals and reduce the likelihood of false and nuisance alarms. The discussion of circuit types and allowable wiring methods includes references to other NFPA codes and standards. The signaling section describes the goals and methods for both occupant notification and off-premises signaling for staff and emergency forces notification. A review of testing and maintenance needs for fire detection and signaling systems provides the reader with an understanding of how to extend a system's life, reduce nuisance alarms, and ensure system operation during a fire emergency. This supplement also contains comments on modeling the performance of fire detection and occupant notification. This supplement does not discuss specific requirements and designs for various

occupancies. The occupancy chapters of the *Life Safety Code* should be consulted for specific requirements. The additional commentary contained in other chapters of this handbook provides a good explanation of the requirements and the philosophy behind their intent. This supplement provides an introduction to the operation of required devices and systems. Designers, owners, installers, and inspectors will find useful information to assist them in choosing among options not specifically addressed within the *Code*. For example, a choice might need to be made between using photoelectric or ionization smoke detectors, or information might be required on how to reduce the likelihood of false and nuisance alarms.

OVERVIEW OF FIRE ALARM SYSTEMS

Four principal types of fire alarm systems are required or recommended by various chapters of the *Life Safety Code*:

- (1) Smoke alarms or household fire alarm equipment
- (2) Manual fire alarm systems

- (3) Automatic fire alarm systems
- (4) Supervisory systems for extinguishing systems or other fire or building systems

Each of these categories can be viewed as consisting of three components, as shown in Exhibit S2.1. Detection and initiating devices are either manual or automatic, as shown in the figure, and are referred to as input devices. Manual initiating devices, such as manual fire alarm boxes, are operated by people and, in turn, signal the control system. Automatic detection devices sense a change in the environment or equipment that is monitored and signal the control portion of the system. The control or processing section receives the incoming signals and initiates output signals. The control system can also supply power and supervise the system’s various components and circuits and provide output signals when a fault occurs or maintenance is needed. The control or processor interfaces with people and other systems through output signals.

The simplest form of system described in Exhibit S2.1 is a self-contained smoke alarm. It contains a smoke sensor and a control system that includes a power source and a notification system, usually a horn, used for occupant notification. In more complex systems, initiating devices and notification appli-

ances are separate, self-contained units connected to a control panel by electrical circuits or radio waves. In these component systems, power is usually provided to the input and output devices through the control unit. However, it is also possible for power to be provided directly to those units that require it. Each of these three principal components (input, control, and output) is discussed in more detail in later sections of this supplement.

Where appropriate, each occupancy chapter of the *Life Safety Code* specifies fire alarm requirements, including subsections that provide the requirements for initiation and notification. Where initiation is addressed, the occupancy chapter might refer to either a complete system or a partial system. In addition, the system will be described as manual, automatic, or both. Chapter 9, Building Service and Fire Protection Equipment, defines complete, partial, manual, and automatic systems. Where automatic detection is required, most chapters of the *Code* specify either partial or complete smoke detection. If an automatic fire detection system is required but the type of detection is not specified, any automatic units that comply with *NFPA 72*,[®] *National Fire Alarm Code*^{®1}, are permitted to be used interchangeably. An occupancy chapter might also require separate smoke detection within dwelling units in addition to any required partial or complete system for the public or tenantless sections of the building.

Household fire alarm equipment is intended for use within dwelling units such as apartments, hotel rooms, dormitory rooms, lodging or rooming houses, and one- and two-family dwellings. These devices or systems are intended to detect smoke conditions and alert the occupants of the dwelling units or guest rooms. In occupancies such as hotels, apartment buildings, and dormitories, these devices are not intended to be connected to the overall building fire alarm system.

Within the dwelling unit, household fire alarm equipment might be self-contained smoke alarms, or it might be a small system with detectors, a control panel, and notification appliances such as bells, horns, or strobe lights. The building system can consist of manual and automatic initiating devices, extinguishing system supervisory devices, and notification appliances that are all connected to a control unit. Therefore, there are two categories of fire alarm: one that is located within the family dwelling unit and one that is intended to protect the entire building.

In some cases, an occupancy chapter of the *Code* might require a partial automatic detection system that covers all common spaces. In addition, household fire alarm equipment might be required in

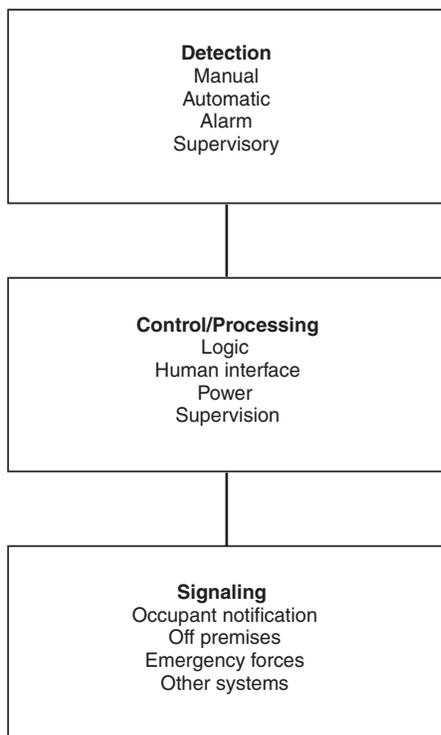

Exhibit S2.1 Overview of components of fire alarm systems.

dwelling units. For purposes of occupant notification, the building system would cover all occupiable spaces, including the dwelling units. The household equipment is required to signal only within the dwelling unit. Some building fire alarm systems are capable of having system-connected smoke detectors in the dwelling units programmed to operate like smoke alarms. In this configuration, they receive power, including backup power, from the building system and are monitored for faults and sensitivity. When they alarm, these systems provide an alarm signal (audible, visible, or both) only in the dwelling unit. They can also send a supervisory signal to an attended location.

In other cases, a complete automatic detection system might be required in addition to the requirements for the dwelling unit. The building system must then provide detection within all spaces, including the dwelling units. This detection for the dwelling units is not redundant. The intent is for the household fire alarm equipment to provide an alarm of smoke conditions to the occupants of the dwelling unit. The additional detectors connected to the building system would be heat detectors, which would notify the other occupants before a fire in the dwelling unit became a threat to those outside the dwelling unit.

NFPA 72, National Fire Alarm Code, addresses the application, installation, performance, and maintenance of fire alarm systems and their components. The 2002 edition of *NFPA 72* was completely rewritten and reorganized as follows:

- Chapter 1, Administration
- Chapter 2, Referenced Publications
- Chapter 3, Definitions
- Chapter 4, Fundamentals of Fire Alarm Systems
- Chapter 5, Initiating Devices
- Chapter 6, Protected Premises Fire Alarm Systems
- Chapter 7, Notification Appliances for Fire Alarm Systems
- Chapter 8, Supervising Station Fire Alarm Systems
- Chapter 9, Public Fire Alarm Reporting Systems
- Chapter 10, Inspection, Testing, and Maintenance
- Chapter 11, Single- and Multiple-Station Alarms and Household Fire Alarm Systems

Similar to this handbook, the *National Fire Alarm Code Handbook*² contains the text of *NFPA 72* along with explanatory information. The *National Fire Alarm Code Handbook*, by Lee Richardson and Wayne D. Moore,

P.E., is a good source of background information on the *National Fire Alarm Code*.

FIRE SIGNATURES

Fire signatures are changes in the normal environment caused by a fire. An understanding of fire signatures is important because it affects the choice of fire detector for a given area. The objective is to choose a fire detector that will respond to an expected fire signature without responding to similar signatures that might normally be present in the area. At the same time, the response time of the detector in reaction to the range of expected fires must meet the fire safety goals and objectives of the system.

Fire signatures can be placed in two categories, as shown in Exhibit S2.2. The first group is categorized by the energy produced by the fire, which is transferred in three ways—conduction, convection, and radiation. The second signature group is categorized by the physical/chemical changes that take place. This group is composed of solids, liquids, and gases produced by the fire. The solid and liquid particles are grouped together and called smoke or aerosols.

Conduction occurs when, during the combustion process, some of the energy released is conducted through the fuel to further the combustion process. Any time the temperature of one part of a material differs from another part, heat energy is conducted from the hotter portion to the cooler portion.

Convection occurs when heat is transferred by fluid motion. During combustion, hot fire gases rise, entraining fresh air, which then heats and also rises until the mixture either collects at the ceiling or cools

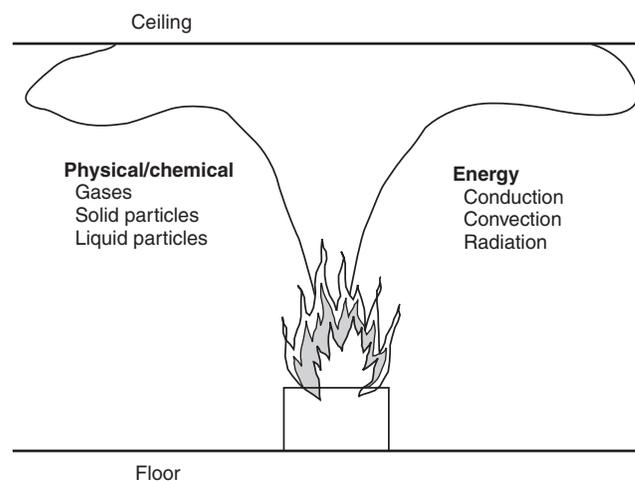

Exhibit S2.2 Fire signatures.

to approximately room temperature. The energy carried away by the hot gases is referred to as convected energy.

Electromagnetic radiation is the third mode of energy transfer that occurs during the combustion process. Thermal radiation is one form of electromagnetic radiation and is proportional to an object's temperature. Light is another form of electromagnetic radiation produced during the combustion process. Unlike conduction and convection, a solid, liquid, or gaseous material is not needed to transfer energy by radiation. Electromagnetic radiation can travel through a vacuum such as space. Radiation travels in all directions and in straight lines. Thermal radiation behaves in the same way as visible light radiation; if you turn your back to it, you can't "see" it. Therefore, when you stand in front of a fire, your face is warmed by thermal radiation, but your back is not heated. You might, however, see or feel the effects of reflected radiation.

Smoke and gases are produced by all fires in varying quantities. Perfect combustion of most fuels (hydrocarbon-based) produces only carbon dioxide and water, in addition to the energy released. Other materials are produced when combustion is not 100 percent efficient. These materials include gases such as carbon monoxide and liquids and solids such as tar, carbon soot, and more complex hydrocarbon particles.

The solid and liquid particles, which together are called smoke, are produced in a wide range of sizes. Some are small and invisible to the human eye, while others are large and obscure our vision. Some particle sizes are produced in larger quantities than others. The color of the smoke also varies. Many of these factors depend on the fuel and also on the efficiency of the combustion process. For instance, well-ventilated, hot, flaming, efficient fires produce mostly small, invisible, grayish particles in large quantities. In comparison, inefficient, smoldering combustion produces mainly a smaller number of large black particles.

INITIATING DEVICES

Manual Fire Alarm Boxes

Manual fire alarm boxes are either coded or non-coded. Noncoded manual fire alarm boxes are the most common in use on new systems. When a non-coded fire alarm box is operated, a switch closes. All noncoded devices produce the same single bit of information—a switch closure. Therefore, if more than one switch is on a circuit, the circuit does not

know which switch operated. The exception is addressable, microprocessor-based systems that can "talk" to and recognize each device.

Coded manual fire alarm boxes house a mechanical code wheel that, when operated, turns and, through its teeth, taps out a coded signal on a circuit. These coded wheels are essentially automatic telegraph keys, and each box has a different code through which information is transmitted. This code might be transferred to a bell circuit to notify the occupants of a building as to which box has been operated.

Today's addressable systems act like the older manually coded systems. Because the control unit knows exactly which device has originated an alarm, it can generate unique alarm signals. The control unit can also activate or actuate a unique set of output functions, such as starting or stopping certain fans and closing some doors but not others.

Manual fire alarm boxes, coded or noncoded, can be single-action or double-action. When operating a single-action box, the hand is used to pull the station. When operating a double-action station, two actions are required—either the door is opened and the station is pulled or the glass is broken and a button is pushed. Double-action manual fire alarm boxes tend to reduce false alarms caused by accidental operation. They also reduce nuisance alarms to some degree.

Pull station protectors are clear plastic covers that are mounted over manual boxes to provide protection from weather, dust, dirt, and mechanical damage. They also serve to convert a single-action station into a double-action station. When these covers are placed over a double-action station, three actions are required to initiate an alarm signal—the protector must be lifted, the cover must be opened, and the box must be pulled.

Some versions of pull station protectors are available with an internal battery-operated buzzer. This feature has been shown to greatly reduce nuisance alarms in schools, shopping centers, and other public areas. When the cover is lifted, the local buzzer sounds, which tends to scare away vandals before they can operate the station. In locations such as schools or other crowded public areas, someone is likely to see or catch a vandal before the station is operated. However, when the cover is removed and the local buzzer sounds, a person might think the building's fire alarm system has been initiated. For this reason, it is important that pull station protectors be labeled properly and that the usual occupants of the area be instructed in their use.

The *Life Safety Code* permits either single- or double-action manual fire alarm boxes. The use of pull station protectors is neither required nor restricted.

The choice for both is up to the designer, the owner, and the authority having jurisdiction.

Where an occupancy chapter of the *Life Safety Code* requires manual fire alarm boxes, Chapter 9 specifies the quantity and location. *NFPA 72* also contains requirements concerning the location and operation of manual fire alarm boxes. Essentially, manual fire alarm boxes are located at each required exit in the natural path of egress.

In a corridor with exits at each end, a manual fire alarm box is located at the door to each exit. The box should be located on the same side as the door handle so that it is easily seen by someone exiting from the space. In most cases, it is best to locate the box within the corridor, not on the other side of the door, so that the pull station is located within the space it serves. If a manual box were located on the other side of the door—for instance, in the stair tower—an occupant from the fifth floor might pull the box on the second floor, possibly slowing discovery of the fire's location.

In addition to locations at required exits, additional manual fire alarm boxes are required to ensure that there is less than a 60-m (200-ft) travel distance to a station. It is often good practice to provide manual fire alarm boxes near the telephone operator's area of a hotel or hospital and near portable extinguishers placed adjacent to hazardous operations in a factory. *NFPA 72* requires the mounting height of boxes to be between 1.1 m (3½ ft) and 1.37 m (4½ ft), although some locally adopted codes for the disabled might limit the height to no more than 1.2 m (4 ft).

Automatic Fire Detectors—General

Chapter 5 of *NFPA 72* classifies automatic fire detectors as either spot-type, line-type, or air-sampling detectors. Spot-type detectors include conventional smoke and heat detectors. A spot-type detector's response to a given fire varies with the radial distance from the detector—the farther the detector is from a fire, the slower its response time. To illustrate, if a circle is drawn and the detector placed in the center, a given fire anywhere along the perimeter of the circle would result in the same response time. If the same fire occurs closer to the detector at the center of the circle, the response time decreases; if it occurs farther away, outside the circle the same detector would have a longer response time. Engineers may adjust detector spacing to change the coverage radius and achieve shorter detection times for expected fires. Conversely, the spacing, hence radius, may be increased where longer response times are tolerable.

Projected beam smoke detectors and heat-sensitive cable are examples of line-type detectors. The

response time is about the same when a particular fire is burning anywhere directly under the line, except where close to the ends. As that same fire moves farther away to a position perpendicular to the line-type detector, response time increases. Similarly, response time anywhere along a line parallel to the line-type detector, except at the ends, would be about the same for a given fire.

Air-sampling detectors draw air samples from the protected area back to a remotely located detector. The tube or pipe might have several holes or sampling ports or it may have only one. In any case, *NFPA 72* treats the sampling port like a spot-type detector with respect to its location and spacing.

Spot- and line-type detectors can be restorable or nonrestorable. Restorable detectors reset themselves after the fire signature is no longer present, provided they are not severely exposed to a fire. For instance, some heat detectors absorb heat until they respond, and may then cool off until they return to their original state. Self-contained household smoke alarms automatically reset after the smoke has cleared from their chamber (a slight time delay is generally built into the detector to ensure a minimum ring time). Nonrestorable detectors are destroyed with use and must be replaced after exposure to the fire signature for which they were designed.

There are advantages and disadvantages to both restorable and nonrestorable detectors. Nonrestorable detectors generally provide a positive visual indication of operation, whereas a restorable detector might not have any visual cue that it is, or has been, in the alarm state. This is true of most heat detectors, but not smoke detectors, which have visual alarm indicators. Restorable heat detectors can also be provided with visual indicators, although this feature greatly increases the cost of a relatively inexpensive detector. One key advantage to restorable detectors is their ability to test the units with the same signature for which they are designed to respond. Most addressable heat detectors are restorable and include an indicator light on the unit.

Heat Detection

Three basic types of heat detectors are available commercially—fixed-temperature, rate-of-rise, and rate compensation detectors. The *Life Safety Code* allows any of these units to be used interchangeably wherever heat detection is utilized. Addressable, analog, thermistor-type heat detectors may exhibit a combination of conventional detector characteristics depending on how they are programmed by the manufacturer.

Heat detectors respond to hot smoke and fire gases—that is, to convected energy. Because it takes time for a heat detector to absorb heat, the air and fire gases surrounding a detector might be much hotter than the detector element. This response delay is called thermal lag. Thermal lag can be illustrated by imagining a fixed-temperature heat detector, such as a 74°C (165°F) sprinkler, that is dropped into a pan of boiling water. Although the water is 100°C (212°F), there is a time delay before the sprinkler link melts. The longer the delay, the greater the thermal lag. The smaller the mass of the link or detector element, the shorter the thermal lag. Thermal lag is a measure of detector sensitivity. The shorter the thermal lag, the greater the sensitivity of the unit.

Thermal lag enables a detector with a fixed temperature of 93°C (200°F) to respond to a fire more quickly than would a sprinkler with a fixed temperature of 74°C (165°F). It is only necessary to use a detector with a more sensitive element (shorter thermal lag) than the sprinkler. It is detector sensitivity that determines the number of detectors needed for a particular application.

There are several ways to measure detector sensitivity. The term *response time index* (RTI) is used to measure sprinkler sensitivity. The smaller the RTI, the more sensitive the unit. The RTI of a unit can be used in calculations to determine when that unit will respond to a given fire scenario. For heat detectors, the current measurement of sensitivity is the Underwriters Laboratories listed spacing or Factory Mutual approved spacing. The higher the spacing rating, the more sensitive the detector. For instance, a detector with a listed spacing of 15 m (50 ft) is more sensitive than one with a listed spacing of 9.1 m (30 ft). The listed spacing of a detector is determined by fire testing and cannot be used directly as part of any engineering calculations.

Where heat detectors are used, *NFPA 72*, Chapter 5, requires that they be spaced on smooth ceilings less than 3 m (10 ft) high, in accordance with their listed spacing. The installed spacing is equal to the listed or approved spacing. For ceilings higher than 3 m (10 ft), *NFPA 72* contains reduction factors to be applied to the listed spacing. Therefore, as ceiling height increases, the installed spacing becomes less than the listed spacing. Reduction factors for joisted, beamed, and sloped ceilings are also contained in *NFPA 72*. The beams or joists must be at least 100 mm (4 in.) deep before reductions are required for heat detectors. Each of these factors (high ceilings, ceilings that are not smooth, and so on) affects detector response. The reduction and correction factors contained in *NFPA 72* are intended to provide some

adjustments for these effects. *NFPA 72* should be referenced for a list of all the various correction factors. Spacing reductions are often missed by designers, installers, and inspectors; yet they can have a dramatic effect on detector response time during a fire.

Fixed-Temperature Detectors. A fixed-temperature heat detector responds when the temperature of its element reaches a preset level. To reduce the likelihood of false alarms, the temperature rating selected for an application should be at least 11°C (20°F) above the maximum expected ambient temperature. These detectors are available in a wide range of temperature ratings, the most common being 57°C to 60°C (135°F to 140°F) and 88°C to 93°C (190°F to 200°F). Fixed-temperature detectors are available as spot-type and as line-type.

Fixed-temperature heat detectors use several methods of operation. The two most common use a fusible or bi-metal element. Fusible elements melt at a preset temperature and are spring-loaded to close or open a set of electrical contacts. Bi-metal units use two or more metals that expand at different rates, causing the element to change shape and initiate operation of a set of electrical contacts. Line-type, fixed-temperature heat detectors generally operate either when insulation melts, allowing two conductors to short circuit, or when heat causes a decrease in electrical resistance and an increase in conductivity between two conductors.

NFPA 72, Chapter 5, contains basic, operational descriptions of these and other detection principles. For a more detailed discussion of the many different types of heat detectors available, consult the *NFPA Fire Protection Handbook*³ or the *Fire Alarm Signaling Systems Handbook*⁴.

Rate-of-Rise Detectors. A rate-of-rise heat detector responds when its temperature, or the temperature of the air surrounding it, rises faster than some preset rate—regardless of its actual fixed temperature. Units are available with various alarm rates, a common one being 8°C/min (15°F/min). The speed with which a detector responds depends on how hot the fire gases are compared to the detector's starting temperature and also on the detector's sensitivity. Therefore, if a rate-of-rise detector is initially monitoring a room temperature of 18°C (65°F) and a fire causes the temperature around the detector to rise quickly, it will respond in a given time. If the detector is in a freezer at -29°C (-20°F) and the temperature rises at the same rate, the response time would be about the same.

Depending on environmental conditions, detector sensitivity, and the fire growth rate, rate-of-rise

detectors can respond much faster than fixed-temperature units. In many situations, however, a rate-of-rise detector will not respond to a real fire, for example, a slowly developing fire. For this reason, testing laboratories, codes, and standards require these detectors to be supplemented with fixed-temperature elements.

As with fixed-temperature detectors, rate-of-rise heat detectors are available in many different configurations. The most common spot-type unit works on a pneumatic principle. As the detector is heated, air inside a chamber is heated and expands. The air escapes through a vent hole when heated slowly. However, when heated faster than its preset rate, the air cannot escape quickly enough, and pressure builds up in the detector. As the pressure increases, a diaphragm moves and activates a set of electrical contacts. Line-type, rate-of-rise detectors are also available using this pneumatic principle. Other rate-of-rise detectors use bi-metal elements or electrical conductivity to detect rapid temperature changes.

When using rate-of-rise heat detectors, it is important to ensure that they will not be subjected to changes in ambient conditions that might cause false alarms. For instance, they should not be located too close to air supply vents or directly over heat sources such as ovens, radiators, or large sinks, where hot steam might set them off. They can be used in high-temperature areas, but caution should be used in situations where the temperature might cool rapidly, then rise again quickly enough to set off the rate-of-rise units. In a large boiler house, for example, the temperature at the ceiling might be 38°C to 66°C (100°F to 150°F) under normal circumstances. As long as the fixed-temperature backup to the rate-of-rise detector is at least 77°C (170°F), there should be no false actuation. However, if a large door is opened in the winter, the temperature could drop quickly. When the door is closed, the temperature at the ceiling could rise fast enough to set off the rate-of-rise portion of the detector.

Rate Compensation Detectors. Rate compensation heat detectors are more complex in operation than either fixed-temperature or rate-of-rise devices. In short, they combine the principles of both in order to compensate for thermal lag. When the air temperature is rising at a rate of about 22°C/min (40°F/min) or less, the unit is designed to respond almost exactly at the point when the air temperature reaches the unit's rated fixed-temperature; it does not lag while it absorbs the heat and rises to that temperature. At faster rates of temperature rise, the unit responds more quickly than most fixed-temperature detectors,

even though some thermal lag does occur. In addition, with these very fast temperature rises, rate-of-rise detectors generally respond more quickly than either fixed-temperature or rate compensation detectors.

Because of the precision associated with their operation, rate compensation heat detectors are well suited for use in areas where thermal lag must be minimized to provide fast response when temperatures exceed a certain level. At the same time, they are stable even in areas where temperatures fluctuate but do not exceed the preset alarm level. Therefore, rate compensation detectors respond more quickly to most fires than do fixed-temperature detectors without producing false alarms due to moderate temperature fluctuations, which can occur with the use of rate-of-rise units. They are also suitable where precise temperature actuation is needed.

Smoke Detection

General. Four principal types of smoke detection equipment are currently on the market:

- (1) Spot-type ionization detectors
- (2) Spot-type, light-scattering, photoelectric detectors
- (3) Line-type, projected beam, light obscuration detectors
- (4) Air-sampling detectors

The *Life Safety Code* allows each of these types to be used interchangeably wherever smoke detection is required.

By definition and by design, smoke detectors respond to the solid and liquid aerosols produced by a fire. Each type responds differently to different types of smoke. Because they respond to aerosols from non-fire sources, an understanding of their operating characteristics is helpful in their correct selection and placement to reduce the chances of false and nuisance alarms. Therefore, selection of smoke detection equipment should be based on the type of fire and fuel expected, as well as on environmental characteristics.

At some point, the smoke detector transmits an alarm signal either by sounding an internal alarm or by signaling a control panel. With newer digital and analog/digital systems, the detector can send information on the amount of smoke in the chamber back to the control panel, where a decision is made to perform some function, such as sounding an alarm. Such units are often called "smart" or "intelligent" devices. Because they send all information back to a control panel or processor and do not make alarm

decisions, these units are often referred to as “sensors” rather than detectors. In the case of conventional detectors, a decision to alarm is made internally. The conventional detector then signals an alarm with either an internal audible or visual device or by signaling the control panel. Additional information on how conventional and digital smoke detectors signal a control panel is contained later in the subsection Wiring Methods.

Where required by an occupancy chapter of the *Life Safety Code*, household smoke detectors, often called single- or multiple-station smoke alarms, must be located and installed in accordance with *NFPA 72*, Chapter 11. The location and placement of required smoke detectors for protected premises systems is governed by *NFPA 72*, Chapter 5. Unless otherwise noted, all requirements and recommendations for smoke detector spacing contained in Chapter 5 apply equally to ionization or photoelectric spot-type smoke detectors, to projected beam detectors, and to the sampling ports or heads of a sampling-type system.

For general area coverage with smoke detectors, Chapter 5 of *NFPA 72* requires that spacing be based on manufacturer’s recommendations. Chapter 5 also recommends an installed spacing of 9.1 m (30 ft) between detectors. This recommendation applies to smooth, flat ceilings and is also in agreement with the recommendation of most manufacturers. Therefore, in many cases, the installed spacing is the manufacturer’s recommended spacing, which is usually 9.1 m (30 ft), center to center. There is no listed or approved spacing of smoke detectors as is provided for heat detectors. Also, there is no specific requirement for changing detector spacing, depending on the sensitivity of the unit.

Chapter 5 of *NFPA 72* requires detector spacing to be reduced for ceilings with beams or solid joists 100 mm (4 in.) deep or more. Spacing adjustment is also required when airflow in the space is greater than about 8 minutes per air change. The adjustment requirements for smoke detector spacing on beamed or joisted ceilings, sloped ceilings, and in the presence of high airflow are cumulative and very complex. *NFPA 72* should be consulted and studied in detail to determine the ultimate installed spacing requirement.

Unlike its provisions for heat detectors, Chapter 5 of *NFPA 72* does not contain specific spacing reductions for smoke detectors where ceiling height exceeds 3 m (10 ft). Instead, it advises on the use of the manufacturers’ recommendations and good engineering judgment. Other factors that must be considered are discussed later in the section Selection and Placement.

Spot-type smoke detector sensitivity is generally based on the percentage of light obscuration per foot required for the unit to signal an alarm. The alarm threshold can also be expressed in optical density per foot or per meter, which can be converted to obscuration per foot.

The *Life Safety Code* does not require that detectors have any minimum or maximum sensitivity, only that they comply with the *National Fire Alarm Code*. Neither of these documents contains any explicit requirements regarding detector sensitivity. *NFPA 72*, Chapter 5, only requires the detector to be tested and listed for its intended use. It is the listing laboratory, acceptable to the authority having jurisdiction, that determines the range of acceptable smoke detector sensitivity for a given application.

The *National Fire Alarm Code* requires detectors to be tested and listed. ANSI/UL 217, *Standard for Single and Multiple Station Smoke Detectors*⁵, and ANSI/UL 268, *Standard for Smoke Detectors for Fire Protective Signaling Systems*⁶, contain requirements for minimum and maximum detector sensitivity to gray smoke.

The range of possible sensitivities for spot-type detectors is generally between 1.0 and 4.0 percent per foot (0.3 m) of obscuration due to gray smoke. This range provides the designer of a smoke detection system some choice with regard to sensitivity. The importance of this is covered more under the heading Selection and Placement later in this supplement.

Ionization Detectors. Exhibit S2.3 shows a schematic diagram of an ionization smoke detector. Ionization smoke detectors have two parallel electrically charged plates separated by an air gap. A small, low-strength radioactive source causes the air between the plates to be ionized. Because of the voltage be-

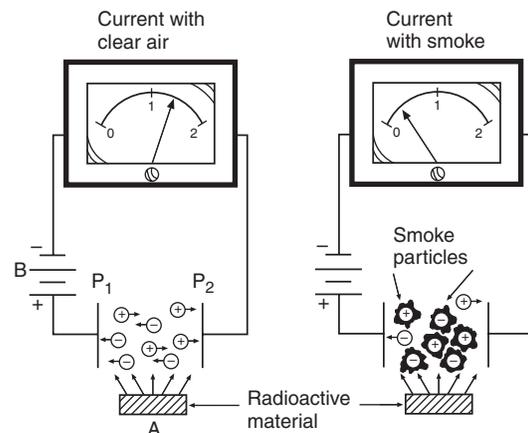

Exhibit S2.3 Ionization smoke detector.

tween the plates, the positive ions travel to the negative plate and the negative ions travel to the positive plate. This creates a small electrical current. As smoke particles enter the detector, they slow down the movement of the ionized air between the plates. The corresponding change in electrical current is measurable by the detector and is proportional to the number and size of the smoke particles between the plates. In the case of ionization smoke detectors, the strongest signal is obtained when there are a large number of small particles in the chamber.

Photoelectric Detectors. Exhibit S2.4 shows a schematic diagram of a photoelectric smoke detector. Spot-type photoelectric smoke detectors operate on the light-scattering principle. A small light source, usually an infrared LED, shines a beam into the detector chamber. A light-sensitive receiver is located so that it normally sees only a very small amount of light from the source reflected from the detector chamber. When smoke enters the detector chamber, additional light is scattered within the chamber, some of which reaches the photosensitive receiver and changes the detector signal. As with ionization detectors, the magnitude of the signal is related to the number and size of the smoke particles.

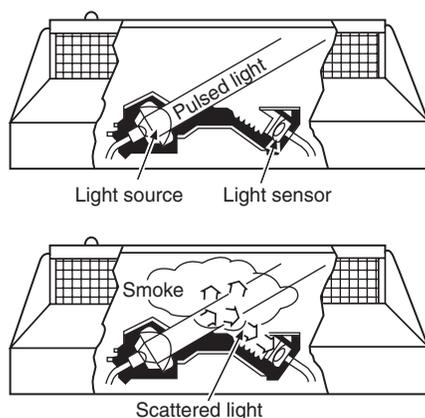

Exhibit S2.4 Photoelectric smoke detector.

Many other factors also affect the signal from a light-scattering smoke detector. The color of the smoke affects the amount of light that is scattered. Dark smoke, such as that from some plastics and hydrocarbon fuels, absorbs more light than it reflects. Light-colored particles reflect a lot of light, so smaller quantities can produce strong signals. Particle shape also affects the amount of light reflected or refracted, as does the wavelength of the light source and the angle between the source and receiver. However, in general, in the case of a particular scattering-type

photoelectric detector design, the strongest signal is obtained when large, light-colored smoke particles are in the chamber.

Projected Beam Detectors. Projected beam smoke detectors, as illustrated in Exhibit S2.5, operate on the light obscuration principle. These detectors consist of a source that projects a light beam across a space to a receiver. As smoke enters the beam path, some of the light is absorbed and some is scattered, reducing the total amount reaching the receiver. The color and shape of the smoke particles are not as important as for spot-type photoelectric detectors. In the case of projected beam smoke detectors, it is the size and quantity of smoke particles in the path that has the greatest effect on the detector's signal.

A projected beam smoke detector responds to the total amount of light obscuration in its path. When the percentage of light obscured reaches a given threshold, the unit sounds an alarm. Typically, the units are available with adjustable sensitivities between 20 and 70 percent total obscuration. If the light beam is suddenly and totally obscured, the unit should not alarm but should give a trouble signal after a short time period. In general, fires do not suddenly and totally obscure a light beam. Similarly, a very slow, gradual loss of light is also probably not indicative of a fire but is more likely an accumulation of dust or a misalignment of the beam. This situation should also produce a trouble signal, not an alarm signal.

Very large, fast developing fires, such as one resulting from a large spill of flammable liquid, can cause a rapid decrease in the signal received by a projected beam smoke detector. For this reason, the detector must have a setting that permits it to be set up to allow a fast blockage to cause an alarm signal rather than a trouble or supervisory signal. This setting should be used only where there is a real possibility of these types of fires.

Air-Sampling Detectors. Sampling-type smoke detection devices are designed to draw air samples from

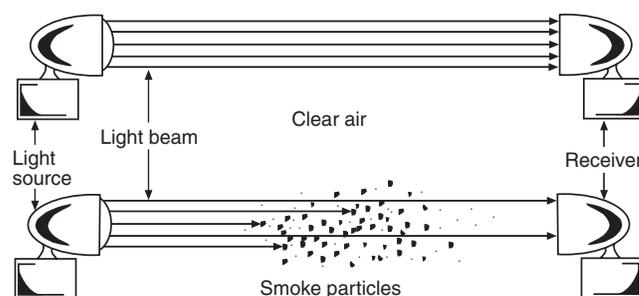

Exhibit S2.5 Projected beam smoke detector.

the protected space to a separate detection chamber. The sampling portion might consist of a combination of air pumps, filters, and tubing or piping fitted with sampling heads or perforated to draw room air samples. The detection device might be self-contained or might be part of, or served by, a control panel.

Air-sampling detectors should not be confused with duct smoke detectors. Sampling-type detectors use positive ventilation methods to draw air samples. Duct smoke detectors are usually spot-type photoelectric or ionization detectors in special housings. Duct smoke detectors might use a sampling tube that penetrates the duct to allow natural pressure differences to draw air into the detector housing.

There are two principal types of air-sampling smoke detection systems. One type uses a cloud chamber to detect very small particles in the air from the protected space. In a cloud chamber, humidity is added to the air sample, and the pressure is reduced to lower its temperature. This causes water to condense on small particles present in the sample. The resulting cloud is measured by an LED light source and a phototransistor light receiver. These units are extremely sensitive to very small (submicron) particles.

The second principal type of air-sampling smoke detection system uses a very sensitive photoelectric light-scattering detector. Unlike a spot-type, light-scattering smoke detector, this system uses a high-power strobe light or a laser beam rather than an infrared LED. When combined with a sensitive light receiver, the unit can detect submicron-sized particles in very small concentrations. Other sampling-type smoke detectors might use other detection principles such as an ionization chamber.

Other Detection Principles

Radiant Energy Detectors. Radiant energy detectors are often called flame detectors. However, the broader name, radiant energy detectors, includes units designed to sense smoldering and glowing ember combustion.

The radiant energy emitted during combustion of a fuel falls predominantly into three categories, distinguished by the wavelength of the radiation:

- (1) *Ultraviolet*: wavelength smaller than visible radiation (smaller than about 0.35 microns)
- (2) *Visible*: wavelength larger than ultraviolet radiation but smaller than infrared radiation (between about 0.35 microns and 0.75 microns)
- (3) *Infrared*: wavelength larger than visible radiation (more than about 0.75 microns)

The two most common wavelengths used by radiant energy detectors are the ultraviolet and infrared band widths. Except in very special applications, visible light comes from so many normal sources that it cannot be used effectively as a fire signature.

The application of radiant energy sensing detectors is beyond the scope of this supplement. The selection and use of flame and spark detectors is complex and requires thorough knowledge of fuel behavior, environmental conditions, and specific detector characteristics. Generally, these detectors are used in special applications such as in aircraft hangars and areas where flammable and combustible solids, liquids, and gases are handled, used, or conveyed. Subject to the approval of the authority having jurisdiction, these detectors can be used as part of an automatic fire detection system required by the *Life Safety Code* where a specific system, such as smoke detection, is not mentioned in the occupancy chapter.

Chapter 5 of *NFPA 72* contains descriptions of these radiant energy detection principles. For more detailed information on these detectors and their applications, consult the *Fire Protection Handbook*, the *Fire Alarm Signaling Systems Handbook*, and manufacturers' literature.

Other Fire Detectors. Chapter 5 of *NFPA 72* recognizes that there are, or might someday be, detectors suitable for use as automatic fire detectors other than those already discussed. As with any detector, their selection, application, and use are governed by their principle of operation, their testing and/or listing, if any, and their manufacturers' recommendations.

Any fire detector listed or approved for its specific intended purpose is permitted to be used where the *Life Safety Code* requires automatic fire detection but does not specify the type. The selection must be approved by the authority having jurisdiction.

Monitoring Other Fire Protection Systems

Fire detection and alarm systems can be interconnected to receive signals from other fire prevention and protection systems. These systems, which might be required by the *Life Safety Code*, include the following:

- (1) Sprinkler systems
- (2) Fire pumps
- (3) Other extinguishing systems (CO₂, water spray, dry chemical, wet chemical, foam, etc.)
- (4) Heating, ventilating, and air-conditioning systems
- (5) Smoke control systems

The signals received from systems or devices such as those already listed might be a fire alarm or a supervisory signal indicating the status of the system or device. Detailed descriptions of these systems are not possible in this brief introduction to detection and alarm signaling. However, some information on sprinklers, the most common of these systems, is warranted.

Where an occupancy chapter of the *Life Safety Code* requires an automatic sprinkler system, the requirement indicates whether the system must be supervised. Under Extinguishment Requirements, each specific occupancy chapter might also state that the system is required to be connected to the fire alarm system. Under Detection, Alarm, and Communications Systems of the same occupancy chapter, the section titled Initiation indicates whether alarm signals must be activated by the sprinkler system.

Where a supervised automatic sprinkler system is required, it must produce a distinct signal to indicate conditions that might impair its satisfactory operation. This requires monitoring of such features as the opening and closing of control valves and fire pump operation and water tank level. The supervisory signals must also terminate within the protected premises at a constantly attended location or in an approved remote receiving facility.

Chapter 7 of the *Life Safety Code* also requires waterflow alarm signals from required, supervised sprinkler systems to be transmitted to an approved auxiliary, remote station, proprietary, or central station facility. These systems are introduced later in this supplement in the section entitled Signaling. Where the occupancy chapter requires a sprinkler system to be monitored by and to produce an alarm on the protected premise system, *NFPA 72* contains requirements for its connection.

At the local protected premise, *NFPA 72* has specific definitions of *alarm*, *trouble*, and *supervisory signals*. Alarm signals indicate an emergency requiring immediate action. A supervisory signal indicates the need to initiate a specific action regarding some type of protective service or equipment, such as guard tour or extinguishing systems. For example, a closed-valve signal on a sprinkler system is a supervisory signal indicating the need to investigate the signal and take corrective action (that is, open the valve) when appropriate. A trouble signal, on the other hand, indicates a fault or problem with a protective signaling system. Trouble signals occur because of faults in the protective signaling system, and supervisory signals are signals initiated in conjunction with other systems or services.

The three different signals must be distinct from

one another. In the case of trouble and supervisory signals at the protected premise, they are permitted to have the same audible signal as long as they have separate and distinct visual signals. Therefore, it is clear that the old practice of wiring a valve tamper switch to open the waterflow alarm circuit and cause a trouble signal is not acceptable. The valve tamper switch would break the circuit just as a broken wire would. Both would result in a trouble condition at the control panel. Correct and incorrect methods for monitoring supervisory devices are addressed in the section on wiring.

Selection and Placement

Within the context of the *Life Safety Code*, some degree of decision-making is necessary concerning the type of detector to be used in a given situation. For instance, where the *Code* requires a supervised fire alarm system with initiation by smoke detection, it does not specify what type of smoke detection is permitted to be used. In such a case, the *Code* intends that life safety fire detection goals for this particular occupancy be met by smoke detection designed, installed, maintained, and tested in accordance with *NFPA 72*. The same is true for a required household fire alarm smoke detector in a dwelling unit. The opportunity to choose a smoke detection method allows design flexibility for performance and economy.

The majority of detectors used to meet the intent of this *Code* are spot-type ionization, spot-type photoelectric, or projected beam. Air-sampling smoke detectors are very sensitive and cost more than systems using spot- and beam-type detectors. Their use is generally limited to clean, high-value areas such as computer rooms and industrial clean rooms for manufacturing semiconductors. They have also found use in telecommunications facilities and power plant control rooms. Because of their cost and sensitivity, these detectors are not a common choice for meeting requirements of most chapters of the *Life Safety Code*, despite the fact that they are allowed. Design considerations for these systems are complex and beyond the scope of this supplement.

The first step in selecting a smoke detector is to consider the type of fire likely to occur in the area. Photoelectric or projected beam detectors would provide a faster response if the fire is likely to smolder for some time, because of the large particles produced during smoldering combustion. If the fire is most likely to be fast and hot with open flames, the larger quantity of small smoke particles it would set off an ionization smoke detector more quickly than it would either a photoelectric or projected beam detector.

The expected color of smoke should also be considered. Color is important to photoelectric light-scattering detectors but not to projected beam and ionization detectors. If black smoke is expected, projected beam or ionization detectors will give the best response. If the smoke is expected to be mostly large black particles, the ionization detector falls further down the list of choices. The projected beam detector would probably respond first, followed by either photoelectric or ionization detectors.

Ambient environmental conditions must also be considered when selecting a smoke detection method. Smoke detectors cannot be used where the temperature is above or below the manufacturer's stated range. This range is usually 0°C to 49°C (32°F to 120°F), although lower and higher temperature units might be found.

Cooking odors are blamed for a large number of nuisance alarms. The odors that are produced by cooking contain a large number of small invisible particles. A smoke detector's response to cooking odors is not a false alarm; it is a response to a valid fire signature. An ionization smoke detector would probably trigger a nuisance alarm in response to cooking odors, whereas a photoelectric smoke detector would probably not activate the alarm unless the food was well burnt and producing visible smoke. Therefore, unless the detector can be located far enough from the kitchen to avoid odors, the better choice is a photoelectric detector.

Steam from showers and large sinks contains lots of small water drops and has much the same effect as cooking odors in causing nuisance alarms from ionization smoke detectors. The heavier the steam, the more likely it is to also cause photoelectric smoke detectors to alarm. However, the highly reflective nature of small water droplets in steam may cause photoelectric detectors to alarm even at low levels. Detectors can often be located to avoid these sources of false fire signatures.

Insects can set off either type of spot smoke detector. They are not likely to cause an alarm from a projected beam smoke detector because of the small amount of light they obscure. Detectors with good bug screens stop most insects, but some still manage to get into the detector chamber. Ionization smoke detectors are less prone to nuisance alarms from insects than are spot-type photoelectric smoke detectors. Another solution that has been reported to be successful is to place an insecticide strip on or near the detector. The detector manufacturer should be consulted before taking this action. Some insecticides might produce enough fumes to set off ionization detectors or harm electronic components. An insecti-

cide should never be sprayed in or near a functioning detector. It would probably set off the alarm, as would any aerosol spray, and it could harm the detector.

Cigarette smoke causes nuisance alarms from ionization and photoelectric smoke detectors. When the smoke dissipates to a light cloud, the ionization detector is likely to alarm first. When the smoke is heavy and thick, either type will alarm. Often, detectors can be placed to avoid such conditions. For instance, in elevator lobbies, smoke detectors should not be placed directly in front of the doors where people stand and where drafts from the shaft might bring dust into contact with the detector. In office areas, smoke detectors should not be placed directly over a smoker's desk or too close to a break room or cafeteria room, where smokers might congregate or where cooking might take place. Incidental cigarette smoke is not likely to set off projected beam smoke detectors. As a smoker passes near the beam, a cloud of smoke 900 mm to 3 m (3 ft to 10 ft) wide might be produced, but it would not be dense enough to alarm the detector.

Detectors of the ionization or photoelectric type can be purchased with different sensitivities. Detector sensitivity is usually labeled on the detector and on its specification sheet. The sensitivity is typically between 1 percent and 4 percent per foot (0.3 m) obscuration. This is the amount of light obscuration measured immediately outside the detector when it alarms during tests with gray smoke. Comparing labels on photoelectric and ionization smoke detectors usually indicates the ionization unit to be more sensitive. Typically, ionization smoke detectors have labeled sensitivities on the order of 1 percent to 2 percent per foot (0.3 m). Photoelectric detectors range from 1 percent to 4 percent per foot (0.3 m). This does not mean that ionization detectors are always more sensitive than photoelectric detectors, only that they might be more sensitive to fires that produce smoke similar to the gray smoke used in the test. A true comparison of detector sensitivity must include consideration of the type of smoke expected, as discussed in the previous paragraphs and in the section on fire signatures.

Sensitivity comparison is made more difficult by the fact that the light obscuration measurement used by the listing laboratories to rate sensitivity is not comparable to the factors that actually set off either spot detector type. For photoelectric detectors, it is the light scattered, not the light obscured, that is important. For ionization units, it is the quantity and size of the particle. The amount of light obscured across a given distance is only partly related to these factors. The published numbers are useful only as a

relative comparison between detectors as they react to a given type of smoke. A photoelectric detector having an alarm threshold of 2 percent per foot (0.3 m) obscuration is more sensitive than one with a threshold of 3 percent per foot (0.3 m). Similarly, an ionization detector with an alarm threshold of 1 percent per foot (0.3 m) is more sensitive than one with a threshold of 2 percent per foot (0.3 m). However, one cannot say that a photoelectric detector with a 2 percent per foot (0.3 m) threshold is as sensitive as an ionization detector with a 2 percent per foot (0.3 m) threshold. It might be equally sensitive to the same gray smoke used by the testing laboratories to evaluate the units, but, in a real fire, many factors, including smoke color and size, cause one detector to respond before the other.

By nature of their design, projected beam smoke detectors are a good choice for large, open spaces. The source and the receiver of commercially available units might be placed as far as 91 m (300 ft) apart, with 9 m (30 ft) or more between adjacent beams. Therefore, there might be considerably fewer units to install. The sensitivity of projected beam smoke detectors is stated in total percent obscuration required to alarm the unit, not percent per foot, as is the case with spot-type detectors. The sensitivity is usually adjustable, between about 20 percent and 70 percent total obscuration, allowing adjustment for different distances between the source and the receiver.

Because projected beam detectors respond to the accumulated smoke in their path, they are sensitive to real fires while remaining insensitive to many environmental factors that would alarm a spot-type detector. For instance, insects in the light path are not likely to block 20 percent of the beam. Similarly, a cigarette smoker might create a cloud of 1 percent to 2 percent per foot (0.3 m) smoke, which would be 1.5 m or 3 m (5 ft or 10 ft) in diameter. If this cloud were under a spot-type smoke detector, it would probably alarm unless a less sensitive unit were installed. However, the same cloud produces between 5 percent and 20 percent total obscuration of a beam projected through the cloud, which projected beam detectors can be set to disregard. Nevertheless, in a real fire scenario, a 6- to 9-m (20- to 30-ft) cloud of smoke, which is 1 percent to 2 percent per foot (0.3 m) on average, is likely to be produced by the time a spot-type detector is activated and goes into alarm. A beam projected through this cloud would be obscured about 20 percent to 60 percent, which would set off a beam detector that had been calibrated in that range. The projected beam detector could be set for 30 percent total obscuration to respond sooner than a spot type

detector to a real fire while still disregarding small sources of activation such as tobacco smokers, sinks, and kitchenettes.

Many other factors should be considered when selecting smoke detectors. For instance, in a room with moderate to high air movement, smoke from a fire that would normally set off a spot-type detector might be dissipated to form a thin haze. The fire must grow larger before there is enough smoke present to set off a spot-type detector. Use of either projected-beam or air-sampling detectors would overcome this delayed response. For more discussion of this and other factors affecting detector selection, consult *NFPA 72*, Chapter 5, as well as the *National Fire Alarm Code Handbook*, the *Fire Protection Handbook*, or the *Fire Alarm Signaling Systems Handbook*. A review of manufacturers' specification sheets and the standards used by testing laboratories for listing or approval can also provide some insight on detector selection.

The *Code* contains other choices concerning detector selection. In some cases, heat detectors might be required or smoke detection simply cannot be used due to normal ambient conditions. In some locations, the authority having jurisdiction might require the area be made suitable for smoke detectors. In other cases, it might be judged that heat detectors could be used and the life safety intent of the *Code* would still be met. These situations demand that a choice be made between the various types of heat detectors.

If the area has no friendly sources that produce rapid temperature changes, rate compensation or combination rate-of-rise/fixed-temperature heat detectors provide good results. If a fast-growing fire occurs, these detectors respond before a fixed-temperature heat detector. If a fire is slow-growing, they respond in about the same time as a fixed-temperature heat detector. Where rapid temperature changes are expected during normal conditions, fixed-temperature detectors should be chosen.

Detectors installed as household fire alarm equipment must be installed in accordance with *NFPA 72*, Chapter 11. This category includes single- and multiple-station self-contained smoke alarms and small systems installed to meet the requirements within the dwelling unit. (The distinction among single, multiple, and system detectors is explained in the section on wiring.) Application of the *Life Safety Code*, combined with Chapter 11 of *NFPA 72*, usually results in the installation of smoke detectors on each level of a dwelling unit, outside of the bedrooms, and at the base of any stairs leading to upper levels. In new construction, detectors would also be placed in each bedroom.

However, where the smoke detectors also contain the alarm sounder to alert occupants, additional units might be needed to achieve audibility in all spaces of the dwelling unit. Additional detectors might also be warranted to provide longer escape times for some occupants or to provide faster response when complex floor plans are involved and smoke must travel a good distance to reach a required detector.

Where the *Code* requires an automatic fire alarm system initiated by smoke detection or heat detection, the spacing and placement of the chosen detectors is governed by *NFPA 72*, Chapter 5. The first step is to place detectors as close as possible to known hazards and as far away as possible from nuisance alarm sources. Any remaining space is then covered with evenly spaced detectors. This approach might result in a few more detectors than are required but will provide better fire detection and reduced chances of false and nuisance alarms. For example, in a hall of a college dormitory, conditions might allow smoke detectors to be spaced 10.7 m (35 ft) on center. However, if such spacing results in a detector immediately outside a shower room, it might be best to use a different increment of spacing, such as 8.5 m (28 ft), and to put detectors no closer to the shower room door than 4.3 m (14 ft).

The maximum spacing between detectors and the maximum distance from any point on the ceiling to a detector is determined by the many factors previously discussed for each detector type. For heat detectors, begin with the listed or approved spacing, then make corrections for ceiling height, beams, joists, and slopes. Where using smoke detectors, start with the manufacturer's recommended spacing, usually 9 m (30 ft), and make adjustments for ceiling height, beams, joists, slopes, and high airflow. Consult *NFPA 72* for the exact correction factors to be used. Note that the actual correction factors in *NFPA 72* for smoke detectors are different from the factors for heat detectors.

Once a detector spacing has been determined, detectors must be located in accordance with other requirements of *NFPA 72*. Exhibit S2.6, reproduced from Chapter 5 of *NFPA 72*, shows that ceiling-mounted detectors must be installed at least 100 mm (4 in.) from walls. If the detector is to be wall-mounted, it should be installed at least 100 mm (4 in.), but no more than 300 mm (12 in.), from the top of the wall. The 100 mm × 100 mm (4 in. × 4 in.) space is called the dead air space. Detectors in that space will respond more slowly because smoke and heat from a small fire tend to circumvent the wall-ceiling intersection.

When all correction factors have been applied

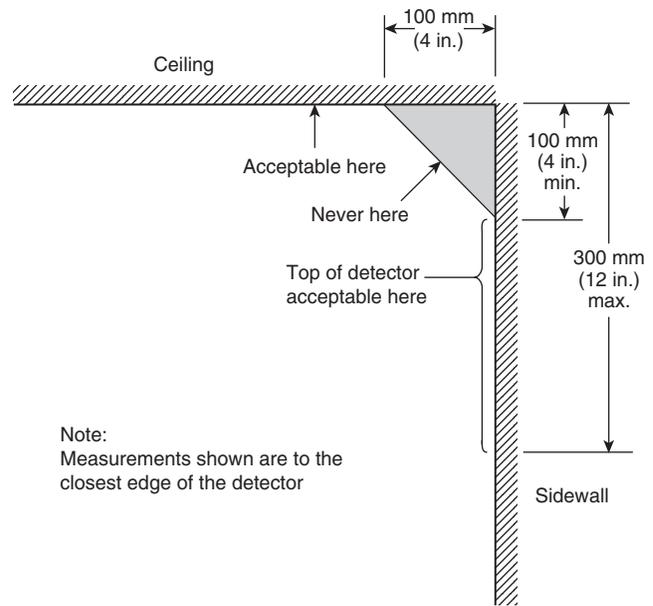

Exhibit S2.6 Dead air space.

to determine a required spacing for detectors, area coverage begins by locating the first detectors at one-half that distance from a wall. Exhibit S2.7, reproduced from *NFPA 72*, demonstrates this concept. The left side of Exhibit S2.7 illustrates how spot-type detectors would be spaced; the right side indicates how line-type detectors would be evenly located. In the diagram, *S* is the corrected, or installed, spacing. These examples assume that the corrected spacing results in a square, such as 9.1 m × 9.1 m (30 ft × 30 ft) or 7.6 m × 7.6 m (25 ft × 25 ft). In the case of beams or joists, the corrected spacing would create a rectangle such as 4.6 m × 9.1 m (15 ft × 30 ft), the shorter distance being measured perpendicular to the joists or beams. Note in Exhibit S2.7 that no point on the ceiling can be farther from a detector than 0.7 times the installed spacing. This maximum distance applies to all points on a ceiling and is useful in laying out systems in irregularly shaped spaces. This concept is discussed in detail in *NFPA 72*.

If a ceiling has solid beams or joists, it must be decided whether the detector should be located on the bottom of the beams or joists or in the ceiling pocket. In the case of beamed ceilings, the detector could be located on the bottom of the beams or on the ceiling in the pocket, depending on the beam depth, beam spacing, and ceiling height. The reader should refer to *NFPA 72* for specific requirements. Note that bar joists and trusses might not significantly impede the movement of smoke and heat. Unless the top cord of the bar joist or truss that is in direct contact

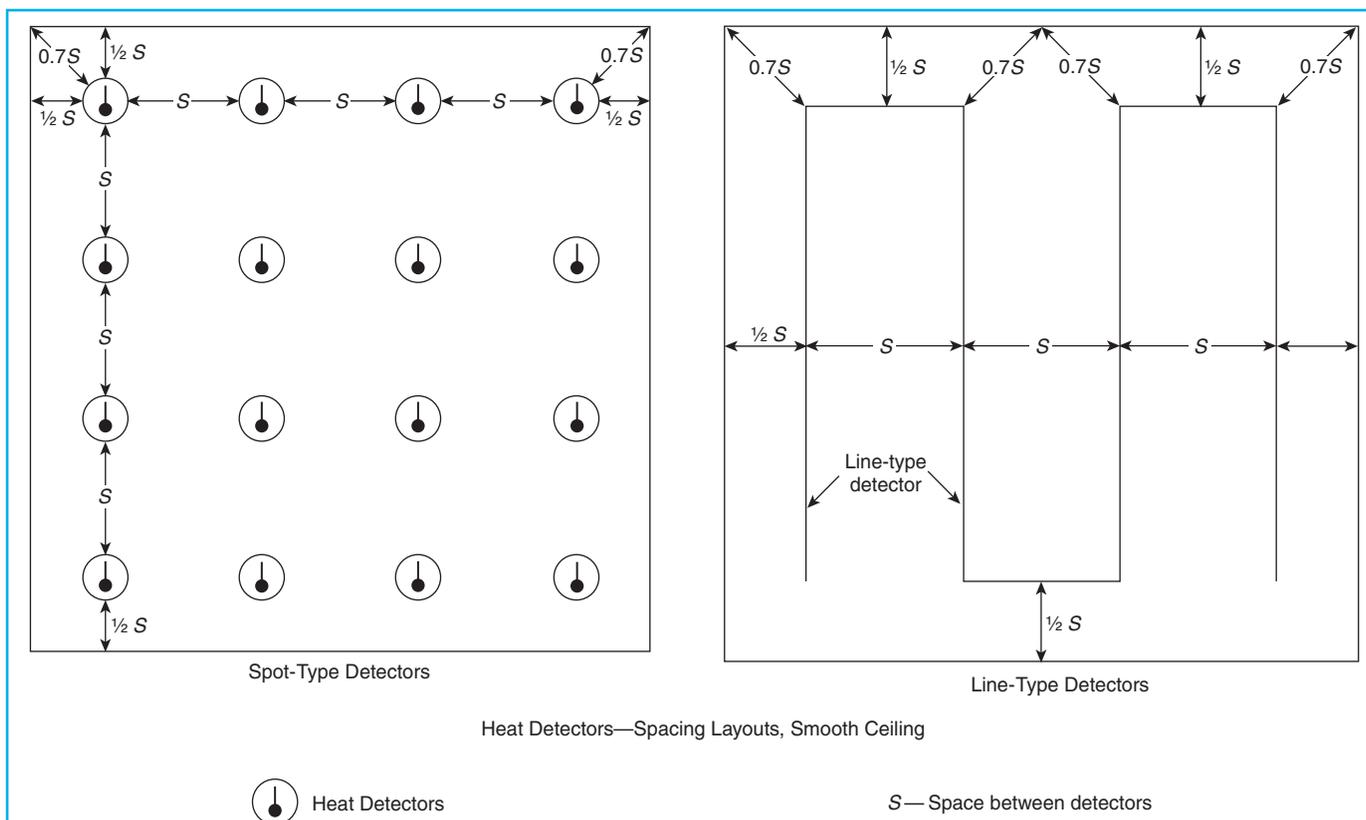

Exhibit S2.7 Spot- and line-type detector spacing.

with the ceiling is more than 100 mm (4 in.) deep, the ceiling is considered smooth. In that case, the detectors must be mounted on the ceiling. Required detectors are not permitted to be mounted on the bottom of bar joists or trusses.

Detectors must also be located for ease of testing and maintenance. A smoke detector located over the open part of a stair tower probably cannot be reached very easily once scaffolding is removed. As a result, smoke detectors are often not tested or cleaned and might fail in a fire or cause false or nuisance alarms. They should be located over a landing or where a ladder can be placed to reach them. There is no need to place the detector in the middle of the space. The space is considered to be adequately covered as long as all points on the ceiling are within the detector's protection radius (0.7 times the installed spacing). Thus, in most stair towers, wall mounting would be sufficient to cover the space.

Construction dust is one of the largest causes of false and nuisance alarms from smoke detectors. When smoke detectors are installed before all construction work is complete, they collect dust in their chambers. The dust can cause immediate alarms, or it can bring the detector close to alarming. As a result,

the slightest physical disturbance, such as air movement or people walking, might set it off. If dust has caused a detector to become more sensitive, even small amounts of cigarette smoke or other aerosols could set it off. Note that many analog, addressable smoke detectors have drift compensation algorithms to compensate for dirty chambers. Plaster and gypsum board dust are very difficult to clear from a detector without disassembly and recalibration after cleaning by factory-trained service personnel.

Early installation of detectors must be resisted despite demands for a certificate of occupancy. This will only lead to future problems. *NFPA 72* specifically states that smoke detectors are not permitted to be installed prior to the completion and cleanup of all other trade work. If acceptable to the authority having jurisdiction, however, the detectors might be installed while covered with bags or part of their original packaging, though covering will render the smoke detectors unable to respond to smoke during a fire. The remainder of the system will be operational. Nevertheless, the life safety aspects of the system will have been compromised until the smoke detectors are uncovered.

In an open office area with a 6-m (20-ft) ceiling

height, spot-type detectors might be used. However, once the area is occupied, maneuvering a high ladder for the purpose of testing is nearly impossible. This constitutes the perfect application for a projected beam smoke detector. The sender and receiver can be located on opposite walls where a ladder can be leaned to reach the units for cleaning and testing.

Many factors other than those discussed here affect the selection and placement of fire detectors. Temperature stratifications might prevent smoke from reaching the ceiling; airflow might speed the response of properly located detectors and slow the response of poorly located ones; the height and width of fire and smoke doors might require additional smoke detectors for door release; machinery vibrations or radio frequency interference might result in the relocation of detectors to avoid false alarms. Complete familiarity with *NFPA 72* is the source of a reliable system. The reference list following this supplement contains other valuable references to assist designers, installers, inspectors, and owners in achieving reliable fire detection while minimizing the chances of false or nuisance alarms.

POWER SOURCES AND SYSTEM WIRING METHODS

Household Fire Alarm Equipment

Dwelling units are most often equipped with either single-station or multiple-station smoke alarms. In some cases, small systems designed as household fire alarm equipment, with detectors, a control panel, and some notification appliances, are used. Often, the control panel also serves as part of a security system.

Single-station smoke alarms are stand-alone units that detect smoke and provide occupant notification. Multiple-station units are actually single-station detectors that can be interconnected so that, if one is activated, all units sound an alarm. Most single- and multiple-station smoke alarms contain only an internal horn, although some contain flashing lights as well. Units are also available with internal relays that can be used to control other functions, such as door release, a nurse call signaling system, activation of a bed shaker to alert a hearing-impaired person, or operation of a light outside the dwelling unit.

For some existing occupancies, the detectors may be permitted to be powered by battery or by commercial light and power (usually 120 V AC). *NFPA 72*, Chapter 11, requires detectors used in new construction to have both primary AC power and secondary power by a battery. Alternatively, a detector with a non-removable, 10-year battery is permitted. In existing households, AC power is preferred. However,

where that is not practical, *NFPA 72* allows the use of a monitored battery as the power source. Within the *Life Safety Code*, some occupancy chapters require AC power, even in existing facilities, where *NFPA 72* would allow battery-operated units.

One reason AC-powered detectors are preferred is that the detector is less likely to be subject to tampering. Battery-powered (only) units are often disabled when the battery is “borrowed” for a toy or other device or removed due to false or nuisance alarms. Also, when batteries die they are often not replaced for some time, leaving part or all of the dwelling unit without smoke detection. Some argue that battery power is superior because, during a power outage, people resort to candles for light and to fireplaces, stoves, or portable heaters for heat, all of which increase the possibility of fire. However, the increased chance of fire may not offset the fact that, over time, loss of commercial power is less likely and shorter in duration than loss of battery power. *NFPA 72* reflects the belief that the chance of fire during a power outage is smaller than the chance of fire occurring when a detector is rendered useless because it has no functioning battery.

Single-station smoke alarms are now available with AC power and integral battery backup. Required for new construction by both the *Life Safety Code* and *NFPA 72*, such units are allowed but not required for existing construction. Local codes, ordinances, or authorities can, however, require their use in existing buildings as well.

NFPA 72, Chapter 11 requires that AC power not be controlled by a switch and that the circuit not have a ground fault interrupter—except where a ground fault interrupter serves all electrical circuits in the dwelling. Direct wiring to a power circuit is preferred. However, if a plug-in electrical cord is used, the standard requires some restraining method to make certain the unit is not accidentally unplugged. *NFPA 72* permits AC power to come from either a dedicated circuit or an unswitched power or lighting circuit. Some experts prefer that AC-powered detectors be connected to an often-used light circuit, such as one feeding kitchen or hallway lights. Then, if a fault occurs, such as a blown fuse or circuit breaker, it is likely to receive immediate attention. If the detectors were connected to their own dedicated circuit or to one infrequently used, loss of power might go unnoticed until the units were tested. AC-powered units must also have a visual “power on” indicator.

Chapter 11 of *NFPA 72* contains requirements for units that use batteries for primary power. Basically, they must be designed so the battery will last for at least one year of normal use, including weekly test-

ing. Also, they must provide an audible trouble signal when the battery is low, well before the unit fails to operate. The unit must be capable of sounding a trouble condition at least once a minute for seven days and still have enough battery power to operate the alarm sounder for 4 minutes. Because of this requirement, it is very important that only battery types recommended by the manufacturer be used. Additionally, the smoke detectors must visually indicate when the battery has been removed.

Where multiple-station units are used, they most often are connected to the same power circuit and also have a trip wire that interconnects them. When using multiple-station detectors, the manufacturer's wiring diagrams and instructions should be followed closely. There is a limit on how many units should be interconnected; some models allow only 5 or 6 to be interconnected, while others allow up to 30 in a chain. However, Chapter 11 does not allow more than 12 multiple-station smoke alarms to be interconnected unless the interconnection is monitored for integrity. Detectors from different manufacturers cannot be interconnected. Different models from the same manufacturer might not be compatible for interconnection. Compatibility between different models allows both ionization and photoelectric detectors to be used on the same circuit where each is advantageous and also allows various sensitivities to be used in different areas of the dwelling unit.

The *Life Safety Code* and *NFPA 72*, Chapter 11, both allow the use of component systems, rather than single- or multiple-station units, within a dwelling unit. The system must be listed or approved for use as household fire alarm equipment. *NFPA 72* contains requirements, including supervision of detector circuits, for the performance of component systems used within the dwelling unit. The use of wireless radio as the signal transmission medium, is permitted provided each detector has its own transmitter and the unit automatically sends a test signal at least once every 24 hours. The installation of hard wiring for component systems is required to meet Article 760 of *NFPA 70*, *National Electrical Code*^{®7}.

The use of combination systems is allowed by *NFPA 72*, provided the fire detection and alarm portion takes precedence over all other functions. Alarm signals for fire and any other function, such as burglary, must be distinctive.

NFPA 72 Protected Premises and Supervising Station Systems Power

Systems intended to meet the requirements of *NFPA 72* are required to have two power sources—primary

power and secondary power. Primary power must come from a reliable source and is usually taken from a commercial light and power source, although *NFPA 72* allows other sources, such as engine-driven generators, to provide primary power. Primary power must come from a dedicated branch circuit. Access to the circuit disconnecting means must be restricted and clearly marked "FIRE ALARM CIRCUIT."

Secondary power is intended to operate all functions of the system in the event that primary power is lost. Most often, secondary power is provided by standby batteries. Engine-driven generators are also permitted to be used. All systems must be provided with secondary power capable of operating the system for 24 hours under normal loading conditions. Prior to the 2002 edition of *NFPA 72*, some systems required 24 hours and others required 60 hours of supervisory power. At the end of the normal supervisory period, each system must have 5 minutes of alarm power available or, if it's an emergency voice/alarm communication system, 15 minutes of full load power.

NFPA 72 Circuit Classifications. In addition to power supply circuits, three principal types of circuits are used in fire protective signaling systems:

- (1) Initiating device circuits (IDCs)
- (2) Signaling line circuits (SLCs)
- (3) Notification appliance circuits (NACs)

An initiating device circuit (IDC) connects manual and automatic devices to a control panel or system. The main characteristic of an initiating device circuit is that the signal received at the control panel does not identify the device that operated. These circuits are also called initiating zones of the fire detection panel. Because the devices are not readily identified at the panel, the quantity of devices on a circuit and the area served by the circuit should be limited to make identification of the source a bit easier.

In addition, because the control panel cannot recognize the individual devices on the circuit, alarm devices cannot be mixed with supervisory devices, such as valve tamper switches, on the same circuit. Exhibit S2.8 shows one version of incorrect and correct methods for monitoring waterflow and valve tamper switches where using initiating device circuits.

A signaling line circuit (SLC) might connect initiating devices to a control panel or system or might interconnect various pieces of control equipment. An SLC is characterized by its ability to carry multiple signals, often in two directions, and to identify the source of the signal. For instance, multiplex systems,

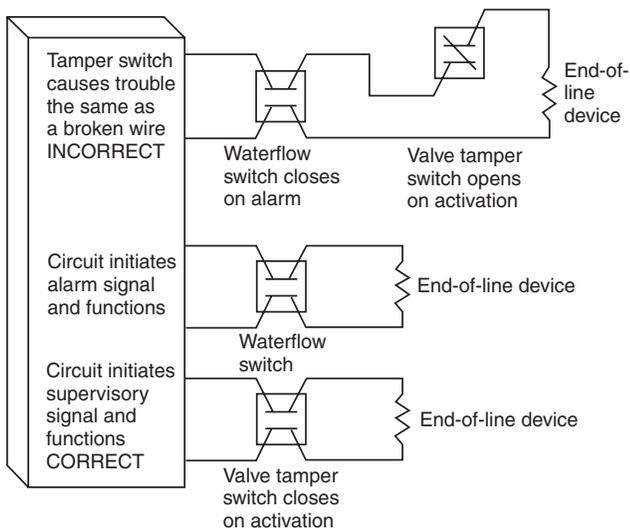

Exhibit S2.8 Incorrect and correct wiring of valve tamper switch.

often called smart systems, communicate with initiating and control devices. Each device or group of devices might have a unique address. The panel signals to a specific address and asks for the status of that "point." The device responds by repeating its address and its current status, such as "alarm" or "trouble." Therefore, the circuit is carrying multiple pieces of information and there is two-way communication.

Where signaling line circuits are used, it is possible to combine alarm and supervisory devices on the same circuit or data pathway. Because each device or group of devices is recognized at the control equipment, different output signals can be programmed for each.

The third type of circuit, the notification appliance circuit (NAC), serves appliances such as horns, bells, lights, and other notification appliances. NACs are often called signal circuits because they connect to devices intended to signal the occupants of a fire emergency. Even though occupant notification appliances generate a signal, care must be exercised not to confuse the circuit designations within the scope of *NFPA 72*. There are requirements for signaling line circuits that differ from those for notification appliance circuits.

Circuit Supervision. *NFPA 72* requires all means for interconnecting equipment and devices to be monitored for integrity. This is commonly referred to as circuit supervision. The *Code* also contains requirements for monitoring power supplies as well as the circuits to detectors and notification appliances. Monitoring power sources is primarily a function of the control equipment. Compliance with *NFPA 72* re-

quirements is checked during testing and listing or approval of the system. See *NFPA 72*, Chapters 1 and 3, for performance and installation requirements.

The performance of IDCs, SLCs, and NACs is a function of the equipment and the installation of the circuits. Tables in *NFPA 72* describe the performance of each type of circuit, including open circuits, ground faults, and short circuits, during various faults. Circuits are categorized by class and by style. IDCs, SLCs, and NACs are either Class A or Class B, depending on their ability to operate during a single open circuit or ground fault condition. Circuit style designations are based on their ability to operate during different combinations of faults, including grounds, opens, and short circuits. Neither the *Life Safety Code* nor *NFPA 72* specify the class or style of circuits that must be used for a given application. Unless the authority having jurisdiction specifies a certain style, it is up to the designer to make a selection.

Some systems use selective signaling systems for occupant notification during a fire. These systems would sound evacuation signals or relocation signals only to certain areas of a building, such as the fire floor, floor above, and floor below. These are often part of a protected premises system, forming what is called a "combination system." The circuits connected to speakers and lights are still referred to as notification appliance circuits. Because these systems are most often used in high-rise buildings or in areas subject to levels of hazard that are higher than normal, *NFPA 72* contains requirements for survivability of the notification functions when the circuits are attacked by fire. By requiring the system to survive an attack by fire in certain locations, the standard narrows the choice of circuit styles and the methods of installation. For more information on these requirements, consult *NFPA 72*, Chapter 6.

The discussion of circuits for controlling auxiliary functions, such as door release, fan control, and elevator recall, is beyond the scope of this supplement. Note, however, that the *Life Safety Code* and *NFPA 72* require these circuits to be supervised to within 3 ft of the device being controlled. See Chapter 9 of the *Life Safety Code* and Chapter 3 of *NFPA 72* for more information on these circuits.

Device Compatibility. Initiating devices and notification appliances must be compatible with the control equipment to which they are connected. Where addressable, multiplex-type equipment is used, there is no doubt that the equipment must be compatible and designed specifically to work together. With notification appliances and conventional initiating devices, however, there is more flexibility in choice.

In the case of notification appliances, compatibility is primarily a function of voltage and power consumption. Therefore, it is easy for designers, suppliers, and installers to match devices from one source with control equipment from another source. For initiating devices, compatibility depends on whether the device requires operating power. Mechanical devices such as manual fire alarm boxes, most heat detectors, and waterflow switches do not require power to operate. When they go into alarm, they close a set of contacts, as a light switch does, to signal the control panel. There is no compatibility issue; these devices can be mixed and matched among various manufacturers.

If a device does require operating power, as a smoke detector does, compatibility depends on whether its source of operating power comes from the initiating device circuit (often called the detection zone) or from a separate, external power circuit. Where power comes from a circuit other than the one used to signal the control panel, there is no compatibility issue. As in the case of notification appliances, compatibility is then only a function of voltage and power consumption from the external power circuit. When the detector alarms, it closes a set of contacts to signal the control panel via the initiating device circuit in the same way a mechanical pull station does.

However, where a device such as a smoke detector obtains its operating power from the same circuit it uses to signal an alarm, compatibility is very important. These devices are often referred to as two-wire, zone-powered, or circuit-powered detectors. The electrical characteristics of the control panel and the detectors, including supervisory currents and alarm currents, must be matched carefully to ensure proper operation. Detector compatibility is a very complex issue. For more information on this subject, consult manufacturers' data sheets, *NFPA 72*, the *Fire Alarm Signaling Systems Handbook*, and the approval or test agency's performance standards. To check system compatibility, it is necessary to know the specific model of control panel as well as the model and quantity of the initiating device in question. Compatibility should be checked by consulting each manufacturer and the testing or approval agency acceptable to the authority having jurisdiction.

Wiring Methods. Article 760 of *NFPA 70*, *National Electrical Code*, covers the installation of wiring for fire alarm systems operating at 600 V or less. Two types of wiring methods are allowed by Article 760—power-limited and non-power-limited. For a circuit to be designated as power-limited, it must meet certain voltage and power limitations. These are checked

by the listing or approval agency. Where a circuit is designated as power-limited, the requirements for the wiring type and installation are less restrictive than if the circuit is non-power-limited. In addition to defining power-limited and non-power-limited circuits, Article 760 provides detailed requirements for wiring methods. Included are requirements for wire gauges, insulation requirements, minimum requirements for stranded wires, overcurrent protection, circuit identification, and wiring raceways. Also included are restrictions on combining the use of power-limited and non-power-limited circuits and other nonfire circuits in the same raceway or enclosure.

The *National Electrical Code* should be consulted for details on wiring requirements. Additional discussion of Article 760 is contained in the *National Electrical Code Handbook*⁸, which provides an explanation of the reasoning and intent behind specific code paragraphs.

SIGNALING

The subject of this section is output signaling, as opposed to the type of signaling that occurs between detectors and control equipment discussed in the section on wiring. The principal signaling functions of a system are off-premises signaling to emergency forces and occupant notification.

Off-premises signaling may be transmitted to a supervising station that is part of a central station system, an auxiliary system, a remote station system, or a proprietary signaling system in accordance with *NFPA 72*. Where off-premises signaling is required or desirable, *NFPA 72*, Chapter 8, should be consulted concerning installation and performance requirements for the system. That chapter contains requirements for the transmitter at the protected premises, the transmission method, and the receiving system. The standards allow only certain signaling methods that have shown themselves to be reliable. Telephone tape dialers, for example, are not recognized by *NFPA 72*. Similarly, digital communicators with only one phone line are not permitted, except for household fire alarm systems.

Each occupancy chapter of the *Life Safety Code* clearly states where occupant notification and/or emergency forces signaling is required. The chapter might also require specific occupant notification systems such as emergency voice/alarm communication systems in high-rise buildings. Each occupancy chapter should be carefully reviewed to determine which initiating devices are required to activate occupant

notification signals and off-premises signaling. In most cases, all initiating devices operate as general alarm devices and activate all output functions. However, there are cases where detectors in specific areas of a building might not be required to sound evacuation signals. For example, duct smoke detectors may be permitted, or even required, to sound only a supervisory signal, not an alarm signal.

Where occupant notification is required, it must be distinct and clearly audible in all occupiable spaces. *NFPA 72*, Chapter 7, contains criteria for the definition of *audible*. The recommended noise level from an alarm system is at least 15 dBA above the 24-hour average ambient level or at least 5 dBA above any peak background noise that lasts one minute or more; dBA stands for decibels, A-weighted. This is a way of measuring sound pressure levels and adjusting for the way the human ear hears. In areas used for sleeping, a minimum of 75 dBA is required. This is an increase of 5 dB over the previous editions, which required a minimum of 70 dBA.

There has been some concern that audible fire alarm signals may be insufficient to awaken some people, including young children. The 75 dBA requirement (and the previous 70 dBA requirement) are based on actual testing of a variety of age groups. The subjects were not impaired by drugs or alcohol. For some subjects, actual awakening at these levels was achieved in seconds, while others were not awakened for several minutes. It is expected that these levels are sufficient for a very high percentage of the general population. However, if you suspect the regular occurrence of drug or alcohol impairments, heavy sleepers, or persons not capable of self-rescue, other signaling strategies may be warranted, beyond what the code requires.

The use of inexpensive meters (under \$40) allows background levels in existing areas to be checked and systems to be installed appropriately. Ambient and fire alarm noise levels should be measured with all intervening doors closed and with common equipment such as air conditioners operating. For new construction, *NFPA 72*, Annex A, provides examples of ambient noise levels in a variety of occupancies.

Once background levels have been determined, design methods can be used to determine where audible notification appliances should be located. One such procedure is presented and discussed in *The SFPE Handbook of Fire Protection Engineering*⁹. Calculations are not needed for existing construction. Portable appliances can be tried in a variety of locations before final mounting.

In most new construction, due to minimum insulation requirements and privacy laws, it is not possi-

ble to place alarm devices in common hallways and expect them to meet audibility requirements in adjacent spaces. Tests show that, in most cases, an audible device may be loud enough in only one or two immediately adjacent spaces. Therefore, a large number of units would be required in the common halls of occupancies such as apartments or dormitories. Cost estimates often indicate that it is less expensive to put smaller devices in each space, rather than to provide the required number of larger devices in common spaces.

The 2002 edition of *NFPA 72* includes provisions allowing the use of narrow-band noise analysis and signaling. By analyzing the frequency content of noise, it is often possible to design more efficient fire alarm signaling systems compared to those designed using dBA measurements. Often, the noise is concentrated in one or more octave bands. By using a signal in a different octave band, the alarm can be heard even though a dBA measurement might not “hear” the signal. For more information, consult the *National Fire Alarm Code Handbook* and the 19th edition of the *NFPA Fire Protection Handbook*.

In addition to audible appliances, the *Life Safety Code* might require visual appliances for occupant notification. *NFPA 72*, Chapter 7, would then be consulted for the proper selection and placement of visual appliances to meet specific needs. For instance, unlike the Americans with Disabilities Act Accessibility Guidelines (ADAAG), *NFPA 72* treats visible signaling differently in nonsleeping versus sleeping areas. The requirements for visible signaling are based on actual research on threshold alerting levels for hearing impaired persons conducted by Underwriters Laboratories. The 1996 and 1999 editions of *NFPA 72* have been determined to be “equivalent facilitation,” and in some cases superior, to the ADAAG.

The signal produced by notification appliances must also convey the following information: FIRE EMERGENCY. This is where the requirement for distinct signals is applied. For instance, in a school, bells should not be used on a fire alarm system if bells are also used to signal class changes and recess. Similarly, in buildings equipped with earthquake warning systems, the fire signal needs to be distinct and recognizable by the occupants. *NFPA 72* permits more than one signal to be used in a building, such as chimes in patient care areas of a hospital and horns elsewhere. However, both must be distinct and not used for any other purpose.

NFPA 72 has a requirement for a standard audible evacuation signal. The signal, referred to as a temporal coded three signal, can be produced on a variety of appliances such as bells, horns, speakers, and

chimes. A coded three signal is recognized internationally as a distress signal. Thus, it would be the pattern of the signal, not the particular sound, that would convey the information that there is a fire emergency.

Improvements and cost reductions in emergency voice alarm communication (EVAC) systems have made it economical to provide recorded and manual voice announcement systems in many applications. Most codes, including the *Life Safety Code*, require the use of voice signaling in high-rise buildings, in large assembly occupancies, and in difficult-to-evacuate situations. Nevertheless, these systems can be used effectively in a variety of applications. Because the NAC circuits are connected to speakers, driven by amplifiers, it is easier and less restrictive to add additional appliances when audibility is an issue than with conventional direct current devices. Also, speakers generally have adjustable power taps permitting minor adjustment in audibility that is not possible with most conventional sounders. Finally, it is well known that a properly implemented voice announcement will result in faster and more complete evacuation of occupants.

Fire alarm systems that only use audible tones and/or flashing strobe lights impart only one bit of information: Fire Alarm. It has long been recognized that environments having complex egress situations or high hazard potentials require occupant notification systems that provide more than one bit of information. To reduce the response time of the occupants and to effect the desired behavior, the message should contain several key elements. These include the following:

- What has happened and where
- What occupants should do
- Why occupants should do it

It is not possible to measure the audibility of a voice signal in the same way as tone signals. In addition, *audibility* is insufficient to ensure that the message is clear and understood. The *intelligibility* of the voice signal is measured in a different way that includes audibility, clarity, distortion, reverberation, and several other important components. The *National Fire Alarm Code Handbook* includes a supplement describing voice intelligibility.

In a large space used for public meetings, conventions, and trade shows, an EVAC system needs to be reliably intelligible because it is intended to give information to the general public that is not familiar with the space. In large public spaces, people should not have to move any great distance to find a place where they can understand the message.

However, in a high-rise apartment building, is voice intelligibility required in all spaces? It may not be necessary for the EVAC system to be intelligible in all parts of the apartment, even though it must be audible in all parts. It may be sufficient to provide a speaker in a common space to produce an adequate audible tone to awaken and alert. When the voice message follows, it may not be intelligible behind closed bedroom and bathroom doors. The occupants, in a familiar space, can move to a location where a repeating message can be intelligibly heard. The same signaling plan may work for office complexes—people may have to open their office doors to reliably understand the message.

While an EVAC system is the most common method of communicating information to occupants, it is not the only method. Research has shown that text and graphical messaging greatly enhance occupant movement during evacuation and relocation. The message delivery can be via large screens used in sports arenas or by small LCD display or CRT information kiosks located throughout a property.

Other types of output signaling that a fire alarm system might be required to provide include the following:

- (1) Fan and damper control
- (2) Heating, ventilating, and air-conditioning systems
- (3) Smoke control systems
- (4) Elevator control systems
- (5) Emergency lighting systems
- (6) Process control systems

The design, installation, testing, and maintenance of these systems should be performed by qualified fire protection engineers, technicians, and inspection professionals. Where activation of these or other emergency control systems is required by a chapter of the *Life Safety Code*, specific requirements are found in Chapter 7.

SYSTEM INSPECTION, TESTING, AND MAINTENANCE

Surveys and general field experience continue to demonstrate the importance of continued testing and maintenance of fire detection and signaling systems. Inspections are used to find changes in the building or environment that might affect a system. Testing identifies problems before they impair a system's ability to perform during an emergency. Maintenance reduces false and nuisance alarms and keeps systems in service.

The *Life Safety Code* requires all fire detection and signaling equipment to be maintained and tested in accordance with the appropriate signaling standard. In the case of household fire alarm equipment, *NFPA 72*, Chapter 11, is the governing standard. For other systems, *NFPA 72*, Chapter 10, contains requirements for acceptance and periodic tests, visual inspections, and maintenance.

NFPA 72, Chapter 10, contains three important tables. The first lists the methods for testing specific components, devices, and appliances. The second table lists the required frequency for visual inspections. The third table lists the required frequency for actual testing of the specific components, devices, and appliances.

Whenever a system or device is to be tested, it is important to notify those who might hear or receive a signal from the system. Usually, this means several days of advance notice to authorities and regular occupants of the area. In addition, when testing or working on systems, the authority having jurisdiction must be notified, even for periodic tests that they might not witness. Other trades or specialists might require notice to participate in the tests. For instance, testing of smoke detectors used for elevator recall might require elevator technicians to be present. Similarly, HVAC mechanics or electricians may be required to reset air-moving equipment or dampers after the system is tested. In addition, posting notices at entrances to the premises to alert people as they arrive is usually advisable. Notices should include phone numbers or brief procedures for reporting emergencies while the system is being tested or serviced.

When testing occupant notification systems, it is important to keep to a posted schedule and minimize the time of testing to prevent occupants from becoming desensitized to the signaling. This requires having sufficient personnel and equipment to do a thorough and fast test. Consider recruiting key occupants to assist in qualitative examination of the notification system. Try to minimize the frequency and duration of the tests. For example, test only at 10:00 a.m. and again at 2:00 p.m., for only 30 to 60 seconds.

Household Fire Alarm Equipment

The requirements for testing and maintenance of household fire alarm equipment are kept simple so that, in most cases, the work can be done by the homeowner. *NFPA 72* requires that battery-operated units get new batteries in accordance with the manufacturers' recommendations. In most cases, manufacturers recommend replacement of batteries at least

once a year. Recent educational and awareness programs have promoted battery changing at the same time that clocks are changed from daylight savings time to standard time in the fall of each year. Scheduled replacement tends to increase confidence that the detector will work when needed, rather than waiting for the signal that indicates the need for replacement. Facilities with large numbers of battery-operated detectors save time and labor by replacing all batteries at the same time, whether or not it is necessary.

NFPA 72 requires monthly testing of household fire alarm equipment. Where small systems with detectors and control panels are used in lieu of single- or multiple-station smoke alarms, *NFPA 72* requires the owner to have the system tested by qualified technicians at least every 3 years. All tests, inspections, and maintenance recommended by the manufacturer must be performed in accordance with its instructions. This emphasizes the importance of providing the owner, member of the household, or occupant with the manufacturer's instruction booklet(s). Without the proper documentation, the individuals performing the test may not be aware of their responsibilities or the correct methods for testing and maintenance. *NFPA 72* requires the installer or supplier to provide this and other information to the owner. In addition to the instructions, the owner must receive information on how to establish an evacuation plan and information on parts that require regular replacement, such as batteries. The owner must also receive written information on where to obtain repair and replacement service. It is important that users of household fire alarm equipment understand that the code-required minimum may give them only seconds to react and get out. In situations where a person might be impaired due to alcohol or drugs, or where elderly persons, young children, or impaired persons need evacuation assistance, the warning given by code-minimum coverage may be insufficient.

Each smoke detector for use in an *NFPA 72*, Chapter 11, application is required to have an integral test method to permit testing of the system and sensitivity. This is usually a test button or switch. Unless otherwise recommended by the manufacturer, this test button is the best way for the occupant to test the detector. By using the test button, the detector is checked for operation at the limit of sensitivity allowed by the ANSI/UL test standards for the detector. Using unmeasured aerosols such as cigarette smoke or canned smoke does not measure sensitivity. This might prove that a detector is operational, but the sensitivity may be so low that the amount of smoke required to alarm it is enough to have already caused

harm or a delay in detector response to a real fire. An aerosol should be used to verify that the smoke detector is not blocked by excessive dust accumulation or by intentional blocking of the screen or ports. It is often not possible to tell by visual inspection alone if a detector has been blocked.

Cleaning of smoke detectors is necessary to prevent false and nuisance alarms and to ensure detector operation during a fire. *NFPA 72* leaves the methods and frequency of cleaning up to each manufacturer. Most manufacturers recommend cleaning once or twice a year by vacuuming around the outside of the detector. Some detectors are now available that can be washed in a soap/water solution. Most manufacturers do not recommend disassembly of detectors for cleaning except by qualified technicians. If the detector is cleaned and properly maintained from the time it is new, the need for factory cleaning and calibration is almost eliminated.

Acceptance Testing

NFPA 72 requires 100 percent testing of the entire system upon completion of any installation or alteration. The test must include all devices and equipment and must test the system in all modes, including alarm, trouble, and supervisory. Satisfactory tests must be made in the presence of the authority having jurisdiction or a designated representative. *NFPA 72* recognizes reacceptance tests on parts of systems affected by alterations or repairs.

A preliminary certificate of completion is required to be issued to the owner and, if requested, to the authority having jurisdiction prior to the final acceptance test. The preliminary certificate is issued after installation and wiring tests have been completed. A final version is to be issued and distributed after all operational acceptance tests have been completed. A sample copy of a certificate of completion is included in *NFPA 72*.

Following final acceptance of the system, the installer or supplier must provide the owner with an owner's manual or manufacturer's installation instructions as well as final "as-built" drawings. During acceptance or reacceptance testing, the certificate of completion and as-built drawings must be verified for accuracy and completeness. If necessary, corrections should be made to the master documents, and any old copies should be replaced or updated.

Installation testing includes checking the entire system for stray voltages, ground faults, short circuits, and open circuits. Ground fault testing includes testing all conductors not intentionally connected to ground.

The loop resistance of initiating and notification appliance circuits must be measured and recorded. The measured value should be checked against the maximum allowable loop resistance indicated by the manufacturer of the control equipment. Signaling line circuits should also be tested in accordance with the manufacturer's recommendations. This will usually include measurement of circuit capacitance in addition to resistance.

System testing is done after all installation tests have been performed. After replacing any equipment removed during testing of the circuits, the control unit and all devices should be verified as being in the normal supervisory mode. Each circuit should be checked for proper supervision and integrity. This includes testing open circuit trouble indication as well as ground fault and short circuit fault indicators where provided. Where the style of circuit allows alarm receipt during specific faults, correct operation should be checked by testing devices electrically before and after the location of the test fault. It is useful during the testing to use a copy of the wiring style tables from *NFPA 72* as a checklist.

Every initiating device and indicating appliance must be checked for correct alarm operation. This verifies correct operation of the device, the circuit, and the control equipment. For systems that respond differently and result in different outputs depending on the device(s) in alarm, a programming matrix should be prepared and checked. The matrix, or system description, should explain what occurs when each particular device or group of devices is operated. For instance, an alarm from any first floor detector might cause bells to ring, doors to release, and a connection to the fire department to be activated. On the other hand, perhaps only certain smoke detectors will activate a smoke management system. The use of a table or matrix describing these options speeds testing and future work on the system. Exhibit S2.9 shows a partial system operation matrix.

Power supplies must also be tested during acceptance and reacceptance tests, including testing the switchover from primary to secondary power by disconnecting the primary supply. While the system is powered by the secondary supply, the standby current should be measured in accordance with the manufacturer's recommendations. The required standby capacity can then be calculated and compared to that which was provided. While on secondary power, the system should be tested for full alarm performance for at least 5 minutes. This test should be repeated with the system on primary power and with any secondary supply disconnected. Supervision of power supplies should also be tested.

Exhibit S2.9 Partial system input/output matrix.

Smoke detectors must be tested in accordance with Chapter 10 of *NFPA 72*. During an acceptance test, it is not necessary to measure the detector’s sensitivity. A pass/fail or go/no-go test using smoke or another unmeasured aerosol is acceptable. All smoke detectors, including duct and air-sampling types, must be checked to ensure that smoke is entering the detector’s chamber. In all cases, the manufacturer’s directions should be followed.

The *NFPA 72* requirement for retention of test records is 2 years. All equipment should be tested in accordance with the requirements of the standards and the manufacturers’ recommendations.

Periodic Testing

In addition to provisions for acceptance testing, *NFPA 72* contains requirements for periodic tests and maintenance. Essentially, *NFPA 72* requires all testing to be performed by qualified persons who understand the equipment. Ultimately, the owner of the system is responsible for ensuring that all required tests are done on time. Owners are permitted to rely on a written maintenance agreement with others rather than develop and use their own specialists. Delegation of responsibility for testing and maintenance must be in writing.

The required frequency for testing a device var-

ies. Chapter 10 of *NFPA 72* contains the required frequencies for all devices.

NFPA 72 requires the sensitivity of all smoke detectors to be checked within 1 year of the acceptance test, and every other year thereafter. During the years when sensitivity tests are not required, a pass/fail test using smoke or another unmeasured aerosol is still required. The intent of the sensitivity test is to ensure that the detector is within its listed and marked sensitivity range. Detectors that are more than 0.25 percent per foot (0.3 m) obscuration out of range must be recalibrated or replaced.

The most common methods for testing detector sensitivity use either control panels that can check detector sensitivity remotely or meters that plug into the detector for testing. In some cases, the meters are common volt-amp meters and in other cases they are factory-supplied devices. There are also test instruments that generate measured smoke clouds that can be used to test any brand of detector. Using unmeasured aerosols such as cigarette smoke or canned smoke does not measure sensitivity. It might prove that a detector is operational, but the sensitivity might be so low that the amount of smoke required to cause an alarm is enough to have already caused harm or a delay in detector response to a real fire. On the other side of the issue, a detector might alarm when tested with cigarette smoke but be so sensitive that

it would also nuisance alarm due to small amounts of friendly smoke.

In terms of smoke detector cleaning, NFPA 72 simply states that the frequency of service should be based on the ambient conditions. If the area is very clean, 1 to 2 years between cleanings might be possible. In very dusty or dirty areas, or areas with high airflow, cleaning might be required every 3 to 6 months. In most residential, business, and institutional-type occupancies, yearly cleaning is usually sufficient. A sensitivity test must be performed on any detector that has been washed or disassembled for any reason, including cleaning.

Once a year, air duct smoke detectors must be checked to verify that they are properly sampling the air stream. The manufacturer's recommendations for testing should be followed. This may involve measuring the pressure difference between the air sampling and air return tubes.

CONCLUSION

Fire alarm systems range from very simple units to large complex systems. This supplement has only briefly introduced the reader to the many requirements and good practices associated with their design, installation, testing, and use.

One of the most common failures associated with fire detection and alarm systems is the failure to provide fire protection. A fire detection and alarm system is not a fire protection system unless it does something to affect the fire, the property, or the people. For example, a complete fire detection system with smoke detectors and heat detectors in every room and space does little good if the system sounds a local alarm in the middle of the night when the building is not occupied and does not automatically communicate to the fire department. If it does summon the fire department, what good is it if the fire is too large for the arriving fire fighters to safely attack? Perhaps this system is protecting an historic library in a community with a part-paid fire department whose nearest apparatus is 5 miles distant—uphill. This is a failure to engineer. The *Life Safety Code* and the *National Fire Alarm Code* address common occupancy and hazard conditions. Many requirements for fire detection and alarm are “pre-engineered” solutions for the expected conditions. However, where performance-based solutions are used, or in situations where owners have goals that go beyond simple code compliance, the designer may need to provide more than what the code requires.

The *Life Safety Code* and the *National Fire Alarm*

Code contain a wealth of information for persons involved with any phase of a fire alarm system's life. By drawing on the expertise of hundreds of professionals and specialists, users of these NFPA documents benefit from years of combined experience, which no one person or company could hope to attain.

A Brief Introduction to Sprinkler Systems for *Life Safety Code* Users

Revised by
Christian Dubay, P.E.

Editor's Note: Sprinkler systems provide a very high level of protection to buildings and building occupants. This supplement is an introduction to sprinkler systems. It covers sprinkler system standards; fire hazard determination, system components, and hardware; and inspection, testing, and maintenance.

Christian Dubay is a senior fire protection engineer at NFPA and editor of the Automatic Sprinkler Systems Handbook, 2002 edition. He holds a Bachelor of Science in Fire Protection Engineering from the University of Maryland.

The very first edition of the *Life Safety Code*, published in 1927, included provisions for the use of sprinkler systems. Back in 1927, however, sprinkler systems were associated more with property protection than with life safety. This is not surprising, since in 1896, it was largely property insurance interests that developed the first set of rules for sprinkler system installations in North America. Since that time, however, the effectiveness of sprinkler systems as life safety devices has been widely demonstrated.

Sprinkler system effectiveness in terms of life safety is best summarized by the following statement, which is based on fire incident data. "NFPA has no record of a fire killing more than two people in a completely sprinklered building where the system was properly operating, except in an explosion or flash fire or where industrial or fire brigade members or employees were killed during fire suppression operations." This statement is particularly impressive because it pertains to statistics concerning system performance since the turn of the twentieth century, when sprinkler system effectiveness was uncertain.

Over the years, technological advancements and experience have increased sprinkler system effectiveness and reliability, improved design and installation practices, and produced more cost-effective systems. Where properly designed, installed, and maintained, no other stand-alone fire protection system, active or passive, provides a higher level of protection to building occupants. The use of a sprinkler system in combination with other life safety systems such as fire alarms and compartmentation results in a much more complete and comprehensive life safety package.

NFPA SPRINKLER SYSTEM STANDARDS

The National Fire Protection Association publishes three standards that address the design and installation of sprinkler systems. NFPA 101 references each of these standards. NFPA 13, *Standard for the Installation of Sprinkler Systems*¹, has the broadest scope and is the oldest and most comprehensive of the sprinkler system standards. NFPA 13 addresses both property

protection and life safety for a wide range of facilities, including those used for public assembly, education, detention, health care, residential, business, mercantile, manufacturing, and storage.

Interestingly, it was concerns about a lack of a uniform set of rules for sprinkler system installations that prompted the creation of the National Fire Protection Association and NFPA 13 in 1896. Once established, NFPA expanded its scope to address many safety-related concerns, including those associated with electricity, which was a new technology back at the turn of the twentieth century.

NFPA also publishes NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*², and NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*³. These standards are relatively new compared to NFPA 13, having been developed within the past 25 years primarily to address life safety concerns in certain types of residential occupancies. Property protection is not the primary objective for NFPA 13D and NFPA 13R.

Other NFPA codes and standards also include information about sprinkler system design and installation for specialized hazards. In all, over 40 such documents exist. For example, NFPA 30, *Flammable and Combustible Liquids Code*⁴, addresses sprinkler systems for the protection of flammable liquids, and NFPA 130, *Standard for Fixed Guideway Transit and Passenger Rail Systems*⁵, includes requirements for sprinkler systems specific to transit systems.

NFPA 101 does not reference standards specific to specialized hazards, because the sprinkler system information in those standards usually extends beyond that needed for life safety. Fire safety objectives concerning property protection are usually more difficult to achieve than those for life safety. NFPA 13, NFPA 13D, and NFPA 13R are adequate for the life safety concerns addressed by NFPA 101. It is worth noting that starting with the 1999 edition, NFPA 13 has expanded to include or reference sprinkler system information from all other NFPA codes and standards.

Some Basic Principles of NFPA 13

Certain underlying principles about sprinkler systems have existed since the first edition of NFPA 13. To begin, sprinkler systems are designed to protect against the occurrence of a single fire in a building at one given time. Designing for more than one fire is usually considered unnecessary, given the rarity of multiple ignition sources. Designing for more than

one ignition source would greatly increase sprinkler system costs while providing minimal benefit.

Sprinkler systems are limited in size, depending on the associated fire hazards in the building. This restriction serves to control the impact of a sprinkler system impairment on the overall fire protection of large facilities. Additionally, each sprinkler system is required to be equipped with a waterflow indicating device, as well as a local alarm that indicates when waterflow is occurring.

Sprinkler systems are characterized as being automatic and must include an automatic water supply. Sprinkler systems are designed to discharge a specified amount of water from a predetermined number of sprinklers during a fire. An automatic sprinkler system will automatically flow water when one or more sprinklers on the system activate. A sprinkler system that relies on human intervention to initiate waterflow is not considered automatic, is not permitted by NFPA 13, and would be ineffective for most life safety concerns.

A sprinkler system's water supply must be adequate and reliable. This statement means the available water supply must meet or exceed the sprinkler system's water demand 24 hours a day, 7 days a week, 365 days a year. A sprinkler system's water demand is most commonly determined through hydraulic calculations and is expressed in units of flow, pressure, and time. The requirement for reliability exists because it is often impossible to predict with a sufficient degree of confidence when a fire will occur. As a means of further addressing the reliability of water supplies consisting of a water works system, NFPA 13 requires a certain allowance for fire hose demand. In addition, most systems require a connection for the fire department to supplement the automatic water supply.

With the exception of certain types of systems used for industrial and commercial property protection concerns, most automatic sprinkler systems utilize automatic sprinklers. Automatic sprinklers are heat-sensitive devices that operate only when exposed to a certain quantity of heat. Therefore, only those sprinklers close to a fire will operate. Unlike incorrect portrayals often depicted in movies and television shows, automatic sprinklers do not operate when exposed to smoke or when someone initiates the building fire alarm. Additionally, when one automatic sprinkler activates, all the sprinklers in the building or the compartment do not activate unless the entire space protected by the sprinklers is burning.

For a sprinkler system to be effective, sprinklers must be located where a fire is anticipated. The suc-

cess of a sprinkler system in controlling or suppressing a fire depends on the sprinkler discharge reaching the fire area when the fire is in its early stages of development and relatively small. Where a fire is severely shielded from sprinkler system discharge or the fire starts in an unsprinklered area, the chances for successful sprinkler system performance greatly decrease. With few exceptions, NFPA 13 requires that sprinklers be located in all areas throughout the building, that each sprinkler cover a certain size floor area, and that sprinklers be positioned to allow for timely activation and an undisrupted spray pattern.

Piping, sprinklers, valves, and other components that make up a sprinkler system are regulated to ensure an adequate degree of overall system reliability. Like other fire protection systems, sprinkler systems are emergency systems and, as such, are not intended to operate routinely as are other building systems. When the sprinkler system does operate, it is during a fire and, therefore, the system and all its components must perform as intended under adverse conditions. One means of ensuring proper system reliability is to require the use of only listed system components. Listed components are thoroughly evaluated by a testing laboratory and have a higher degree of reliability than nonlisted components. Another means necessary to achieve adequate system reliability is to conduct routine inspection, testing, and maintenance activities on the system. These activities are discussed later in this supplement.

Modifications to the Basic Principles of NFPA 13

Because NFPA 13 addresses both property protection and life safety, its requirements are the most restrictive of the three sprinkler system standards. Other NFPA codes and standards, including NFPA 101, supplement or modify the requirements of NFPA 13 to achieve other objectives related to protection against certain types of fire hazards. The most obvious of the modifications to NFPA 13 concerns the location of sprinklers.

As already noted, NFPA 13 requires that sprinklers be located throughout the premises with very few exceptions. Although NFPA 13 acknowledges the concept of a partial sprinkler system, it provides no provisions for such a system. NFPA 101, on the other hand, permits partial systems for certain types of facilities. For example, Chapter 31, dealing with existing apartment buildings, allows an option for providing sprinkler coverage in selected areas of the building only. More specifically 31.3.5.6 requires that

sprinklers be provided only in corridors, provided the doors to the dwelling units have at least a 20-minute fire protection rating and are self-closing. This partial sprinkler system is intended to protect building occupants against a fire that would impede the occupants' ability to exit the building. Sprinkler protection against fires in other areas that could cause severe property damage is not required because it is expected that building occupants can safely egress the building with the aid of other fire protection systems and features. However, it is important to note that partial sprinkler protection is permitted by NFPA 101 only for specific facilities and under limited conditions.

Another of the differences between NFPA 101 and NFPA 13 concerns the sounding of the sprinkler's waterflow alarm. NFPA 13 requires that initiation of the waterflow device only sound a local alarm at some point on the premises. Where NFPA 101 requires a supervised sprinkler system, the waterflow device must be part of the building's fire alarm system and initiation of the waterflow device must send an alarm signal to the fire department or approved alarm monitoring facility.

The differences between NFPA 13 and NFPA 101 with respect to sprinkler system requirements can best be explained by the purpose of NFPA 13: to protect property as well as human life. In most cases, where sprinklers are used to protect property, protection of life will also be accomplished. Property protection is usually a more difficult goal than life safety to achieve with sprinklers. Areas exempted from requiring sprinklers in NFPA 101 are those in which sprinklers would not be expected to have an impact on the number of injuries or fatalities from a fire. That same fire, however, might result in significant property damage; therefore, NFPA 13 contains no similar exemptions.

NFPA 13D

NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, was first published in 1975 in response to *America Burning: The Report of the Commission on Fire Prevention and Control*⁶, which was released in 1973. The America Burning Report revealed that, of the estimated 12,000 fire deaths occurring in the United States each year, a disproportionate number occurred in the home. The commission recommended that a low-cost fire protection system for the home be developed.

The first edition of NFPA 13D included the use of existing technology addressed by NFPA 13 for the

protection of commercial properties, with broader exceptions for omitting sprinkler coverage and reducing water supply duration. NFPA 13D mandates a minimum water supply duration of 10 minutes, whereas NFPA 13's minimum is 30 minutes under certain conditions. Shortly after the first edition of NFPA 13D was published, the United States Fire Administration (USFA) announced a research program to develop residential sprinkler system technology specifically for life safety.

Automatic sprinkler systems using standard spray sprinklers have been effective in reducing loss of life due to fire, primarily by providing protection to occupants in areas adjacent to or outside the room of fire origin. The aim of the USFA residential sprinkler research program was to develop a sprinkler that would control a fire in an occupied room for the period of time necessary for occupants to escape.

Response time, discharge pattern, duration of water supply, and fire loading in residential occupancies were among other factors investigated during the research program. The outcome of the program was the development of the residential sprinkler. The residential sprinkler differs from existing standard spray sprinklers in that it has a fast-response operating element—that is, the sprinkler responds sooner during a fire because it requires less heat to activate. It also possesses a discharge pattern that sprays water higher on a wall. The higher wall wetting characteristics of the sprinkler impede radiative feedback from the wall onto other combustibles in the room; they also significantly slow fire growth and spread. The second edition of NFPA 13D, published in 1980, incorporated the new technology of residential sprinklers.

NFPA 13R

NFPA 13R, *Standard for the Installation of Sprinkler Systems in Residential Occupancies up to and Including Four Stories in Height*, was first published in 1989 and is also geared toward life safety. The scope of NFPA 13R is limited to apartments, hotels, motels, select board and care facilities, and rooming houses four stories or less in height. NFPA 13R provides a high but not absolute level of life safety to building occupants and a lesser degree of property protection than NFPA 13.

NFPA 13R was developed in response to the success of the residential sprinkler and the growing need to apply this technology to larger residential occupancies. Certain communities were requiring sprinkler systems in multifamily residential occupancies and were developing their own installation rules. Al-

though NFPA 13 would have been acceptable for use in such properties, these communities desired a more cost-effective option that would provide a sufficient level of life safety and some degree of property protection.

NFPA 13R considers the economics of sprinkler protection by allowing the omission of sprinklers from more areas than that permitted by NFPA 13. However, the omissions are not as extensive as those in NFPA 13D. Such omissions result in the need for less hardware and therefore less labor to install the systems, thus reducing overall costs. NFPA 13R permits the omission of sprinklers in certain bathrooms, closets, porches, balconies, and concealed spaces that contain combustible construction materials. A significant area from which sprinklers are exempted is the attic. This exemption is based on the attic's not being used for living purposes or for storage. In most parts of the United States, an attic would require the use of a dry pipe system or an antifreeze system. These systems can significantly increase overall costs.

As with NFPA 101, the primary distinction between NFPA 13 and NFPA 13R is the designation of areas that do and do not require sprinklers. Rules concerning component installation, allowable materials, and design are identical in NFPA 13R and NFPA 13.

NFPA 13R is specified for use in numerous occupancies by NFPA 101, including those addressed in Chapters 24 through 33. One difference in scope between NFPA 13R and NFPA 101 centers on the application of NFPA 13R in certain residential board and care occupancies. In 33.3.3.5.1.1, NFPA 101 permits the use of NFPA 13R systems, regardless of the evacuation capability of residents, in existing facilities defined as "large." Conversely, NFPA 13R has intended to limit its scope to board and care facilities having 16 or fewer occupants in the slow evacuation category or any number of occupants who might fit into the prompt evacuation category. Since NFPA 13R permits the omission of sprinklers in a number of spaces, fires that occur in these unsprinklered areas are likely to have a greater impact on residents who require additional evacuation time.

DETERMINING THE FIRE HAZARD

Proper determination of the fire hazards present is crucial to the overall success of a sprinkler system. Sprinkler systems are not generic, where "one size fits all." Each system must be individually designed so that it can adequately control or suppress the fire hazards anticipated in a given facility.

With few exceptions, such as where certain sprin-

klers will be used for storage facilities or dwelling units, fire hazards are to be categorized according to one of five *occupancy hazards* presented in NFPA 13. The occupancy hazards range from the least severe (light hazard) to the most severe (extra hazard, group 2).

The occupancy hazards provide a convenient means for categorizing the fuel loads and fire severity associated with certain building operations, and they present a relationship between the burning characteristics of these fuels and the ability of a sprinkler system to control the associated types of fires. The likelihood of ignition is not considered in the occupancy hazard classifications.

To a large degree, determination of the proper occupancy hazard classification in accordance with NFPA 13 is the most critical decision. This determination affects all sprinkler system design and installation factors such as sprinkler discharge criteria, sprinkler spacing, and water supply requirements. Fundamentally, the less severe the fire hazard, the smaller the water demand for the sprinkler system. Additionally, each sprinkler will be permitted to cover a larger floor area, thus resulting in fewer sprinklers for the building. Likewise, the more severe the fire hazard, the larger the total water demand and the smaller the floor area that can be protected by a single sprinkler.

It is important to note that an entire building does not necessarily have to fall within a single occupancy hazard classification. Rather, each space needs to be considered individually when determining the occupancy hazard. For example, NFPA 13 would typically treat an educational facility as a light hazard occupancy, a classification that holds true for spaces such as classrooms, offices, and cafeteria seating areas. However, the light hazard classification is not valid for such areas as a wood shop, laboratory, or food preparation area. Spaces such as the wood shop contain more hazardous materials with a higher heat release rate; therefore, that portion of the sprinkler

system that is effective for classrooms cannot be expected to be effective for a fire in a wood shop.

The occupancy hazards presented in NFPA 13 should not be interpreted as a generic description or quantification of fire hazards, and they are not intended to parallel the occupancy classifications used in the *Life Safety Code*. Although these two concepts are similar in some ways, they have different meanings. *Occupancy classification* refers to the relative fire threat to building occupants from the contents and operations of that building. *Occupancy hazard* is associated with the description of the relative fire challenge present in a building and the ability of the sprinkler system to control it.

NFPA 13 provides a comprehensive list of *occupancy hazards* to determine the design parameters for a sprinkler system, in a similar way that Chapter 6 of the *Life Safety Code* provides descriptions of the classification of occupancies. Table S3.1 illustrates some of the differences between the occupancy hazards defined in NFPA 13 and the hazard of contents classifications used by the *Life Safety Code*. Table S3.1 represents a partial listing of the occupancies addressed by NFPA 13 and NFPA 101 and is representative of the 2002 and 2003 editions of these documents, respectively.

SYSTEM COMPONENTS AND HARDWARE

Regardless of which sprinkler standard is used, similar components and concepts are employed for the design and installation of a sprinkler system. For example, all systems consist of a pipe network for delivering water to the sprinklers. Hangers attached to the building structure support the pipe network. Control valves serve to isolate the water supply and other portions of the system. A waterflow device and an alarm mechanism notify building occupants or others that water is flowing through the system. NFPA's sprinkler standards ensure that all system compo-

Table S3.1 NFPA 13/NFPA 101 Occupancies

Occupancy	NFPA 13 Occupancy Hazard	NFPA 101 Hazard of Contents
Assembly	Light hazard	Ordinary hazard
Health care	Light hazard	Ordinary hazard
Mercantile	Ordinary hazard (group 2)	Ordinary hazard
Storage up to 3.7 m (12 ft) in height	Ordinary hazard (group 2)	Ordinary hazard
Industrial (using flammable and combustible liquids)	Extra hazard (group 2)	High hazard

nents are properly coordinated to provide reliable and effective system performance.

Sprinklers

Sprinklers vary in shape and form and differ in use or purpose. When the first “conventional” sprinkler was developed in the 1870s, it was primarily intended for use in industrial environments. In the 1950s, the spray sprinkler was introduced and became the dominant sprinkler. The standard spray sprinkler continues to be effective in controlling fires for a broad range of occupancies. However, other types of sprinklers have since been introduced.

The standard spray sprinkler is available as an upright, pendent, or sidewall model. Exhibit S3.1 illustrates a standard spray pendent and an upright sprinkler manufactured by Viking. As will be discussed, this sprinkler uses a standard response operating element. Depending on the occupancy being protected and the construction features of the space, the sprinkler’s discharge could adequately cover a floor area of up to 20.8 m² (225 ft²).

Since the introduction of the standard spray sprinkler, numerous other varieties of sprinklers have been introduced. Technology associated with sprinklers has advanced further than the technology for any other sprinkler system component. These advances have been spurred by past successes with sprinkler systems, the desire for more cost-effective systems, and the need for systems to specifically achieve life safety and fire suppression.

Residential Sprinklers. Since 1896, sprinklers have been designed to control fire growth rather than to suppress or extinguish fire. This concept was especially apparent during the residential sprinkler program undertaken in the mid-1970s that focused on

and resulted in the production of listed residential sprinklers. Residential sprinklers are designed to provide a tenable environment for occupants in the room of fire origin, not necessarily to protect an occupant in the room of fire origin who is intimate with the ignition source.

Although residential sprinklers were specifically developed for use in NFPA 13D systems, they are acceptable for use in any of the residential occupancies addressed by NFPA 13R and NFPA 13. Residential sprinklers are currently listed using UL 1626, *Standard for Residential Sprinklers*⁷, and FM Class 2030, *Approval Standard for Residential Automatic Sprinklers*⁸. Residential sprinklers are evaluated for their ability to control air temperatures at a level 1.5 m (5 ft) above the floor and to minimize the production of carbon monoxide. In addition, residential sprinklers are thermally sensitive and are designed to activate during a fire’s early stages of development. Residential sprinklers fall under the category of fast-response sprinklers. The fast-response characteristic, along with the sprinkler’s unique discharge pattern, makes it possible to maintain tenable conditions in the room of fire origin.

Residential sprinklers are available in either pendent or sidewall models. Exhibit S3.2 shows a horizontal sidewall residential sprinkler manufactured by Viking Corporation. Exhibit S3.3 shows the installation of a sidewall sprinkler in a hotel room. The criteria for installing residential sprinklers differ from those required for standard spray sprinklers and are addressed by NFPA 13, NFPA 13R, and NFPA 13D. In general, the minimum required flow rate from each residential sprinkler is determined when the sprinkler is listed and in accordance with the limitations established by NFPA 13, NFPA 13R, and NFPA 13D for residential sprinklers.

Over the course of approximately 14 years, the

Exhibit S3.3 Installation of sidewall sprinkler in a hotel room.

use of the residential sprinkler has been responsible for several “saves,” as documented by Operation Life Safety, a program conducted by the International Association of Fire Chiefs. Residential sprinklers performed as intended in fires characterized by a wide range of residential fire scenarios.

Quick-Response Sprinklers. A direct result of the residential sprinkler program was the development of other fast-response sprinklers such as the quick-response (QR) sprinkler. Listed QR sprinklers are similar to standard spray sprinklers except that they possess a fast-response operating element. Other characteristics, such as discharge pattern, remain the same. QR sprinklers are available as upright, pendant, or sidewall sprinklers. Exhibit S3.4 illustrates a standard response sprinkler and a quick response sprinkler.

Exhibit S3.4 Grinnell Model A standard-response spray sprinkler (left) and Viking Model A quick-response standard spray sprinkler (right). (Courtesy of TYCO and Viking)

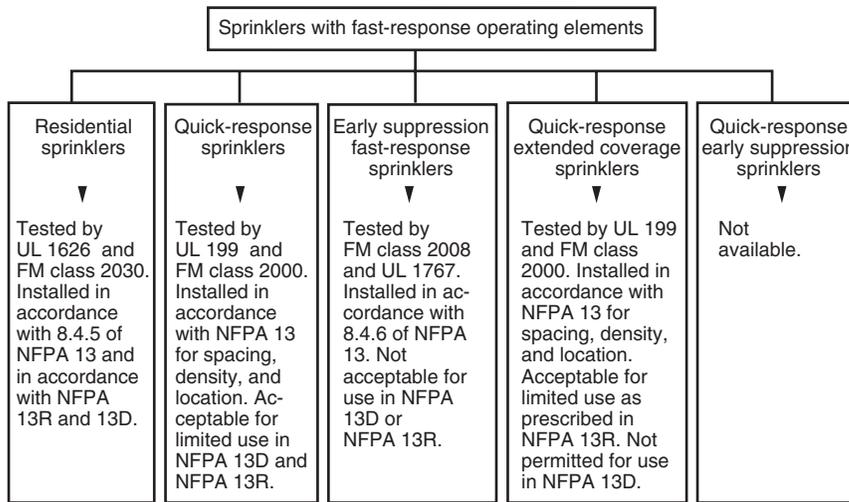

Although differences between QR sprinklers and residential sprinklers exist, QR sprinklers are permitted for use in both residential and nonresidential occupancies, with certain limitations. The QR sprinkler is evaluated according to UL 199, *Standard for Automatic Sprinklers for Fire Protection Service*⁹, or FM Class 2000, *Approval Standard for Automatic Sprinklers for Fire Protection*¹⁰. These product standards are used to evaluate the effectiveness of QR sprinklers as well as other types of standard response sprinklers.

QR sprinklers discharge their spray pattern in a manner that differs from that of residential sprinklers. Therefore, QR sprinklers are not specifically designed for the same purpose as residential sprinklers, although they provide a higher level of protection to occupants than standard response sprinklers. In recognition of this fact, NFPA 101 allows the use of QR sprinklers in certain occupancies in the same manner as the residential sprinkler.

Recognizing the associated life safety benefits, NFPA 13 mandates the use of quick-response sprinklers in all light hazard occupancies as defined by NFPA 13. The exception is that residential sprinklers can be used in residential occupancies. Additionally, NFPA 13 includes incentives for using QR sprinklers in ordinary hazard occupancies. Because of the types of fires expected and the overall fire safety objectives, the use of QR sprinklers in extra hazard occupancies is not currently advocated.

There is a tendency to use the terms *residential sprinkler* and *quick-response sprinkler* interchangeably.

Exhibit S3.5 Types of fast-response sprinklers.

Although similar in some respects, these two sprinklers differ in terms of their intended use, discharge characteristics, and positioning requirements. Exhibit S3.5 provides an overview of the various types of fast-response sprinklers.

The most common measure for determining a sprinkler’s responsiveness to heat from a fire is the response time index (RTI). RTI values are used to gauge the thermal sensitivity of a sprinkler to determine whether it meets the criteria for a fast-response sprinkler. In general, this measurement is determined by the rapidity at which the thermal element will operate under a standardized test condition.

Other Sprinkler Types and Styles. In addition to the creation of the residential sprinkler, the USFA residential program initiated further sprinkler research. Today, numerous types and styles of sprinklers exist. Sprinklers have literally become a specialty item, considering the form and function of sprinklers in today’s market. For example, sprinklers are now available with custom color finishes that blend with certain wall and ceiling finishes. Other devices are low profile and streamlined to the point that they are not easily noticed. Certain sprinklers can be installed behind special concealed plates coated by the sprinkler manufacturer to match the ceiling background. Exhibits S3.6, S3.7, and S3.8 illustrate the use of concealed sprinklers in residential dwelling units. It is important to note that coatings applied to a sprinkler to enhance its appearance or corrosion protection are permitted to be applied only by the sprinkler manufacturer.

Extended coverage (EC) sprinklers are available for use in today’s sprinkler systems. As its name implies, this device is tested and listed to cover relatively

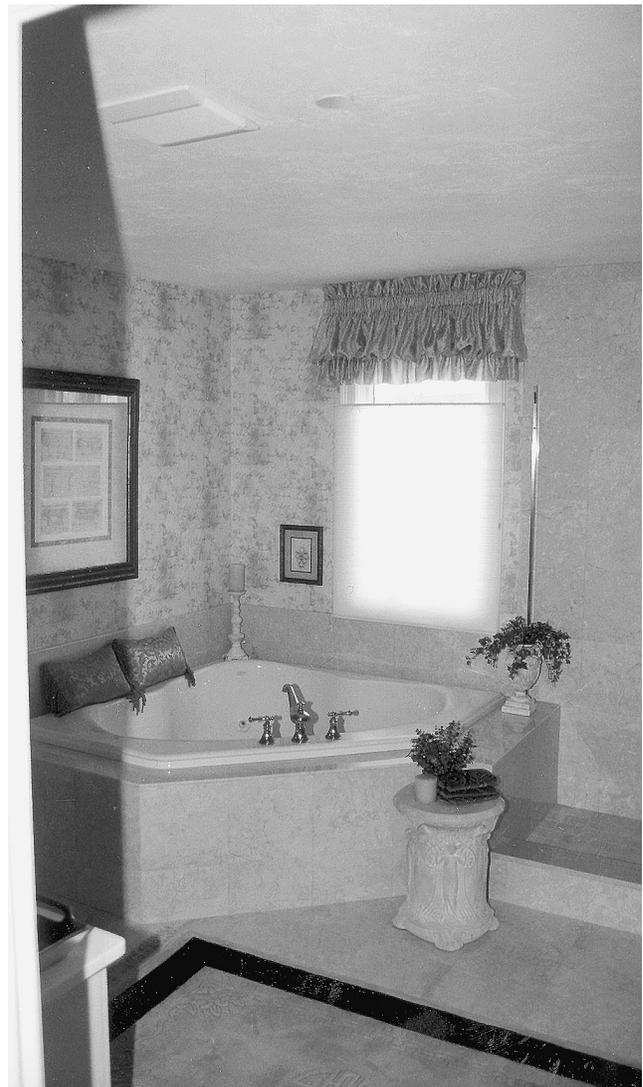

Exhibit S3.6 Concealed sprinkler application in a bathroom.

Exhibit S3.7 Concealed sprinkler application in a living room.

Exhibit S3.8 Concealed sprinkler application in a residential kitchen.

large areas. For example, some EC sprinklers are capable of covering a 6.1 m × 6.1 m (20 ft × 20 ft) area, whereas a standard spray sprinkler is limited to maximum of 4.6 m × 4.6 m (15 ft × 15 ft) under ideal conditions.

Exhibit S3.9 illustrates a pendent-mounted EC sprinkler. One advantage of this sprinkler's ability to protect larger floor areas is that fewer sprinklers are needed to protect a building than with standard spray sprinklers. However, the downside is that EC sprinklers require a higher operating pressure and a greater rate of waterflow.

EC sprinklers are available as upright, pendent, or sidewall models. In addition, EC sprinklers can possess more thermally sensitive operating elements,

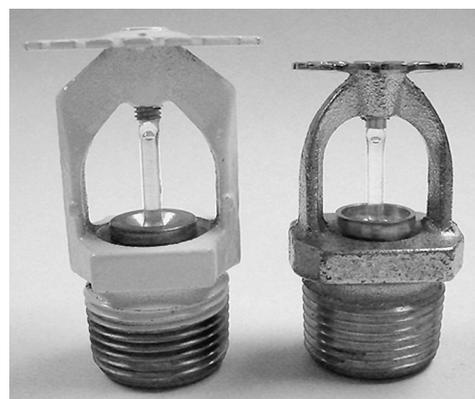

Exhibit S3.9 Pendent-type extended coverage sprinklers.

since the sprinklers can be located at a distance farther from a potential fire. However, just because an EC sprinkler contains a more thermally sensitive operating element, it should not be considered a fast-response sprinkler unless specifically listed as such. On the other hand, some EC sprinklers are listed as such and are referred to as quick-response, extended-coverage (QREC) sprinklers.

Identification of Sprinklers. One of the changes to the 1999 edition of NFPA 13 included the establishment of a sprinkler identification marking, which became effective in January 2001. The marking has provided a degree of order among the large number of sprinkler types and styles available on the worldwide market and has served to better facilitate the interchangeability of sprinklers. The marking is stamped on the sprinkler and entered into a database maintained by the listing laboratories and the International Fire Sprinkler Association. The database is currently accessible via the Internet.

The sprinkler marking identifies the manufacturer and the model number so that the sprinkler's function and application can be more easily identified. Sprinkler characteristics such as orifice size and shape, deflector characteristic, and thermal sensitivity are now more easily referenced. It is intended that the marking be checked against the database to ensure that the sprinklers are used properly and within the limitations of their listings.

In addition to the model number, other markings may also be imprinted on the device. These additional items can include the temperature rating, orifice diameter, identification of the listing organization, and a designation indicating the orientation or type of sprinkler. Although not specifically mandated, the coding given in Table S3.2 is often used to identify certain sprinkler types.

Sprinklers for High-Challenge Fires. In the case of high-challenge fires, such as those found in warehouses, standard spray sprinklers with large orifices, large-drop sprinklers, and early-suppression, fast-response (ESFR) sprinklers are commonly used.

These sprinklers have undergone a significant amount of full-scale fire testing in conjunction with the application of fire engineering principles to verify their performance and installation criteria.

The large-drop sprinkler program managed by the Factory Mutual Research Corporation in the mid-1980s developed a sprinkler capable of producing water droplets of size and mass sufficient to penetrate the fire plumes typical of storage-type fires. The result of this effort was the large-drop sprinkler as shown in Exhibit S3.10. Formerly, a standard response sprinkler was used to control warehouse fires. This research program continued to pursue the development of a sprinkler that could suppress rather than just control a warehouse fire.

In 1988, Factory Mutual granted approval for the ESFR sprinkler. This device combines fast-response technology, a very high rate of waterflow, and the production of large water droplets to penetrate the upward momentum of the fire plume and deliver water to the surface of the burning materials. Several varieties of ESFR sprinklers are now available, as shown in Exhibit S3.11. The largest of these has an orifice of about 25 mm (1 in.) and is required to flow approximately 178 gpm (674 L/min). The ESFR sprinkler is the only suppression-mode sprinkler currently available.

High-challenge sprinklers are not intended for use in most of the occupancies addressed by NFPA 101. These sprinklers are intended for use in large storage facilities and are not specified for use by NFPA 101.

Table S3.2 Identification Codes for Sprinkler Types

Sprinkler	Coding
Standard spray pendent	SSP
Standard spray upright	SSU
Extended coverage	EC
Quick-response	QR
Quick-response, extended-coverage	QREC
Residential	RES

Pipe Materials

Some pipe materials have been permitted for use by NFPA 13 for more than 100 years. For example, schedule 40 steel pipe has been the prominent material used for sprinkler systems for many years. In the 1950s, copper tubing was introduced as an acceptable material, but its use was not fully recognized by NFPA 13 until 1965. The standard currently allows three different types of copper tubing to be used. Both steel pipe and copper tube fabricated to one of the manufacturing standards identified by NFPA 13, 13R, and 13D do not need to be specifically listed for fire protection service.

NFPA 13 also permits the use of steel pipe that is not fabricated to one of the manufacturing standards specified, provided such steel pipe is specifically listed for fire protection service. Thin-wall steel pipe has been made available for use in sprinkler systems. This material results in somewhat better hydraulic characteristics and is easier to handle due to its lighter weight.

In 1984, the Shell Oil Company made a significant breakthrough in sprinkler system component technology when it introduced the first nonmetallic pipe for sprinkler systems. This material, polybutylene (PB) pipe, is specifically listed for fire protection service and was initially permitted for use only in systems designed under the requirements of NFPA 13D. In 1986, permission for its use was extended to all light hazard occupancies as defined by NFPA 13. This material continues to be acceptable for use in light hazard occupancies as well as in those facilities addressed by NFPA 13R and NFPA 13D. However, the resin used in the manufacture of various grades of PB pipe is no longer produced because of problems with other types of PB products.

Another nonmetallic product entered the market in 1986. The BF Goodrich Tire and Rubber Company developed a resin and licensed several manufacturers to produce chlorinated polyvinyl chloride (CPVC) pipe. This pipe is also specifically listed for fire protection service and is fully recognized as an acceptable component in sprinkler system design. As with PB pipe, its use is limited to light hazard occupancies as defined by NFPA 13 and to systems designed according to NFPA 13D and NFPA 13R.

Both PB and CPVC pipe come with unique installation restrictions and rules as set by the manufacturer and the listing laboratory. These rules include but are not limited to (1) use only in wet pipe systems; (2) mandatory installation behind a protective barrier, such as a ceiling (note that the CPVC product is permitted to be installed exposed under special conditions); and (3) support of the pipe in accordance with the manufacturer's instructions.

Selection of those pipe materials permitted by NFPA's sprinkler system standards for a specific project could be based on a number of factors that need to be considered in unison. Each pipe material possesses its own advantages and disadvantages. For example, the advantage of using a lighter material, such as nonmetallic pipe, needs to be weighed against the need to follow specific manufacturer's technical data sheets to ensure correct installation. Another example includes schedule 40 steel pipe, which has a thicker wall and is more forgiving when threading or cut grooving the ends. In this instance, the tradeoff involves greater weight per length of pipe, which might translate to higher labor costs and perhaps less effective hydraulic characteristics when compared to thinner-walled pipe.

Some sprinkler contractors prefer the use of copper tube or nonmetallic pipe for the installation of new systems in existing buildings. The advantage of lighter materials plus the flexibility associated with these materials is a key consideration. This can result in reduced labor costs. In many cases, the pipe material is chosen on the basis of the capabilities, resources, and comfort level of the installing contractor.

Fittings

NFPA 13 has similar rules for fittings as it does for pipe materials. NFPA 13 permits the use of nonlisted cast iron, malleable iron, steel, and copper fittings to be used provided they are manufactured to certain standards. A number of special fittings that are specifically listed for fire protection service are also available. Specially listed fittings usually reduce the effort needed to join pipe materials, but they can possess

less desirable hydraulic characteristics. Additionally, special fittings possess unique installation instructions as set by the manufacturers and the listing laboratory.

Specially listed fittings are evaluated for their compatibility with specific types of pipe and their ease of installation. Grooved end fittings, for example, are listed for use only with specific types of listed couplings and listed rubber gaskets. In most cases, the fitting, coupling, and gasket are made by the same manufacturer. The availability of such fittings can decrease installation time and effort, but it requires that the authority having jurisdiction verify the compatibility of the assemblies.

INSPECTION, TESTING, AND MAINTENANCE OF SPRINKLER SYSTEMS

Inspection, testing, and maintenance activities are crucial for effective sprinkler system performance. This is especially true because of the inactive nature of a sprinkler system. Unlike other types of building systems intended for use on a routine basis, the sprinkler system will only be used during emergency situations. The system's proper operating condition is not verifiable through day-to-day operations as are those of heating, air-conditioning, and plumbing systems. Therefore, NFPA 13 requires that the building owner or designated representative employ and follow an inspection, testing, and maintenance program specified in NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*¹¹. Additionally, NFPA 101 requires compliance with NFPA 25.

NFPA 25 provides a detailed program for conducting visual examinations (inspections), physical checks (tests), and work (maintenance) on various system components to keep water-based fire protection systems in proper working condition. Chapter 5 of NFPA 25 pertains specifically to sprinkler systems. However, certain portions of Chapter 12 from NFPA 25 are also applicable, since that chapter addresses all valves associated with water-based fire protection systems, including sprinkler systems. Table S3.3, from NFPA 25, summarizes the requirements specific to sprinkler systems.

Some of the inspection items are relatively straightforward and require only a visible observation of the specified component. For example, when inspecting sprinklers, it must be verified that the sprinklers have not been damaged or painted and that their discharge pattern will remain unobstructed. Inspection of pipe and pipe hangers should determine

that the pipe is undamaged and that hangers remain securely attached to the building structure and the pipe they are supporting.

Testing of certain system components requires a more hands-on approach and a more thorough understanding of sprinkler systems. Testing normally requires that water be flowed through portions of the system and that certain measurements such as elapsed time and pressure change be recorded. Testing activities serve to ensure proper operation of the component being operated during the test as well as to verify overall operation of the system.

Maintenance activities typically require more effort. Even the more basic activities such as replacing a painted sprinkler require that the entire sprinkler system or a portion of it be shut down and drained before the sprinkler can be replaced. Other maintenance activities can become more involved, such as investigating the interior of system piping to determine whether obstructions are present and then removing the obstructions.

Although inspection, testing, and maintenance activities are usually associated with specific components of the sprinkler system, the scope of NFPA 25 extends beyond these activities. The purpose of NFPA 25 is to provide a means to ensure that the sprinkler system will perform as intended in accordance with NFPA 13 or NFPA 13R. Therefore, NFPA 25 addresses any occurrence that can impair a sprinkler system's ability to control or suppress a fire. Changes in building use or construction fall into this category. The operations of a given facility can vary significantly over time and change the overall fire hazard or the fire hazard in certain spaces. More common is the relocation of walls and other building features that can delay sprinkler activation times and obstruct spray patterns. These potential building modifications must be properly accounted for when conducting inspection, testing, and maintenance activities, and when evaluating the adequacy of an existing sprinkler system.

A sprinkler system not in compliance with the requirements of NFPA 25 is not in compliance with NFPA 13. An improperly maintained system is likely to be impaired in some way and cannot be expected to meet its fire protection objectives. In terms of life safety, an impaired system can have a more detrimental effect on overall building fire safety than if no sprinkler protection was provided at all. For example, the *Life Safety Code* provides certain provisions for increasing travel distances and reducing construction ratings where sprinkler systems are installed. Therefore, if a sprinkler system is impaired, the building occupant would be at a greater disadvantage.

Table S3.3 Summary of Sprinkler System Inspection, Testing, and Maintenance

Item	Activity	Frequency	NFPA 25 Reference
Gauges (dry, preaction, and deluge systems)	Inspection	Weekly/monthly	5.2.4.2, 5.2.4.3
Control valves	Inspection	Weekly/monthly	Table 12.1
Alarm devices	Inspection	Quarterly	5.2.6
Gauges (wet pipe systems)	Inspection	Monthly	5.2.4.1
Hydraulic nameplate	Inspection	Quarterly	5.2.7
Buildings	Inspection	Annually (prior to freezing weather)	5.2.5
Hanger/seismic bracing	Inspection	Annually	5.2.3
Pipe and fittings	Inspection	Annually	5.2.2
Sprinklers	Inspection	Annually	5.2.1
Spare sprinklers	Inspection	Annually	5.2.1.3
Fire department connections	Inspection	Quarterly	Table 12.1
Valves (all types)	Inspection		Table 12.1
Alarm devices	Test	Quarterly/Semiannually	5.3.3
Main drain	Test	Annually	Table 12.1
Antifreeze solution	Test	Annually	5.3.4
Gauges	Test	5 years	5.3.2
Sprinklers—extra-high temperature	Test	5 years	5.3.1.1.1.3
Sprinklers—fast response	Test	At 20 years and every 10 years thereafter	5.3.1.1.1.2
Sprinklers	Test	At 50 years and every 10 years thereafter	5.3.1.1.1
Valves (all types)	Maintenance	Annually or as needed	Table 12.1
Obstruction investigation	Maintenance	5 years or as needed	13.2.1, 13.2.2
Low point drains (dry pipe system)	Maintenance	Annually prior to freezing and as needed	12.4.4.3.3

CLOSING REMARKS

Sprinkler systems have established an enviable record for achieving life safety and property protection for well over 100 years. However, it is imperative that the appropriate NFPA sprinkler system standard be followed for designing, installing, and maintaining these systems. While NFPA's sprinkler system standards provide many options for achieving effective system performance, these documents are not textbooks providing basic instruction about sprinkler systems. Proper sprinkler system performance requires that only knowledgeable, qualified people design, install, maintain, inspect, and review plans for these systems.

Through the Fire Protection Research Foundation and other associated organizations, as well as the research and development activities undertaken by sprinkler system component manufacturers and insurance interests, new sprinkler system breakthroughs occur each year. These efforts continue to build on the impressive record of sprinkler systems and will lead to even more options for effective and economical systems.

SUPPLEMENT 4

Extracts from ASME Elevator Code and Handbook

Editor's Note: This supplement provides the reader with detailed information on elevator emergency operation and signaling devices. It consists of extracted material from ASME A17.1, Safety Code for Elevators and Escalators, and its accompanying handbook.

EXTRACTS FROM ASME A17.1, SECTION 2.27, EMERGENCY OPERATION AND SIGNALING DEVICES[†]

NOTE (2.27): Additional requirements may be found in the building code.

2.27.1 Car Emergency Signaling Devices

2.27.1.1 Emergency Communications

2.27.1.1.1 A two-way communications means between the car and a location in the building, that is readily accessible to authorized and emergency personnel shall be provided.

2.27.1.1.2 When the two-way communications location in the building is not staffed 24 h a day, by authorized personnel who can take appropriate action, the means of two-way communications shall automatically be directed within 30 s to an additional on- or off-site location, staffed by authorized personnel, where an appropriate response can be taken.

2.27.1.1.3 The two-way communication means within the car shall comply with the following requirements:

(a) In jurisdictions enforcing NBCC, Appendix E of CAN/CSA B44, or in jurisdictions not enforcing NBCC, ICC/ANSI A117.1.

(b) A push button to actuate the two-way communication means shall be provided in or adjacent

to a car operating panel. The push button shall be visible and permanently identified as "HELP." The identification shall be on or adjacent to the "HELP" button. When the push button is actuated, the emergency two-way communication means shall initiate a call for help and establish two-way communications.

(c) A visual indication on the same panel as the "HELP" push button shall be provided, which is activated by authorized personnel, to acknowledge that two-way communications link has been established. The visual indication shall be extinguished when the two-way communication link is terminated.

(d) The two-way communication means shall provide on demand to authorized personnel, information that identifies the building location and elevator number and that assistance is required.

(e) After the call acknowledgement signals are sent [2.27.1.1.3(c)], the two-way voice communications shall be available between the car and authorized personnel.

(f) The two-way communications, once established, shall be disconnected only when authorized personnel outside the car terminate the call.

(g) The two-way communication means shall not use a handset in the car.

(h) The two-way communications shall not be transmitted to an automated answering system. The call for help shall be answered by authorized personnel.

(i) Operating instructions shall be incorporated with or adjacent to the "HELP" button.

[†]Reprinted from ASME A17.1—2000 by permission of The American Society of Mechanical Engineers. All rights reserved.

2.27.1.1.4 Where the elevator travel is 18 m (60 ft) or more, a two-way voice communication means within the building shall be provided and comply with the following requirements:

(a) The means shall enable emergency personnel within the building to establish two-way voice communications to each car individually. Two-way voice communication shall be established without any intentional delay and shall not require intervention by a person within the car. The means shall override communications to outside of the building.

(b) Two-way voice communications, once established, shall be disconnected only when emergency personnel outside the car terminates the call.

(c) Once the two-way voice communication has been established, the visual indication [see 2.27.1.1.3(c)] within the car shall illuminate. The visual indication shall be extinguished when the two-way communication is terminated.

(d) Operating instructions shall be incorporated with or adjacent to the two-way voice communication outside the car. Instructions shall conform to 2.27.7.3.

2.27.1.1.5 If the emergency communication means is normally connected to the building power supply, it shall automatically transfer to a source of standby or emergency power as required by the applicable building code or, where applicable, Standard for Health Care Facilities (ANSI/NFPA-99), after the normal power supply fails. The power source shall be capable of providing for illumination of the visual indication [see 2.27.1.1.3(c)] within the car, and the means of emergency communications for at least 4 h; and the audible signaling device (see 2.27.1.2) for at least 1 h.

2.27.1.2 Emergency Stop Switch Audible Signal. When an emergency stop switch (2.26.2.5) is provided, an audible signaling device shall be provided. The audible signaling device shall

(a) have a rated sound pressure rating of not less than 80 dBA nor greater than 90 dBA at 3 m (10 ft);

(b) respond without delay after the switch has been activated;

(c) be located inside the building and audible inside the car and outside the hoistway; and

(d) for elevators with a travel greater than 30 m (100 ft), be duplicated as follows:

- (1) one device shall be mounted on the car; and
- (2) a second device shall be placed at the designated level.

2.27.2 Emergency or Standby Power System

Where an emergency or standby power system is provided to operate an elevator in the event of normal power supply failure, the requirements of 2.27.2.1 through 2.27.2.5 shall be complied with.

2.27.2.1 The emergency or standby power system shall be capable of operating the elevator(s) with rated load (see 2.16.8), at least one at a time, unless otherwise required by the building code.

2.27.2.2 The transfer between the normal and the emergency or standby power system shall be automatic.

2.27.2.3 An illuminated signal marked "ELEVATOR EMERGENCY POWER" shall be provided in the elevator lobby at the designated level to indicate that the normal power supply has failed and the emergency or standby power is in effect.

2.27.2.4 Where the emergency or standby power system is not capable of operating all elevators simultaneously, requirements of 2.27.2.4.1 through 2.27.2.4.5 shall be conformed to.

2.27.2.4.1 A selector switch(es) marked "ELEVATOR EMERGENCY POWER" in red lettering a minimum of 5 mm (0.25 in.) in height, which is key-operated or under a locked cover (see 2.27.8), shall be provided to permit the selection of the elevator(s) to operate on the emergency or standby power system. The key shall be Group 3 Security (see 8.1).

2.27.2.4.2 The selector switch(es) positions shall be marked to correspond with the elevator identification number (see 2.29) and a position marked "AUTO."

2.27.2.4.3 The selector switch(es) shall be located at the designated level in view of all elevator entrances, or if located elsewhere means shall be provided adjacent to the selector switch(es) to indicate that the elevator is at the designated level with the doors in the normally open position.

2.27.2.4.4 When the selector switch is in the "AUTO" position, automatic power selection shall be provided which will return each elevator that is not on designated attendant operation, inspection operation or Phase II In-Car Emergency Operation, one or more at a time, to the recall level. Failure of the selected car to move shall cause power to be transferred to another car.

2.27.2.4.5 The selector switch(es) positions corresponding to the elevator identification numbers (see 2.29.1) shall override the automatic power selection.

Operation of the selector switch(es) shall not cause power to be removed from any elevator until the elevator is stopped.

NOTE (2.27.2.4): The selector switch(es) should normally be placed in the "AUTO" position.

2.27.2.5 When the emergency or standby power system is designed to operate only one elevator at a time, the energy absorption means (if required) shall be permitted to be located on the supply side of the elevator power disconnecting means, provided all other requirements of 2.26.10 are conformed to when operating any of the elevators the power might serve. Other building loads, such as power and lights that can be supplied by the emergency or standby power system, shall not be considered as a means of absorbing the regenerated energy for the purposes of conforming to 2.26.10, unless such loads are normally powered by the emergency or standby power system.

2.27.3 Firefighters' Emergency Operation—Automatic Elevators

Firefighters' Emergency Operation shall apply to all automatic elevators except

(a) where the hoistway or a portion thereof is not required to be fire-resistive construction (see 2.1.1.1), the travel does not exceed 2000 mm (80 in.), and the hoistway does not penetrate a floor;

(b) in jurisdictions enforcing the NBCC where the NBCC does not require Firefighters' Emergency Operation.

Where Firefighters' Emergency Operation is provided voluntarily these requirements shall also apply.

2.27.3.1d Phase I Emergency Recall Operation

2.27.3.1.1 A three-position key-operated switch shall be

(a) provided only at the designated level for each single elevator or for each group of elevators;

(b) labeled "FIRE RECALL" and its positions marked "RESET," "OFF," and "ON" (in that order), with the "OFF" position as the center position. The "FIRE RECALL" letters shall be a minimum of 5 mm (0.25 in.) high in red or a color contrasting with a red background;

(c) located in the lobby within sight of the elevator or all elevators in that group and shall be readily accessible.

2.27.3.1.2 An additional key-operated "FIRE RECALL" switch, with two-positions, marked "OFF"

and "ON" (in that order), shall be permitted only at the building fire control station.

2.27.3.1.3 The switch(es) shall be rotated clockwise to go from the "RESET" (designated level switch only), to "OFF" to "ON" positions. Keys shall be removable only in the "OFF" and "ON" positions.

2.27.3.1.4 Only the "FIRE RECALL" switch(es) or fire alarm initiating device located at floors that are served by the elevator, or in the hoistway, or in the elevator machine room (see 2.27.3.2) shall initiate Phase I Emergency Recall Operation.

2.27.3.1.5 All "FIRE RECALL" switches shall be provided with an illuminated visual signal to indicate when Phase I Emergency Recall Operation is in effect.

2.27.3.1.6 When a "FIRE RECALL" switch is in the "ON" position all cars controlled by the switch shall operate as follows:

(a) A car traveling towards the designated level shall continue nonstop to the designated level and power-operated doors shall open and remain open.

On cars with two entrances, if both entrances can be opened at the designated level, only the doors serving the lobby where the "FIRE RECALL" switch is located shall open and remain open.

(b) A car traveling away from the designated level shall reverse at or before the next available landing without opening its doors and proceed to designated level.

(c) A stopped car shall have the in-car stop switch (see 2.26.2.21) and the emergency stop switch in the car (see 2.26.2.5) when provided, rendered inoperative as soon as the car moves away from the landing. A moving car shall have the in-car stop switch and the emergency stop switch in the car when provided, rendered inoperative without delay. Once the emergency stop switch in the car and the in-car stop switch have been rendered inoperative, they shall remain inoperative while the car is on Phase I Emergency Recall Operation. All other stop switches required by 2.26.2 shall remain operative.

(d) A car standing at a landing other than the designated level, with the doors open and the in-car stop switch and the emergency stop switch in the car when provided, in the run position, shall conform to the following:

- (1) Elevators having automatic power-operated horizontally sliding doors shall close the doors without delay and proceed to the designated level.

(2) Elevators having power-operated vertically sliding doors provided with automatic or momentary-pressure closing operation per 2.13.3.4 shall have the closing sequence initiated without delay in accordance with 2.13.3.4.1, 2.13.3.4.2, 2.13.3.4.3, and 2.13.3.4.5, and the car shall proceed to the designated level.

(3) Elevators having power-operated doors provided with continuous pressure closing operation (see 2.13.3.2), or elevators having manual doors, shall be provided with a visual and audible signal system [see 2.27.3.1.6(h)] to alert an operator to close the doors and shall, when the doors are closed, proceed to the designated level. Sequence operation, if provided, shall remain effective.

(e) Door reopening devices for power-operated doors that are sensitive to smoke or flame shall be rendered inoperative without delay. Door reopening devices not sensitive to smoke or flame (e.g., mechanically actuated devices) are permitted to remain operative. Door closing for power-operated doors shall conform to 2.13.5.

(f) All car and corridor call buttons shall be rendered inoperative. All call registered lights and directional lanterns shall be extinguished and remain inoperative. Car position indicators, where provided, shall remain operative. Where provided, landing position indicators shall be extinguished and remain inoperative, except at the designated level and the building fire control station, where they shall remain operative.

(g) Where provided on elevators with vertically sliding doors, corridor door open and close buttons shall remain operative.

(h) All cars shall be provided with an illuminated visual and audible signal system which shall be activated to alert the passengers that the car is returning nonstop to the designated level. The visual graphic shall be as shown in Exhibit S4.1. The signals shall remain activated until the car has returned to the designated level.

(i) A car stopped at a landing shall have the in-car door open button rendered inoperative as soon as the car moves away from the landing. The in-car door open button shall remain inoperative when a car stops to reverse direction. Once the in-car door open button has been rendered inoperative, it shall remain inoperative until the car has returned to the designated level.

(j) Where an additional "FIRE RECALL" switch is provided, both "FIRE RECALL" switches shall be in the "ON" position to recall the elevator to the designated level if the elevator was recalled to the alternate level (see 2.27.3.2.4).

(k) To remove the elevator(s) from Phase I Emergency Recall Operation, the "FIRE RECALL" switch shall be rotated first to the "RESET," and then to the "OFF" position, provided that

- (1) the additional two-position "FIRE RECALL" switch, where provided, is in the "OFF" position; and
- (2) no fire alarm initiating device is activated (see 2.27.3.2).

(l) Means used to remove elevators from normal operation, other than as specified in this Code, shall not prevent Phase I Emergency Recall Operation.

(m) No device, which measures load, shall prevent operation of the elevator at or below the capacity and loading required in 2.16.

2.27.3.2 Phase I Emergency Recall Operation by Fire Alarm Initiating Devices

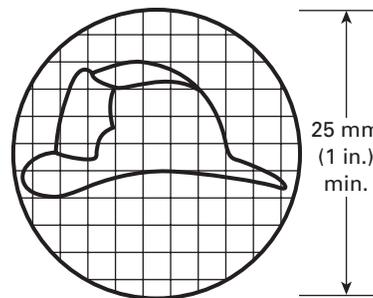

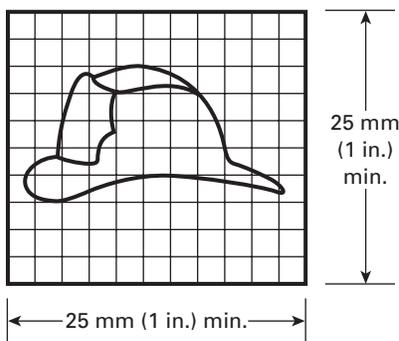

Exhibit S4.1 Visual signal [From ASME A17.1, Section 2.27, Fig. 2.27.3.1.6(h)]

GENERAL NOTE: Grid is for scaling purposes only.

2.27.3.2.1 In jurisdictions not enforcing the NBCC, fire alarm initiating devices used to initiate Phase I Emergency Recall Operation shall be installed in conformance with the requirements of NFPA 72, and shall be located

- (a) at each floor served by the elevator;
- (b) in the associated elevator machine room; and
- (c) in the elevator hoistway, when sprinklers are located in those hoistways.

2.27.3.2.2 In jurisdictions enforcing the NBCC, automatic Emergency Recall Operation shall be permitted when the following devices, complying with the requirements in the NBCC, initiate the operation:

- (a) smoke detectors installed in each elevator lobby, or the building fire alarm system;
- (b) smoke detectors installed in the elevator lobby at the designated level, if that floor area is not sprinklered throughout; and
- (c) smoke detectors installed in the machine room if the machine room is sprinklered.

2.27.3.2.3 Phase I Emergency Recall Operation to the designated level shall conform to the following:

(a) The activation of a fire alarm initiating device specified in 2.27.3.2.1 or 2.27.3.2.2(a) at any floor, other than at the designated level, shall cause all elevators that serve that floor, and any associated elevator of a group automatic operation, to be returned nonstop to the designated level.

(b) The activation of a fire alarm initiating device specified in 2.27.3.2.1(b) or 2.27.3.2.2(c) shall cause all elevators having any equipment located in that machine room, and any associated elevators of a group automatic operation, to be returned nonstop to the designated level. If the machine room is located at the designated level, the elevator(s) shall be returned nonstop to the alternate level.

(c) The activation of a fire alarm initiating device specified in 2.27.3.2.1(c) shall cause all elevators having any equipment in that hoistway, and any associated elevators of a group automatic operation, to be returned nonstop to the designated level, except that initiating device(s) installed at or below the lowest landing of recall shall cause the car to be sent to the upper recall level.

(d) The Phase I Emergency Recall Operation to the designated level shall conform to 2.27.3.1.6(a) through (m).

2.27.3.2.4 Phase I Emergency Recall Operation to an alternate level (see 1.3) shall conform to the following:

(a) the activation of a fire alarm initiating device specified in 2.27.3.2.1(a) or 2.27.3.2.2(a) that is located at the designated level, shall cause all elevators serving that level to be recalled to an alternate level, unless a "FIRE RECALL" switch is already in the "ON" position;

(b) the requirements of 2.27.3.1.6(f), (j), and (m);

(c) the requirements of 2.27.3.1.6(a), (b), (c), (d), (e), (g), (h), (i), (k), and (l), except that all references to the "designated level" shall be replaced with "alternate level."

2.27.3.2.5 The recall level shall be determined by the first activated fire alarm initiating device for that group [see 2.27.3.2.1 or 2.27.3.2.2, see also 2.27.3.1.6(j)].

2.27.3.2.6 When activated, a fire alarm initiating device in the machine room shall cause the visual signal [see 2.27.3.1.6(h) and Exhibit S4.1] to illuminate intermittently only in car(s) with equipment in that machine room. When activated, a fire alarm initiating device in the hoistway shall cause the visual signal [see 2.27.3.1.6(h) and Exhibit S4.1] to illuminate intermittently only in car(s) with equipment in that hoistway.

2.27.3.3 Phase II Emergency In-Car Operation. A three-position ("OFF," "HOLD," and "ON," in that order) key-operated switch shall be labeled "FIRE OPERATION"; provided in an operating panel in each car; and shall be readily accessible. The label "FIRE OPERATION" lettering shall be a minimum of 5 mm (0.25 in.) high in red or a color contrasting with a red background. It shall become effective only when Phase I Emergency Recall Operation is in effect and the car has been returned to the recall level. The switch shall be rotated clockwise to go from "OFF" to "HOLD" to "ON."

The key shall only be removable in the "OFF" and "HOLD" position. The "OFF," "HOLD," and "ON" positions shall not change the mode of operation within Phase II Emergency In-Car Operation until the car is at a landing with the doors in the normal open position, except as required by 2.27.3.3.4.

2.27.3.3.1 When the "FIRE OPERATION" switch is in the "ON" position, the elevator shall be on Phase II Emergency In-Car Operation, for use by emergency personnel only, and the elevator shall operate as follows:

(a) The elevator shall be operable only by a person in the car.

(b) The car shall not respond to landing calls. Directional lanterns, where provided, shall remain inoperative. Car position indicators, where provided,

shall remain operative. Landing position indicators, where provided, shall remain inoperative, except at the designated level and the building fire control station, where they shall remain operative.

(c) Door open and close buttons shall be provided for power-operated doors. The door open and close buttons shall be labeled "OPEN" and "CLOSE."

(d) The opening of power-operated doors shall be controlled only by a continuous-pressure door open button. If the button is released prior to the doors reaching the normal open position, the doors shall automatically reclose. Requirements 2.13.3.3, 2.13.3.4, 2.13.4.2.1(b)(2), and 2.13.4.2.1(c) do not apply.

On cars with multiple entrances, if more than one entrance can be opened at the same landing, separate door open buttons shall be provided for each entrance.

(e) Open power-operated doors shall be closed only by continuous pressure on the door close button. If the button is released prior to the doors reaching the fully closed position, horizontally sliding doors shall automatically reopen, and vertically sliding doors shall automatically stop or stop and reopen.

On cars with multiple entrances, if more than one entrance can be opened at the same landing, a separate door-close button shall be provided for each entrance.

(f) Opening and closing of power-operated car doors or gates that are opposite manual swing or manual slide hoistway doors shall conform to 2.27.3.3.1(d) and (e).

(g) All door reopening devices except the door open button shall be rendered inoperative. Full speed closing shall be permitted.

Landing door opening and closing buttons, where provided, shall be rendered inoperative.

(h) Every car shall be provided with a button marked "CALL CANCEL," located in the same car operating panel as the "FIRE OPERATION" switch, which shall be effective during Phase II Emergency In-Car Operation. When activated, all registered calls shall be canceled and a traveling car shall stop at or before the next available landing.

(i) Floor selection buttons shall be provided in the car to permit travel to all landings served by the car, and they shall be operative at all times, except as in 2.27.3.3.2. Means to prevent the operation of the floor selection buttons or door-operating buttons shall be rendered inoperative.

(j) A traveling car shall stop at the next available landing for which a car call was registered. When a

car stops at a landing, all registered car calls shall be canceled.

(k) Means used to remove elevators from normal operation, other than as specified in this Code, shall not prevent Phase II Emergency In-Car Operation.

(l) No device, which measures load, shall prevent operation of the elevator at or below the capacity and loading required in 2.16.

2.27.3.3.2 When the car is at a landing, with the doors open, and the "FIRE OPERATION" switch is in the "HOLD" position, the car shall remain at the landing with the doors open. The door close buttons shall be inoperative, and car calls shall not be registered.

2.27.3.3.3 When the car is at a landing other than the recall level, with the doors in the normal open position, and, the "FIRE OPERATION" switch is in the "OFF" position, power operated doors shall operate as follows:

(a) Horizontal sliding doors shall close automatically. All door reopening devices shall remain inoperative. Door open buttons shall remain operative. Full-speed closing is permitted. If the "FIRE OPERATION" switch is turned to the "ON" or "HOLD" position prior to the completion of door closing, the doors shall reopen.

(b) Elevators having vertically sliding doors shall have corridor door open and close buttons rendered inoperative. All door reopening devices shall remain inoperative. Door closing shall be in accordance with 2.27.3.3.1(e). Full-speed closing is permitted. If the "FIRE OPERATION" switch is turned to the "ON" or "HOLD" position prior to the completion of door closing, the doors shall reopen.

2.27.3.3.4 When the car is stopped with the doors in the closed position, or in motion, and the "FIRE OPERATION" switch is in the "OFF" position, the elevator remains on Phase II Emergency In-Car Operation and shall return to the designated level in conformance with 2.27.3.1.6(a) through (m).

2.27.3.3.5 Elevators shall be removed from Phase II Emergency In-Car Operation only when the "FIRE OPERATION" switch is in the "OFF" position and the car is at the designated level and the doors are in the normal open position.

2.27.3.3.6 The occurrence of an accidental ground or short circuit in elevator electrical equipment located on the landing side of the hoistway enclosure, and in associated wiring, shall not disable Phase II Emergency In-Car Operation once it has been activated.

2.27.3.4 Interruption of Power. Upon the resumption of power (normal, emergency, or standby), the car shall be permitted to move to reestablish absolute car position. Restoration of electrical power following a power interruption shall not cause any elevator to be removed from Phase I Emergency Recall Operation or Phase II Emergency In-Car Operation.

2.27.3.5 Multicompartment Elevators. Multicompartment elevators shall also conform to 2.27.3.5.1 and 2.27.3.5.2.

2.27.3.5.1 The “FIRE RECALL” switch (2.27.3.1) shall be located at the designated level served by the upper compartment.

2.27.3.5.2 The “FIRE OPERATION” switch (see 2.27.3.3) shall be located in the upper compartment. The elevator shall be provided with a means for placing the lower compartment out of service, located in that compartment or adjacent to the entrance at the lower lobby landing.

2.27.4 Firefighters’ Emergency Operation—Non-Automatic Elevators

Firefighters’ Emergency Operation shall apply to all non-automatic elevators except as follows:

(a) where the hoistway or a portion thereof is not required to be fire-resistive construction (see 2.1.1.1), the travel does not exceed 2 000 mm (80 in.), and the hoistway does not penetrate a floor;

(b) in jurisdictions enforcing the NBCC where the NBCC does not require Firefighters’ Emergency Operation;

(c) where Firefighters’ Emergency Operation is provided voluntarily these requirements shall also apply.

2.27.4.1 Phase I Emergency Recall Operation. A three-position key-operated switch shall be provided at the designated level for each single elevator or for each group of elevators. The three-position switch shall be labeled “FIRE RECALL” and its positions marked “RESET,” “OFF,” and “ON” (in that order), with the “OFF” position as the center position. The “FIRE RECALL” letters shall be a minimum of 5 mm (0.25 in.) high in red or a color contrasting with a red background. The three-position switch shall be located in the lobby within sight of the elevator or all elevators in that group and shall be readily accessible.

An additional “FIRE RECALL” switch with two-positions, “OFF” and “ON” (in that order), shall be permitted only at the building fire control station.

The switch(es) shall be rotated clockwise to go from the “RESET” (designated level switch only), to the “OFF” and to the “ON” positions. All keys shall be removable only in the “OFF” and “ON” positions.

Only the “FIRE RECALL” switch(es) or fire alarm initiating devices located at floors that are served by the elevator, or in the hoistway, or in the elevator machine room (see 2.27.3.2) shall initiate Phase I Emergency Recall Operation. All “FIRE RECALL” switches shall be provided with an illuminated visual signal to indicate when Phase I Emergency Recall Operation is in effect.

When all switches are in the “OFF” position, normal elevator service shall be in effect and the fire alarm initiating devices required by 2.27.4.2 shall be operative.

When a “FIRE RECALL” switch is in the “ON” position, a visual and audible signal shall be provided to alert the attendant to return nonstop to the designated or alternate level. The visual signal shall read “FIRE RECALL—RETURN TO _____” [insert level to which the car should be returned (the designated or alternate level)]. The signal system shall be activated when Phase I Emergency Recall Operation is in effect.

Where an additional “FIRE RECALL” switch is provided, both “FIRE RECALL” switches must be in the “ON” position to recall the elevator to the designated level if the elevator was recalled to the alternate level.

Where an additional “FIRE RECALL” switch is provided, it shall not affect the visual signal if the designated level fire alarm initiating device (see 2.27.3.2.4) has been activated.

To extinguish the audible and visual signals, the “FIRE RECALL” switch shall be rotated first to the “RESET” and then to the “OFF” position, provided that:

(a) the additional two-position “FIRE RECALL” switch, where provided, is in the “OFF” position; and

(b) no fire alarm initiating device is activated (see also 2.27.3.2.4).

No device, which measures load, shall prevent operation of the elevator at or below the capacity and loading required in 2.16.

2.27.4.2 Phase I Emergency Recall Operation by Fire Alarm Initiating Devices. Fire alarm initiating devices shall be installed at each floor served by the elevator, and in the associated machine room and elevator hoistway, in compliance with the requirements in NFPA 72 or NBCC, whichever is applicable

(see Part 9). In jurisdictions enforcing the NBCC, compliance with 2.27.4.2 is not required where the NBCC specifies manual Emergency Recall operations only.

Phase I Emergency Recall Operation, conforming to 2.27.4.1, shall be initiated when any Phase I Emergency Recall Operation fire alarm initiating device at the elevator lobbies, machine room, or hoistway is activated.

Phase I Emergency Recall Operation, when initiated by a Phase I Emergency Recall Operation fire alarm initiating device, shall be maintained until canceled by moving the “FIRE RECALL” switch to the “RESET” position.

When activated a fire alarm initiating device in the machine room shall cause the visual signal [see 2.27.3.1.6(h) and Exhibit S4.1] to illuminate intermittently only in car(s) with equipment in that machine room. When activated a fire alarm initiating device in the hoistway shall cause the visual signal [see 2.27.3.1.6(h) and Exhibit S4.1] to illuminate intermittently only in car(s) with equipment in that hoistway.

2.27.5 Firefighters’ Emergency Operation—Automatic Elevators with Designated-Attendant Operation

2.27.5.1 When designated-attendant operation is not in effect, elevators shall conform to 2.27.3.

2.27.5.2 When operated by a designated attendant in the car, except hospital service:

(a) elevators parked at a floor shall conform to 2.27.3.1.6(h). At the completion of a time delay of not less than 10 s and not more than 30 s, elevators shall conform to 2.27.3.

(b) A moving car shall conform to 2.27.3.

2.27.5.3 When on hospital service, the elevator shall conform to 2.27.3.1.6(h) while Phase I Emergency Recall Operation is in effect. An elevator on firefighter emergency operation shall not be placed on hospital service.

2.27.6 Firefighters’ Emergency Operation—Inspection Operation

When an elevator that is provided with firefighters’ service is on inspection operation (see 2.26.1.4 and 2.26.1.5) or when the hoistway access switch(es) have been enabled [see 2.12.7.3.3(a)], a continuous audible signal, audible at the location where the operation is activated shall sound when the “FIRE RECALL” switch(es) (see 2.27.3.1) is in the “ON” position or when the fire alarm initiating device (see 2.27.3.2) is activated to alert the operator of an emergency. The

car shall remain under the control of the operator until removed from inspection operation or hoistway access operation. Inspection operation or hoistway access operation shall take precedence over Phase I Emergency Recall Operation and Phase II Emergency In-Car Operation.

2.27.7 Firefighters’ Emergency Operation—Operating Procedures

2.27.7.1 Instructions for operation of elevators under Phase I Emergency Recall Operation shall be incorporated with or adjacent to the “FIRE RECALL” switch at the designated level. The instructions shall include only the wording shown in Exhibit S4.2.

FIREFIGHTERS’ OPERATION

To recall elevators
Insert fire key and turn to “ON”

Exhibit S4.2 Phase I emergency recall operation instructions. (From ASME A17.1, Section 2.27, Fig. 2.27.7.1)

2.27.7.2 Instructions for operation of elevators under Phase II Emergency In-Car Operation shall be incorporated with or adjacent to the switch, in or adjacent to the operating panel in each car. They shall include the wording shown in Exhibit S4.3.

2.27.7.3 Instructions shall be in letters not less than 3 mm (0.125 in.) in height and shall be permanently installed and protected against removal or defacement.

2.27.7.4 In jurisdictions that enforce the NBCC, a symbol showing a red firefighters’ hat on a contrasting background, as shown in Exhibit S4.1 (figure not to scale), shall be used exclusively to identify elevators that comply with 2.27.3 and additional NBCC requirements. This identification shall be located on the elevator entrance frame or adjacent to it at each emergency recall level. The identification on the entrance frame, or adjacent to it, shall be a minimum of 50 mm (2 in.) in height.

2.27.8 Switch Keys

The key switches required by 2.27.2 through 2.27.5 for all elevators in a building shall be operable by the same key. The keys shall be Group 3 Security (see 8.1). There shall be a key for each switch provided.

FIRE OPERATION	
When	
	Flashes, exit elevator
To operate car	Insert fire key and turn to "ON." Press desired button.
To cancel floor selection	Press "CALL CANCEL" button.
To close power-operated door	Press and hold "DOOR CLOSE" button.
To open power-operated door	Press and hold "DOOR OPEN" button.
To hold car at floor	With doors open, turn key to "HOLD."
To automatically send car to recall floor	Turn key to "OFF."

Exhibit S4.3 Phase II emergency in-car operation. (From ASME A17.1, Section 2.27, Fig. 2.27.7.2)

These keys shall be kept on the premises in a location readily accessible to firefighters and emergency personnel, but not where they are available to the public. Where provided, a lock box, including its lock and other components, shall conform to the requirements of UL 1037 (see Part 9).

NOTE (2.27.8): Local authorities may specify additional requirements for a uniform keyed lock box and its location to contain the necessary keys.

EXTRACTS FROM ASME A17.1 HANDBOOK, SECTION 2.27, EMERGENCY OPERATION AND SIGNALING DEVICES[‡]

A note was added in the 2000 edition of ASME A17.1 to recognize that additional requirements may be found in the building codes. An example is the requirement in the IBC for fire department communi-

[‡]Reprinted from ASME A17.1 Handbook—2000, by Edward A. Donoghue, by permission of The American Society of Mechanical Engineers. All rights reserved.

cation system in high-rise building (IBC Section 907.2.12.3).

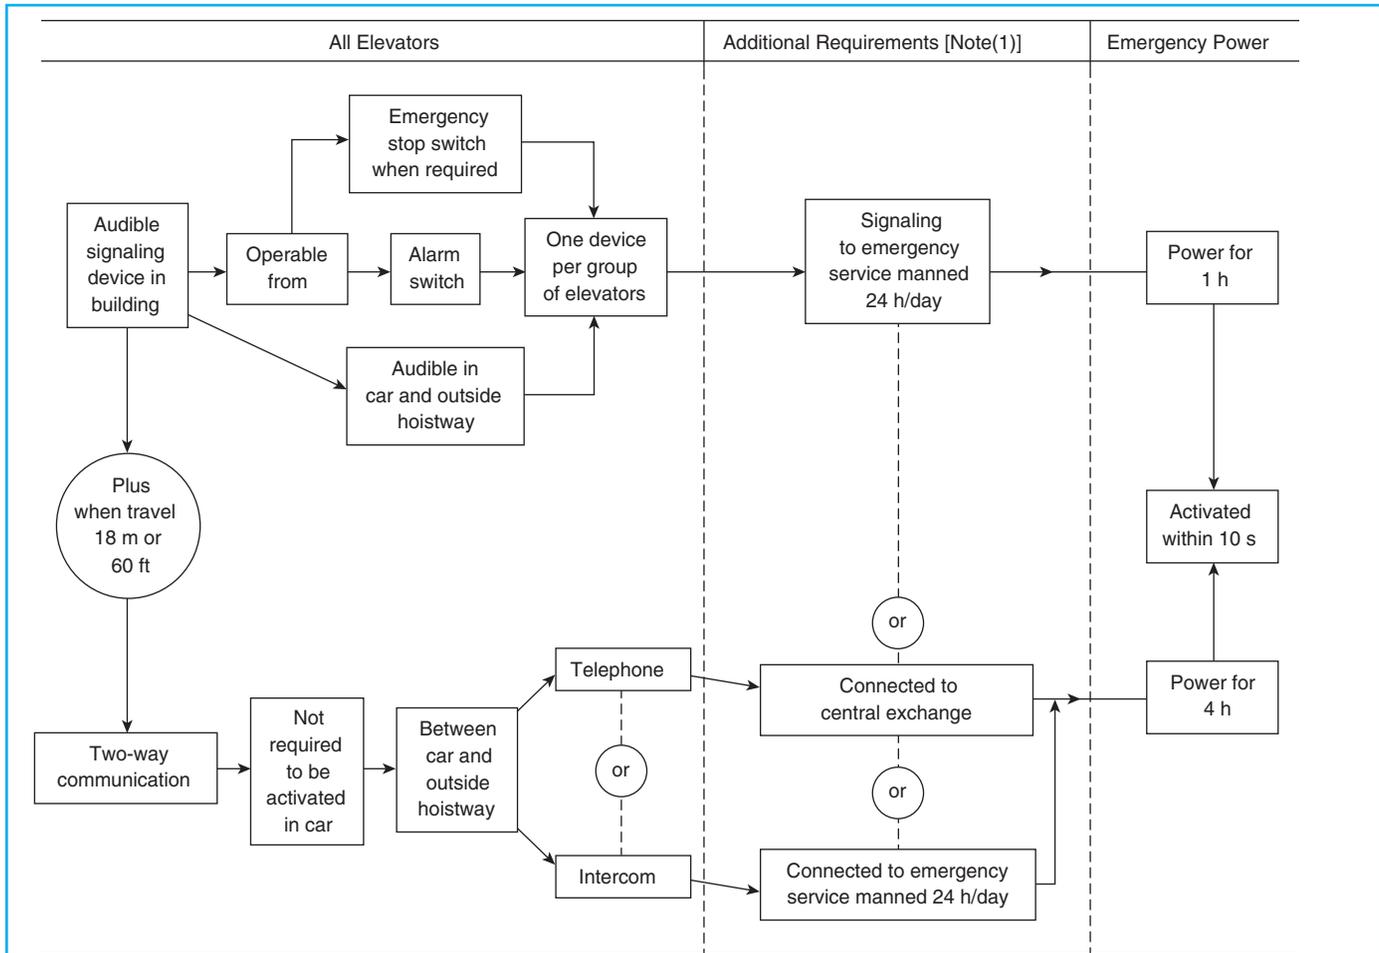

2.27.1 Car Emergency Signaling Devices

All elevators must be provided with an audible signaling device. A means of two-way communications to an accessible point outside the hoistway is required in elevators with a travel of 18 m or 60 ft or more. See Exhibit S4.4 for a diagrammatic description of these requirements. The two-way communications system does not have to be provided with a means of activation from within the car. Most communications systems, excluding telephones, are activated in the main lobby or building emergency control center. The alarm bell is a means that is provided to signal that there is a problem. The means of two-way communications is provided to assure occupants that their signal has been received and measures are being instituted to get them out of the stalled car.

One telephone could be used to meet both the requirements of 2.27.1.1.2 and 2.27.1.2, provided that it is capable of reaching someone outside of the hoistway who can take appropriate action.

The intent of 2.27.1.1.2 is that the telephone or intercom is to be connected to a point where two-way communications can be established by emergency personnel with the occupants of the car, assuring them that help is on the way. A "readily accessible point" is a location that is accessible to emergency personnel. The intent of this requirement is that emergency personnel have the ability to establish a communications link from within the building to the car. It was determined that when the travel is less than 18 m or 60 ft that communications could be established from outside the hoistway to the occupants of a car without the need of a two-way communications device. The exact location is determined on a local basis. The emergency signaling system is used to signal a problem and the communication system is then used to communicate with the occupants of the car, to alleviate fears, prevent panic, and prevent dangerous attempts to exit the car without assistance.

A means of signaling or communicating with a service, which can take appropriate action in an emergency, is required by 2.27.1.2 in buildings where authorized personnel (see 1.3) are not continuously available. If a building is occupied, at off hours, by a single person (e. g., watchman, building engineer) that person may use the elevator and 2.27.1.2 would be applicable. See also 8.6.10.4 for written emergency evacuation procedures plan that must be provided in every building. It should be noted that a means of only signaling is acceptable.

NOTE:
 (1) In a building in which a building attendant, building employee, or watchman is not continuously available to take action when an emergency signal is operated.

Exhibit S4.4 Emergency signaling devices. (From ASME A17.1 Handbook, Section 2.27, Diagram 2.27.1)

Requirements for emergency communications can also be found in the Americans with Disabilities Act Accessibility Guidelines (ADAAG) ICC/ANSI A117.1 and Uniform Federal Accessibility Standards. All three standards state, “the emergency intercommunication system shall not require voice communication.” These requirements address the needs of those with hearing and speech impairments.

The use of a light indicating the call has been received and responded to will provide a system that meets the intent for the hearing impaired. The light on the handsfree phone panel should only be illuminated or blink when activated by the recipient of the call. Those who are blind will be able to use the phone to hear that help is on the way. The instructions on the use of the light(s), need not be raised or in Braille as this feature is not being provided for those with a vision impairment. Finally, although an illuminated

alarm button is required by ASME A17.1, it does not by itself meet the full intent of ADAAG or ICC/ ANSI A117.1.

In addition to these requirements, the building codes require that all elevators in high-rise buildings (see building code for definition) have a communication system from the elevator lobby, car, and machine rooms to the building’s central control station. See commentary on car lighting in 2.14.7.1.

2.27.2 Emergency or Standby Power System

Emergency or standby power for an elevator is not required by this Code. If provided, then it must comply with 2.27.2. The building codes typically require standby power for at least one elevator that can travel to each floor in a high-rise building (see definition of building code in 1.3). One elevator does not have to stop at every floor, but every floor must be served

by at least one elevator that is supplied with standby power. As an example, in a 20-story building elevator group A serves floors 1 through 10 and elevator group B serves floors 1 and 11 through 20. Standby power would have to be supplied to one elevator in group A and one elevator in group B. If the same 20-story building had an elevator that served all floors 1 through 20, then standby power could be supplied to that elevator only.

The US building codes address the need to provide accessible means of egress during a fire. Accessible means of egress typically include elevators, operating on Phase II emergency operation. When accessible means of egress include elevators, they shall be provided with standby power.

The *National Electrical Code*[®] (*NEC*[®]) has requirements for both legally required standby power systems (Article 701) and optional standby power systems (Article 702). Legally required standby power systems provide electric power when normal power is interrupted to aid fire fighting, rescue operations, control of health hazards, and similar operations. Optional standby power systems provide electric power when normal power is interrupted to eliminate physical discomfort, interruption of an industrial process, damage to equipment, or disruption of business.

Emergency power systems are those power systems that are essential for safety to human life and must conform to the requirements of the *NEC*[®] Article 700. For additional information, see the NFPA 110 standard for emergency and standby power systems.

Legally required standby power systems have requirements that are very similar to emergency power systems. At the loss of normal power, the legally required standby power system must be able to supply power within 60 s whereas emergency power system must be able to supply power within 10 s. Wiring for legally required standby power systems can be installed in the same raceway, cables, and boxes as other general wiring. Emergency power system wiring must be kept entirely independent of all other wiring.

Elevators are normally connected to legally required standby power systems and not emergency power systems. Some hospital elevators are hooked into emergency power systems.

Requirement 2.27.2.1 facilitates the availability of power for the elevator system. It speeds up the evacuation process, minimizes entrapments, and allows the use of the elevator by firefighters.

Requirement 2.27.2.4 requires automatic sequence operation. Automatic sequencing must be so arranged that it can be overridden by the manual selection switch. This switch must not stop the eleva-

tor when in motion; power will be transferred only after the elevator is stopped.

See also the commentary on 2.26.10 and Section 620-101 of the National Electrical Code (r).

2.27.3 Firefighters' Emergency Operations—Automatic Elevators

NOTE: The author expresses his appreciation to John J. O'Donoghue for his extensive contribution to 2.27.3.

In 1998, the National Fire Protection Association reported 4,035 fire deaths in the United States. Of these deaths, 5 were the result of fires in high-rise buildings. Since 1980, NFPA has recorded 184 fatal fires in high-rise buildings in the United States and Canada. These fires resulted in 783 deaths of the public and firefighters. The last available set of figures showing a comparison of the two countries is from 1995. The total fire incidents in the United States were 1,965,500 with 4,585 deaths resulting. In Canada, the comparative figures were 64,300 fire incidents, resulting in 399 deaths. An equally important set of figures is the total number of injuries, in both the United States (25,775) and Canada (2,455). When these are examined, only then will we get a true picture of the fire problem that we are facing today. Between both countries, it is estimated that in the past 20 years, there have been thousands of new high-rise buildings (22.9 m/ 75 ft) built. In the past, office occupancies had been classified as a low-risk fire hazard.

This was true in older, compartmentalized high-rise buildings, with no multi-floor HVAC systems, and with office furnishings made of wood or metal. However, the modern high-rise building is a different creature. Fire and smoke spreading to other floors of the structure, or to adjoining ones (i. e., World Trade Center bombing of 1993), is the true nightmare facing the firefighting forces of both countries today. Other factors in this fire problem are the furnishings. The vast majority of today's building interiors are made up of plastic in one form or another. Among firefighters, plastic is referred to as frozen gasoline. As plastic is heated from exposure to fire, it goes through a decomposition process that emits toxic, disabling gases (e. g., hydrogen chloride) and flammable hydrocarbon gases, which readily spread and cause a rapid, lightning-fast propagation of the fire across large areas. The smoke from these products of combustion is dense and black, causing trapped occupants to have little or no visibility, encounter choking smoke, and face heat of temperatures well above what a human being can endure.

Today's high-rise buildings present new and different problems to fire suppression personnel and

techniques. Yet the cause of fires in high-rise buildings and the materials used in them, including furniture and fixtures, are not any different from those used in conventional low-rise structures. However, if a fire breaks out in the top story of a high rise, the fire service must transport their firefighters and equipment to the upper floors via elevators operating on firefighters' in-car operation. Some fires have necessitated the use of stairs to reach the fire floor. Keep in mind that the firefighters, with wearing all of their protective gear, weigh an additional 65 lb, and they are carrying long lengths of hose and attachments that weigh an additional 50 lb to 65 lb. Using the stairs to gain access to upper floors in a highrise structure is the last resort. Elevators must be made a reliable tool to be utilized by the firefighters in the performance of their duties; however, elevators cannot be relied upon during a fire in a building. A firefighting commander would take a fire any day of the week, which is located on the top floor of a building, rather than one on a lower floor. Why? Because the life hazard is on the fire floor, with only the roof and the sky being exposed. In contrast, a fire on the 10th floor of a 34-story building has a life hazard on all floors above the fire, as well as the fire floor, requiring additional staffing to accomplish the tasks of search, rescue, and fire extinguishment. Firefighters have immediate concerns relating to smoke and heat spread, stack effect, and the mass, uncontrolled evacuation down the same stairways that firefighters are trying to use to move up to locate, surround, and extinguish this fire. Remember a few points: At the Meridian Plaza fire in Philadelphia, there was a total failure of all building systems early in the fire, and secondly, the World Trade Center explosion and resulting fire was below grade, and it took 11 h to complete the evacuation.

Let's review some of the reasons why elevators are unsafe in a fire and what led to the Code requirements for firefighters' operation of elevators. Elevators are unsafe in a fire because:

- (a) person may push a corridor button and have to wait for an elevator that may never respond; valuable time to escape is lost;
- (b) elevators respond to car and corridor calls; one of these may be at the fire floor;
- (c) elevators cannot start until the car and hoistway doors are closed. This could lead to overcrowding of an elevator and the blockage of the doors, and thus prevent closing.
- (d) power failure during a fire can happen at any time and thus lead to passenger entrapment.

Fatal delivery of the elevator to the fire floor can be caused by any of the following:

- (1) an elevator passenger pressing the car button for the fire floor;
- (2) one or both of the corridor call buttons may be pushed on the fire floor;
- (3) heat may melt or deform the corridor push button or its wiring at the fire floor;
- (4) normal functioning of the elevator, such as high or low reversal, may occur at the fire floor.
- (5) heat from the fire or loss of air conditioning in the machine room or hoistway may have a detrimental effect on solid-state control equipment, resulting in erratic elevator operation.

The A17.1 Code recognized all of these conditions and has reacted by mandating elevator recall, more commonly referred to as Phase I Emergency Recall Operation. The building code also requires a sign in elevator lobbies similar to that shown in Exhibit S4.5 to advise building occupants not to use elevators in a fire.

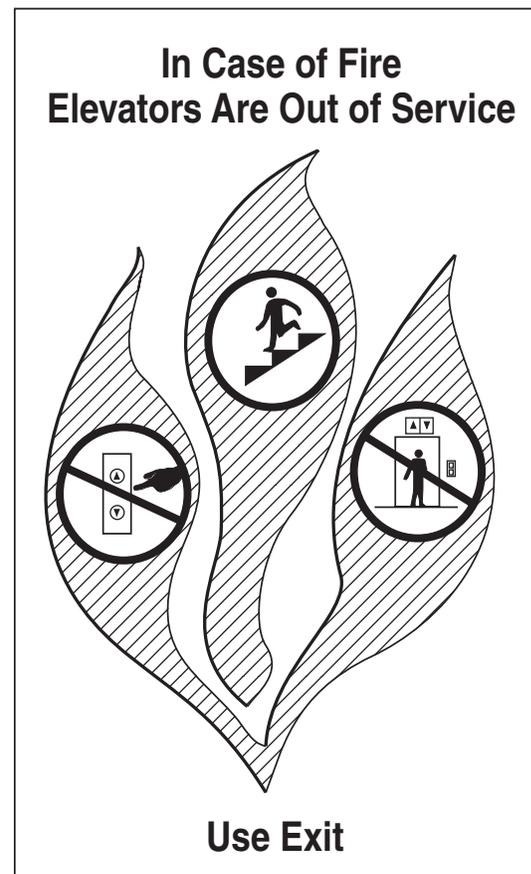

Exhibit S4.5 Elevator corridor call station pictograph. [From ASME A17.1 Handbook, Section 2.27, Diagram 2.27.3(a)]

The features described in 2.27.3 are also known as Firefighters' Service or special emergency service [SES] features. The Code Committee has strived to standardize the operation to ensure that there are no variations thereby eliminating confusion of firefighters during an emergency. The automatic or manual return of elevators to the designated level (see 1.3 for definition) is referred to as Phase I Emergency Recall Operation. The provision to allow emergency personnel to operate the elevator from within the car on emergency in-car operation is commonly referred to as Phase II Emergency In-Car Operation.

2.27.3.1 Phase I Emergency Recall Operation. A17.1b-1989 through A17.1b-1992 required Phase I for an elevator with a travel of 7.62 m (25 ft) or more. Under earlier editions of the Code, an elevator could have nearly 15.24 m (50 ft) of travel [just less than 7.62 m (25 ft) above and below the designated landing], and still not have been required to have Phase I and Phase II operation. The term "designated level" (see 1.3) refers to the main floor or other level that best serves the needs of emergency personnel for firefighting and rescue purposes. The term "alternate landing" (see 1.3) refers to a floor level identified by the building code or fire authority, other than the designated landing. The term "recall level" (see 1.3) refers to the designated or alternate level that the car returns to when Phase I Emergency Recall Operation is activated. These requirements apply for all automatic elevators except when the hoistway or a portion thereof is not required to be constructed of fire-resistant construction (2.1.1.1), the travel does not exceed 2 000 mm or 80 in., and the hoistway does not penetrate a floor. An example of this would be an elevator that would allow a person to be transported from one level in a lobby to a second level not penetrating the next floor or fire barrier. This can be seen in department stores or malls, where this exception has been applied. Where Firefighters' Emergency Operation is provided voluntarily, (e. g., Canada) the requirements in 2.27.3 apply.

A three-position key-operated switch must be provided in the designated level lobby for each single elevator or for a group of elevators. The location of the three position Phase I Emergency Recall switch has been specified for standardization and to make sure that it is located where all of the elevators will be within sight and readily accessible from this location. The key is to be removable only in the "ON" and "OFF" positions. The specified key positions standardize a clockwise rotation to reach the "ON" position similar to the requirements for the Phase II Emergency In-Car Operation switch. Prior to the 2000 edi-

tion of ASME A17.1 the three-position Phase I key switch included the "BYPASS" position. This allowed building or emergency personnel to return elevators to normal service in event that the activated (alarmed) fire alarm initiating device (e. g., smoke detector) could not be cleared. However, the great drawback to this feature was that because one faulty smoke detector could not be cleared, the entire Phase I Emergency Recall system would be disabled when the "BYPASS" was activated. The fire alarm initiating devices that are used today are far superior to the ones that were first used. Today's systems can be monitored, maintained, and cleared from their control panel. In the 1996 edition of the ASME A17.1 Code, the expertise of NFPA 72, Chapter 3 was recognized as the proper authority to determine the number and location of fire alarm initiating devices in a building. In continuing with this transition, in ASME A17.1-2000 the "BYPASS" position was replaced with the "RESET" position on the three-position Phase I Emergency Recall Operation switch. The "RESET" feature will be utilized by emergency personnel (1.3) to reset the elevators returning them to normal service, after Phase I Emergency Recall Operation has been activated. If the fire alarm initiating device has not been cleared before using the "RESET" feature, then the Phase I Emergency Recall Operation will continue in effect until the device has been replaced, repaired, or bypassed by the fire alarm system. The switch shall be labeled "FIRE RECALL" and its positions marked "RESET," "OFF," and "ON" (in that order), with the "OFF" position as the center position. An additional key-operated "FIRE RECALL" switch, with two positions, marked "OFF" and "ON" (in that order), is permitted only at the building fire control station. Keys shall be removable in the "OFF" and "ON" positions only.

Phase I operation ensures that the elevator is not available to the general public when automatic elevator operation may be hazardous during a fire emergency. When an elevator is out of service during a fire, the public is unable to use it as a means of exiting from the building. Depending on the building fire plan, occupants will be directed to either the stairwells, places of refuge, or to be active participants in the emergency plan developed for their safety by the building owners/ operators. Earlier editions of the ASME A17.1 Code addressed only automatic door operations. The 1981 and later editions of the ASME A17.1 Code cover the operation of vertically sliding doors, doors controlled by constant pressure buttons, and manual doors. The only time an automatic elevator will not return upon activation of Phase I is when that car is at a landing with its door(s) open and the

in-car stop switch, emergency stop switch (in-car, top-of-car, pit, etc.), or some other electrical protective device is activated. Requirement 2.27.3.1.6(b) recognizes that an elevator at a landing with the in-car stop switch or emergency stop switch in the “STOP” position should not be captured, as this is not a normal condition. The stop switch may have been activated to facilitate an inspection or maintenance and capturing the elevator could be a hazard to the elevator personnel. The in-car stop switch is disabled, just like the in-car emergency stop switch, so that the car cannot be inadvertently taken off of recall operation. A person with access to the key for the in-car stop switch, after the doors are closed and the elevators start such as a building cleaning person might be inclined to activate the switch while the elevator is being recalled. This would create an unsafe condition, as the firefighters’ would have to search for the car immediately, and the occupant could be putting himself or herself into great danger. For passenger safety, 2.27.3.1.6(e) requires elevators to close their doors at a slower speed when a door-reopening device is rendered inoperative. Mechanically actuated door-reopening devices are not sensitive to smoke or flame and can remain operative. Flame is the glowing, gaseous, visible part of a fire. Smoke or flame can register a signal, whereas direct flame impingement by the fire will destroy. In actuality, unless the fire was started within the car’s contents, the cars would all have responded to the recall level well before in advance of the fire growing to that stage. The reference to 2.13.5 recognizes “nudging” and, therefore, it is not unsafe to disconnect mechanically actuated door-reopening devices.

Requirements 2.27.3.1.6(f) and (g) allow full control of those doors that may have to be closed from the corridor. Also, the automatic closing of vertical slide doors requires an active “OPEN” or “STOP” button on the corridor. The corridor “DOOR OPEN” button must be operative to cover the case where a manual gate is open with the hoistway door closed. A firefighter may need the “DOOR OPEN” button to open the door to see if anyone is in the car. Operating hall position indicators [2.27.3.1.6(f)] may convey a message that the elevators may be used. Only where elevator location is important to firefighters, such as the designated level, the alternate level, and the building fire control station are the hall position indicators to remain in operation. Car position indicators are always required by the firefighters utilizing the elevators, thus these devices are to remain operative.

Unless the car is at the fire floor, it is safer to keep the doors open. Arriving firefighting forces will

be able to immediately determine that all cars have answered the recall, and have the knowledge that no passengers are trapped in cars within the hoistway. The visible and audible signals [2.27.3.1.6(h)] alert passengers in an automatically operated elevator of the emergency and can minimize any apprehension that the passengers may have while the elevator is returning to the main floor. In an attendant-operated elevator, this signal alerts attendant of the emergency and warns him to return immediately to the designated level. When on inspection operation, the inspector or maintenance personnel are also alerted to the emergency by this signal.

Requirement 2.27.3.1.6(j) recognized that if the smoke detector at the designated level is activated, turning the additional Phase I switch to the “ON” position will not override the fire alarm initiating device sending the car to the designated level. This switch may be at a location where the condition of the designated level lobby cannot be determined. Where an additional “FIRE RECALL” switch is provided, both “FIRE RECALL” switches must be in the “ON” position to recall the elevator to the designated level if the elevator was recalled to the alternate level (2.27.3.2.4). To remove the elevators from Phase I, the “FIRE RECALL” switch shall first be rotated to the “RESET” position, and then to the “OFF” position.

If a second recall switch is provided, it must be in the “OFF” position to remove the elevator from Phase I Emergency Recall Operation. Means used to remove elevators from normal operation, other than as specified in this code, shall not prevent Phase I Emergency Recall Operation. Plainly, this means that the many uses of elevators by service personnel, movers, locked out, etc., will no longer prevent the firefighters from having all the available elevators at their disposal during a fire. This feature has been included at the request of the fire service community, who on too many occasions, have arrived at a fire, only to find that most of the elevators were not accessible for their use.

2.27.3.2 Phase I Emergency Recall Operation by Fire Alarm Initiations Device. An initiation device is defined by NFPA 72 as a system component that originates transmission of a change-of-state condition, such as in a smoke detector, etc.

2.27.3.2.1 The reference to the National Fire Alarm Code (r), NFPA72 is to a standard with expertise to specify the type and installation of automatic initiating devices. NFPA 72 has been revised, at the request of the ASME A17 Committee, to address fire alarm systems in all building types. The expertise for determining when conditions, due to a fire, require au-

omatic elevator recall are within the jurisdiction of the National Fire Alarm Code (r), NFPA 72. Beginning with ASME A17.1b–1997 a fire alarm initiating device must be provided at all floors. ASME A17.1 recognizes that devices other than smoke detectors may be more appropriate under some conditions. Those conditions are specified within NFPA 72.

2.27.3.2.2 This requirement recognizes that only manual Emergency Recall Operation is required by the NBCC. Note that within this requirement the terms “ smoke detector” and “ elevator lobby” have been utilized because of requirements in the NBCC.

2.27.3.2.4 The following is the basis for alternate floor recall. It is not preordained that the designated level has the lowest fuel load of any other floor in the buildings. This may be the case in some major, high-rise office buildings, but it certainly is not applicable to many other buildings, such as apartments, hotels, showrooms, or buildings with elaborate reception areas. However, even if it were a fact, a firebomb can suddenly provide an enormous fuel load on an otherwise fire-resistant floor.

The preponderance of buildings have elevators without an express zone. In the event that there are express zones, it is safer to park elevators away from any potential fire floor. It is feared that if the mandatory alternate floor requirement is repealed and made permissive, then many buildings would ultimately revert to the early Code requirements that only required return to the designated level.

What is often overlooked is the fact that if the elevators are returned to an alternate level, the firefighters have not lost control of the elevators. If conditions dictate that the designated level can provide safe egress, there is no reason why the firefighters cannot exercise the option of calling the elevators to the designated level by turning the required three-position keyed switch to the “ ON” position. The key switch overrides the alternate floor recall operation and will return all elevators to the designated level, even though the elevators may be parked at a floor above an express zone.

Typically, the designated level is also the location of the central command station. It would be difficult to effectively utilize a designated level central command station if the designated level is engulfed in a rapidly spreading fire such as the one that destroyed the main floor of the MGM Hotel. Elevators that are returned to, or parked at, the main floor are of no value if the result is loss of life.

It may also be assumed that sprinklers will reduce the probability of a large fire, but one cannot rule out the possibility that smoke in dangerous quantities

may be produced. Although sprinkler manufacturers say that sprinklers have been proven effective in stopping fire in a large number of buildings, smoke control advocates note that smoke, not the flames themselves cause the majority of fire deaths and say that sprinklers allow too much smoke to develop before the sprinklers are activated.

The effectiveness of smoke detectors for the recall function has also been questioned because of the possibility that smoke may be present on floors above and/or below the fire floor. The Code has addressed this in 2.27.3.2.5 by indicating that the first smoke detector activation determines the recall level (see 1.3). This is based on the fact that it is highly improbable that the smoke detectors on floors other than the fire floor would be activated beforehand.

As a corollary to smoke detectors that are now required to initiate elevator recall, it has been cited that the water flow switch associated with the on-floor sprinkler system is more positive. Smoke detectors were chosen in order to initiate elevator recall, as soon as possible in order to prevent the elevators from being used by building occupants during a fire when their use may be hazardous.

2.27.3.2.5 This requirement specifically states that the elevator only need to respond to the first detector, which was activated. The likelihood of two simultaneous fires is infinitesimal. It is assumed that the smoke detector at the fire floor will be the first one that is activated. Subsequent alarms would most likely occur due to smoke migration and should not affect the choice of the recall floor.

2.27.3.3 Phase II Emergency In-Car Operation. Phase II firefighters’ operation is for the benefit of firefighters. Some of the input received from firefighters is as follows:

Firefighters need the elevator for their use. The Fire Services have long complained of elevators not being available to them upon arrival at the fire building. This will provide the maximum number of elevators available to them. Firefighters’ will take command during a fire, and they will determine whether and how many elevators are to be used. Firefighters’ are willing to accept the risks that are associated with running elevators during a fire. It is standard operating procedure for the firefighters to use the elevators not only to carry equipment for firefighting or evacuation purposes, but to also disperse fire personnel to non-fire involved floors. The presence of a firefighter reduces occupant fears, and firefighters can direct occupant movement strategy since they are in constant communication with the fire command post.

Many firefighters stated that there are times when they cannot afford the luxury of using personnel to operate an elevator on a return trip to the main floor. They requested placing the Phase II switch in the elevator to the "OFF" position to automatically cause the elevator to return to the main floor for use by later arriving firefighters. However, standard operating procedures dictate that whenever staffing does permit, a firefighter with a radio be dedicated as the operator of any car being placed onto Phase II operation. That firefighter would be responsible for the shuttling of firefighters and their equipment to the discharge floor, usually a minimum of two stories below the fire floor. This would be their task until relieved by another firefighter assigned that position. There also is a requirement that when the car is on Phase II operation, turning the switch in the car to the "HOLD" position at a floor will permit the firefighter to remove the key, and leave the car without the danger of an unauthorized person taking the car to another floor.

Beginning with the 1981 edition of ASME A17.1, Phase II operation is required whenever Phase I operation is provided. The previous A17.1 requirement was predicated on the needs of emergency personnel only. The current requirement takes into account the need for evacuating the disabled during an emergency by firefighters. Disabled persons are always a concern, but the term "handicapped" in the normal context is no longer applicable; under fire conditions, even a firefighter can be considered disabled, especially when near exhaustion or if their compressed air supply is gone. Further, able-bodied occupants can become disabled from smoke, from walking up or down steps, or from hysteria. Therefore, when you hear that provisions must be made for the disabled during a fire, expand your overall picture, because even normal ambulatory persons can suddenly become non-ambulatory.

The A17 Code Committee was aware of the need to evacuate the disabled during a fire. A17.1a-1992 and later editions require firefighters' service on all elevators. The building codes, Life Safety Code (NFPA 101) and American with Disabilities Act Accessibility Guidelines (ADAAG) envision the use of elevators operating on Phase II as a principal means of evacuating the disabled during a fire. The use of Phase II is certainly a major step in providing the fire service with the necessary tools to accomplish this task, but the elevator industry must continue its research and development into making the elevator a reliable part of the picture. We are constructing buildings today, and placing those who will need this assistance into higher parts of the building, with no

guarantee that we will have a means to get them down via the elevator. The firefighters will always go after anyone in danger, but the industry must provide the necessary equipment for the firefighter to do their job.

Some major changes have been added to 2.27.3.3. First, the key-operated switch is now called the "FIRE OPERATION" switch, labeled "OFF," "HOLD" and "ON," in that order. It shall be rotated clockwise, to go from "OFF" to "HOLD" to "ON." Removable only in the "OFF" and "HOLD" position, it shall not change the mode of operation within Phase II Emergency In-Car Operation until the car is at a landing with its doors in the normal open position. By preventing the key from being removed from the fire operation switch, when in the "ON" position, reduces the potential of leaving a car stranded after a fire emergency. It also reduces the possibility of unauthorized personnel entering an empty car, and taking it to another floor, as it is unlikely a firefighter would not remove their fire operations key when exiting a car.

Firefighters are allowed to reverse their direction at the next available landing by turning Phase II switch to "OFF" (2.27.3.3.4). This change has been requested by the firefighters. The car shall remain on Phase II operation, and, without going through a door open and close sequence, will return to the designated level. This provides the firefighter with a means of aborting an upward flight when conditions warrant their return to the designated level where they can review their options.

Means used to remove elevators from normal operation, other than as specified in this Code, shall not prevent Phase II Emergency In-Car Operation.

Appropriate requirements for cars with more than one entrance are established [2.27.3.3.1(d)]. Requirement 2.27.3.3.1(e) recognizes that on large vertically sliding doors with continuous pressure closing, reopening is impractical and could introduce a delay factor that may impair safety. Requirement 2.27.3.3.1(g) recognizes that door-reopening devices are not necessary since constant pressure operation is required.

For standardization, 2.27.3.3.3 and 2.27.3.3.4 define Phase II operation in the "OFF" position and the car is not at the designated level.

2.27.3.3.6 To prevent water from automatic sprinklers and/or fire department hose streams from causing an occurrence of an accidental ground or short circuit in elevator electrical equipment that is located on the landing side of the hoistway enclosure, once it has been activated, Phase II shall not be deactivated.

2.27.3.4 Interruption of Power. This requirement clarifies that even in the case of power interruption upon restoration of power, Phase I or Phase II would continue to remain in effect.

2.27.4 Firefighters' Emergency Operation—Non-Automatic Elevators

A “designated attendant” (see 1.3) is where the elevator is controlled solely by authorized personnel (see 1.3) such as attendant service, independent service, hospital service, and similar operations.

This Rule establishes the operation requirements of elevators, which are not covered by 2.27.3. A standard sign is required to alert the operator as to which floor the elevator should be returned to. See commentary on 2.27.3.

2.27.5 Firefighters' Emergency Operation—Automatic Elevators with Designated Attendant Operation

A car could be left at the fire floor, exposing the hoistway to fire, when it could be recalled. The delay is to give ample warning prior to recall. “Hospital Service” (see 1.3) is a special case of operation by a designated attendant (see 1.3) used only for medical emergencies. Hospital service has been excluded, since there may be valid reasons for not returning the car.

2.27.6 Firefighters' Emergency Operation—Inspection Operation

This requirement recognizes that taking the elevator control away from elevator personnel may be hazardous.

2.27.7 Firefighters' Emergency Operation—Operating Procedures

Operating procedures must be incorporated with or be adjacent to the Phase I and Phase II key-operated switches to assure that during an emergency, emergency personnel have quick access to available instructions for their use. Since firefighters' service is now standardized, the Code specifies signs with simple and clear wording that explain the operation of the elevators. An explanation of the “RESET” position is not necessary on the Phase I sign because this is a building function, not a firefighters' operation.

Requirement 2.27.7.4 recognizes a requirement in NBCC.

2.27.8 Switch Keys

A Note is included to suggest that local jurisdictions may legislate uniform keyed lock box requirements to assure the availability of emergency keys when building personnel are not available. It is not within the jurisdiction of A17 to make such a requirement so it is only suggested through the use of the Note. The use of lock boxes is one means of assuring that the fire service community has access to the keys to operate this system. In some jurisdictions, a common key has been designated as the Fire Service Key. The distribution of the uniform key can be controlled through laws and training.

The required switch keys for Phase I and Phase II operation must be the same to assure a speedy response to the emergency situation. A key is required for all Phase I and Phase II key switches, to allow for simultaneous operation of all key switches.

Fire Tests for *Life Safety Code* Users

Marcelo M. Hirschler

Editor's Note: This supplement is written to assist the reader in determining the applicability of fire test standards, especially those found in the Life Safety Code.

Dr. Marcelo M. Hirschler is a fire safety consultant with GBH International. He chairs the NFPA Technical Committee on Hazard and Risk of Contents and Furnishings and is a member of various other NFPA technical committees, including the Technical Committee on Fire Tests. He is also active in the ASTM committee E05 on Fire Standards and in a number of other codes and standards arenas.

FIRE PROPERTIES

Fire test standards typically relate to two types of fire properties: fire resistance and reaction-to-fire. Fire resistance is associated with fire barriers and opening protection; fire resistance tests are concerned with preventing fire (or smoke) from penetrating into a compartment. Reaction-to-fire is associated with materials and products, including interior finishes, furnishings and contents. Reaction-to-fire tests are concerned with preventing the fire itself from causing damage, by minimizing or eliminating the release of heat, smoke, and combustion products or the spread of flame. Performance-based provisions related to fire modeling generally use results of reaction-to-fire tests.

Evaluating the level of performance or prescribed function offered by tested materials or assemblies requires an understanding of both the mechanics of a particular test and its limitations. Every test standard contains, in its scope and applicability, information explaining what it is supposed to do (namely what properties it measures) and for what type of materials it should be used. This is very important because it is a common error to use a test for the wrong material or to test for the wrong issue. A test that is commonly used incorrectly is NFPA 255, *Standard Method of Test*

of Surface Burning Characteristics of Building Materials, because it is so extensively used in many codes (including the *Life Safety Code*). NFPA 255 is a reaction-to-fire test that is used to determine the flame spread index and smoke developed index of materials. To be suitable for this test, a material must, by its own structural quality or the manner in which it is applied, be capable of supporting itself in position or of being supported in the test apparatus. This test has often been specified, incorrectly, to obtain results on properties like fire resistance (which should be measured using NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*), or to determine whether a material is noncombustible (which should be assessed with ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*), or whether it is limited combustible (which is determined by testing in accordance with NFPA 259, *Standard Test Method for Potential Heat of Building Materials*). See also the discussion on combustibility fire testing below. Other misapplications include using the test for products, such as furniture, that cannot be physically placed in the apparatus, or for materials that cannot be supported in the apparatus throughout the test.

Many of the tests referred to in the *Life Safety*

Code have equivalent counterparts administered by other standards-writing organizations such as the American Society for Testing and Materials (ASTM) and Underwriters Laboratories (UL). See Table S5.1. Section 1.4 of the *Life Safety Code* permits the application or use of equivalent alternatives. Alternatives could include fire test documents different from those specified, or different test protocols—if the proper technical documentation is provided to demonstrate equivalency between the tests and verify that the alternative approach fulfills the intended purpose of the applicable code requirement.

FIRE RESISTANCE TESTING

Buildings or structures occupied or used in accordance with the individual occupancy chapters of the *Life Safety Code* (Chapters 12 through 42) are required to meet the minimum construction requirements of those chapters. NFPA 220, *Standard on Types of Building Construction*, as referenced in Chapter 8 of the *Life Safety Code*, describes the types of building construction (that is, construction classifications) and the fire resistance ratings applicable to each construction element for each type of building. The fire test to be used to assess fire resistance ratings is NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials* (see also Table S5.1 for alternative similar fire test methods). NFPA 251 (also referenced primarily in Chapter 8) applies to assemblies of masonry units, composite assemblies of structural materials for buildings (including interior and exterior bearing and other walls and partitions, columns, girders, beams, slabs, and composite slab and beam assemblies for floors and roofs), as well as other assemblies and structural units that constitute permanent integral parts of a finished building. The fire test has specific testing criteria for each type of assembly. Fire barriers, or fire barrier assemblies, are intended to be used as separation barriers or to provide protection of building elements from the effects of fire for a given time as required by Chapter 8, Features of Fire Protection.

NFPA 251 exposes one side of an assembly (construction element) to a standard time-temperature curve (as shown in Exhibit S5.1) inside a furnace leaving the other side unexposed. This is known as a time-temperature curve because the test method specifies the temperature that needs to be measured in the furnace at each point in time. The furnace used must be capable of providing the prescribed temperatures over a given period of time, by following the time-temperature curve shown in Exhibit S5.1. The test method provides criteria for assessing

how long (in hours or minutes) it takes for heat to penetrate each assembly and reach an unacceptable temperature rise on the exposed side, and how long it takes for the flame or hot gases penetrating through the assembly to ignite cotton waste placed on the unexposed side. The fire resistance rating will be the time at which the first of the failure criteria is reached. The temperature rise failure criterion on the unexposed side is 140°C (250°F) above the test specimen's initial temperature for walls and partitions.

The test can also be conducted with a load placed on the assembly, to evaluate the load-bearing capacity of the assembly. Some construction assemblies are simply intended to limit the transmission or temperature and/or flames to the unexposed surface. On the other hand, many construction assemblies, such as beams and columns, and floor and roof assemblies, must also sustain an applied load for a period of time equal to the desired classification, and must, therefore, be tested under the relevant applied load. Walls and partitions are thus permitted to be tested either with load or without.

Depending on the structural design of the assembly, certain levels of temperature must not be exceeded at any one point, or an average temperature cannot be exceeded, with temperature limitations ranging from 427°C to 704°C (800°F to 1,300°F). An alternative test exists for structural steel columns, designed not to carry a load, and it measures the ability of the protection to control the transmission of heat through the specimen during the specified period of fire exposure. The average temperature of the steel in such columns must not rise above 538°C (1,000°F), and the temperature in any one of the measured points cannot exceed 649°C (1,200°F).

In many cases, the assembly is also subjected to a hose stream test which simulates the effect of water hoses used by emergency personnel to fight fires. If an assembly is required to pass a hose stream test, an assembly with a fire rating of 1 hour or more will have to survive exposure to a hose stream test for half the period of its fire resistance rating, but not for more than 1 hour. When the condition of acceptance requires a hose stream test, after the fire resistance rating has been established, a duplicate assembly is exposed in the furnace to the time-temperature curve for the period required by the hose stream test conditions, then removed from the furnace and immediately subjected to the hose stream test. The hose stream is delivered under pre-set conditions (based on a certain hose, play pipe nozzle, distance from the test specimen, nozzle pressure, and test duration). The hose stream is applied in a specific pattern to fully develop the effects of impact, cooling, and ero-

Note: Table contains NFPA fire test standards and those fire test standards from other organizations that are either similar to NFPA fire test standards or relevant to the *Life Safety Code*.

sion on the entire test specimen. The specimen must withstand the hose stream test such that no openings are created that would permit projection of water from the hose stream to the unexposed side.

Further information on specific testing criteria and testing limitations can be found in NFPA 251, which should be consulted before making any firm decisions about the applicability or testing of certain assemblies.

Other fire resistance tests used by the *Life Safety Code* are NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*; NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*; and NFPA 288, *Standard Methods of Fire Tests of Floor Fire Door Assemblies Installed Horizontally in Fire Resistance-Rated Floor Systems*. All of these tests (as well as ASTM E 814, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*) use basically the same standard time-temperature curve that NFPA 251 uses (except that the curve in NFPA 257 includes more detail at the short time periods; see Exhibit S5.1), but they also have other differentiating characteristics, which are related to the products being tested. NFPA 80, *Standard for Fire Doors and Fire Windows*, contains installation requirements associated with all types of fire doors and windows, and thereby regulates the installation and maintenance of assemblies and devices used to protect openings in walls, floors, and ceilings against the spread of fire and smoke within, into, or out of buildings. NFPA 80 is extensively referenced in the *Life Safety Code*, especially in Chapters 7 (Means of Egress) and 8 (Features of Fire Protection).

Fire Tests of Door Assemblies (see also Table S5.1 for alternative similar fire test methods). NFPA 252 provides methods for measuring the relative performance of fire door assemblies where subjected to a prescribed fire test exposure followed by a prescribed hose stream application, using the same time-temperature curve as NFPA 251 (see Exhibit S5.1). The fire door assembly must be tested as a complete assembly, because the effectiveness of the opening protective depends on a satisfactory performance of the entire door assembly, which consists of the door, door frame, and associated hardware. In NFPA 252, the fire door assembly specimen is mounted in a furnace wall and exposed to the standard time-temperature curve. The door assembly is not permitted to develop gaps or openings through the assembly, nor is flaming permitted to occur on the unexposed surface of a door assembly during the first 30 minutes of the classification period, although some intermittent light flames no greater than 150 mm (6 in.) are permitted for periods not exceeding 10-second intervals. After that 30 minute period, intermittent flames are permitted to occur along the edges of the unexposed surface area of the door, if they do not to exceed 5 minutes and are no greater than 150 mm (6 in.). For doors having a fire resistance rating of 45 minutes or greater, flames not greater than 150 mm (6 in.) in length are permitted to occur on the unexposed surface area of the door during the last 15 minutes of the fire test classification period, provided such flaming is contained within a distance of 38 mm (1½ in.) from the vertical edge and 76 mm (3 in.) from the top edge of the door or frame of the vision panel. When the door hardware is also evaluated for use on fire doors, it must keep the door in a closed position for an exposure period of 3 hours. The latch bolt must remain projected and be intact after the fire exposure

Building Products

Fire Doors. Door assemblies in fire barriers must be tested according to NFPA 252, *Standard Methods of*

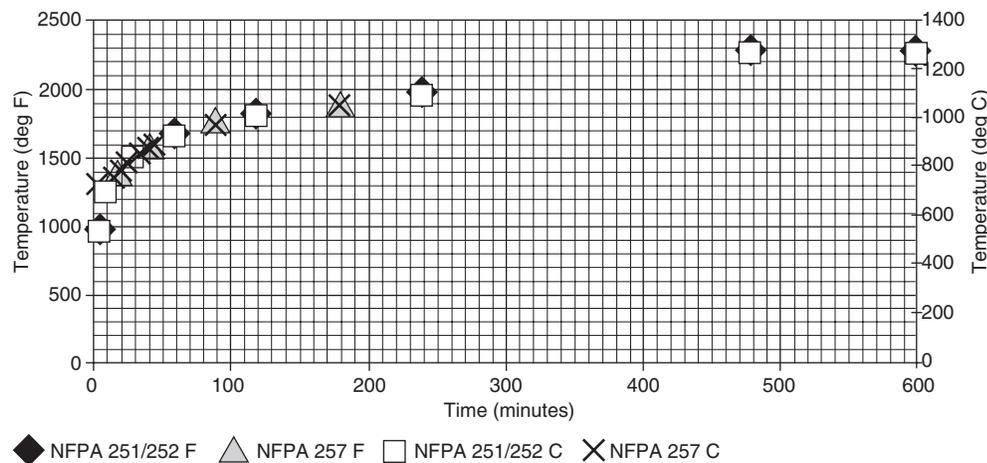

Exhibit S5.1 Standard time-temperature curves for NFPA 251/252 and for NFPA 257.

test. The fire doors must usually also be exposed to a hose stream test, which subjects the test assembly to the impact, erosion, and cooling effects of the hose stream, immediately following the fire resistance test. The hose stream is directed at the middle and then at all parts of the exposed surface, slowly making changes in direction. However, certain provisions within the *Life Safety Code* provide for the installation of door assemblies without the hose stream test. One must carefully evaluate the particular requirements associated with the opening protective so that it satisfies the minimum acceptable criteria.

A recent trend within code-writing organizations is to require certain applications of fire door assemblies to be tested under a positive pressure scenario. This provision requires that the door assemblies be tested with a neutral pressure plane located 1015 mm (40 in.) above the finished floor. NFPA 252 does not stipulate the height of the neutral plane but records the height in the test results. This revision permits the test standard to accommodate the many gradients of pressure planes at which a furnace can be operated. The test report document issued following a classification test records the location of the neutral pressure plane to which the door assembly has been tested. The *Life Safety Code* does not stipulate the minimum required height of the neutral pressure plane for testing the door. If a neutral plane is not established along the height of the test specimen, then it is assumed that the door will be tested under normal testing procedures, which is running the furnace at near atmospheric pressure. This would establish the neutral pressure plane at the top of the door assembly. It is generally recognized that, if a lower neutral pressure plane is established on the door assembly within the furnace, then the test could be considered to be more severe. A door tested under a positive pressure should be accepted as meeting the requirements established for a door tested at atmospheric pressure. Listing agencies have different approaches on how to list and label doors being tested under positive pressure. Additional information associated with these criteria can be found in NFPA 80, *Standard for Fire Doors and Fire Windows*, which should be consulted for the installation requirements associated with all types of fire doors.

Fire Window Assemblies. Fire window assemblies are permitted to be used in fire barriers if they have a fire resistance rating of 1 hour or less and represent up to 25 percent of the fire barrier. Fire windows must be tested in accordance with NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies* (see also Table S5.1 for alternative similar fire test meth-

ods, and Exhibit S5.1 for the time-temperature curve). The NFPA 257 test method is intended to evaluate the ability of a window or other light-transmitting assembly to remain in an opening during a predetermined test exposure period. In the 2000 edition of NFPA 257, there are no references to a particular time limit for testing, and time-temperature guidelines are included for up to 3 hours. Earlier editions limited testing to 45 minutes, but now the test is permitted to be run for the length of time a test sponsor requests. The period of time is then recorded on the appropriate test records. A testing time limit is no longer relevant because new materials and technology exist for window assemblies that will permit increased exposure times and maintain the integrity of the fire barriers in which they are installed. Discussions are continuing on the amount of radiant heat permitted to transfer through the window assembly to the unexposed side of the window. Currently, the radiant heat transferred is not required to be recorded. A test procedure is available to measure this radiant heat flux and is detailed in Annex C of NFPA 257, with some additional information on radiant heat transmissions in Annex B. The conditions associated with radiant energy could be considered as a factor in the application of a fire modeling program that might have an occupant passing by such opening protectives, or could, in principle, be used as pass-fail criteria. All considerations and applications for a material's particular use should be reviewed with the limitations of the test results in mind.

In NFPA 257, the test specimen is exposed to the standard time-temperature curve, with the specimen mounted in a furnace wall. A window assembly is considered to have met the requirements for acceptable performance if it remains in the opening during the fire endurance and hose stream tests, within the following five criteria:

- (1) No flaming shall occur on the unexposed surface of the assembly.
- (2) There shall be no separation of the glazing material edges from the glazing frame that creates openings.
- (3) At the perimeter of operable components, movement from the initial closed position shall not exceed the thickness of the frame member at any point.
- (4) The window assembly shall not move away from the wall to the extent that an opening is created.
- (5) There shall be no openings in the window assembly.

Exhibits S5.2 and S5.3 represent two views of an assembly that has been exposed to both the fire en-

Exhibit S5.2 Unexposed side of window assembly after fire exposure and hose stream application.

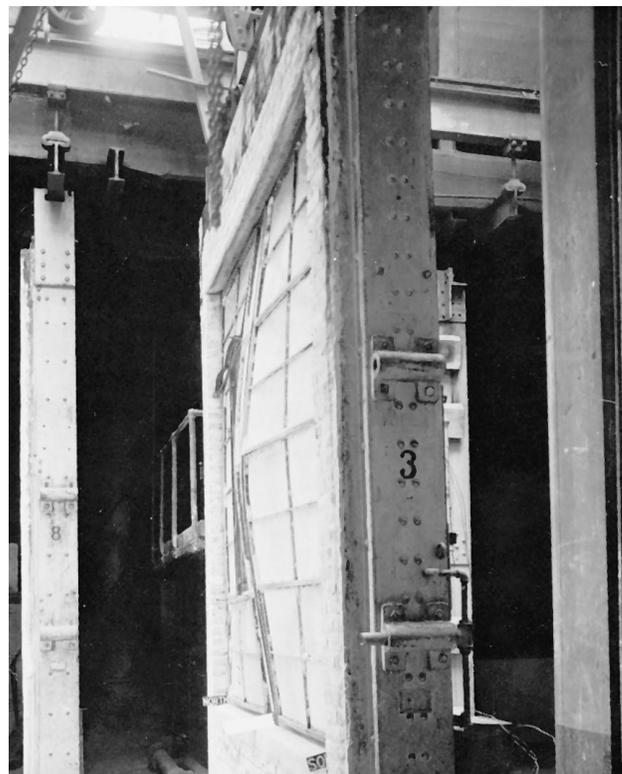

Exhibit S5.3 Exposed side of window assembly after fire exposure and hose stream application.

duration and the hose stream tests. As with fire doors, fire windows are installed in accordance with the provisions of NFPA 80, *Standard for Fire Doors and Fire Windows*, which should be consulted for the installation requirements associated with all types of fire windows. It includes limitations in the size and total area permitted for the glazing material installed in fire window assemblies and also requires that each individual glazing unit have a label that is visible after installation. Also, in NFPA 80, fire window assemblies having a rating of 20 minutes or 30 minutes are limited to the size that has been tested. A window protection of 45 minutes is limited to the maximum area tested and must have no exposed area of individual glazing material exceeding 0.84 m² (1296 in.²) and no dimension exceeding 1370 mm (54 in.), unless it has been specifically tested with dimensions in excess of those values. Glazing is currently available that has been tested with dimensions that exceed that size limitation. One should review the appropriate listing associated with the protection rating given to a fire window assembly.

Many types of glazing materials are constantly being introduced into the market, and several types of fire-rated glazing products (including wire glass)

can satisfy the acceptance criteria of NFPA 257. It is important that the installation and testing limitations be reviewed for the particular installation.

Technological advances within the glazing industry have provided systems using fire-resistant glazing materials that are actually fire barrier walls. These glazing walls would have been tested in accordance with NFPA 251 and satisfy the particular pass/fail criteria for fire barriers. These criteria include, as discussed above, the limitation of temperature rise on the unexposed side of the test specimen and a hose stream application. The installation requirements and limitations for these glazing wall assemblies would be highlighted in the applicable listing requirements and the manufacturers' specifications. This type of glazing would not be required to comply with the provisions of NFPA 80 for installation requirements, because it is not considered an opening protective device.

Through-Penetrations. Generally, when fire barriers are tested for a particular hourly rating, these assemblies are tested without any penetrations. It is recognized that within a building these fire barriers will have various penetrations for building services, utili-

ties, and other applications. Penetrations of fire barriers require the appropriate protection by devices or materials that have been tested and listed for that particular application to maintain the fire barrier's integrity. In this edition of the *Life Safety Code*, through-penetrations and membrane penetrations—for cables, cables trays, conduits, pipes, tubes, combustion vents, exhaust vents, wires, and similar items to accommodate electrical, mechanical, plumbing and communications systems that pass through a wall, floor or floor/ceiling assembly constructed as a fire barrier—are required (rather than recommended) to be protected by a firestop system or device, and tested (see paragraphs 8.3.5.1 and 8.3.5.6) in accordance with ASTM E 814, *Standard Method for Fire Tests of Through-Penetration Fire Stops*, which establishes the testing protocols for through-penetrations.

Penetrations of a rated assembly that require special consideration are usually tested to a recognized test procedure, also based on the standard time-temperature curve, normally that contained within ASTM E 814. Additional information can be found in documents published by the individual listing agencies for assemblies that have been tested for specific fire ratings.

The ASTM E 814 test protocol establishes F and T ratings as one part of the acceptance criteria for through-penetration systems. The F rating signifies the ability of the penetrating firestop system to withstand a prescribed fire test for a period of time without permitting the passage of flame through the opening or the occurrence of flaming on any element of the unexposed side of the penetrating firestop system. The T rating relates to the transmission of heat through the penetrating firestop system for a given period of time. An acceptable T rating is one that limits the rise of the temperature on the unexposed surface of the penetrating firestop system or penetrating item to no more than 181°C (325°F) above the initial temperature and for which there is no flame occurrence on the unexposed side. The penetrating firestop is exposed to the same fire test conditions created by the time-temperature curve in NFPA 251, *Standard Methods of Tests of Fire Endurance of Building Construction and Materials*. The *Life Safety Code*; NFPA 5000, *Building Construction and Safety Code*; NFPA 221, *Standard for Fire Walls and Fire Barrier Walls*; and other codes require that the penetrating firestop be under a minimum positive pressure differential of 2.5 Pa (0.01 in. of water) at the location of the penetrating item. This positive pressure must be maintained for the duration for which it is being tested. The penetrating firestop system must have the same time period as that of the fire barrier in which it is installed. The

penetrating firestop system must also be subjected to the effects of an applied hose stream test.

Joints. Joints used in the construction of fire barriers can include expansion, seismic, and control joints. These joints are tested at their maximum joint width in accordance with NFPA 251. The test includes joints to their full height or length of the test assembly. The fire-resistive joint system tested must include a splice or a method of connecting two or more lengths of the joint system. The test must be conducted so that the joint system is tested under a minimum positive pressure differential of 2.5 Pa (0.01 in.) of water for the total time of the test. There is an exception for expansion or seismic joints designed to prevent the penetration of fire and shown to have a fire resistance rating of not less than the required fire resistance rating of the floor when tested in accordance with UL 2079, *Test of Fire Resistance of Building Joint Systems* (see subsection 8.6.3 of NFPA 101). Fire-resistive joint systems that are designed to accommodate movement must be preconditioned by cycling under the conditions of ASTM E 1399, *Standard Test Method for Cyclic Movement and Measuring the Minimum and Maximum Joint Widths of Architectural Joint Systems*.

Fire Dampers. Chapter 7, Means of Egress, states that fire barriers forming horizontal exits shall not be penetrated by ducts, unless such ducts are existing penetrations protected by fire dampers approved and listed for the particular application. Fire dampers are tested either for static systems, where the HVAC system is automatically shut down in the event of a fire, or for dynamic systems, where the HVAC system does not shut down. Fire dampers used in dynamic systems are investigated for closure under their maximum recommended airflow. Fire dampers are tested in accordance with UL 555, *Standard for Fire Dampers*. Fire dampers used in rated fire-resistive floor-ceiling and roof-ceiling assemblies are tested in accordance with UL 555C, *Standard for Ceiling Dampers*. The fire dampers are tested in assemblies under the conditions of the fire exposure of the same time-temperature curve as in NFPA 251. The UL documents provide the acceptance criteria in regard to the flaming on the unexposed side, closing time of the damper, air leakage, if applicable, and hose stream application. It should be noted that fire dampers are not tested for the limitation of heat transmission through the fire damper assembly. This particular condition is recognized in the requirements of NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*, associated with the limitation on the number of fire dampers permitted to be installed in a vertical duct that has multiple floor penetrations.

Smoke Dampers. Paragraph 8.5.4.2 discusses the use of smoke dampers. Where a smoke barrier is penetrated by a duct or air transfer opening, a smoke damper designed and tested in accordance with the requirements of UL 555S, *Standard for Leakage Rated Dampers for Use in Smoke Control Systems*, must be installed. Where a smoke barrier is also constructed as a fire barrier, a combination fire/smoke damper designed and tested in accordance with the requirements of both UL 555S and UL 555, *Standard for Safety Fire Dampers*, must be installed.

Floor Fire Doors. Paragraph 8.3.3.4 regulates floor fire doors. It states that floor fire door assemblies shall be tested in accordance with NFPA 288, *Standard Method for Fire Tests of Floor Door Assemblies Installed Horizontally in Fire Resistance-Rated Floor Systems*, and shall achieve a fire resistance rating not less than the assembly being penetrated. It also states that floor fire doors assemblies shall be listed and labeled for the application. The time-temperature curve in NFPA 288 is the same as in NFPA 251, but there is no required hose stream test. The transmission of heat through the specimen during the classification period shall not raise the average temperature on its unexposed surface more than 139°C (250°F) above its initial temperature. Additionally, a temperature rise of 181°C (325°F) shall not be exceeded at any one point.

Critical Test Limitations of Fire Resistance Tests

Although test assemblies have been rated for a specific period using a fire resistance test, it must be recognized that the test is only intended to be a comparative test. Therefore, under actual field conditions, some assemblies fail prematurely and others remain in place longer than expected. The simulated test exposure used in the test protocol was established around 1920; it represents one level of fire severity considered to be a “typical office building” scenario of that era. Research continues to determine whether the varying types of fuel loads found in more modern occupancies would require a different type of time-temperature curve. Such research is always ongoing and differing opinions are expressed by various investigators. It is worth mentioning, however, that the time-temperature curve from the test used by European countries for assessing fire resistance, namely ISO 834, *Fire-resistance tests - Elements of building construction*, is very similar to that in NFPA 251.

Currently, discussions are ongoing regarding the application of particular fire modeling programs to predict the results of testing of assemblies, as well as what the pass/fail criteria should be. It is always important to remember that new materials may pre-

sent unforeseen issues that will need to be resolved. A good example is the recent understanding that high-strength concrete can cause explosive spalling to occur at relatively low temperatures. This finding could have an adverse effect on the fire protection properties assumed for a construction element using such materials.

Another area of concern for the fire resistance of a test assembly is its integrity, or the protection of through-penetrations. The test criteria in NFPA 251 do not address conventional openings found in assemblies, such as those needed for incorporation of electrical receptacles, or penetrations by electrical wires, cables or raceways, plumbing pipes, utility services, and construction joints, unless they have been specifically tested as part of the assembly. All penetrations require special review and consideration. A source for evaluating certain penetrations permitted in rated assemblies is found in the introduction of the *UL Fire Resistance Directory*. This document addresses the hourly ratings for beams, floors, roofs, columns, walls, and partitions. Its design information section provides information pertaining to the different penetrations found in rated assemblies and the required protection or limitations.

A publication entitled “Guideline on Fire Ratings of Archaic Materials and Assemblies,” by Robert Brady Williamson, Cecile Grant, Joseph Zicherman, Fred Fisher, Harry Hasegawa, Herman Spaeth, Harriet Watson, Vytenis Babrauskas, and Norman Kornsand, for the National Institute of Building Sciences for the Department of Housing and Urban Development contains information on construction materials typical of an earlier time, generally prior to 1950. It contains data on fire resistance and reaction-to-fire, including flame spread, smoke production, and degree of combustibility. The information has also been included in NFPA 909, *Code for the Protection of Cultural Resources*, as Appendix L, and in NFPA 914, *Code for Fire Protection of Historic Structures*, as Annex I.

REACTION-TO-FIRE TESTING

Major Properties and Products

Interior finish as it relates to the *Life Safety Code* refers to the exposed interior wall surfaces, exposed interior ceiling finishes, and exposed interior floor finishes. The reaction-to-fire properties associated with the regulation of interior wall and ceiling finish are flame spread and smoke development in a traditional standard test (NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*; see also Table S5.1 for alternative similar fire test methods)

or, alternatively, heat and smoke release and flame propagation (potentially leading to flashover), in a room-corner test or in a specialized large-scale test. The reaction-to-fire properties associated with interior floor finish are ignition characteristics (in accordance with ASTM D 2859, *Standard Test Method for Ignition Characteristics of Finished Textile Floor Covering Materials*) and critical radiant flux (in accordance with NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*; see also Table S5.1 for alternative similar fire test methods). These provisions should not be associated or confused with fire resistance ratings. As discussed above, the properties associated with interior finish are reaction-to-fire properties and not fire resistance properties. They refer to the ability of a material to contribute to overall fire and smoke growth and spread. An interior finish classification should also not be compared or confused with a material's combustibility or the degrees of combustibility.

Interior Wall and Ceiling Finish. There are two types of approaches being used to evaluate interior wall and ceiling finishes. Each use of a material for a particular application of interior finish needs to be coordinated with the appropriate testing procedure, and each interior finish testing method has a specific scope and application. There is a possibility that a single product could be used in different applications and be tested using different fire test methods. The end use application must be identified, because that knowledge stipulates the appropriate test method and applicable results.

Steiner Tunnel Test. The traditional approach to testing interior wall and ceiling finish for use within a code involves the use of NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, which is conducted in a piece of equipment known as the Steiner tunnel. In this way the approach is that, depending on occupancy and use within the occupancy, the *Life Safety Code* limits the use of interior wall and ceiling finish materials to minimize flame propagation and smoke development on the exposed wall and ceiling surfaces. This approach consists of evaluating the flame spread over the surface of a material, and the smoke developed, when the material is exposed to a prescribed gas-fed fire. The *Life Safety Code* provides, in 10.2.3, three classifications for interior finish, based on a flame spread index (FSI) and a smoke development index (SDI), as tested in accordance with NFPA 255 (see also Table S5.1 for alternative similar fire test methods). The classifications (with their corresponding flame spread index

and smoke development index values) are shown in Table S5.2. The flame spread index and the smoke development index both reflect the comparative fire-test-response of a material when compared with two established benchmarks: a 6.3-mm (0.25-in.) thick inorganic reinforced cement board (assigned both an FSI and an SDI of 0) and a nominal 19.8-mm (25/32-in.) select grade red oak flooring board (assigned both an FSI and an SDI of 100). The FSI is a comparative nondimensional figure and does not directly represent a flame speed, flame velocity, or flame propagation. The SDI is also a comparative nondimensional figure and does not directly represent optical density or smoke release rate.

The testing apparatus used in NFPA 255 is shown in Exhibits S5.4 and S5.5. The specimens are required to be at least 508 mm (20 in.) wide by 7.3 m (24 ft) long and are placed within the test apparatus. A gas flame of approximately 89 kW (300,000 BTU/s) is applied at one end of the tunnel, and a regulated constant draft is applied through the tunnel from the flame end. The progress of the flame front is observed through side windows for 10 minutes. The FSI is a relative indication of flame propagation, but is not, in any way, an indication of fire resistance or of combustibility, but only of the ability of the material to resist propagation of flame spread across its surface. It is possible that a material with a low ability to spread flame (for example, bare sheet metal) could also exhibit little or no fire resistance when exposed to the testing criteria of NFPA 251. The smoke development represents a degree of obscuration and is measured by a photoelectric cell mounted in the test chamber's exhaust outlet, opposite a light source. A reduction in the light transmitted, due to the smoke particulates that pass by the photoelectric cell, is recorded and used to calculate the SDI. It should be noted that there is no direct relationship between the flame spread and smoke development values. It is possible that a material having a low flame spread index could have a very high smoke development index. Specimens tested in the Steiner tunnel test must be representative of the material for which test

Table S5.2 Flame Spread Index (FSI) and Smoke Development Index (SDI) Values for Interior Wall and Ceiling Finish Classifications

Class	FSI	SDI
Class A	0–25	0–450
Class B	26–75	0–450
Class C	76–200	0–450

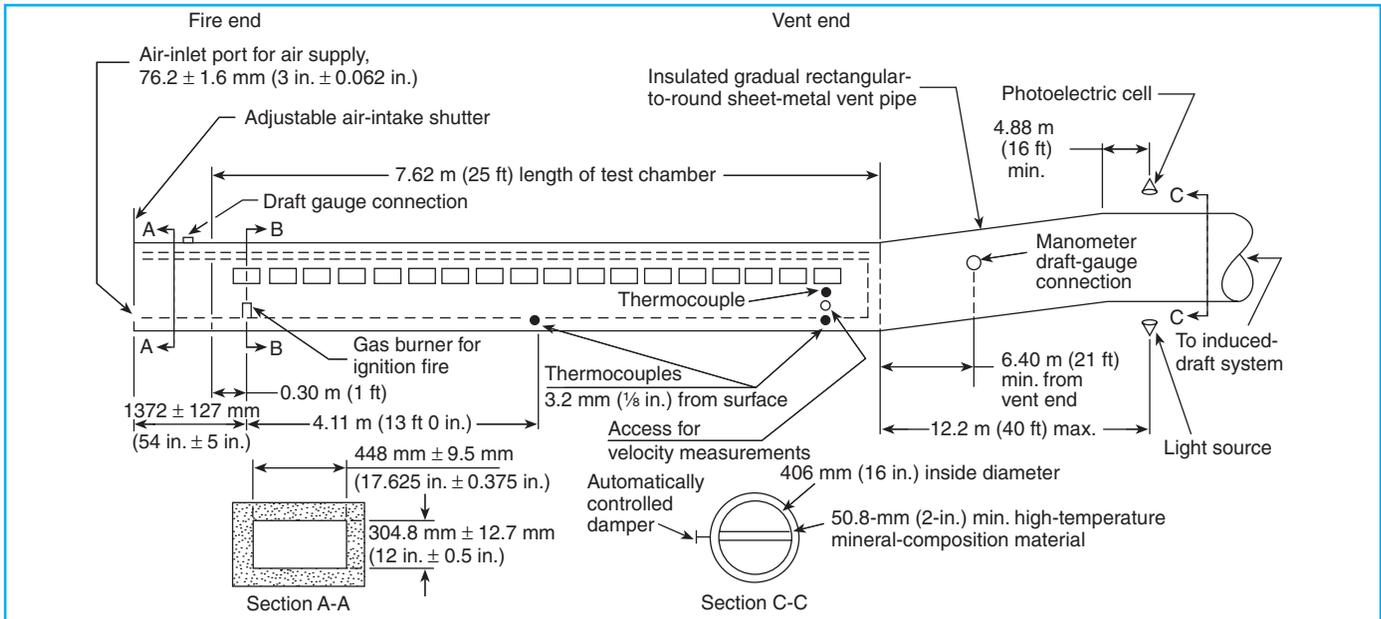

Exhibit S5.4 Schematic diagram of tunnel test apparatus used to characterize the surface burning of materials.

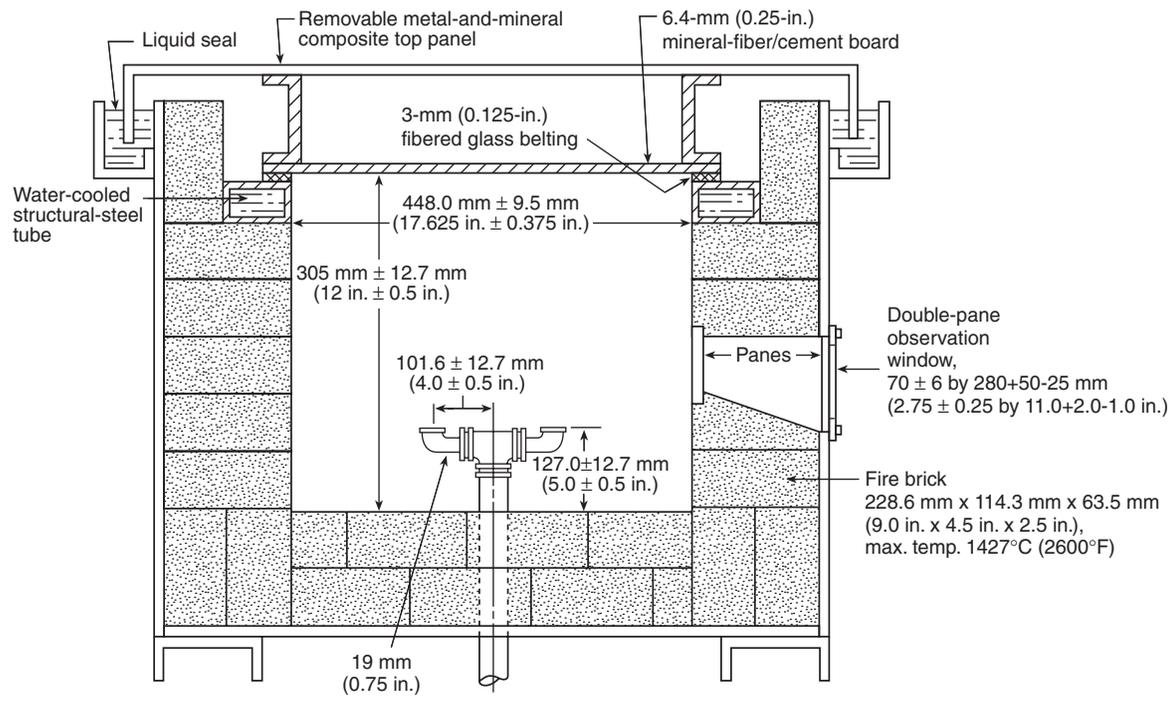

Exhibit S5.5 Cross-sectional view of the tunnel test apparatus.

results are desired. When specific materials and products are considered for use or are reviewed for compliance with a provision of the *Life Safety Code*, it is critical that the intended end use correspond with the tested configuration. If the material or product differs in composition or is mounted or applied in a

manner that deviates from the tested specimen, it could have an adverse effect. The actual FSI and SDI is likely to be different from those established from the original test results. It is very important, therefore, to follow the manufacturer or listing instructions when installing or applying the interior finish mate-

rial. Annex B of NFPA 255 provides guidance on the different mounting configurations for some types of building materials when tested in the Steiner tunnel. This appendix is provided as a guide, and caution should be used when applying it to particular materials.

The ASTM committee on Fire Standards has developed a standard practice detailing how to test some materials (pipe and duct insulation materials, namely ASTM E 2231, *Standard Practice on Specimen Preparation and Mounting for Pipe and Duct Insulation for Flame Spread and Smoke Obscuration*) in the Steiner tunnel test, and is developing further standard practices for other building materials. It has been demonstrated that some materials that cannot support themselves in the tunnel and that are artificially supported by a wire mesh can have FSI characteristics that are significantly different from those found in actual field installations. It has also been established that this test method is not suitable for building materials that, by their own structural quality or the manner in which they are applied, are not capable of supporting themselves in position or of being supported in the test furnace, at a thickness comparable to their recommended use. Consideration should be given when using these materials as interior finishes that a different test protocol might be required. An appropriate test for these types of materials would be NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*.

Table A.10.2.2 provides a compilation of the interior finish requirements, based on NFPA 255, of the occupancy chapters (Chapters 12 through 42) of the *Life Safety Code*. Wherever the use of Class C interior wall and ceiling finish is required, Class A or Class B is permitted, and wherever Class B interior wall and ceiling finish is required, Class A is also permitted.

Room-Corner Test. Alternatively, 10.2.3.2 explains that materials can be tested in accordance with a room-corner test, NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, and, if they pass the appropriate criteria (from 10.2.3.7.3), they can be used anywhere a material is required to meet Class A, Class B, or Class C, in accordance with NFPA 255, as above. This is a critical difference in approach, since a room-corner test exposes an interior wall or ceiling finish material when applied to walls (or walls and ceilings) of a room and it measures heat and smoke release. Historically, codes have regulated materials on walls and ceilings using NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*.

Full-scale room-corner fire test research has shown that flame spread indices produced by NFPA 255 may not reliably predict all aspects of the fire behavior of textile wall and ceiling coverings. NFPA 286, known as a room-corner test, was developed for assessing the fire and smoke obscuration performance of interior wall and ceiling finish materials. As long as an interior wall or ceiling finish material is tested by NFPA 286, using a mounting system, substrate, and adhesive (if appropriate) that are representative of actual use, the room-corner test provides an adequate evaluation of a product's flammability and smoke obscuration behavior. Manufacturers, installers, and specifiers should be encouraged to use NFPA 286, because this standard fire test has the ability to characterize actual product behavior, as opposed to data generated by tests using NFPA 255, which only allows comparisons of one product's performance with that of another. If a manufacturer or installer chooses to test a wall finish in accordance with NFPA 286, additional testing in accordance with NFPA 255 is not necessary. The test results from NFPA 255 are suitable for classification purposes but should not be used as input for fire models, because they are not generated in units suitable for engineering calculations. Actual test results for heat, smoke, and combustion product release from NFPA 286 are suitable for use as input for fire models for performance-based design.

In NFPA 286, the test compartment is a "standard" room, with dimensions of 2.4 m × 3.7 m × 2.4 m high (8 ft × 12 ft × 8 ft high), including a 0.76 m × 2.03 m (30 in. × 80 in.) doorway in the center of the 2.4 m × 2.4 m (8 ft × 8 ft) wall. See Exhibit S5.6. The test material is installed completely covering the three walls of the "standard" room (all except for the wall containing the doorway), as well as the entire ceiling (if appropriate). If a ceiling covering only is being tested, the test material covers the ceiling only.

The ignition source is a gas burner with a nominal 305 mm × 305 mm (nominal 12 in. × 12 in.) porous top surface of a refractory material, as shown in Exhibit S5.7, which produces a diffusion flame that will expose the walls in the corner of the room where the specimens are mounted to a predetermined energy source. The gas burner is located flush against the two back walls and is used at a net heat output of 40 kW ± 1 kW for the first 5 minutes, followed by a net heat output of 160 kW ± 5 kW for the next 10 minutes. The combustion products from the test room are collected in a hood that is fed into a 0.91 m × 0.91 m (3 ft × 3 ft) plenum that is connected to an exhaust duct, just outside the doorway. Within this exhaust duct, measurements of gas velocity, temperature, and concentrations of selected gases are made. The hood

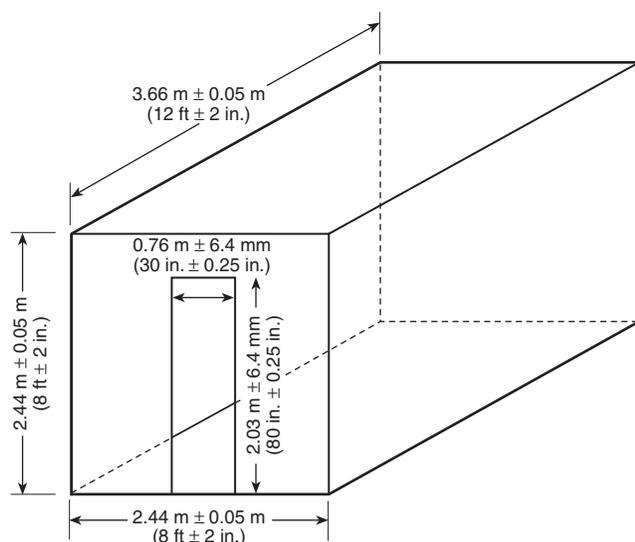

Exhibit S5.6 Interior fire test room dimensions and interior doorway dimensions for the NFPA 286 test.

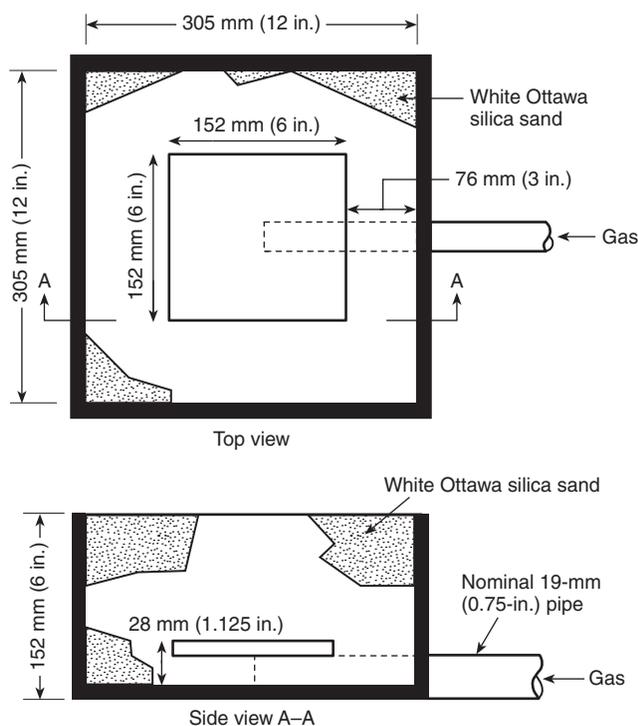

Exhibit S5.7 Gas burner for the NFPA 286 test.

is designed to develop a minimum flow rate, sufficient to capture all the products of combustion being expelled from the fire test room. The canopy hood and exhaust duct are shown in Exhibit S5.8; all the measuring instrumentation is placed in that exhaust duct. The test method assesses heat release (by the

principle of oxygen consumption calorimetry), smoke release into the duct, and also the release of combustion products. It is understood that heat release rate is the most critical reaction-to-fire property, as it parallels the intensity of the fire. The *Life Safety Code*, like most other codes, requires that an interior finish material meet the following conditions in this test:

- (1) Flames shall not spread to the ceiling during the 40 kW exposure.
- (2) During the 160 kW exposure, the following criteria shall be met:
 - a. Flame shall not spread to the outer extremities of the sample on the 2.4 m × 3.7 m (8 ft × 12 ft) wall.
 - b. Flashover shall not occur.
- (3) For new installations, the total smoke released throughout the test shall not exceed 1000 m². Values derived from 286 are in SI units; there is no straightforward inch-pound equivalent.

Flashover is determined to have occurred in the test chamber when any two of the following conditions have been attained:

- (1) A heat flux at the floor reaches 25 kW/m².
- (2) The average upper air temperature exceeds 650°C (1200°F).
- (3) Flames exit the doorway.
- (4) A paper target on the floor ignites spontaneously.

The pass/fail criterion for smoke release was determined following an assessment of smoke released in a room-corner test and in the Steiner tunnel test by a number of interior finish materials, which suggested that a material with a total smoke released value exceeding 1000 m² in a room-corner test would be likely also to exceed an SDI of 450 in the Steiner tunnel test (see Exhibit S5.9). It should be noted that the requirement for smoke release does not apply to existing installations within the *Life Safety Code*. The technical committee determined that this new requirement should not be applied retroactively.

A separate room-corner test has been developed for textile materials that are used as wall coverings: NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Wall Coverings*. The room, burner, and instrumentation are identical to those in NFPA 286. However, NFPA 265 differs from NFPA 286 in two ways: (1) the exposure after 5 minutes at 40 kW increases only to 150 kW for 10 minutes and (2) the gas burner is recessed slightly [approximately 51 mm (2 in.) in each direction] from the walls. This is a critical difference because it means that the flames from the burner itself in NFPA 265 do not reach the ceiling, while those from the NFPA

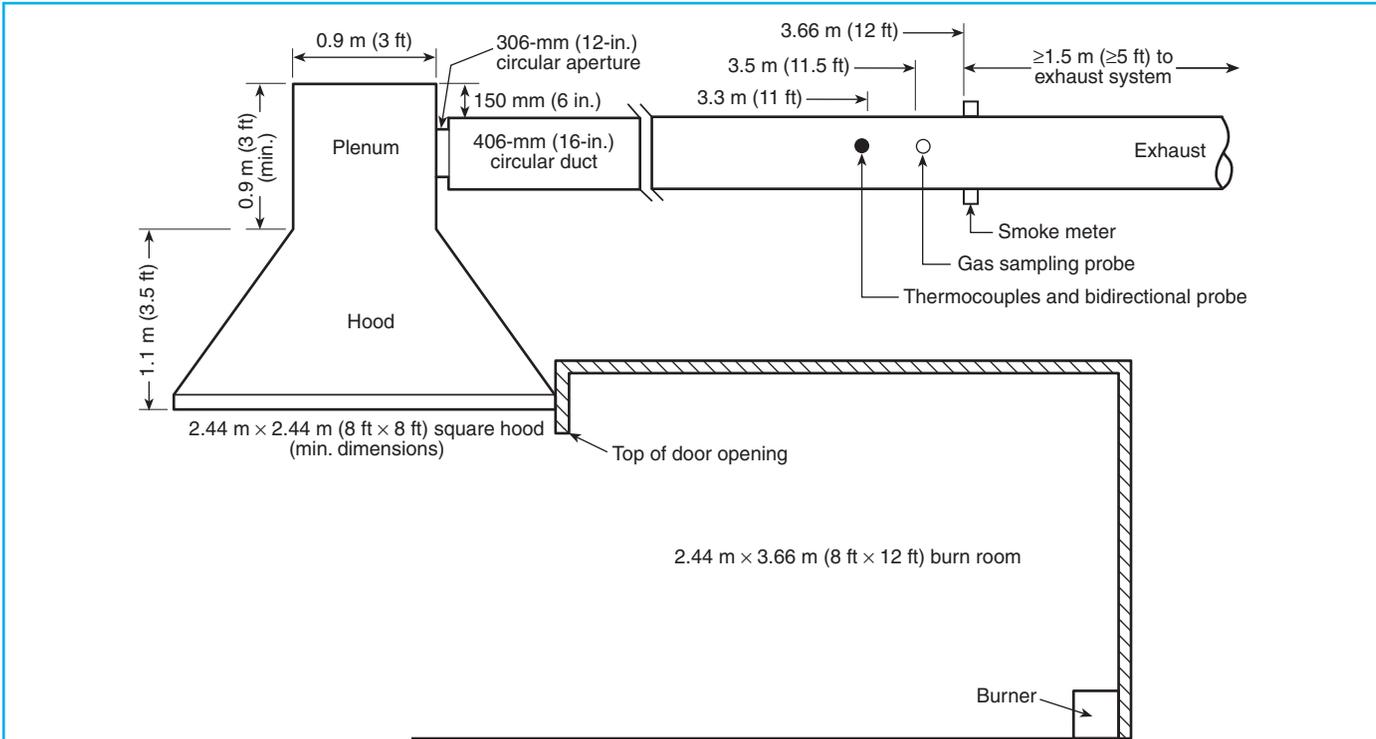

Exhibit S5.8 Canopy hood and exhaust duct for the NFPA 286 test.

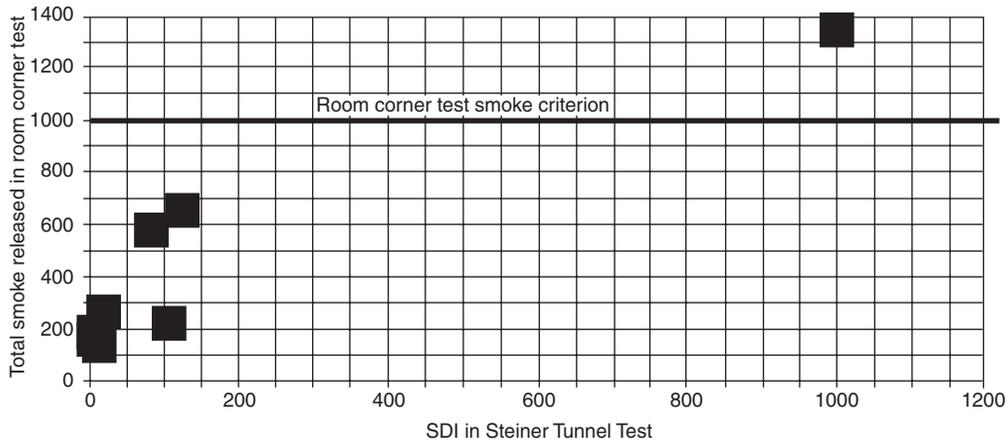

Exhibit S5.9 Comparison of smoke values in different test methods

286 burner do have direct flame impingement on the ceiling. Therefore, the *Life Safety Code*, and other codes, limit the application of NFPA 265 only to textile wall coverings (and expanded vinyl wall and ceiling covering materials).

Interior finishes that are classified as textile materials require special consideration and appropriate testing, due primarily to their very low thickness. Textile wall covering materials can include napped, tufted, looped, woven, and nonwoven or similar materials. The NFPA 265 test procedure was established

because fire research has shown that textile material having a Class A flame spread index does not accurately predict the overall burning characteristic behavior of this material in this particular end use.

Two test protocols, Method A and Method B, are approved for testing a textile material in accordance with NFPA 265. Method A uses a corner test exposure and mounts the test specimen on only sections of two walls of the test compartment: The test specimens are mounted only on the rear wall and on the left side wall and extend 0.6 m (2 ft) down from the ceiling.

Method B uses the same test compartment configuration but requires that the test specimens be mounted so that they fully cover the three complete walls (not the wall containing the doorway) with the test specimen. The test compartment is identical to that in NFPA 286, as is the gas burner (but not its intensity or location, as described above). See Exhibit S5.10. Interestingly, when a textile wall covering is tested in accordance with Method A of NFPA 265 (a frequent occurrence), the corresponding results are suitable for code approval but not for computer modeling of the fire hazard.

For a textile wall covering material to be considered acceptable by the *Life Safety Code*, when tested in accordance with NFPA 265, flames must not spread to the ceiling during the 40 kW exposure, flames must not spread to the outer extremity of the test specimen during the 150 kW exposure, and the test specimen in the room cannot reach flashover.

Fire research involving the full-scale room corner fire test scenarios has documented that Class A (in the Steiner tunnel test) textile materials can have a burning behavior that is unsatisfactory, so that the fire safety conclusions to be drawn from the two test methods can be different; it was decided that the conclusions drawn from the more realistic room-corner tests were more likely to be correct. Because of this activity, the *Life Safety Code* now requires that textile wall covering materials be tested in accordance with NFPA 265, and pass the requirements of 10.2.3.7, or be tested in accordance with NFPA 255 and obtain a Class A rating and be installed in an occupancy that is fully sprinklered if it extends from the floor to the ceiling (see 10.2.4.1). It is important to note that the pass/fail criteria associated with NFPA 265 are very similar to those associated with NFPA 286, except that the measurement of smoke release is not a requirement.

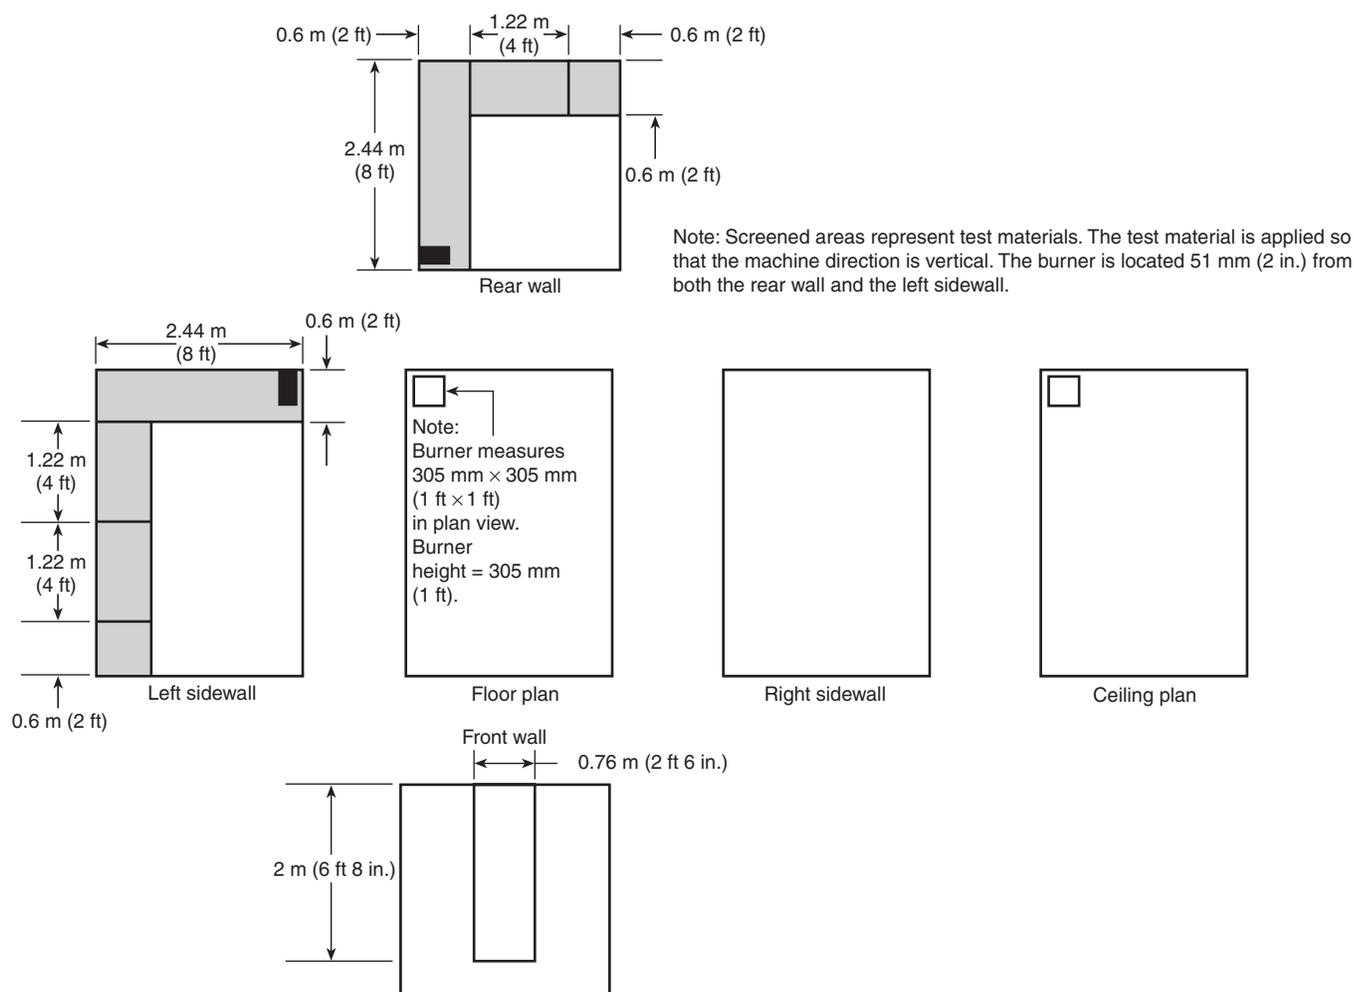

Exhibit S5.10 Specimen mounting for Method A test protocol of the NFPA 265 test.

Expanded vinyl wall and ceiling covering materials can be tested in the same way as textile wall covering materials, namely using NFPA 255 or NFPA 265, but with the same limitations of use. Alternatively, they can be tested as other interior finish materials, namely using NFPA 286, without limitations of use. Foam plastic insulation cannot be used exposed as an interior finish material, except as tested using NFPA 286, or as covered by a thermal barrier.

Another room corner test that is widely used, although not in the *Life Safety Code*, is ASTM E 2257, *Standard Test Method for Room Fire Test of Wall and Ceiling Materials and Assemblies* (similar to ISO 9705, *Fire Tests—Full Scale Room Fire Tests for Surface Products*), which is used by the European Union for regulation of building products; in NFPA 301, *Code for Safety to Life from Fire on Merchant Vessels*, for case furniture; and in the *High Speed Craft Code* of the International Maritime Organization (IMO) for regulation of interior finish “fire restricting materials.” The test is basically the same as NFPA 286 (see Exhibits S5.5 through S5.7, describing room, ignition burner, and instrumentation), except that the ignition source is a gas burner, which has an output of 100 kW (for the first 10 minutes) followed by an output of 300 kW (for a subsequent 10 minutes). Just like NFPA 286, this test assesses heat and smoke release and the development of flashover. Tested materials can be required to meet different sets of pass/fail criteria or classifications into categories.

A common misapplication of test methods needs to be pointed out here: textile materials normally used as floor coverings, such as carpets or carpet-like materials, that have achieved a Class I or a Class II rating (see details below) cannot be installed as interior wall or ceiling finish; in other words, they cannot be used to cover walls or ceilings where an interior wall or ceiling finish rating is required. The reason for this is that a classification is obtained by testing with NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, and this test method, which generates a critical radiant flux and not a flame spread or heat release, is applicable only when the material is installed as a floor covering, or, interior floor finish.

Another common misapplication of test methods is one whereby a textile material is tested by means of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films* (see more details below), and then installed as interior finish on walls, ceilings, or floors. NFPA 701 is intended to apply to fabrics or other materials used in curtains, draperies, or other window treatments, and, in Test 1, to a number of materials having an area density not greater

than 700 g/m² (21 oz/yd²), and, in Test 2, to fabrics and films, with or without reinforcement or backing, with area densities greater than 700 g/m² (21 oz/yd²). NFPA 701 assesses vertical flame propagation performance criteria, which are suitable for draperies, curtains, and other similarly loosely hanging furnishings and decorations (see 10.3.1 of the *Life Safety Code*) but is insufficiently severe for assessing the fire problem potentially associated with wall linings and inappropriate for assessing textiles installed horizontally on floors or ceilings. As stated above, it is critical that every material be tested by using the tests appropriate to the end-use application. Thus, if the same type of material is employed in different end-use applications, it may require testing via various test methods to be qualified for all applications.

Interior Floor Finish. Interior floor finish is defined in the *Life Safety Code* as the interior finish of floors, ramps, stair treads and risers, and other walking surfaces. Interior floor finish needs to meet the requirements of two different fire tests: an ignition test and a critical radiant flux test.

The United States Flammable Fabrics Act requires that all carpets and rugs manufactured, imported, distributed, or marketed in the United States must comply with the requirements of 16 CFR 1630, “Standard for the Surface Flammability of Carpets and Rugs” (FF 1-70). Because the *Life Safety Code* is applicable outside of the United States, it references (in 10.2.2.2 and 10.2.7.1) a standard test method which is substantially similar to 16 CFR 1630: ASTM D 2859, *Standard Test Method for Ignition Characteristics of Finished Textile Floor Covering Materials* (while explaining that the two are basically equivalent). In the test method, a No. 1588 methenamine timed burning tablet (commonly known as methenamine pill), weighing 0.149 g (0.0052 oz), is placed flat on a test specimen consisting of a section of carpet and ignited with a lighted match (ensuring that the match does not ignite the carpet). Each test specimen passes the test if the charred portion of the test specimen does not exceed 76 mm (3 in.) in length. This test method is not applicable to interior floor finish that is not a textile, because most flooring materials that have a hard surface are known to meet the test requirements.

Interior floor finish materials used in regulated environments, as determined by the *Life Safety Code* or where the authority having jurisdiction determines that their particular burning characteristics are unknown, often must also meet a minimum critical radiant flux when tested in accordance with NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor*

Covering Systems Using a Radiant Heat Energy Source (see also Table S5.1 for alternative similar fire test methods). Paragraph 10.2.2.2 of the *Life Safety Code* lays out when interior floor finishes are required to have a fire safety classification rating, and Subsection 10.2.7 describes the criteria needed: interior floor finishes are grouped in two classes in accordance with their critical radiant flux ratings.

- (1) Class I Interior Floor Finish: critical radiant flux not less than 0.45 W/cm^2 .
- (2) Class II Interior Floor Finish: critical radiant flux not less than 0.22 W/cm^2 but less than 0.45 W/cm^2 .

The *Life Safety Code* also states (10.2.7.2) that a critical radiant flux of 0.1 W/cm^2 is minimally required for floor coverings other than carpets (which is basically considered to be equivalent to a “pass” in the ASTM D 2859 test). This applies to floor coverings with unknown fire performance, and is discussed in more detail in A.10.2.7.2 and A.10.2.7.3.

The NFPA 253 test method measures the critical radiant flux (CRF) behavior of a horizontally mounted floor covering system exposed to a radiant heater, inside a test chamber (see Exhibits S5.11 through S5.13, which show the apparatus used to test the floor covering specimens in this test method). A gas-fired panel serving as a radiant heat energy source is installed at one end of the test chamber, on an incline (at a 30° angle) so that it extends over the test specimen. The radiant heater applies a graded heat flux that ranges between approximately 0.1 and 1.1 W/cm^2 (close to the two ends of the test specimen). The test specimen is ignited by a pilot flaming ignition source at the end of the test chamber where the heat flux applied is highest. The test chamber is calibrated by assigning a heat flux to each position along the length of the test chamber.

Thus, the test method measures the heat flux at the point of flame-out, which is when the material does not continue to support flaming, and that value is considered the CRF. The test specimens are required, to the extent possible, to simulate actual field installation practices. For example, if a carpet is to be mounted with a pad and/or an underlayment, it must be tested in that same way. The CRF provides a basis for estimating a critical aspect of fire exposure behavior for floor covering systems. It should be noted that this test is intended primarily for regulating floor coverings installed in building corridors, exits, and exit access corridors, which often have little or no combustible wall or ceiling finish. An occupancy with combustible finishes would be expected to contribute much more to fire hazard.

Exhibit S5.11 Flooring radiant panel tester apparatus. (Courtesy of Fire Testing Technology Ltd.)

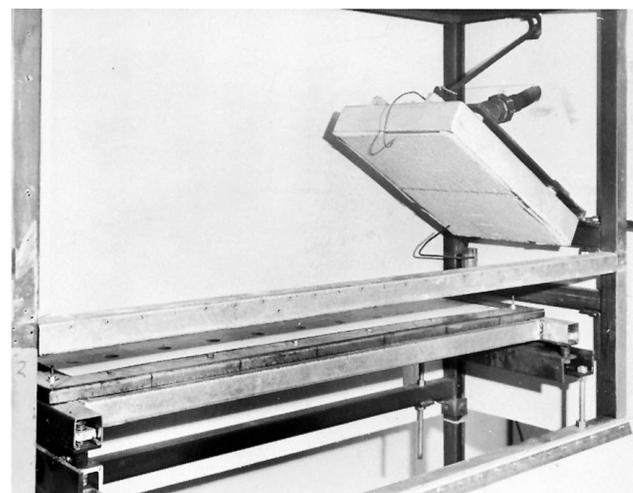

Exhibit S5.12 Flooring radiant panel test showing carpet specimen and gas-fueled panel.

The CRF is determined by measuring the distance that has burned. The test specimen is tested for 10 minutes following the exposure to a radiant energy source to a maximum of 1 W/cm^2 . The distance

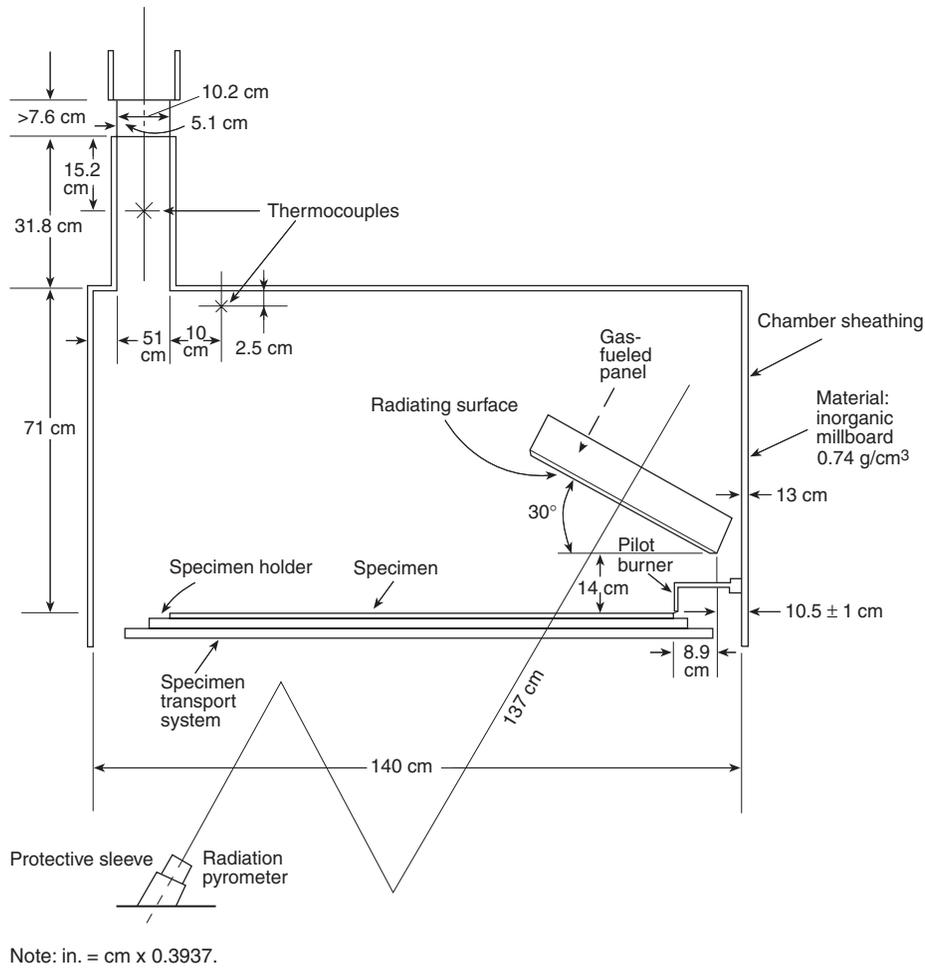

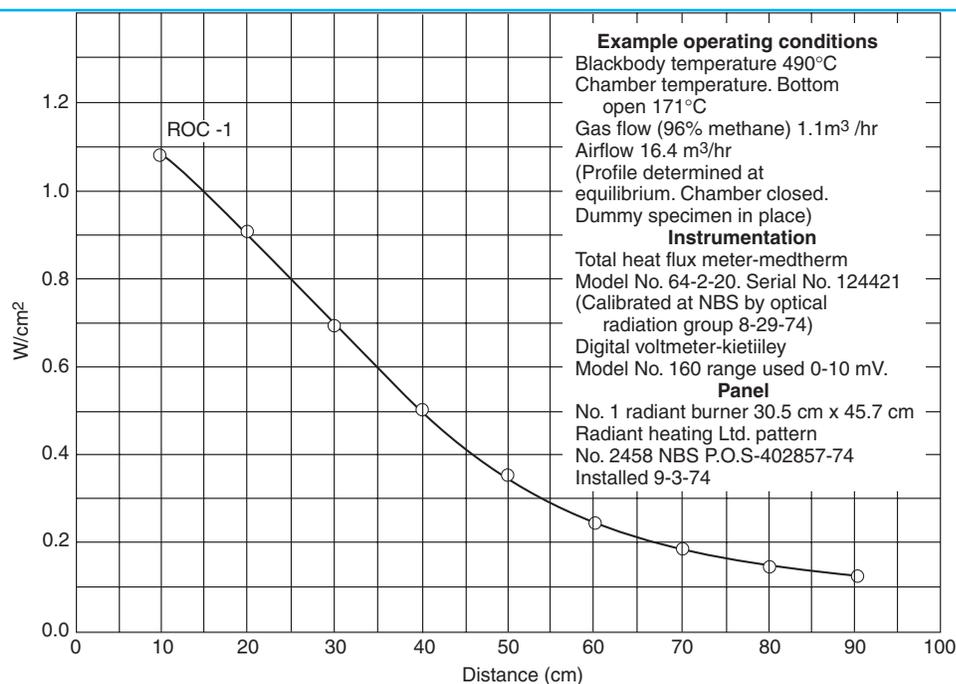

Exhibit S5.13 Flooring radiant panel schematic side elevation.

burned is converted to a CRF value by plotting the distance on the standard radiant heat energy flux profile, as shown in Exhibit S5.14, which shows the calibration curve used. The CRF is the level of incident radiant heat energy at the time the test specimen ceases flaming or glowing activities. The higher the CRF, the more resistant to the radiant exposure the material is and, subsequently, flame propagation across the surface, than materials with a lower CRF.

As discussed above, it is important to point out that carpet-like materials, when used in applications other than as floor coverings, must be tested using the fire test method appropriate for the application. Thus, carpet-like materials used as wall or ceiling finish must be tested using the Steiner tunnel test (NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials*, or equivalent) or a room-corner test (NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*; NFPA 265, *Standard*

Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile Coverings on Full Height Panels and Walls; nor their equivalents). Similarly, carpet-like materials used as curtains or drapes must be tested using a vertical flame propagation test (NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*). In neither case is it acceptable to test via NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, or equivalent.

Interior Contents and Furnishings. Beyond interior finish, compartments tend to have a number of combustibles brought in by the occupier. Such contents and furnishings need to be considered for fire involvement. They include furnishings such as upholstered furniture, mattresses, curtains, draperies, and other similar loosely hanging materials and decorations. Certain occupancies in the *Life Safety Code* require that these particular elements possess a certain

Note: in. = cm x 0.3937; Btu/ft² • sec = W/cm² x 1.135.

Exhibit S5.14 Standard radiant heat energy flux profile.

degree of flame resistance and do not propagate or assist in flame spread. Test requirements (if applicable) are found in Section 10.3. The overall fire growth in certain fires has been related directly to the types of furnishings and decorations found within the facility.

Upholstered Furniture. The *Life Safety Code* contains provisions for upholstered furniture to comply with requirements for smoldering ignition (similar to cigarette ignition) and flaming ignition, if applicable according to the occupancy chapters (Chapters 12 through 42). The applicable provisions of the *Life Safety Code* that address the requirement for upholstered furniture to resist cigarette ignition are found in subsection 10.3.2. There are two relevant fire test methods: NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*, and NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes* (see Table S5.1 for alternative similar fire test methods). The major difference between the two test methods is that NFPA 260 addresses individual components that will be used to make an upholstered furniture item and NFPA 261 addresses small mock-ups of the various composites used for the upholstered furniture item. In both tests, a lit cigarette, covered by a layer of

sheeting material, is placed on the test item, and the resulting char (or flame) assessed visually. The char length is the distance, to the nearest 0.2 in. (5 mm), from the center of the original location of the lit cigarette.

NFPA 260 contains tests for assessing components such as cover fabrics, welt cords, decking materials, interior fabrics, and filling and padding materials. This test method was originally developed by the Upholstered Furniture Action Council (UFAC) and compliance with it for residential upholstered furniture, on a voluntary basis, is managed by UFAC itself. The test method establishes a classification system for determining the resistance of upholstered furniture components to ignition by a smoldering cigarette. A Class 1 designation is given to materials that are considered resistant to cigarette ignition; the material does not show evidence of flaming ignition on any part of the test assembly and the resulting char length does not exceed 38 mm (1.5 in.).

NFPA 261 provides test methods to evaluate the resistance of upholstered furniture assemblies to smoldering ignition, when exposed to a lit cigarette under specific conditions, in a "mock-up" test assembly. This test was initially developed by the National Bureau of Standards (now the National Institute of Standards and Technology). The individual materials assessed include cover fabrics, filling materials, and

welt tapes. In this test, the results are not identified in Classes, such as in NFPA 260, but a material will fail if flaming ignition occurs or if the maximum char length exceeds 38 mm (1.5 in.).

Two California documents are referenced by some state agencies for investigating the effect of smoldering cigarettes on upholstered furniture components: California Technical Bulletin 116, *Cigarette Test of Upholstered Furniture*; and California Technical Bulletin 117, *Flame and Smoldering Resistance of Furniture Components*. California Technical Bulletin 116 requires that three cigarettes (each covered by a layer of sheeting material) be placed at each of a number of locations (as relevant) of an actual full-scale item of upholstered furniture: smooth surfaces, decking, welts, quilted locations, tufted locations, crevices, and tops of arms and backs. In each case, the test item fails if there is ignition or if the char length exceeds 51 mm (2 in.). In California Technical Bulletin 117 (which contains flaming ignition tests also), individual upholstery items are tested, and the test item fails if there is ignition or if the char length exceeds 51 mm (2 in.). There are some differences in the pass/fail criteria of each of these tests, which is critical if a comparison is made between the test results. These California Technical Bulletin test methods are not used in the *Life Safety Code* for assessing resistance to smoldering ignition. It should also be mentioned that California Technical Bulletin 117 is likely to undergo a complete revision in 2003, which will involve using different test methods.

The most important requirement that addresses the fire hazard of upholstered furniture is testing that assesses the heat released. The *Life Safety Code* recognizes, in subsection 10.3.3, ASTM E 1537, *Standard Test Method for Fire Testing of Upholstered Furniture*, as the relevant test method for assessing heat release of upholstered furniture. This test is substantially similar to NFPA 266, *Standard Method of Test for Fire Characteristics of Upholstered Furniture Exposed to Flaming Ignition Source*, which was recently withdrawn to avoid duplication. In this test method, a full-scale upholstered furniture item (or a full-scale mock-up) is ignited with a gas burner to assess the heat release, smoke obscuration, mass loss, and generation of toxic gases. These fire properties are important when developing certain fire hazard considerations during fire modeling. The test item is placed in a standard room (which could be the same room as that used for NFPA 265 or NFPA 286, or a slightly different room, known as the “California room”) or in a furniture calorimeter. The test scenarios can be used interchangeably because it has been demonstrated that they provide comparable results for test specimens

having heat release rates of 600 kW or less (and those providing higher heat release rates would not be considered safe anyway). The test specimen is ignited with a square gas burner; the burner applies a volume flow rate of 13 L/min \pm 0.5 L/min of propane (ca. 19.3 kW) for 80 seconds. See Exhibit S5.15 for the application of the gas burner in this test. Generally, the requirements are waived if suitable active fire protection measures (such as sprinklers) are present. If applicable, the pass/fail criteria are:

- (1) The peak rate of heat release for the single upholstered furniture item shall not exceed 250 kW.
- (2) The total energy released by the single upholstered furniture item during the first 5 minutes of the test shall not exceed 40 MJ.

California Technical Bulletin 133, *Flammability Test Procedures for Seating Furniture and Use in Public Occupancies*, is technically equivalent to ASTM E 1537, except that it uses only the California room for testing the furniture items and that it has more severe pass/fail test criteria (as well as additional test criteria related to smoke obscuration and carbon monoxide emission):

- (1) The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.
- (2) The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

Another test procedure used to evaluate the properties of upholstered furniture is NFPA 272, *Standard Method of Test for Heat and Visible Smoke Re-*

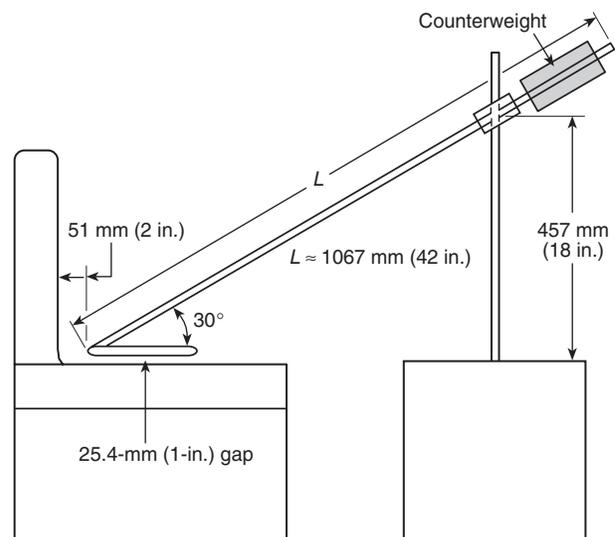

Exhibit S5.15 Positioning of square gas burner on the upholstered furniture item.

lease Rates for Upholstered Furniture Components or Composites and Mattresses Using an Oxygen Consumption Calorimeter (renumbered from NFPA 264A; see also Table S5.1 for alternative similar fire test methods). This test is an application of the cone calorimeter (see below, NFPA 271, *Standard Method of Test for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*), and uses an oxygen consumption calorimeter to assess ignitability, heat release, smoke obscuration, mass loss, and generation of toxic products from a small section of an upholstered furniture component or composite (test specimens are 100 mm × 100 mm × ≤51 mm thick). In the test method, the samples are exposed to a controlled level of radiant energy from a conical electric heater: 35 kW/m². Data from this test has been shown to be useful in predicting the fire performance of the actual full-scale item (or of the full-scale test methods discussed above). However, the results are affected by issues such as product design and minor components.

Mattresses. The *Life Safety Code* contains provisions for mattresses to comply with requirements for smoldering ignition (that is, cigarette ignition) and flaming ignition, if applicable according to the occupancy chapters (Chapters 12 through 42). The requirements for mattresses are very similar to those for upholstered furniture. The applicable provisions of the *Life Safety Code* that address the requirement for a mattress to resist cigarette ignition are found in subsection 10.3.2. There is one relevant fire test method, which is actually a federal requirement in the United States: the cigarette ignition of mattresses, mattress tickings, and mattress pads must comply with Department of Commerce (DOC) FF 4-72 or CFR 1632. In the test, a lit cigarette is placed on the test item, and the resulting char (or flame) assessed visually; the test item fails if there is ignition or if the char length exceeds 51 mm (2 in.).

The most important requirement that addresses the fire hazard of mattresses is (just like with upholstered furniture) testing that assesses the heat released. The *Life Safety Code* recognizes, in subsection 10.3.4, ASTM E 1590, *Standard Test Method for Fire Testing of Mattresses*, as the relevant test method for assessing heat release of upholstered furniture. This test is substantially similar to NFPA 267, *Standard Method of Test for Fire Characteristics of Mattresses and Bedding Assemblies Exposed to Flaming Ignition Source*, which was recently withdrawn to avoid duplication. In this test method, a full-scale mattress is ignited with a gas burner to assess the heat release, smoke obscuration, mass loss, and generation of toxic gases.

These fire properties are important when developing certain fire hazard considerations during fire modeling. The test item is placed in a standard room (which could be the same room as that used for NFPA 265 or NFPA 286, or the California room) or in a furniture calorimeter. The test scenarios can be used interchangeably because it has been demonstrated that they provide comparable results for test specimens having heat release rates of 600 kW or less (and those providing higher heat release rates would not be considered safe anyway). The test specimen is ignited with a T-shaped gas burner; the burner applies a volume flow rate of 12 L/min ± 0.5 L/min of propane (ca. 17.8 kW) for 180 seconds. See Exhibit S5.16 for the application of the gas burner in this test. Generally, the requirements are waived if suitable active fire protection measures (such as sprinklers) are present. If applicable, the pass/fail criteria are:

- (1) The peak rate of heat release for the single mattress shall not exceed 250 kW.
- (2) The total energy released by the single mattress during the first 5 minutes of the test shall not exceed 40 MJ.

California Technical Bulletin 129, *Flammability Test Procedures for Mattresses for Use in Public Buildings*, is technically equivalent to ASTM E 1590, except that it uses only the California room for testing the mattresses and that it has more severe pass/fail test criteria (as well as an additional test criterion related to mass loss):

- (1) The peak rate of heat release for the single mattress shall not exceed 100 kW.
- (2) The total energy released by the single mattress during the first 10 minutes of the test shall not exceed 25 MJ.

The cone calorimeter application standard, NFPA 272, can also be used for mattress composites or com-

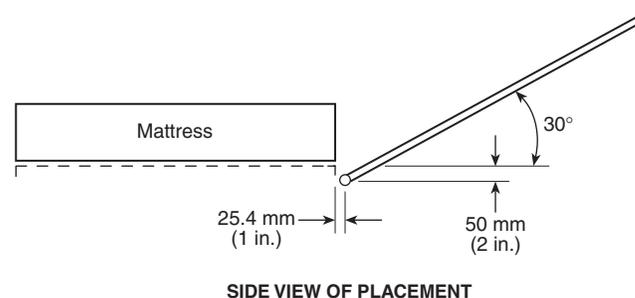

Exhibit S5.16 Positioning of T-shaped gas burner on the mattress.

ponents, in a similar fashion to the way it can be used for upholstered furniture test specimens.

Curtains, Draperies, and Decorations. NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, is mandated for testing of curtains, drapes, or similar loosely hanging furnishings or decorations. NFPA 701 provides the means to evaluate the vertical propagation of a small flame beyond the area exposed to the source of ignition. NFPA 701 includes two methods of assessing flame propagation propensity. The test method to be used depends on the areal density of the test specimen (weight per unit surface) and some other characteristics. Test Method 1 is used for fabrics that weigh up to 700 g/m² (21 oz/yd²), and in particular for single-layer fabrics and multilayer curtain and drapery assemblies, but is not permitted to be used for vinyl-coated fabric blackout linings (because it has been shown that they produce erroneous results with this method). In relation to NFPA 701, Test Method 1, curtains and drapes also include the following items [if they weigh up to 700 g/m² (21 oz/yd²)]: window curtains, stage or theater curtains, vertical folding shades, roll-type window shades, hospital privacy curtains, window draperies, fabric vertical shades or blinds, horizontal folding shades, swags, and fabric horizontal shades or blinds. Test Method 1 also applies to the following textile items [if they weigh up to 700 g/m² (21 oz/yd²)]: table skirts, table linens, display booth separators, and textile wall hangings. Test Method 2 is to be used for the heavier fabrics and films (with or without reinforcement or backing), weighing over 700 g/m² (21 oz/yd²) and for fabrics used in awnings and tents and for vinyl-coated fabric blackout linings and lined draperies using a vinyl-coated fabric blackout lining.

The test methods in the 1999 edition of NFPA 701 were introduced in the revisions between the 1989 and 1996 editions which eliminated the “small-scale test,” because it was found that a “pass” in that test was not indicative of a good fire performance. The difference between the NFPA 701 Test Method 1 and the small-scale test previously included in the standard is that the test specimen is now larger and the overall time exposure to the flame is increased. Test Method 1 employs 10 specimens of material, each of which is 150 mm × 400 mm (2.9 in. × 15.75 in.) that are exposed to a Bunsen gas burner for 45 seconds. The pass/fail criterion, addressing vertical flame propagation performance, requires that there be no flaming for more than 2 seconds after the test flame is removed and that the average weight loss of the test specimen not be greater than 40 percent. Test

Method 2 of the 1999 edition of NFPA 701 is similar, in specimen size and test protocol, to the previous “large-scale test” but differs somewhat in the test enclosure. Test Method 2 employs test specimens that are tested in a folded or flat configuration, and that have sizes 610 mm × 1.2 m (24 in. × 46.25 in.) or 125 mm × 1.2 m (5 in. × 46.25 in.), respectively. Each test specimen is then exposed to a Bunsen gas burner for 2 minutes. The pass/fail criterion, addressing (vertical) flame propagation performance, also requires that there be no flaming for more than 2 seconds after the test flame is removed. Additionally, it requires that the length of char on an individual folded test specimen not exceed 1050 mm (41.3 in.), and that the length of char on any flat test specimen not exceed 1035 mm (40.7 in.). Both test methods require that, if any portions or residues of the test specimen drip or fall to the test chamber floor during or after application of the test flame, flaming will not continue. The results of the two tests contained in NFPA 701 should not be compared to each other, as they use different types of pass/fail criteria. However, it can be validly assumed that Test Method 2 represents a more severe condition than Test Method 1.

NFPA 701 stipulates that each fabric is also to be subjected to exposures applicable to its intended use, such as laundering, dry cleaning, weathering, and other exposure to water. It is believed that the accelerated exposure tests detailed in NFPA 701 (akin to weathering or aging, to some extent) provide sufficient conditioning to permit a reasonable appraisal of the durability of the fire retardant treatment for the useful life of the fabric. Procedures on how to provide accelerated dry cleaning, laundering, weathering, and water leaching for the fabrics are also provided in NFPA 701.

The text of NFPA 705, *Recommended Practice for a Field Flame Test for Textiles and Films*, was originally contained in Chapter 10 of the 1989 edition of NFPA 701; it was developed as a stand-alone document during the revision leading to the 1996 edition of NFPA 701. NFPA 705 is a recommended practice that provides guidance to enforcement officials confronted with the assessment of products already installed. Thus, they can use this test for the field application of an open-flame ignition source to textiles and films that have been in use in the field or for which reliable laboratory data are not available. This recommended practice provides the authority having jurisdiction with a field procedure for determining the tendency of textiles and films to sustain burning subsequent to the application of a relatively small open flame. There is no correlation between the testing provisions found in NFPA 705 and the testing methods of NFPA

701. Field application of the NFPA 705 testing procedures is somewhat useful but must be used with good judgment and within limitations. Field tests should not be relied on as a sole means for ensuring adequate flame resistance of decorative materials. However, they have some utility in augmenting a comprehensive regulatory program. Within the *Life Safety Code*, this test method is only referenced as a suggestion in A.12.7.4.3.4(3) and A.13.7.4.3.4(3) for new and existing assembly occupancies.

Unprotected Foam Plastics. Furnishings and contents made with foamed plastic materials that are unprotected from ignition are required to have a heat release rate not exceeding 100 kW when tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes* (see subsection 10.3.7 of the *Life Safety Code*). The same test method also applies to other foam displays, as follows: (1) in theaters, motion picture theaters, and television stage settings, with or without horizontal projections, to decorative packages of foamed plastic (see 12.4.5.11.4); (2) exposed foamed plastic materials and unprotected materials containing foamed plastic used for decorative purposes or stage scenery (see 12.7.3.3 and 13.7.3.3); (3) foam plastic materials of construction of exhibit booths in assembly occupancies (see 12.7.4.3.4 and 13.7.4.3.4); and (4) foam plastic materials of construction of kiosks in malls (see 36.4.4.8 and 37.4.4.8). In every case, any single fuel package cannot have a heat release rate exceeding 100 kW. There are some other fuel packages that are also tested by means of UL 1975 and that are required to have a heat release rate not to exceed 150 kW: (1) cardboard, honeycombed paper, and other similar combustible materials used for construction of exhibit booths in places of assembly (see 12.7.4.3.4 and 13.7.4.3.4); (2) foamed plastics and materials containing foamed plastics on stages (see 12.7.4.3.6.2 and 13.7.4.3.6.2); and (3) foam plastics used in plastic signs in malls (see 36.4.4.7 and 37.4.4.7). UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, is a "furniture calorimeter" test method, in which the fuel package under test is exposed to a wood crib ignition source (340 g) and where all relevant fire properties are measured, with the critical one being the rate of heat release.

Tests for Other Fire Properties

Combustibility—Noncombustible and Limited Combustible. Many codes, including the *Life Safety Code*, require that certain materials (particularly materials of construction) be classified as "noncombustible." Noncombustibility is assessed by testing a specimen

of a material that is 38 mm × 38 mm × 51 mm (1.5 in. × 1.5 in. × 2 in.) in a vertical tube furnace heated to 750°C (1382°F) and waiting for temperature rises. A material is classified as noncombustible if, when tested in accordance with ASTM E 136, *Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*, it meets the following three criteria:

- (1) The recorded temperature of the surface and interior thermocouples does not at any time during the test rise more than 30°C (54°F) above the furnace temperature at the beginning of the test.
- (2) There is no flaming from the specimen after the first 30 seconds of test.
- (3) If the weight loss of the specimen during testing exceeds 50 percent of the initial weight, the recorded temperature of the surface and interior thermocouples does not, at any time during the test, rise above the furnace air temperature at the beginning of the test, and there is no flaming of the specimen.

Requirements for noncombustible materials are included throughout the *Life Safety Code*, but are particularly prevalent in Chapter 7, Means of Egress. In addition to Chapter 7 and the occupancy chapters (Chapters 12 through 42), references to noncombustible appear in Chapter 8 (8.3.5.5 on transitions and 8.5.5 on penetrations) and Chapter 11 (11.5.3 on means of egress and section 11.9 on permanent membrane structures).

There are many instances in the *Life Safety Code* where the concept of "limited combustible" is used, almost exclusively for materials of construction, a test criterion which is exclusive to NFPA codes and standards. A material is "limited combustible" if it is "a building construction material not complying with the definition of noncombustible material that, in the form in which it is used, has a potential heat value not exceeding 8141 kJ/kg (3500 Btu/lb), where tested in accordance with NFPA 259, *Standard Test Method for Potential Heat of Building Materials*, and complies with (a) or (b): (a) materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm) that has a flame spread index not greater than 50; and (b) materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. (Materials subject to increase in combustibility or flame spread index beyond the limits

herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible.)” Note that the “flame spread index” associated with this definition is based on testing in accordance with NFPA 255, *Standard Method of Test of Surface Burning Characteristics of Building Materials* (see also Table S5.1 for alternative similar fire test methods). Testing in accordance with NFPA 259 requires that a small piece of the material be pulverized and combusted by a combination of tests in an oxygen bomb calorimeter (at very high pressure and in an atmosphere of pure oxygen) to assess the gross (or complete) heat of combustion and in the vertical tube furnace at 750°C (1382°F); the final result is a “potential heat content.” Materials classified as “limited combustible” can be used as replacements for noncombustible materials in a number of applications, albeit only in NFPA codes and standards.

It is important to understand that there is a fundamental difference between the concepts of “gross heat of combustion” (which is the theoretical amount of heat released if a material is completely combusted to its final products—such as carbon dioxide and water—and is measured by oxygen bomb calorimeters) and “effective heat of combustion” (which is the actual amount of heat released in a realistic fire scenario, and is assessed by oxygen consumption, or heat release, calorimeters). Oxygen consumption calorimetry is used in tests of various scales, starting at bench-scale (100 mm × 100 mm, or almost 4 in. × 4 in. test specimens); it is based on the empirical observation that there is a direct relationship between the mass of oxygen consumed during combustion and the heat released: the relationship is that approximately 13.1×10^3 kJ of heat are released per 1 kg of oxygen consumed.

Heat Release Rate: Cone Calorimeter Testing. NFPA 271, *Standard Method of Test for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*, is a small-scale test procedure for determining the ignitability, heat release rate, mass loss rate, smoke obscuration, effective heat of combustion, and toxic gas release from burning of materials and products. The test procedure uses a cone calorimeter apparatus that exposes a test specimen to a controlled constant level of radiant heating ranging up to 100 kW/m² (See Exhibit S5.17). The test results are useful in the evaluation of materials, mathematical modeling and product research and development. They are also very useful for predictions of heat release results from larger-scale tests, such as many of the tests discussed earlier, including room-corner tests (NFPA 286 and 265), furniture tests

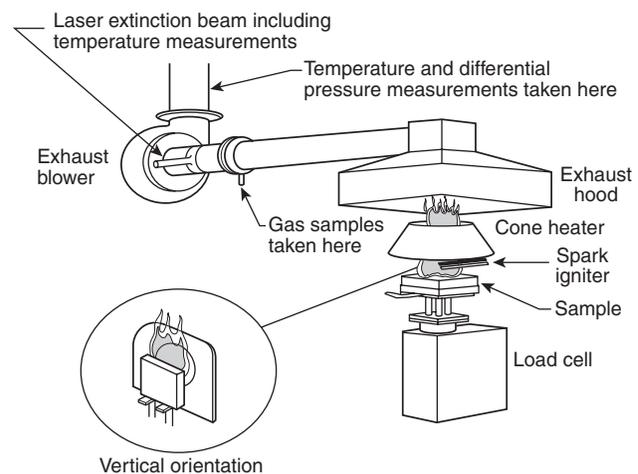

Exhibit S5.17 Schematic diagram of the cone calorimeter.

(ASTM E 1537 and E 1590), furniture calorimeter tests (UL 1975), and so on. Application standards exist for this test method, such as NFPA 272, discussed above for upholstered furniture or mattress composites or components. Test specimens are 100 mm × 100 mm (4 in. × 4 in.) with a maximum thickness of 50 mm (2 in.), and they can be exposed horizontally or vertically. However, test samples are most meaningfully exposed horizontally, irrespective of the application that the test is intended to investigate, due to the configuration of the ignition source. Interestingly, this test is not used for regulatory purposes, but the test itself is an upgrade of the Ohio State University heat release rate calorimeter (ASTM E 906, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products*, which is equivalent to NFPA 263, *Standard Method of Test for Heat and Visible Smoke Release Rates for Materials and Products*, withdrawn to avoid duplication), which is used by the United States Federal Aviation Administration for aircraft regulation. The main use of the cone calorimeter test in the *Life Safety Code* is to obtain input values for use in the performance calculations contained in Chapter 5.

Smoke Obscuration—Small- and Large-Scale Test Methods. Smoke obscuration is a critical fire property, since victims of a fire must be able to see their way to the exits (or rescuers must be able to see the way in) so that they can escape or be rescued. Thus, smoke obscuration is particularly critical in full-scale tests. However, it is important to recognize that the values being developed for smoke obscuration from small-scale tests might not have application or correlation to the particular base performance fire scenarios or other end-use applications, since smoke obscuration is a less easily scalable property than

heat release. Activities are ongoing to address some of these concerns.

Small-scale tests that address smoke obscuration measurements can be subdivided into static and dynamic test methods. There are two static test methods: NFPA 258, *Recommended Practice for Determining Smoke Generation of Solid Materials*, and NFPA 270, *Standard Test Method for Measurement of Smoke Obscuration Using a Conical Radiant Source in a Single Closed Chamber*, and their equivalents (ASTM E 662 and ASTM E 1995, see Table S5.1). Dynamic test methods for smoke obscuration are almost invariably associated with the measurement of other fire properties, typically heat release. In fact, every test method mentioned here regarding heat release measurements can be used for assessing smoke obscuration, both in small-scale and in large-scale.

Finally, NFPA 255 (see discussion of interior finish and Table S5.1) is used for assessing both flame spread and smoke obscuration. NFPA 258, *Recommended Practice for Determining Smoke Generation of Solid Materials*, has long been the most popular test method for assessing the smoke obscuration tendency of materials or products. It uses a small radiant furnace (at an incident heat flux of 25 kW/m²), with a gas igniter, to expose a 75 mm × 75 mm (3 in. × 3 in.) vertical test specimen in a closed chamber where a vertical light beam impinges on a photocell. Smoke obscuration is assessed by the reduction of light reaching the photocell.

The Technical Committee on Fire Tests decided that the test results of this procedure were being used as a regulatory tool and were, incorrectly, finding their way into fire modeling applications. As a result, NFPA 258 was revised to become a recommended practice. The scope of the test method indicates that the measurement of smoke obscuration with this test method should be used as a research and development tool only and should not be used as a basis for determining ratings for building codes or other regulatory purposes. To provide a potential regulatory tool, the committee developed NFPA 270, *Standard Test Method for Measurement of Smoke Obscuration Using a Conical Radiant Source in a Single Closed Chamber*, where smoke obscuration is assessed using a conical radiant source (instead of the original radiant source) on horizontal test specimens, at 2 incident heat fluxes: 25 and 50 kW/m², in the same closed chamber. There remain observations that the measurement of smoke obscuration in small-scale tests is not sufficiently well correlated with the lack of visibility during open burning of the same combustible material in an actual product.

Section D2.3 of NFPA 270 provides some addi-

tional information relating to comparisons of smoke obscuration measurements with different test methods. It notes that little information exists on the correlation (or lack thereof) between the different test methods that measure smoke obscuration. This is important when evaluating the behavior of a material for input into performance criteria associated with a particular fire modeling scenario or code requirement. In fact, only a few test methods generate smoke obscuration data in units that are suitable for such fire modeling calculations, and even then comparisons of numbers with similar units can be misleading. Experience and sound judgment, with additional large-scale testing, is usually essential when using the smoke obscuration values developed from any small-scale smoke obscuration test for particular real-life applications.

In fact, it is important that the results of any test procedure, and especially from those that use a small sample for testing, are used with caution in their final application. Tests that use only a small test specimen, exposed to a controlled energy source, are not likely to truly reflect the end use and the open burning characteristics exhibited by a product.

TESTING LABORATORIES

It is not the intent of the *Life Safety Code* to require the use of any specific testing laboratory. The *Code* leaves the evaluation of laboratories to the authorities having jurisdiction. The *Code* provides the minimum standards that dictate the testing methods and leaves the option as to who will perform this testing procedure and how to the appropriate responsible individuals. NFPA does not approve, inspect, or certify installations, procedures, materials, or equipment, nor does it approve or evaluate testing laboratories. Obtaining information on testing labs is often not a simple task. There are a few directories that provide some categories or listings of fire testing labs by the characteristics of what they do and which fire tests they perform.

The following are among the larger known commercial fire testing laboratories in the United States, in alphabetical order: Applied Textile Lab Services (Byron Center, MI), California Bureau of Home Furnishings and Thermal Insulation (North Highlands, CA), Commercial Testing (Dalton, GA), Delsen Testing Laboratories (Glendale, CA), FM Global (Norwood, MA), Govmark (Framingdale, NY), Guardian Fire Testing Laboratories (Buffalo, NY), Hardwood, Plywood and Veneer Manufacturers Association (Reston, VA), Intertek Testing Services (multiple locations), Johns Manville (Littleton, CO), NAHB Re-

search Center (Upper Merloboro, MD), NGC Testing Services (Buffalo, NY), Omega Point Laboratories (Elmendorf, TX), PFS Corp. (Madison, WI), Pacific Fire Laboratory (Kelso, WA), Ramtech Laboratories (Paramount, CA), SGS US Testing (multiple locations), R&D Services (Cookeville, TN), Southwest Research Institute (San Antonio, TX), Trace Laboratories (Hunt Valley, MD), Underwriters Laboratories (multiple locations), VTEC Laboratories (New York, NY), and Western Fire Center (Kelso, WA). There may well also be other independent testing labs that can perform tests to meet the criteria of the referenced standards in the *Life Safety Code*.

SUPPLEMENT 6

Home Security and Fire Safety

**Sharon Gamache
and Michelle Perrault**

Editor's Note: This supplement reports on the current threat that window and door security bars pose to life safety. It details the efforts of NFPA to address the problem and recommends future action.

Sharon Gamache is executive director for NFPA's Center for High-Risk Outreach. She develops and implements programs for people who are at highest risk of injury from fire and burns. She was formerly manager of community safety programs at the National Safety Council and was a community organizer in St. Paul, MN, and Chicago, IL.

Michelle Perrault is the former Director of Public Affairs for NFPA and has been a member of the Home Security and Fire Safety Task Force since its inception in 1993. She remains active on the security bar issue, helping to track new legislation, creating updated educational information, and tracking new developments from industry and partner programs. Michelle is currently the Director of Career Services & Experiential Education and a faculty member of the Management Department at Curry College.

In recent years, deaths by fire have declined, as have most measures of loss due to crime. However, the public's perception of crime hasn't always kept pace with reality. One result is that more and more people take security measures to protect themselves and their possessions. Some of these security measures to block intruders, such as installation of security bars and grilles, pose a significant risk of trapping occupants fleeing a fire. In fact, since 1980, there has been a dramatic increase in the number and percentage of fire deaths that can be attributed to blocked exits.

PROBLEM DEFINITION

The threat to life safety from security bars is hard to measure but appears to be on the rise. There are three main aspects to the problem: increased use of security measures in homes, difficulty in collecting hard data to quantify the problem, and the essentially unregulated state of the security bar industry.

Home Security Trends

While solid statistics on practices and usage are elusive, most observers of the home security industry believe that fear of crime has led more and more citizens to blockade themselves inside their homes. Some of these measures are ill-conceived, some are makeshift (for example, nailing windows shut), and some are even illegal. In their attempts to protect their families and properties by locking out intruders, these people seem unaware they might be locking themselves into a potentially life-threatening situation.

Despite a downward trend in overall fire deaths in the United States, the number of fire deaths related to the use of security bars has risen. An average of less than one fire death per year was attributed to "illegal gates or locks" for 1980 through 1985. This figure increased dramatically to an average of nearly 16 deaths a year for the 1986 through 1991 period. In 1993, seven children died in a Detroit house fire and

eight family members perished in a dwelling fire in Mississippi. In 1997, four children perished in a fire in Tampa; a family of five died in a Bessemer, Alabama, fire; and in East Palo Alto, California, nine people were killed. In 2002, an Alabama fire killed two adults and a five-year old. The same year, a Georgia fire killed three adults. In all of these fatal fires, security bars on windows and locked doors kept escape from the fire and kept fire fighters from successfully completing their rescue attempts.

Socioeconomic circumstances make the problem worse. Most of these fatal fires occur in low-income, high-crime neighborhoods. Due to a heightened fear of crime in these neighborhoods, people take measures to secure their homes and discourage intruders from entering, thereby, either consciously or unconsciously, placing a higher priority on security than on fire safety. This is particularly dangerous because people living in high-crime and/or low-income areas usually face increased fire risk as well. Increased fire risk, combined with blocked exits, is most dangerous for young children, the elderly, and the disabled, for whom escape might be more difficult, even under ordinary circumstances.

Data Collection Difficulties

Although fire deaths related to security measures have increased dramatically, the number is still small enough to pose a problem for the sample-based estimation procedures used to track U.S. fire issues. This problem is made more severe by the dominance of multiple-death fires among the known incidents. In addition, fire death and injury reports might omit information related to security bars because the question that captures security measure involvement also addresses other issues. On the standard form for such reports, there are a number of possible contributing factors listed, but only one can be selected. A further complication is that many forms refer to only “illegal bars or gates.” Because the legal status of the security bars or gates is often unclear, the likelihood that the gates or bars will be identified as impediments to escape is reduced. The data classification defined in NFPA 901, *Standard Classifications for Incident Reporting and Fire Protection Data*¹, has been changed to delete the term *illegal*. In addition, new systems collecting data are adding the capability of listing multiple contributing factors. However, it will take time before these changes are used by everyone in the field.

The Security Bar Industry

Fragmentation. The nature of the security bar industry presents some substantial obstacles to solving the

life safety problem these bars pose. Research reveals that the security bar and gate industry is highly fragmented, with considerable regional differences in professional standards and little understanding of the possible consequences of permanently installed bars or inadequate release mechanisms. Until recently, there had been no standard of design and no consistent use of quick-release mechanisms on security bars or gates. Differences among installation companies are even greater. Some are one- or two-person welding shops that focus on security and only install permanent window bars. Other companies offer several options, including easy-release components.

Market Forces. Working against standardization are the market forces behind the industry’s product development. Exhibit S6.1 depicts the various market segments of the security and fire safety industries and how they relate to the amount of money and technology invested in them.

The market segments are displayed in pyramid form, with the top, smallest section representing large facilities, such as convention centers and court-houses, which have the most sophisticated types of alarms, locking devices, and fire safety systems. The next section includes large office buildings and shopping centers, which also have relatively sophisticated security and fire safety systems with automatic releases or delayed egress locking devices and which represent a somewhat larger segment of the market. The next section of the triangle represents a still larger segment of the market that includes “middle America.” This market segment is the major customer base for NOMMA (National Ornamental & Miscellaneous Metals Association), a trade group representing manufacturers and suppliers of gates, bars, and other security devices, as well as ornamental iron-

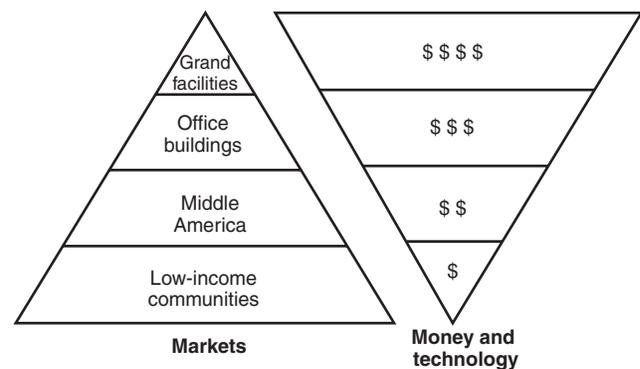

Exhibit S6.1 Security bar industry market segments versus investment.

work. The last and largest segment represents the many low-income communities in both urban and rural areas.

The inverted pyramid on the right represents the amounts of money and technology invested in the corresponding market segments. As you can see, the smallest market segment—grand facilities such as convention centers—has the greatest investment of resources. The largest market segment, which represents numerous low-income communities, has the fewest available resources.

This information about resource distribution shows the economic incentives and possible disincentives for the companies in this business. Clearly, there is more incentive for security bar manufacturers to invest in systems for large, public facilities, which would yield higher profits, than there is to invest in safety measures for low-tech devices in low-income communities.

Range of Products. Security devices that can assure life safety do exist in the low-income market. For example, security locks with inside release and quick-release bars are readily available. Some manufacturers even customize security systems with life safety features such as fluorescent labels that increase visibility at night. Unfortunately, the link between the manufacturers, installers, and end users of these systems is often weak. Manufacturers often don't install their product, and many installers and end users are not aware of the life-safety advantages of some products over others.

Groups Affected by the Problem

The final key to understanding the security bar–life safety issue is the identification of the various groups that would have to contribute to a solution.

Users. Those who have security bars on windows or doors in their homes, particularly those in low-income communities

Security Bar Industry. Those companies that design and manufacture security bars and those that install them

Code Groups. Those groups responsible for creating and revising national codes, such as NFPA 101; NFPA 5000™; *Building Construction and Safety Code*,™2; and regional building codes

Local Fire and Building Officials. Those responsible for local modification and enforcement of fire and building codes

Fire Service. Those involved in fire suppression, fire data analysis, and fire safety education

Law Enforcement. Police groups and associations and, especially, local police officers dealing with citizens' security concerns

Governing Bodies. State legislatures, agencies, and local officials writing bills, regulations, and ordinances

Social Service Agencies. Public and private groups working in low-income communities

Housing Authorities. Local, state, and federal groups dealing with housing issues

Public Health Officials. Those responsible for public health and safety

Insurance Industry. Companies dealing with both property loss and liability issues

PROGRESS TO DATE

The NFPA Center for High-Risk Outreach Home Security and Fire Safety Task Force was established in 1993 to find engineering, enforcement, and educational solutions to the problem of fire victims being trapped by bars on windows or doors. Members of the task force come from diverse backgrounds and include fire marshals, public educators, police officers, and industry representatives. They help track legislation, progress of community outreach programs, and improvements in technology. Some of the accomplishments of the task force include the following:

- Underwriters Laboratories Inc. *Subject 2326 Research Bulletin Releasing Systems for Window Bars in Residential Occupancies*³ has been published. It provides requirements for the evaluation, construction, and performance of window bar releasing systems and can be used as a basis for state and local laws and regulations.
- Changes have been made in NFPA 901, *Standard Classifications for Incident Reporting and Fire Protection Data*, to eliminate the word *illegal* pertaining to security bars, in an effort to improve data collection.
- Incidents and statistics, codes and standards changes, proposed legislation, and updates from the security bar industry are constantly monitored.
- A public education packet including a leader's guide and illustrated brochure describing the dangers of security bars, fire safety messages, and the typical types of release devices has been produced and distributed to thousands of community and church groups, fire safety educators, law enforcement groups, and many others. The

leader's guide and brochure is available in English and Spanish on NFPA's website, www.nfpa.org. It can be duplicated by local fire departments and other organizations.

- Messages regarding the life safety issues associated with security bars have been incorporated in NFPA educational brochures and Fire Prevention Week materials.
- The NFPA Center for High Risk Outreach continues to cooperate with model programs in communities such as Ft. Lauderdale, Florida, and Oakland, California, where coalitions have been formed to provide retrofitting of security bars with quick-release devices and community educational programs on fire safety and security and escape planning.
- A partnership with State Farm Insurance has resulted in the gathering of sample release mechanisms, which helped in the development of the Underwriters Laboratories Inc. bulletin for releasing systems and the development of a State Farm educational video and brochures on the importance of release devices.
- Partnerships with organizations such as the National Association of Hispanic Firefighters (NAHF), the International Association of Black Professional Fire Fighters (IABPFF), and the New York City Police Department have resulted in the dissemination of information and education to their constituents for outreach in urban communities.
- Regulation at the state government level has been encouraged. For example, California passed two bills related to security bars in 1996. One requires emergency escape warning labels on all bars sold through retail outlets, and the other gives local cities and towns the authority to regulate installation of security bars, including those on existing buildings. Related bills have also been passed in Mississippi and Texas.

FUTURE ACTION

Recommendations for future action and potential solutions can be placed in one of three categories: engineering, enforcement, and education.

Engineering

Code Development. The NFPA Technical Committee on Means of Egress, which is responsible for Chapter 7 of NFPA 101, *Life Safety Code*, and Chapter 11 of NFPA 5000,™ *Building Construction and Safety Code*™ should consider several issues related to means of escape in the next code cycle.

First, the minimum number and type of means of escape should be examined. If security measures are employed or if operation of an emergency escape mechanism is somewhat complicated, the time required to operate all of the features of the means of escape might prevent successful escape.

Second, if some, but not all, of the openings provided from a given room or space are used as a means of escape (as is currently the case), some consideration should be given to how these openings should be identified so that occupants can readily identify them in the event of an emergency, or at the very least when preparing their escape plans. At present there are significant differences among manufacturers.

Third, consideration should be given to requirements for mechanical or electrical releasing means for emergency escape openings where those mechanisms are employed. How should they operate? What fail-safe modes or interlocks should be required?

In addition to changes to NFPA 101 and NFPA 5000, efforts should be made to correlate the provisions of NFPA 1, *Uniform Fire Code*⁴, and other nationally recognized fire prevention codes should be undertaken concerning security measures and means of escape. Although widespread concurrence on means of escape requirements, especially opening dimensions, already exists, the regulatory vacuum on security measures has been filled rapidly, and conflicts between the competing objectives of security and fire safety might exist.

In this same vein, security issues should be integrated directly into discussions of code requirements, rather than resolving security/life safety conflicts after they emerge. The emphasis on life safety from fire often produces perceived conflicts with security. While both of these concepts are related to the larger subject of loss prevention, their relationship to each other is often complicated and confusing. In practice, though, both objectives can be satisfied.

Standards Development. Several types of standards might need to be developed to ensure that security-related products and designs meet the intent of code requirements for operability, reliability, and durability. Product standards should be developed to describe the requirements for proper design, installation, and operation of products and their main components. These standards should recognize that window bars are not the only design that can be employed. Grates, shutters, impact-resistant glazing, and locks may also be used. Testing standards should be developed to evaluate how well products perform their intended functions (security and life safety), as

well as how reliably they perform over time. Inspection and maintenance standards, written to be understood by homeowners and describing how to verify and ensure the continued proper operation of products, should also be developed.

Any standards that are developed should be performance-oriented rather than prescriptive or proprietary and should be the product of an open consensus process. Given the current absence of technical standards in this area, the degree of industry inconsistency in design and installation, and the relative lack of recognition of the problems in this area, it should be assumed that the process of developing new code and standards requirements will be lengthy.

Enforcement

New installations of security devices clearly should be regulated via legislation. A generic model could be developed for use by all states. This model should include the following:

- Identification of problem
- Reference to code requirements that only approved (that is, releasing) equipment be used
- Reference to product standard or required listed equipment
- Establishment of penalties (civil and/or criminal)

To address issues surrounding existing security bars and gates, an educational rather than regulatory approach should be taken.

Existing regulatory processes could be used to enforce legislation. To ensure that they are addressed in inspections, security bars could be added to the jurisdiction of fire and building departments. The question of licensing installers remains debatable. On the one hand, licensing ensures higher-quality, regulated work and provides a channel for fire safety information. On the other hand, licensing is not as effective as a permit process—which requires inspection—and involves additional paperwork that could place unnecessary restraints on installers. Additional enforcement steps that should be taken include requiring existing noncomplying security devices to be replaced/fixed upon sale of a building, promoting financial incentives for replacing noncomplying existing devices, and involving the insurance industry in future discussions.

Education

The education component should take a two-tiered approach, targeting the message and outreach to two groups: the experts and the general public.

Experts. Experts consist of industry, law enforcement, and code officials somehow involved specifically in the issue. Efforts to educate the security bar industry should focus on the hazards of security devices if improperly designed, installed, or manufactured. In addition, an industry standard for security devices should be developed and monitored to ensure compliance. Finally, industry should become a partner in educating consumers by developing educational materials for dissemination in conjunction with promotional pieces to potential customers.

The law enforcement community, including the fire service and social service agencies, should recognize that people who install burglar bars are motivated by security concerns and consult the police—not the fire department—for advice about what security measures to take. The police should work with fire departments to ensure that fire and life safety issues are addressed. To facilitate this cooperation, the definition of *security* should be broadened to include fire safety concerns in addition to crime prevention. There are measures one can take to ensure the ability to escape without sacrificing the ability to keep intruders out. To bring all of law enforcement into the loop, a brochure or fact sheet with safety advice, industry standards, and recommended devices should be disseminated to public entities having any exposure to regulations, inspections, or enforcement of codes or ordinances.

Code officials, including permitting, enforcement, and plan review officials, should be educated about standards, requirements, potential hazards, and operations of security devices. These groups could then distribute information on various devices, their use and installation, and design features.

General Public. Schools and community organizations should be actively involved in educating the public about the types of devices available as well as their proper use and application. Insurance companies and other groups should be encouraged to require that minimum standards be met if security devices are installed on premises that are rented, leased, or insured on behalf of others. Most important, widespread dissemination of educational materials is vital. Individuals need to be made aware of the wide variety of fire safety and security measures available.

The Application of Performance-Based Design Concepts for Fire and Life Safety

Milosh Puchovsky, P.E.
James Quiter, P.E.

Editor's Note: This supplement provides a brief overview regarding the application of performance-based design approaches for fire and life safety. Specific examples regarding egress, occupant loading, structural fire protection, smoke management, and sprinkler protection are addressed.

Milosh Puchovsky, P.E., is a principal fire protection engineer with NFPA where he oversees NFPA's projects on Performance-Based Codes and Fire Risk. He also serves as staff liaison to a number of technical committees responsible for NFPA's Building Construction and Safety Code, Life Safety Code, and fire test standards. He was employed as a senior fire engineer for Arup Fire when he co-authored this supplement.

Jim Quiter, P.E., is a Principal of Arup, and the leader of Arup Fire and Arup Risk Consulting in the United States. He is also chair of the Safety to Life Committee and a member of the NFPA 5000 Correlating Committee. He is a registered professional engineer in several states.

The application of performance-based design concepts has been permitted by various codes and standards through equivalency or alternative means of protection provisions. The overall concept was to allow for the use of alternative approaches or technologies in meeting the intent of the code. As such, equivalency concepts were pursued where the code did not specifically address a given situation, or where priority was given to a design concept that called for a building arrangement or feature that was not in strict compliance with the prescriptive provisions of the code. While the equivalency approach has been implemented for decades, no guidance or an established approach existed that would aid both the designer and the enforcing authority in making appropriate decisions about the equivalent means of protection.

Over the past several years, a more formalized

approach to the equivalency concept has been developed. This approach is often referred to as performance-based design. Both the Society of Fire Protection Engineers (SFPE) and NFPA have developed guidance documents in this regard.^{1,2} As noted in Chapters 4 and 5 of the *Life Safety Code*, performance-based design is now specifically addressed and permitted by NFPA 101 as well as NFPA 5000TM, *Building Construction and Safety Code*^{TM 3}.

The application of performance-based design for fire safety should include a risk analysis to identify the types of fires to be considered. This is an important step, as the threat to occupants in terms of fire needs to be identified and quantified if an appropriate fire safety solution is to be developed. It is worth noting that traditional building regulations do not identify the fire hazard against which to be protected. In most cases, building regulations prescribe a solution to

some unidentified or vague fire situation. Performance-based design also typically involves the use of computer fire models or other fire engineering calculation methodologies such as timed egress studies to help assess if the proposed fire safety solutions meet the fire safety goals under the conditions specified.

Performance-based design provides a more flexible approach, allowing greater design freedom while specifically addressing fire and life safety concerns of a specific building project. When properly applied, it provides for a more informed approach so that life safety risks can be more carefully addressed.

Although performance-based design can be applied to any building project, it is most effective for complex and unusual structures, particularly those that do not fit well within the guidelines of prescriptive building regulations. Examples include convention centers, shopping malls, airport terminals, transportation centers, and buildings with unenclosed vertical openings, all of which pose challenges with regard to egress, spread of fire and smoke, and detection and suppression. Museums and historic structures also benefit from performance-based design because the designers of these buildings must balance aesthetics and historic preservation with fire safety concerns. Further complicating matters is that building regulations do not usually address property protection or historic preservation. Industrial facilities with hazardous or sensitive processes and contents also benefit from performance-based design for similar reasons.

EGRESS FROM AN OBSERVATION TOWER

In developing the fire and life safety program for a building such as an observation tower with a large population and amusement rides, numerous issues need to be addressed. The tower rises over 274 m (900 ft) above grade with eight occupied levels and two amusement rides in the “pod,” the upper portion of the tower. At the base of the tower is a casino building. Occupied floors of the pod include two levels of observation deck, a restaurant, a meeting room level, wedding chapels, and a bar level. The top level functions as an amusement level containing a roller coaster and “space shot” ride. Exhibit S7.1 illustrates level 6 of the pod, which functions primarily as a restaurant. Exhibit S7.2 illustrates level 8 of the pod, which functions as the lower observation level. Exhibit S7.3 illustrates level 1 of the pod, which serves as one of two refuge areas.

The most obvious concern is providing for emergency egress, considering that the lowest occupied floor is 242 m (795 f) above grade. In accordance with

applicable regulations, some floors of the structure could include an occupant load in excess of 500 people. Strict adherence to the code requires three remote exit stairs leading from the top of the tower to the base of the building. The physical area of the supporting structure is not large enough to provide remotely located stairs in accordance with the code, and the height of the building makes the use of stairs as a means of egress somewhat impractical. An alternative approach based on performance-based design concepts was necessary to develop a workable egress strategy.

Exit Program

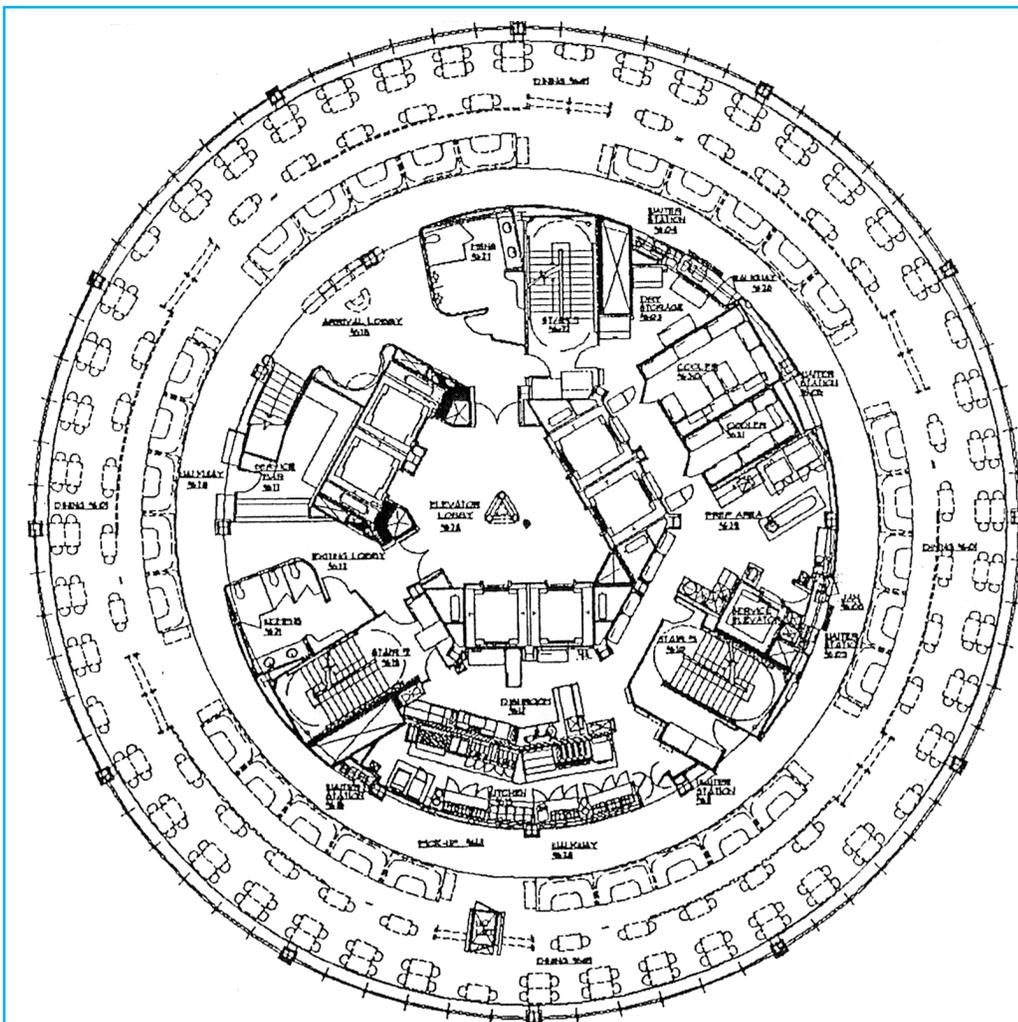

The primary evacuation method for this building is the use of typical exit stairs for the occupied floors discharging to areas of refuge on the lowest two floors of the pod. In other words, from floors 3 through 10 of the pod, three exit stairs are provided, enclosed in 2-hour fire resistant construction, just as would be found in most other buildings. However, these stairs discharge to an area of refuge at the lowest two levels of the pod, which is still 230 m (750 ft) above grade. These two areas of refuge are used for no other purpose, and consist entirely of non-combustible construction. Rather than rely on mechanical systems to maintain the areas of refuge free of smoke in the event of a fire, the two floors are open to the surrounding exterior environment so that natural ventilation occurs. Since the two areas are below the occupied levels, it is unlikely that a fire in an occupied level would spread to the areas of refuge. Additionally, all the floors, including the areas of refuge, are provided with sprinkler, standpipe, detection, and alarm systems, further reducing the likelihood of downward fire spread. (No detectors are located on the open refuge floors.)

From the area of refuge, a single stair leads down through the shaft of the tower to grade. The primary evacuation route from the area of refuge involves the elevators. These elevators are two-level elevators that travel at a speed of up to 1,800 feet per minute and can discharge either within the main casino or at two specially designed discharge levels at the roof of the base building. These discharge levels are enclosed in 2-hour fire resistant construction from the roof to grade, and are separated from all other areas by 2-hour fire resistant construction.

Special Elevator Shaft Protection

To increase the reliability of the elevators and the safety of the elevator car occupants, special protection was provided. The tower design was undertaken dur-

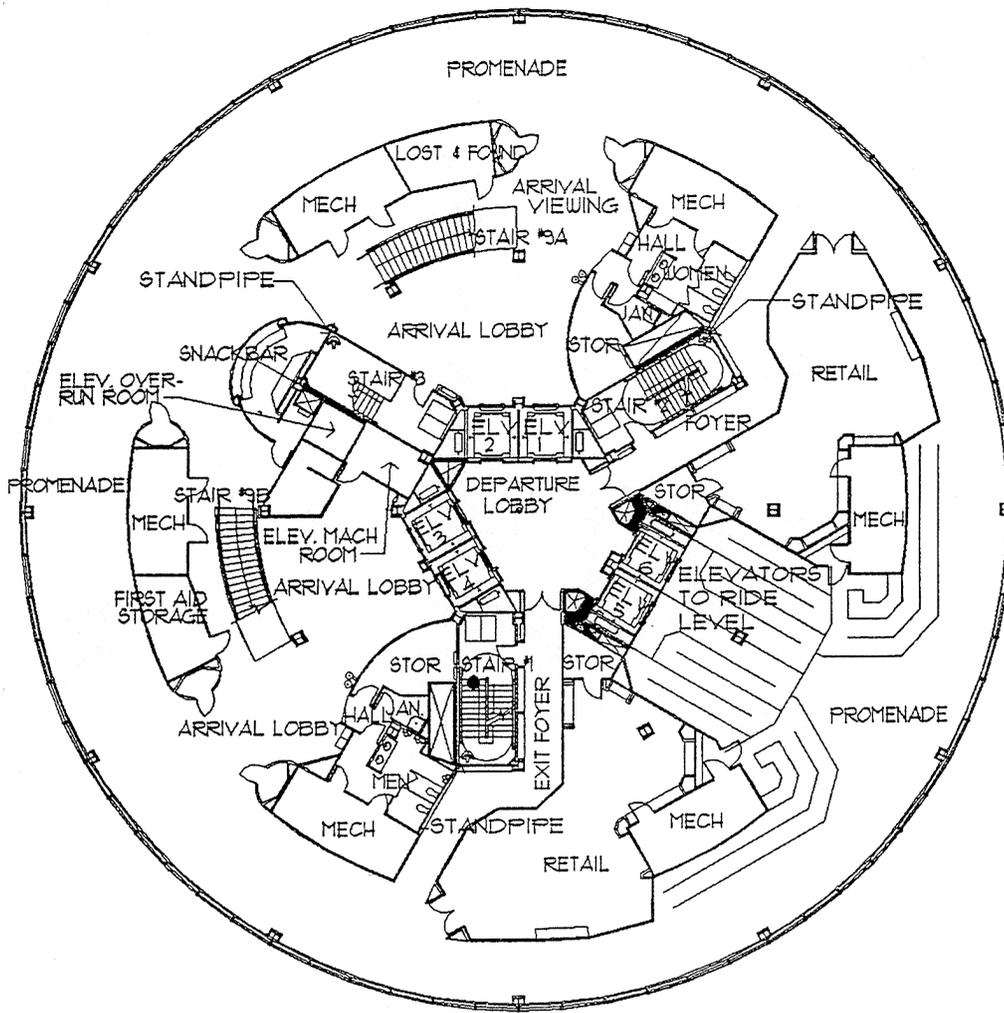

Exhibit S7.1 Observation tower, pod level 6

ing the same time period in which the National Institute of Standards and Technology (NIST) was initiating studies on the use of elevators for building evacuation. Many of the recommendations developed by NIST were incorporated as design concepts for the tower. The concepts include the following:

- (1) Elevators open into 2-hour fire resistance-rated elevator lobbies on all floors, both at the top and at the bottom of the building.
- (2) There are four elevators that travel through the shaft from the base to the top. Two independent elevator machine rooms serve these elevators. The elevator machine rooms are separated by 2-hour fire resistant construction and have a 4-inch curb installed between them so that water-flow in one machine room will not affect the other.
- (3) Elevator lobbies are on a separate smoke control zone to maintain pressurization with relation to adjacent spaces. Therefore, smoke in an adjoining area will not spread into an elevator lobby.
- (4) Openings into the elevators are slightly raised from the remainder of the floor, preventing water flow on a floor level from spilling into the elevator hoistway.
- (5) Because the areas of refuge are at the two lowest floor levels of the pod, the elevators will not need to travel past a fire floor. Elevators will travel only between the areas of refuge and the base building. Areas of refuge for disabled persons are provided within the enclosed pressurized stairwells at each level.
- (6) Elevator shafts are vented to the outside at the top and the vents are separate from the machine rooms. In addition, the machine rooms form separate smoke control zones, and air conditioning for the machine rooms is on emergency power.
- (7) All four elevators are on emergency power. The

Exhibit S7.2 Observation tower, pod level 8

emergency power riser is in a separate dedicated 2-hour shaft.

- (8) Only three of the elevators are assumed to be available for evacuation purposes. The fourth elevator is dedicated for use by the fire department.

Stairs

In addition to the elevator evacuation, a single stair leads down through the tower and discharges to grade. The stair enclosure is pressurized and remains independent of the base building. Enlarged stair landings at predetermined levels allow occupants to stop and rest as they descend through the building. In addition, the three stairs in the pod of the building are enclosed in 2-hour fire resistant construction and pressurized. Each of these stairs has areas of evacuation assistance, with communication capability to the central control room.

Occupant Load Determination

With a building of this type, it is important to understand and control the occupant load. Three methods were used to determine occupant load. Once the three calculations were performed, the lowest occupant load calculated was used as the limiting factor for the building. The three methods used are as follows.

Areas of Refuge. Building codes and the *Life Safety Code* typically allow holding areas or areas of refuge for horizontal exits. Where those holding areas are used, the codes require a minimum of 0.28 m² (3 ft²) per person. Therefore, one of the limiting factors for this building was the size of the areas of refuge. Determining their maximum holding capacity provides a factor of safety for several reasons, as noted below:

- (1) The area of stairs leading to the areas of refuge was not included in the holding area. These stairs

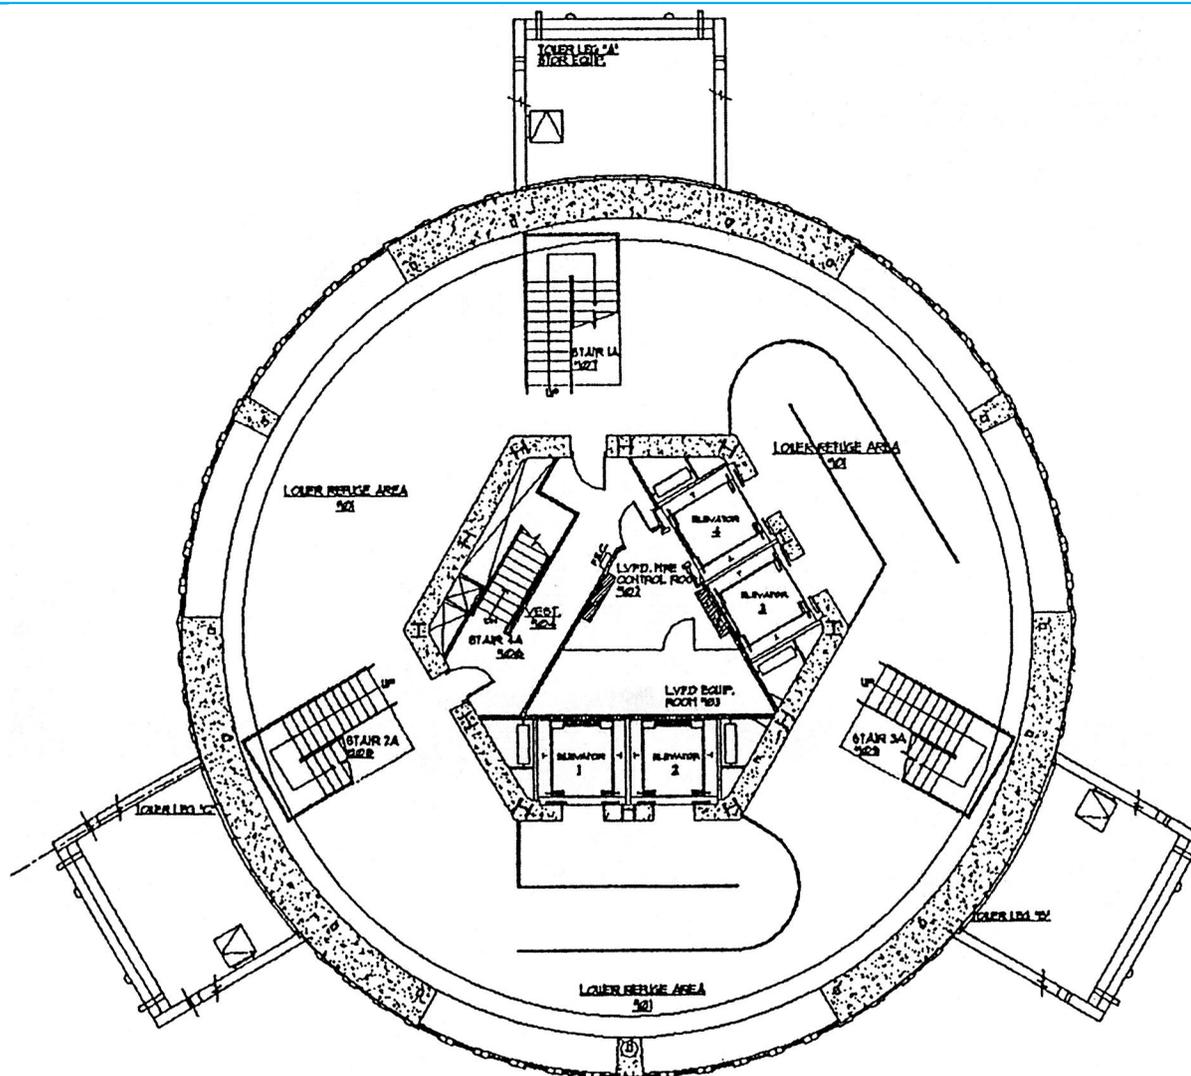

Exhibit S7.3 Observation tower, pod level 1

would significantly increase the number of people that can be safely accommodated within an area separated from the fire by 2-hour construction.

- (2) The calculations assume that no occupants are leaving the building via elevator or stair. Instead, they assume that all occupants are contained within the areas of refuge.
- (3) The evacuation scenario is to evacuate the floor of origin, the floor above, and the floor below. Therefore, only a portion of the building will be simultaneously evacuated. However, the occupant load of the entire building is limited by the size of the area of refuge.

Code Calculations. The second means of determining the occupant load of the building was based on

code calculations. The expected occupant load, based on the applicable building code, was calculated for each floor of the building. The load was then totalled for the entire building and this occupant load was used as a limiting factor for the number of people in the building.

Evacuation Capacity. The third determining factor was the capacity of the elevators to evacuate occupants. The speed of evacuation was based on calculation methods for elevator evacuation contained in NIST studies. For this project, it was concluded that a 1-hour time frame was reasonable to fully evacuate the areas of refuge. This 1-hour time frame was based on three of the four elevators being used for evacuation, with the fourth dedicated solely to fire department use. The 1-hour calculation also ignores the

availability of the stair leading down through the shaft. Therefore, by this calculation, all occupants are expected to leave via the three elevators. It should be noted that operational considerations require the occupant load to be further limited if one of the elevators is out of service for repair.

Once these three methods of calculations were completed, an occupant load of approximately 2,600 people was developed as the expected load of the building. This was the load factor around which the remainder of the building was designed. To ensure that this load factor is not exceeded, the building owner has instituted an occupant counting system that keeps track of the number of people entering and leaving the tower. Therefore, the load of the building will not exceed the calculated occupant load.

A key aspect of the egress program is crowd management during an incident. The tower staff have been trained to direct people to the nearest stair and areas of refuge. Other staff have been trained to respond immediately to the area of refuge, and to direct people to either the stair or the elevator queue. Railings are provided to help establish queues at the elevators. Signage and floor path markings are also evident to help guide people arriving in the refuge area.

Other Features

The evacuation system was not designed as a stand-alone system. The fire protection features for the project were specifically designed to rapidly detect and control a fire, to control smoke generated by likely fires, and to ensure that a back-up electric power system was available.

The building is completely protected with automatic sprinklers. Sprinkler densities exceed those required by the codes. The sprinkler system was calculated to provide a very high density for the first four sprinklers operating, plus ordinary hazard density for the most remote 1,500 square feet.

Water supply is from two pumps at street level, which pump up to the pod. There is on-site water storage within the pod and two additional pumps sized for sprinkler plus standpipe demand in the pod. With these pumps and on-site water storage, redundant water supply is available.

The building is fully protected with automatic smoke detectors, except that kitchens contain heat detection. The smoke detectors are on an addressable system, with alarm verification to reduce the number of unwanted alarms. Manual fire alarm boxes are also provided in the facility. To reduce unwanted alarms, the boxes have been placed within the stairways.

The alarms report to the main central control room for the casino, as well as two auxiliary control rooms. One of the auxiliary control rooms is located at the base of the tower; the second is located within the area of refuge at elevation 230 m (750 ft). The control room within the area of refuge is accessed directly from the fire fighters' elevator. Communication and information flow from the three control rooms is identical.

The fire alarm system is a Class A system, with separate risers running up through the shaft. The risers are separated by 2-hour construction.

Emergency power is sized to accommodate all portions of the fire protection system. This includes the fire pumps, fire alarm system, all elevators, smoke control and necessary lighting. The emergency power riser is routed through a separate 2-hour shaft up through the tower in order to prevent a single event from impacting the primary and emergency power.

The building is provided with an automatic smoke control system. Upon actuation of an alarm, the floor of origin and any floors open to it go to full exhaust while adjoining floors are pressurized. In addition, the elevator lobbies for all floors are pressurized, as is the stair leading down through the shaft of the tower. Exhaust from the smoke control system is ducted to discharge above the ride level at the top of the tower in order to eliminate reintroduction of smoke into the building.

The observation tower required a fire protection approach that departs from the typical building code approach to a building. Use of stairs as the sole evacuation method was not feasible or reasonable. Requiring all of the occupants to utilize stairs would result in an unsafe condition for many of the expected occupants of this building. A more reasonable method was to provide an area where people could be staged until evacuated, and a reliable means to perform that evacuation. The performance-based design approach provides protection in accordance with the overall intent of the building codes, while departing significantly from the detailed prescribed code requirements.

SPRINKLER PLACEMENT IN AN ART GALLERY

The design concept for the upper floor of an art gallery called for a unique roof/ceiling structure consisting of a grid of approximately 800 skylight pockets. NFPA 13, *Standard for the Installation of Sprinkler Systems*⁴, does not address the ceiling arrangement and a fire engineering analysis was necessary to address the relevant fire safety concerns and develop appropriate sprinkler positioning and spacing criteria.

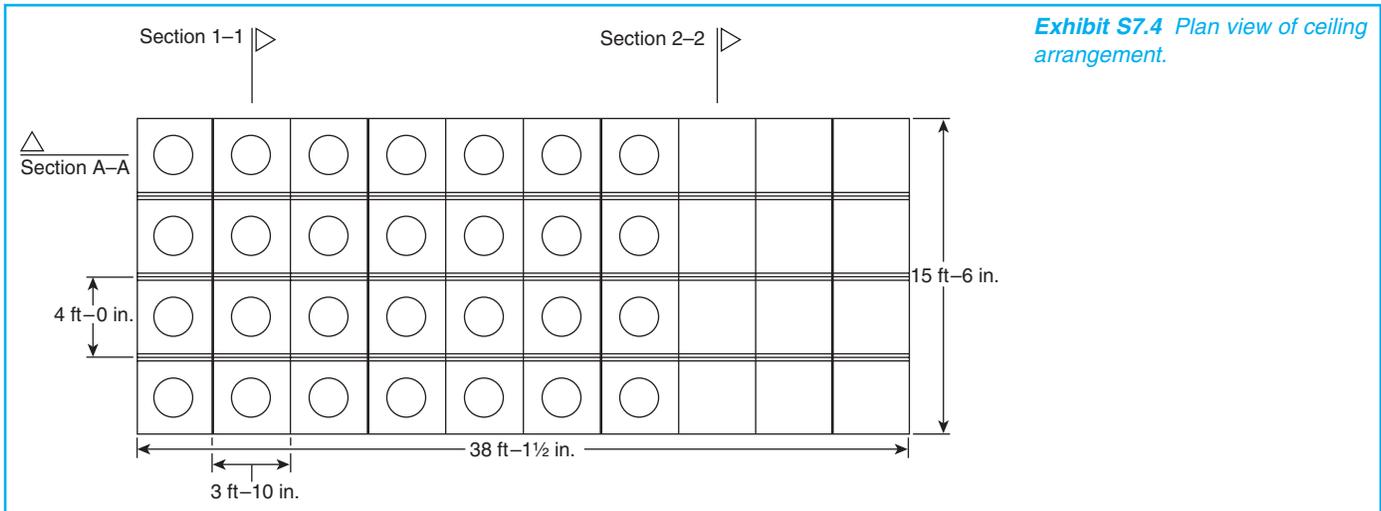

Exhibit S7.4 Plan view of ceiling arrangement.

The ceiling/roof structure consisted of a grid of circular skylight pockets extending approximately 1500 mm (60 in.) from their base to their peak. The opening to the skylight pocket was approximately 1070 mm (42 in.) in diameter. The separation between adjacent skylight pockets was approximately 360 mm (14 in.), with the supporting members approximately 1200 mm (48 in.) apart. The ceiling height (to the base of the skylight pockets) was approximately 5490 mm (216 in.) from the floor below. A rendering of a section of the ceiling/roof arrangement is shown in Exhibits S7.4 and S7.5.

Because of the depth, area, and arrangement of the skylight pockets, the specific rules of NFPA 13 concerning sprinkler positioning are not directly applicable and do not adequately address the relevant fire and life safety concerns.

Locating sprinklers in each pocket is undesirable in terms of both functionality and aesthetics. Locating

sprinklers in the pockets would place them farther away from the floor where a potential fire is expected to occur, prolonging the time to sprinkler activation. Once activated, the sprinklers would not be able to develop their proper spray pattern if positioned in the skylight pocket; the result would be a column of water discharged from each skylight pocket. Also, locating sprinklers in alternating pockets would result in an unacceptable delay in sprinkler activation unless the fire is located directly below a skylight with a sprinkler.

Locating sprinklers in the supporting grid at the base of the pockets appeared to offer the best option. However, because of the depth of the pockets, the sprinklers would be positioned more than the distance permitted by NFPA 13 from the top of the skylight pocket. In this case, proper sprinkler spacing needed to be determined.

Fire engineering employing computer fire models offers an effective means of analyzing how sprinklers would perform under the skylights. During a fire, the skylight pockets, because of their depth and number, would serve as heat reservoirs and have an impact on sprinkler activation. How much of an impact would be a function of numerous factors including the design fire, fire dynamics, ceiling and room geometry, and sprinkler type, spacing, and positioning. It is important to note that NFPA 13 only provides information on how to install sprinklers; it provides no information or criteria as to how soon after the start of a fire the sprinklers are to activate. It is understood, however, that sprinklers need to activate during the early stages of fire development to be effective in controlling the fire.

Computational fluid dynamics (CFD) was applied to help understand the performance expected

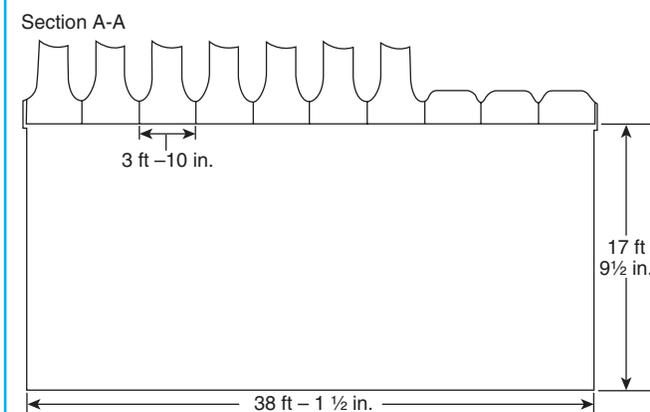

Exhibit S7.5 Section view of ceiling/roof arrangement.

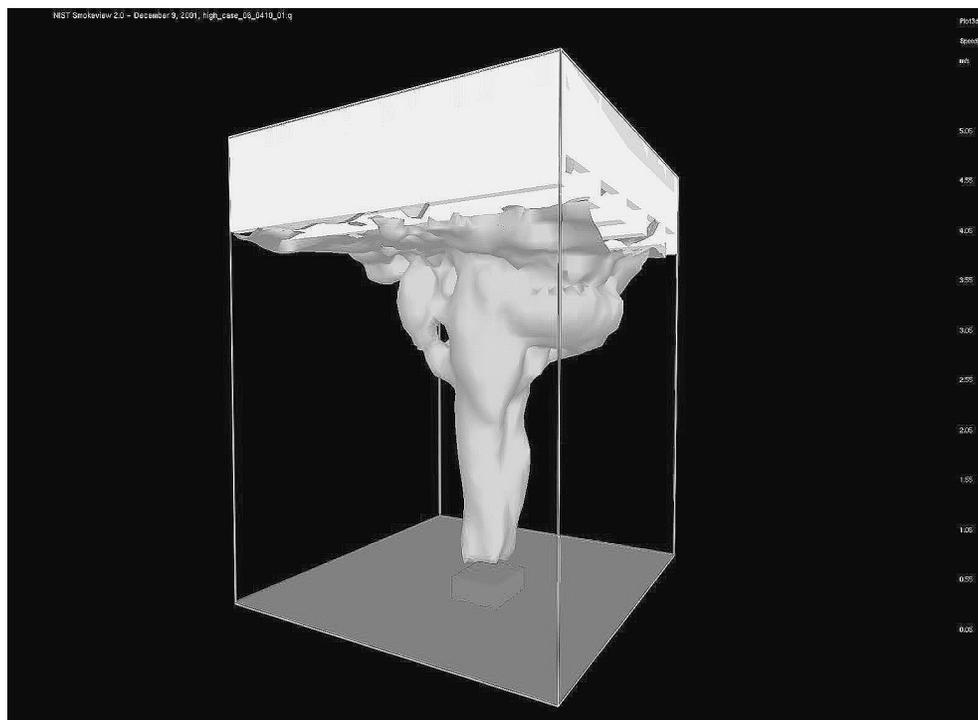

Exhibit S7.6 CFD analysis of sprinkler activation.

from an NFPA 13-specified system, to quantify the associated delay caused by the skylight pockets, and to help determine appropriate sprinkler spacing and positioning to achieve the intent of NFPA 13. In this regard, design fires representative of the fuel load in the gallery were quantified and acceptable sprinkler activation performance criteria determined. Sprinkler positioning and spacing appropriate for meeting the activation criteria for the design fires were identified. Exhibit S7.6 illustrates one scenario modeled and analyzed using Fire Dynamics Simulator, a CFD computer fire model developed and maintained by the NIST.

The overall approach was to establish design fires representative of the types of fires expected in the gallery space. Various ceiling/roof arrangements permitted by NFPA 13 were then evaluated using CFD computer models for the specified design fires to determine sprinkler activation times. These activation times were established as acceptance criteria. Various sprinkler spacing configurations under the roof structure proposed for the Upper Gallery were evaluated to determine those that would result in a time to sprinkler activation that was less than that established as the acceptance criteria.

The analysis established sprinkler activation time criteria for ceiling arrangements addressed by NFPA 13. Three cases (smooth, flat ceiling; ceiling channels; and ceiling grid) were evaluated for the types of fires

expected in the gallery. The maximum sprinkler spacing and maximum distance between the sprinkler deflector and ceiling were evaluated in determining acceptance criteria.

The engineering analysis included several factors to provide for a degree of conservatism to account for uncertainties in both the analysis and the forthcoming installation process, and to allow some flexibility in potential future modification of the design concept. These factors included the following:

- (1) Using ceiling heights less than that proposed for the Upper Gallery in the determination of acceptable criteria as allowed by NFPA 13. This created shorter sprinkler activation criteria.
- (2) Spacing ceiling members closer than the maximum permitted by NFPA 13 in the determination of acceptable criteria. This created shorter sprinkler activation criteria.
- (3) Establishing a design fire with higher rates of heat release than for the types of combustibles typically expected in the gallery. This allowed for more flexibility in contents that might be present in the gallery for special exhibits and functions.

The analysis of the gallery roof structure indicated that a sprinkler spacing arrangement that would result in a sprinkler activation time less than that derived from NFPA 13 could be developed. A performance-based approach was used to develop a

means of protection equivalent to that prescribed by NFPA 13.

STRUCTURAL FIRE PROTECTION FOR A STUDENT CENTER

One of the design objectives for a university student center project was to create an open and uncluttered feel for the atrium. The intent was to use exposed slender structural steel elements to support the glazed façade, the circulation ramps, and the roof.

According to the applicable building regulations, the structural elements in the atrium needed to have a certain fire resistance rating. Conventional methods of achieving such a rating, such as cladding or coating the structural members with a cementitious material or intumescent paint, would be effective but would have diminished the desired architectural effect and negatively affected overall project functionality.

A performance-based design approach was developed as an equivalent means of meeting the building code requirements. A code analysis was conducted, and a fire strategy outlining the approach to resolve the relevant issues was prepared. The concerns of the associated stakeholders, including the local enforcing authorities, were identified and articulated, as were the design fires and criteria for determining acceptance of the alternative design.

Risk analysis principles were used to determine the likely fire hazards expected in the atrium space. Design fires were developed to quantify the relative size, duration, and characteristics of the fires anticipated. At the same time, the failure criteria of the structural steel members proposed in terms of fire resistance were also determined. It was agreed that the alternative design would need to withstand the impact of the design fires for a minimum time period of hourly fire resistance rating specified by the building code.

The performance of the structural steel members when exposed to the specified design fires was evaluated through the use of modeling and with the collaboration of structural engineers. The analysis included the effect of the structural member composition, as well as the means and spacing of structural supports and the methods of fastening. The analysis indicated that the structural elements could withstand the respective fire loads represented by the design fires for the time period associated with the code-prescribed fire resistance rating.

To account for a degree of uncertainty and to provide for a factor of safety, it was proposed that the spacing of the structural members supporting the

walkways and roof structure be decreased from what was initially specified, resulting in some redundancy of the structural support system. The effect of this arrangement is that, should a given structural member prematurely fail, there is a reduced likelihood that the entire structure would fail. Thus, it was demonstrated that the conventional fire resistance rating of the structural elements could be achieved through other means and that an equivalent means of protection could be provided for the anticipated design fires. A timed egress study was also undertaken to verify that occupants would have evacuated from this space before the building structure would have suffered any negative effects from the fire.

An approach based entirely on prescribed code requirements does not specifically consider building performance or occupant response under expected fire conditions. Building codes consider classes of buildings generically and do not address specific fire hazards, unique building features, and occupant characteristics. As a result, code-prescribed solutions can provide for excessive fire protection in some instances and inadequate protection in others. Based on a performance-based approach, the architects were able to implement their design vision while adequately addressing applicable fire safety concerns.

LIFE SAFETY FOR A BOTANICAL GARDEN PROJECT

The design of a botanical garden project consisting of multiple floor levels carved into the surrounding hillside presented unusual challenges for fire and life safety. The project entailed a freestanding structure reaching 55 m (180 ft) at its highest points, and covered an overall area of 21,853 m² (5.4 acres). From the outset, it was clear that a prescriptive code approach would be of limited value for the project.

The applicable building regulations classified the structure as an assembly occupancy, but if the project had been designed to fit the requirements of the prescriptive code, the design team would have been faced with trying to make the building conform to requirements derived from safety measures intended for theatres, arenas, and other more conventional public buildings. The relevance of the prescriptive requirements was clearly limited for the project—there was no ‘rule book’ to follow.

Early on in the design project, it was proposed that fire and life safety provisions be developed through performance-based design. This was discussed and agreed upon with the client and the local building and fire authorities.

The fire hazards in a building like this are very different from those typically encountered in conventional buildings. The vegetation clearly constitutes a fire load, potentially an extremely large one, so the potential for a forest fire-type scenario was discussed. The team carried out a qualitative hazard analysis of the risk, in terms of frequency and consequences, of a vegetation fire in the structure, but this showed such a fire to be of sufficiently low probability that it was an impractical design parameter.

The examination of fire loading, therefore, turned to items other than the vegetation. Throughout the structure, huts are provided as information points for visitors. The huts are built of timber, with thatched roofs, and also have electrical power. Scenarios involving a fire in a hut were therefore developed as the basis for the fire safety design.

Because large visitor populations were anticipated, safe and efficient evacuation was a key concern in developing the fire strategy. The circulation (and, hence, evacuation) routes are far from conventional, as visitors walk around the botanical gardens on winding pathways linked to exits around the perimeter. Also, because the structure cuts into the hillside, pathway elevations vary considerably. A major challenge was to address the scale of the building, reflected in the length of the travel routes. If travel distance requirements of the building regulations were to be met, then escape from the upper parts of the structure would require tunnels cut through the side of the hill. Such tunnels would probably need to have been pressurized, as they would have been at the upper levels of the project near potential smoke layers. Other options were needed.

The fire engineers proposed that evacuation be based on the time period necessary to egress the building rather than strictly on the distance to be travelled. The approach was to demonstrate that occupants could egress the facility prior to the onset of untenable conditions. The majority of the exits were located on the lower grades of the project, so, in the event of a fire, the occupants would travel to lower-level exits rather than use exits at the top of the botanical garden. This was also preferred as it encouraged the population to move away from the upper levels, where smoke would accumulate. While this would result in evacuation distances of up to 137 m (450 ft), these were demonstrated to be acceptable due to the overall low level of hazard and large size of the space.

To verify the proposed strategy, combined smoke and evacuation calculations using computer models were undertaken. Based on the design fires, this allowed for a dynamic fire and smoke spread analysis of the actual geometry of the space. The timed egress

study also considered various scenarios, such as the effect of blocked exits.

Due to the structure's unique geometry, conventional smoke modeling software packages, which assume rectangular "box-type" enclosures, were unsuitable for calculating the rate of smoke fill. Project-specific calculations were therefore developed that allowed for the geometry of botanical garden spaces, using a three-dimensional model of the structure. From the model, it was possible to accurately determine the cross-sectional plan area of the project at various heights, and, hence, assess smoke filling rates using design fire scenarios agreed upon with the local authorities.

The egress modelling showed that the project could be evacuated in five to six minutes, while the smoke modelling indicated that a smoke layer would not descend to levels where it would impede evacuation for 15 to 25 minutes (depending on the fire scenario). The team concluded that the escape distances could be safely extended and evacuation conditions would be acceptable under the conservative scenarios studied.

Many fire safety systems conventionally associated with public assembly spaces were unsuitable. Detection methods including optical and aspirated smoke detection were found to be ineffective, due to the potential for smoke stratification to delay detection at high level, and plants obscuring optical detection sight lines.

Although the associated structures are essentially low fire hazard spaces, the fire safety strategy had to be developed from a common sense, first principles point of view. The recognition that there was little relevant guidance for the project, and that adherence to conventional codes would result in unnecessary, costly, and ineffective measures, unlocked the design process. Close collaboration with the architect, enforcement officials, and other engineering disciplines allowed each team member to fully participate in developing the design and clearly understand the thought process and reasoning behind the proposed strategy. The result is a simple, robust, and cost-effective strategy that provides a high level of fire safety for the botanical garden's occupants.

CULTURAL PRESERVATION OF A HISTORIC BUILDING

For historic structures, performance-based design concepts often offer the most viable and effective solution for meeting both fire safety needs and cultural preservation goals. One such project was a designated landmark building consisting of cast iron and

decorative masonry construction with ornate public and ceremonial spaces centered around an open atrium. The building was originally constructed in the mid 1800s to operate as a courthouse. It consisted of approximately 14,000 m² (150,000 ft²) over several floors.

The proposed design concept for the courthouse building called for a comprehensive, government-funded restoration and rehabilitation program to prepare the building for adaptive reuse as a multi-functional public and cultural facility with exhibition space, offices, and a restaurant. The design concept for the project called for the preservation of a number of areas and building features, including the open atrium, the ornate original wood doors, and numerous cast iron columns.

Although building code requirements are relaxed somewhat for specific features of historic structures, imposing the applicable prescriptive requirements on the project would have affected the overall historic fabric, and compromised the functionality and significance of the public spaces and unique architectural features. The overall fire strategy was, therefore, to identify and meet the intent of the applicable building regulations regarding life safety while minimizing the aesthetic and visual impact of new construction, and maintaining the open environment and original design features to the greatest degree possible. During the early stages of the development of the fire strategy, it became obvious that a conventional, prescriptive code-based approach would have forced a dramatic change to the proposed design concept, and that an alternative approach could provide for a more effective and robust level of fire and life safety.

In most code-mandated prescriptive designs, the various fire safety features and systems are addressed independently of one another. The performance-based concept calls for an integrated approach of fire and life safety systems. Such an approach is especially pertinent to existing and historic building projects because it can result in less intrusive fire and life safety systems and features while meeting the required level of safety. In historic landmark buildings, this integrated approach typically results in improved building functionality and more cost-effective fire protection systems.

One of the major fire and life safety challenges pertained to the compartmentation of building spaces. Building regulations require compartmentation to help prevent the horizontal and vertical spread of fire through the building. The existing building construction did not provide for the rated fire separations required by building regulations. Many doors were of original heavy wood construction with deco-

rative wood and glass features and did not meet current fire protection ratings. It was proposed that the atrium remain open to multiple floors, existing non-rated shafts be re-used as mechanical shafts, and certain building areas be open to each other through open stairways.

In developing an appropriate strategy, the aim was to assess the inherent fire protection qualities of existing building features (such as substantially constructed walls and high ceilings), to take advantage of the inherent degree of fire protection, and to supplement it with certain new active systems where necessary. The overall approach was to identify the fire loads (design fires) to be considered and then demonstrate through fire engineering that sufficient fire safety could be provided for the time period intended by the building regulations. In some cases, it was determined that the prescribed fire resistance rating would be needed; for other situations, a performance-based solution was developed.

In general, a fire that starts in the non-public areas is to be controlled so that it does not develop and grow to a point where it could threaten occupants in public spaces. Therefore, it was proposed that, in addition to active systems, non-public areas—the attic and basement, mechanical spaces, kitchens—be separated from public spaces by fire rated construction. Additionally, areas traditionally constituting a higher fire hazard, such as electrical switch gear rooms, mechanical rooms, and storage areas were also constructed to form separate compartments. As most of these spaces were non-public spaces, the new construction had a limited impact on the aesthetic features of the building.

In addition to compartmentation, other fire and life safety issues were also identified and addressed through a performance-based approach. Issues regarding smoke management, egress, structural fire resistance, active systems, and fire fighting facilities were addressed in a comprehensive manner. The overall fire safety solution integrated existing features with new systems and construction so that the level of safety interpreted to be provided by the building code was satisfied while preserving the historic fabric of the building to the extent possible.

CLOSING REMARKS

While considered by some a relatively new approach, performance-based design has been practiced for many years through the equivalency option in many codes and standards. The past several years have seen the development of a more formalized approach for practicing performance-based design, as well as the

revision of codes and standards that specifically address performance-based design approaches. Even so, where a performance-based design is pursued, it usually involves a variance by the local building official or regulating body. However, the development of guidelines and definition of applicable terms serves to better facilitate the discussion between designers and enforcers and allow for more-informed decisions.

This supplement has provided a brief overview of the types of projects in which performance-based design has been successfully applied and accepted by the authorities having jurisdiction. Even though performance-based design is gaining more acceptance, the prescriptive code is likely to remain the first means of developing a fire safety strategy for a building. Enforcing authorities have a greater comfort level with the prescriptive rules that are, in essence, the law. As such, code reviews and interpretations are often the first step in developing the fire safety design process.

As explained above, for certain projects or for specific aspects of projects, the prescriptive code does not adequately address a given situation or would be incompatible with the developer's or architect's

design vision. In other cases, a more cost-effective alternative would result in the same level of protection as that required by the prescriptive building code. In such cases, performance-based design concepts can be used to develop solutions that address specific issues while complementing the requirements prescribed by traditional building and fire codes.

Life Safety Code Cross-Reference Table 2003–2000 Editions

This table was developed to assist readers familiar with the 2000 Life Safety Code to locate provisions within the 2003 Life Safety Code. To use this table, find the desired paragraph number(s) under the 2000 column. The corresponding paragraph in the 2003 Code will appear in the opposite column. The table also indicates which paragraphs from the 2000 edition might have been renumbered for, deleted in, or added to the 2000 edition. Users who are new to the Code or have used editions prior to 2000 should refer to the expanded index, which follows this cross-reference table. The index will lead the reader to the desired provisions.

About the Editors

Ron Coté, P.E., is the principal life safety engineer in the Building Fire Protection and Life Safety group at NFPA. He joined the NFPA staff in 1981 and serves as staff liaison and secretary to several Safety to Life and Building Code technical committees. Prior to his employment with NFPA, Ron worked for seven years as a fire protection engineer for Factory Mutual Research Corporation. Ron is a registered Professional Engineer in the discipline of Fire Protection in the Commonwealth of Massachusetts.

Gregory E. Harrington, P.E., is a senior fire protection engineer in the NFPA Building Fire Protection and Life Safety group and serves as staff liaison and secretary to several Safety to Life and Building Code technical committees. Prior to joining NFPA in 1996, Greg spent three years as a fire protection engineer with the San Antonio, Texas, Fire Department and also worked as a consulting engineer with Schirmer Engineering Corporation. He holds the degree of Master of Science in Fire Protection Engineering from Worcester Polytechnic Institute and is a registered Professional Engineer in the discipline of Fire Protection in the State of Connecticut.
